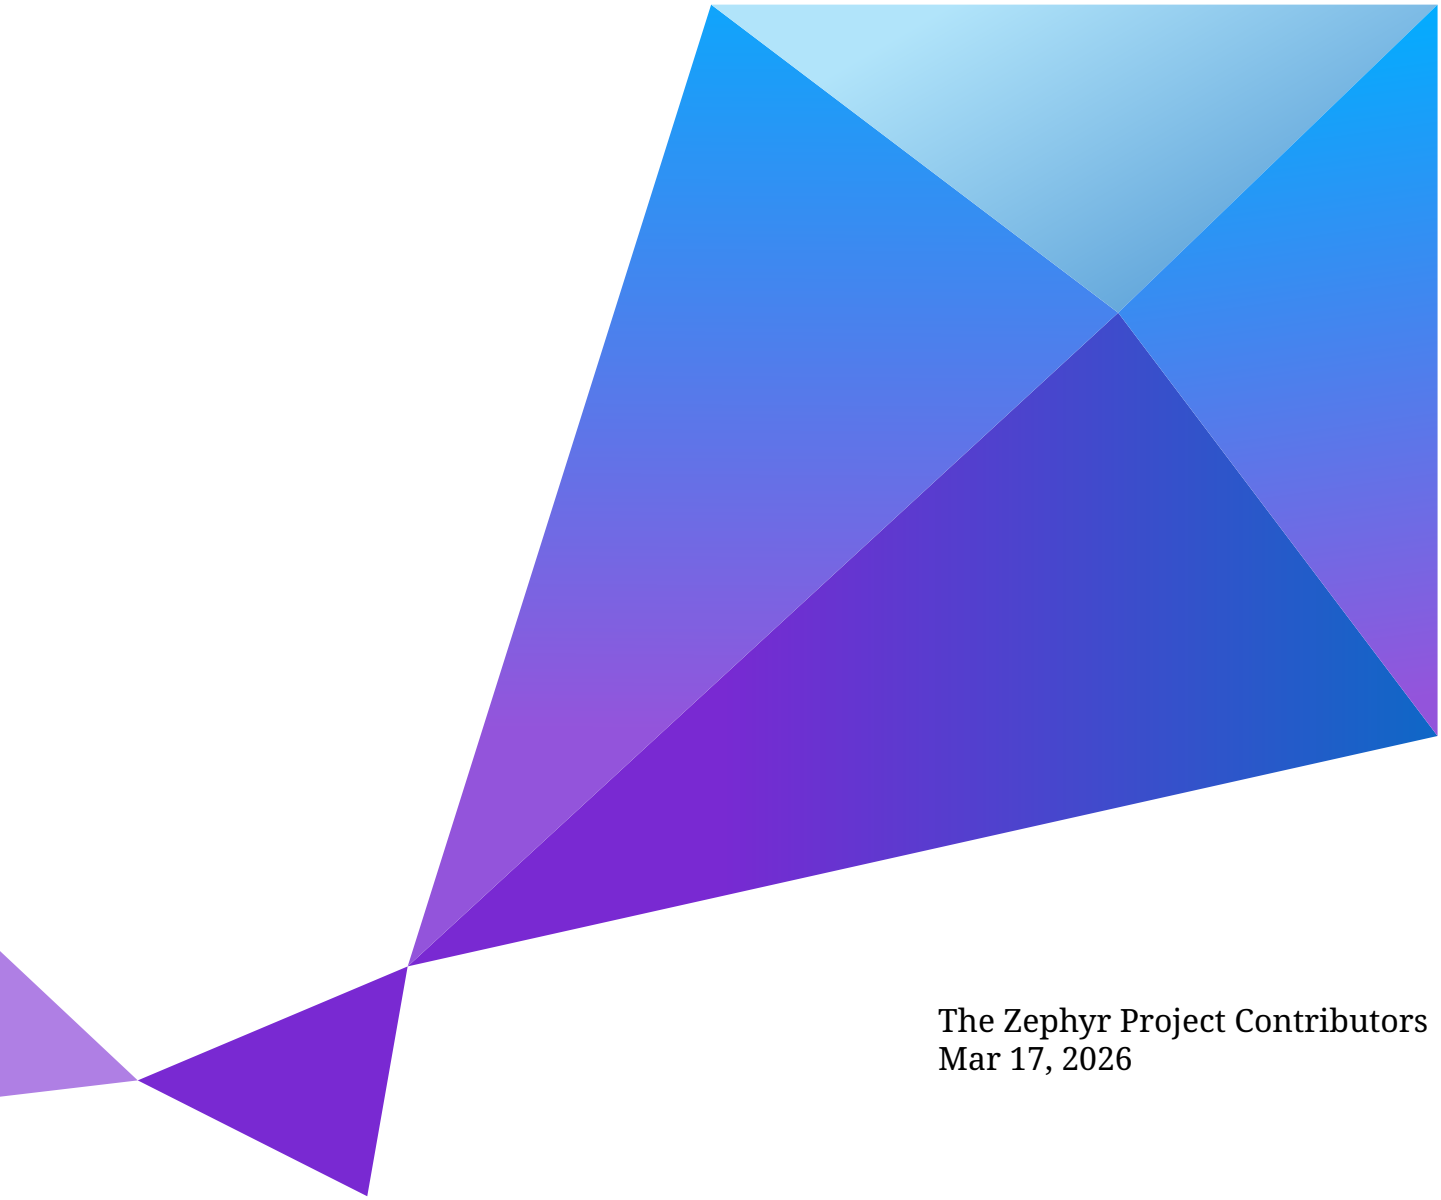
Zephyr Project Documentation

Release 4.3.99



The Zephyr Project Contributors

Mar 17, 2026

Table of contents

1 Introduction **1**
- 1.1 Licensing . . . 1
- 1.2 Distinguishing Features . . . 1
- 1.3 Community Support . . . 3
- 1.4 Resources . . . 4
  - 1.4.1 Getting Started . . . 4
  - 1.4.2 Code and Development . . . 4
  - 1.4.3 Community and Support . . . 4
  - 1.4.4 Issue Tracking and Security . . . 4
  - 1.4.5 Additional Resources . . . 4
- 1.5 Fundamental Terms and Concepts . . . 4

2 Developing with Zephyr **5**
- 2.1 Getting Started Guide . . . 5
  - 2.1.1 Select and Update OS . . . 5
  - 2.1.2 Install dependencies . . . 5
  - 2.1.3 Get Zephyr and install Python dependencies . . . 7
  - 2.1.4 Install the Zephyr SDK . . . 10
  - 2.1.5 Build the Blinky Sample . . . 11
  - 2.1.6 Flash the Sample . . . 12
  - 2.1.7 Next Steps . . . 12
  - 2.1.8 Troubleshooting Installation . . . 13
  - 2.1.9 Asking for Help . . . 13
- 2.2 Beyond the Getting Started Guide . . . 14
  - 2.2.1 Python and pip . . . 14
  - 2.2.2 Advanced Platform Setup . . . 14
  - 2.2.3 Install a Toolchain . . . 18
  - 2.2.4 Updating the Zephyr SDK toolchain . . . 18
  - 2.2.5 Cloning the Zephyr Repositories . . . 18
  - 2.2.6 Export Zephyr CMake package . . . 19
  - 2.2.7 Board Aliases . . . 19
  - 2.2.8 Build and Run an Application . . . 20
- 2.3 Environment Variables . . . 22
  - 2.3.1 Setting Variables . . . 22
  - 2.3.2 Zephyr Environment Scripts . . . 24
  - 2.3.3 Important Environment Variables . . . 24
- 2.4 Application Development . . . 25
  - 2.4.1 Overview . . . 25
  - 2.4.2 Application types . . . 26
  - 2.4.3 Creating an Application . . . 27
  - 2.4.4 Important Build System Variables . . . 30
  - 2.4.5 Application CMakeLists.txt . . . 31
  - 2.4.6 CMakeCache.txt . . . 33
  - 2.4.7 Application Configuration . . . 33
  - 2.4.8 Application-Specific Code . . . 34
  - 2.4.9 Building an Application . . . 35

2.4.10 Run an Application . . . 38
2.4.11 Custom Board, Devicetree and SOC Definitions . . . 39
2.5 Debugging . . . 43
2.5.1 Application Debugging . . . 43
2.5.2 Debug with Eclipse . . . 45
2.5.3 Debugging I2C communication . . . 47
2.6 API Status and Guidelines . . . 48
2.6.1 API Overview . . . 48
2.6.2 API Lifecycle . . . 77
2.6.3 Vendor-Specific API Placement Policy . . . 81
2.6.4 API Design Guidelines . . . 83
2.6.5 API Terminology . . . 85
2.7 Language Support . . . 87
2.7.1 C Language Support . . . 87
2.7.2 C++ Language Support . . . 93
2.7.3 Rust Language Support . . . 96
2.8 Optimizations . . . 97
2.8.1 Optimizing for Footprint . . . 97
2.8.2 Optimization Tools . . . 98
2.9 Flashing and Hardware Debugging . . . 105
2.9.1 Flash & Debug Host Tools . . . 105
2.9.2 Debug Probes . . . 114
2.10 Modules (External projects) . . . 121
2.10.1 Modules vs west projects . . . 122
2.10.2 Module Repositories . . . 122
2.10.3 Contributing to Zephyr modules . . . 123
2.10.4 Licensing requirements and policies . . . 125
2.10.5 Documentation requirements . . . 126
2.10.6 Testing requirements . . . 126
2.10.7 Deprecating and removing modules . . . 126
2.10.8 Integrate modules in Zephyr build system . . . 127
2.10.9 Module yaml file description . . . 127
2.10.10 Submitting changes to modules . . . 136
2.11 West (Zephyr's meta-tool) . . . 137
2.11.1 Installing west . . . 138
2.11.2 West Release Notes . . . 139
2.11.3 Troubleshooting West . . . 152
2.11.4 Basics . . . 155
2.11.5 Built-in commands . . . 157
2.11.6 Workspaces . . . 161
2.11.7 West Manifests . . . 166
2.11.8 Configuration . . . 196
2.11.9 West aliases . . . 199
2.11.10 Extensions . . . 199
2.11.11 Building, Flashing and Debugging . . . 203
2.11.12 Signing Binaries . . . 221
2.11.13 Additional Zephyr extension commands . . . 222
2.11.14 History and Motivation . . . 229
2.11.15 Using Zephyr without west . . . 231
2.12 Testing . . . 233
2.12.1 Test Framework . . . 233
2.12.2 Test Runner (Twister) . . . 243
2.12.3 Twister Status . . . 285
2.12.4 Twister blackbox tests . . . 287
2.12.5 Integration with pytest test framework . . . 290
2.12.6 Generating coverage reports . . . 297
2.12.7 BabbleSim . . . 299
2.13 Static Code Analysis (SCA) . . . 302

2.13.1 SCA Tool infrastructure . . . 302
2.13.2 Native SCA Tool support . . . 303
2.14 Toolchains . . . 312
2.14.1 Zephyr SDK . . . 312
2.14.2 Arm Compiler 6 . . . 315
2.14.3 Arm Toolchain for Embedded (ATfE) . . . 316
2.14.4 Cadence Tensilica Xtensa C/C++ Compiler (XCC) . . . 317
2.14.5 DesignWare ARC MetaWare Development Toolkit (MWDT) . . . 318
2.14.6 GNU Arm Embedded . . . 319
2.14.7 IAR Arm Toolchain . . . 320
2.14.8 Intel oneAPI Toolkit . . . 321
2.14.9 Host Toolchains . . . 321
2.14.10 Other Cross Compilers . . . 321
2.14.11 Custom CMake Toolchains . . . 322
2.15 Tools and IDEs . . . 323
2.15.1 CLion . . . 323
2.15.2 Coccinelle . . . 328
2.15.3 STM32CubeIDE . . . 336
2.15.4 Visual Studio Code . . . 341
2.15.5 Workbench for Zephyr . . . 343

3 Kernel **349**
3.1 Kernel Services . . . 349
3.1.1 Scheduling, Interrupts, and Synchronization . . . 349
3.1.2 Data Passing . . . 409
3.1.3 Memory Management . . . 430
3.1.4 Timing . . . 430
3.1.5 Other . . . 439
3.2 Device Driver Model . . . 449
3.2.1 Introduction . . . 449
3.2.2 Standard Drivers . . . 450
3.2.3 Synchronous Calls . . . 450
3.2.4 Driver APIs . . . 451
3.2.5 Driver Data Structures . . . 451
3.2.6 Subsystems and API Structures . . . 451
3.2.7 Device-Specific API Extensions . . . 452
3.2.8 Single Driver, Multiple Instances . . . 453
3.2.9 Initialization Levels . . . 455
3.2.10 Deferred initialization . . . 455
3.2.11 System Drivers . . . 455
3.2.12 Inspecting the initialization sequence . . . 455
3.2.13 Error handling . . . 456
3.2.14 Memory Mapping . . . 456
3.2.15 API Reference . . . 459
3.3 User Mode . . . 459
3.3.1 Overview . . . 459
3.3.2 Memory Protection Design . . . 462
3.3.3 Kernel Objects . . . 468
3.3.4 System Calls . . . 472
3.3.5 MPU Stack Objects . . . 481
3.3.6 MPU Backed Userspace . . . 482
3.4 Memory Management . . . 482
3.4.1 Memory Heaps . . . 482
3.4.2 Shared Multi Heap . . . 485
3.4.3 Memory Slabs . . . 486
3.4.4 Memory Blocks Allocator . . . 488
3.4.5 Demand Paging . . . 491
3.4.6 Virtual Memory . . . 494

3.5 Data Structures . . . 497
3.5.1 Single-linked List . . . 497
3.5.2 Double-linked List . . . 499
3.5.3 Multi Producer Single Consumer Packet Buffer . . . 500
3.5.4 Single Producer Single Consumer Packet Buffer . . . 503
3.5.5 Balanced Red/Black Tree . . . 503
3.5.6 Ring Buffers . . . 505
3.5.7 Multi Producer Single Consumer Lock Free Queue . . . 510
3.5.8 Single Producer Single Consumer Lock Free Queue . . . 510
3.5.9 Min-Heap Data Structure . . . 510
3.6 Executing Time Functions . . . 512
3.6.1 Configuration . . . 512
3.6.2 Usage . . . 512
3.6.3 API documentation . . . 513
3.7 Object Cores . . . 513
3.7.1 Object Core Concepts . . . 513
3.7.2 Object Core Statistics Concepts . . . 514
3.7.3 Implementation . . . 514
3.7.4 Configuration Options . . . 516
3.7.5 API Reference . . . 517
3.8 Time Utilities . . . 517
3.8.1 Overview . . . 517
3.8.2 Time Utility APIs . . . 518
3.8.3 Concepts Underlying Time Support in Zephyr . . . 520
3.9 Utilities . . . 522
3.10 Iterable Sections . . . 522
3.10.1 Usage . . . 522
3.10.2 API Reference . . . 523
3.11 Code And Data Relocation . . . 523
3.11.1 Overview . . . 523
3.11.2 Details . . . 523
3.12 Scope-based Cleanup Helpers . . . 525
3.12.1 Overview . . . 526
3.12.2 Core Concepts . . . 526
3.12.3 Defining Scoped Types . . . 527
3.12.4 Usage Notes . . . 528
3.12.5 API Reference . . . 529

4 OS Services **531**
4.1 Binary Descriptors . . . 531
4.1.1 Internals . . . 531
4.1.2 Usage . . . 532
4.1.3 API Reference . . . 533
4.2 Console . . . 534
4.3 CPU Frequency Scaling . . . 534
4.3.1 CPU Frequency Scaling Policies . . . 534
4.3.2 Overview . . . 535
4.3.3 Design Goals . . . 535
4.3.4 P-state Policies . . . 535
4.3.5 Metrics . . . 535
4.3.6 P-state Drivers . . . 535
4.3.7 Usage considerations . . . 535
4.4 CPU Load . . . 536
4.5 CRC . . . 536
4.5.1 Overview . . . 536
4.5.2 Configuration . . . 537
4.5.3 API Reference . . . 537
4.6 Cryptography . . . 537

4.6.1 PSA Crypto . . . 537
4.6.2 Random Number Generation . . . 539
4.6.3 Crypto APIs . . . 542
4.7 Debugging . . . 543
4.7.1 Thread analyzer . . . 543
4.7.2 CPU load . . . 544
4.7.3 Core Dump . . . 545
4.7.4 GDB stub . . . 550
4.7.5 Cortex-M Debug Monitor . . . 555
4.7.6 MIPI STP Decoder . . . 556
4.7.7 Symbol Table (Symtab) . . . 556
4.7.8 ARM Coresight Trace Deformatter . . . 557
4.7.9 Zyclictest . . . 557
4.8 Device Management . . . 559
4.8.1 MCUmgr . . . 559
4.8.2 MCUmgr handlers . . . 561
4.8.3 MCUmgr Callbacks . . . 570
4.8.4 SMP Protocol Specification . . . 575
4.8.5 SMP Transport Specification . . . 620
4.8.6 Device Firmware Upgrade . . . 622
4.8.7 Over-the-Air Update . . . 623
4.8.8 EC Host Command . . . 624
4.9 Digital Signal Processing (DSP) . . . 628
4.9.1 Using zDSP . . . 628
4.9.2 Optimizing for your architecture . . . 628
4.9.3 API Reference . . . 629
4.10 Formatted Output . . . 629
4.10.1 Cbprintf Packaging . . . 629
4.10.2 API Reference . . . 631
4.11 Input . . . 631
4.11.1 Input Events . . . 631
4.11.2 Input Devices . . . 632
4.11.3 Application API . . . 632
4.11.4 HID code mapping . . . 632
4.11.5 General Purpose Drivers . . . 632
4.11.6 Detailed Driver Documentation . . . 633
4.11.7 API Reference . . . 637
4.11.8 Input Event Definitions . . . 638
4.11.9 Analog Axis API Reference . . . 638
4.11.10 Touchscreen API Reference . . . 638
4.12 Instrumentation . . . 638
4.12.1 Overview . . . 638
4.12.2 Operational Modes . . . 639
4.12.3 Configuration . . . 641
4.12.4 `zaru.py` Usage . . . 641
4.12.5 Limitations and Considerations . . . 642
4.12.6 API Reference . . . 642
4.13 Interprocessor Communication (IPC) . . . 642
4.13.1 IPC service . . . 642
4.14 JSON Web Token (JWT) . . . 655
4.14.1 Overview . . . 655
4.14.2 Configuration . . . 656
4.14.3 API Reference . . . 656
4.15 Linkable Loadable Extensions (LLEXT) . . . 656
4.15.1 Configuration . . . 656
4.15.2 Building extensions . . . 660
4.15.3 Loading extensions . . . 664
4.15.4 Troubleshooting . . . 665

4.15.5 Debugging extensions . . . 665
4.15.6 API Reference . . . 671
4.16 Logging . . . 672
4.16.1 Global Kconfig Options . . . 674
4.16.2 Usage . . . 675
4.16.3 Rate-limited logging . . . 677
4.16.4 Logging panic . . . 679
4.16.5 Printk . . . 679
4.16.6 Architecture . . . 679
4.16.7 Recommendations and limitations . . . 685
4.16.8 Benchmark . . . 686
4.16.9 Stack usage . . . 686
4.16.10 Logging using ARM Coresight STM . . . 687
4.16.11 API Reference . . . 687
4.17 Tracing . . . 692
4.17.1 Overview . . . 692
4.17.2 Named Trace Events . . . 693
4.17.3 Serialization Formats . . . 693
4.17.4 Tracing Tools . . . 694
4.17.5 Transport Backends . . . 700
4.17.6 Using Tracing . . . 700
4.17.7 Future LTTng Inspiration . . . 701
4.17.8 Object tracking . . . 702
4.17.9 API . . . 703
4.18 Resource Management . . . 705
4.18.1 On-Off Manager . . . 705
4.19 Memory Attributes . . . 706
4.19.1 Migration guide from zephyr,memory-region-mpu . . . 707
4.19.2 Memory Attributes Heap Allocator . . . 707
4.19.3 API Reference . . . 709
4.20 Network Buffers . . . 709
4.20.1 Overview . . . 709
4.20.2 Creating buffers . . . 709
4.20.3 Common Operations . . . 710
4.20.4 Reference Counting . . . 710
4.20.5 API Reference . . . 710
4.21 Modem modules . . . 711
4.21.1 Modem pipe . . . 711
4.21.2 Modem PPP . . . 711
4.21.3 Modem CMUX . . . 712
4.21.4 Modem pipelink . . . 712
4.21.5 Modem chat . . . 712
4.21.6 Cellular Modem . . . 712
4.21.7 CMUX Power Saving . . . 716
4.22 Asynchronous Notifications . . . 718
4.22.1 API Reference . . . 719
4.23 Power Management . . . 719
4.23.1 Overview . . . 719
4.23.2 System Power Management . . . 719
4.23.3 Device Power Management . . . 722
4.23.4 Device Runtime Power Management . . . 734
4.23.5 Power Domain . . . 739
4.23.6 Power Management APIs . . . 742
4.24 OS Abstraction . . . 743
4.24.1 POSIX . . . 743
4.24.2 CMSIS RTOS v1 . . . 771
4.24.3 CMSIS RTOS v2 . . . 771
4.25 Power off . . . 772

4.26 Profiling . . . 772
4.26.1 Perf . . . 772
4.27 Shell . . . 773
4.27.1 Overview . . . 774
4.27.2 Backends . . . 774
4.27.3 Commands . . . 777
4.27.4 Tab Feature . . . 784
4.27.5 History Feature . . . 784
4.27.6 Wildcards Feature . . . 784
4.27.7 Meta Keys Feature . . . 785
4.27.8 sys_getopt Feature . . . 786
4.27.9 Obscured Input Feature . . . 786
4.27.10 Reading User Input . . . 787
4.27.11 Shell Logger Backend Feature . . . 787
4.27.12 RTT Backend Channel Selection . . . 788
4.27.13 Usage . . . 788
4.27.14 API Reference . . . 789
4.28 Serialization . . . 790
4.28.1 CBOR . . . 790
4.28.2 JSON . . . 790
4.28.3 Nanopb . . . 791
4.29 State Machine Framework . . . 792
4.29.1 Overview . . . 792
4.29.2 State Creation . . . 792
4.29.3 State Machine Creation . . . 793
4.29.4 State Machine Execution . . . 794
4.29.5 State Machine Termination . . . 794
4.29.6 Retrieving the Current State . . . 794
4.29.7 UML State Machines . . . 794
4.29.8 State Machine Examples . . . 795
4.29.9 Test Instrumentation . . . 802
4.29.10 API Reference . . . 804
4.30 Storage . . . 804
4.30.1 Disk Access . . . 804
4.30.2 Flash Circular Buffer (FCB) . . . 808
4.30.3 File Systems . . . 809
4.30.4 Flash map . . . 810
4.30.5 Non-Volatile Memory (NVMEM) . . . 812
4.30.6 Non-Volatile Storage (NVS) . . . 814
4.30.7 Retention System . . . 816
4.30.8 Secure Storage . . . 821
4.30.9 Settings . . . 823
4.30.10 Stream Flash . . . 829
4.30.11 Zephyr Memory Storage (ZMS) . . . 830
4.31 Sensing Subsystem . . . 837
4.31.1 Overview . . . 837
4.31.2 Configurability . . . 838
4.31.3 Main Features . . . 838
4.31.4 Major Flows . . . 839
4.31.5 Sensor Types And Instance . . . 840
4.31.6 Sensor Instance Handler . . . 840
4.31.7 Sensor Sample Value . . . 841
4.31.8 Device Tree Configuration . . . 842
4.31.9 API Reference . . . 842
4.32 Task Watchdog . . . 842
4.32.1 Overview . . . 842
4.32.2 Configuration Options . . . 843
4.32.3 API Reference . . . 843

4.33 Trusted Firmware-M (TF-M) . . . 843
4.33.1 Trusted Firmware-M Overview . . . 843
4.33.2 TF-M Requirements . . . 847
4.33.3 TF-M Build System . . . 848
4.33.4 Trusted Firmware-M Integration . . . 852
4.33.5 Test Suites . . . 853
4.34 UUID . . . 854
4.34.1 Overview . . . 854
4.34.2 Configuration . . . 855
4.34.3 API Reference . . . 855
4.35 Virtualization . . . 855
4.35.1 Inter-VM Shared Memory . . . 855
4.36 Real Time I/O (RTIO) . . . 856
4.36.1 Problem . . . 857
4.36.2 Inspiration, introducing io_uring . . . 857
4.36.3 Submission Queue . . . 858
4.36.4 Completion Queue . . . 858
4.36.5 Executor . . . 858
4.36.6 IO Device . . . 858
4.36.7 Cancellation . . . 859
4.36.8 Memory pools . . . 859
4.36.9 When to Use . . . 860
4.36.10 Supported Buses . . . 860
4.36.11 API Reference . . . 860
4.37 Zephyr bus (zbus) . . . 860
4.37.1 Concepts . . . 861
4.37.2 Usage . . . 870
4.37.3 Samples . . . 877
4.37.4 Suggested Uses . . . 878
4.37.5 Configuration Options . . . 878
4.37.6 API Reference . . . 879

5 Build and Configuration Systems 881
5.1 Build System (CMake) . . . 881
5.1.1 Build and Configuration Phases . . . 881
5.1.2 Supporting Scripts and Tools . . . 888
5.2 Devicetree . . . 891
5.2.1 Devicetree Guide . . . 892
5.2.2 Devicetree Reference . . . 957
5.3 Configuration System (Kconfig) . . . 1064
5.3.1 Interactive Kconfig interfaces . . . 1064
5.3.2 Tracing values to their source . . . 1069
5.3.3 Setting Kconfig configuration values . . . 1070
5.3.4 Kconfig - Tips and Best Practices . . . 1075
5.3.5 Custom Kconfig Preprocessor Functions . . . 1090
5.3.6 Kconfig extensions . . . 1092
5.4 Snippets . . . 1094
5.4.1 Using Snippets . . . 1095
5.4.2 Built-in snippets . . . 1095
5.4.3 Writing Snippets . . . 1107
5.4.4 Snippets Design . . . 1111
5.5 Zephyr CMake Package . . . 1111
5.5.1 Zephyr CMake package export (west) . . . 1112
5.5.2 Zephyr CMake package export (without west) . . . 1112

Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- Renesas RX
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa

The full list of supported boards based on these architectures can be found here.

In the context of the Zephyr OS, a *subsystem* refers to a logically distinct part of the operating system that handles specific functionality or provides certain services. Subsystems can include components such as networking, file systems, device driver classes, power management, and communication protocols, among others. Each subsystem is designed to be modular and can be configured, customized, and extended to meet the requirements of different embedded applications.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the `LICENSE` file in the project's GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in *Licensing of Zephyr Project components*.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

Extensive suite of Kernel services
: Zephyr offers a number of familiar services for development:

- *Multi-threading Services* for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- *Interrupt Services* for compile-time registration of interrupt handlers.
- *Memory Allocation Services* for dynamic allocation and freeing of fixed-size or variable-size memory blocks.
- *Inter-thread Synchronization Services* for binary semaphores, counting semaphores, and mutex semaphores.
- *Inter-thread Data Passing Services* for basic message queues, enhanced message queues, and byte streams.
- *Power Management Services* such as overarching, application or policy-defined, System Power Management and fine-grained, driver-defined, Device Power Management.

Multiple Scheduling Algorithms
Zephyr provides a comprehensive set of thread scheduling choices:

- Cooperative and Preemptive Scheduling
- Earliest Deadline First (EDF)
- Meta IRQ scheduling implementing "interrupt bottom half" or "tasklet" behavior
- Timeslicing: Enables time slicing between preemptible threads of equal priority
- Multiple queuing strategies:
  - Simple linked-list ready queue
  - Red/black tree ready queue
  - Traditional multi-queue ready queue

Highly configurable / Modular for flexibility
Allows an application to incorporate *only* the capabilities it needs as it needs them, and to specify their quantity and size.

Cross Architecture
Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

Memory Protection
Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system's hardware. Both the application code and kernel code execute in a single shared address space.

Compile-time resource definition
Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

Optimized Device Driver Model
Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and allows the reuse of drivers across platforms that have common devices/IP blocks.

Devicetree Support
Use of *devicetree* to describe hardware. Information from devicetree is used to create the application image.

Native Networking Stack supporting multiple protocols
Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.

Bluetooth Low Energy 5.0 support
Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth Mesh and a Bluetooth qualification-ready Bluetooth controller.

- Generic Access Profile (GAP) with all possible LE roles
- Generic Attribute Profile (GATT)
- Pairing support, including the Secure Connections feature from Bluetooth 4.2
- Clean HCI driver abstraction
- Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
- Verified with multiple popular controllers
- Highly configurable

Mesh Support:

- Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
- Both Provisioning bearers supported (PB-ADV & PB-GATT)
- Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development
A command-line CMake build environment runs on popular developer OS systems. A native port (native_sim) lets you build and run Zephyr as a native application on Linux, aiding development and testing.

Virtual File System Interface with ext2, FatFs, and LittleFS Support
ext2, LittleFS and FatFS support; FCB (Flash Circular Buffer) for memory constrained applications.

Powerful multi-backend logging Framework
Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, ...) and integration with the shell subsystem.

User friendly and full-featured Shell interface
A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage
The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS)
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native port
Native sim allows running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support

Community support is provided via mailing lists and Discord; see the Resources below for details.

1.4 Resources

Here's a quick summary of resources to help you find your way around:

1.4.1 Getting Started

- Zephyr Documentation
- Getting Started Guide
- Tips when asking for help
- Code samples

1.4.2 Code and Development

- Source Code Repository
- Releases
- Contribution Guide

1.4.3 Community and Support

- Discord Server for real-time community discussions
- User mailing list (users@lists.zephyrproject.org)
- Developer mailing list (devel@lists.zephyrproject.org)
- Other project mailing lists
- Project Wiki

1.4.4 Issue Tracking and Security

- GitHub Issues
- Security documentation
- Security Advisories Repository
- Report security vulnerabilities at vulnerabilities@zephyrproject.org

1.4.5 Additional Resources

- Zephyr Project Website
- Zephyr Tech Talks

1.5 Fundamental Terms and Concepts

See *Glossary of Terms*

Chapter 2

Developing with Zephyr

2.1 Getting Started Guide

Follow this guide to:

- Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in *Install Linux Host Dependencies*)
- Get the source code
- Build, flash, and run a sample application

2.1.1 Select and Update OS

Click the operating system you are using.

Ubuntu

This guide covers Ubuntu version 24.04 LTS and later. If you are using a different Linux distribution see *Install Linux Host Dependencies*.

```
sudo apt update
sudo apt upgrade
```

macOS

On macOS Mojave or later, select *System Preferences* > *Software Update*. Click *Update Now* if necessary.

On other versions, see this Apple support topic.

Windows

Select *Start* > *Settings* > *Update & Security* > *Windows Update*. Click *Check for updates* and install any that are available.

2.1.2 Install dependencies

Next, you'll install some host dependencies using your package manager.

The current minimum required version for the main dependencies are:

Tool	Min. Version
CMake	3.20.5
Python	3.12
Devicetree compiler	1.4.6

Ubuntu

1. Use apt to install the required dependencies:

```
sudo apt install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget python3-dev python3-venv␣
↪python3-tk \
  xz-utils file make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

> **Note**
>
> Due to the unavailability of `gcc-multilib` and `g++-multilib` on AArch64 (ARM64) systems, you may need to omit them from the list of packages to install.

2. Verify the versions of the main dependencies installed on your system by entering:

```
cmake --version
python3 --version
dtc --version
```

Check those against the versions in the table in the beginning of this section. Refer to the *Install Linux Host Dependencies* page for additional information on updating the dependencies manually.

macOS

1. Install Homebrew:

```
/bin/bash -c "$(curl -fsSL␣
↪https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
```

2. After the Homebrew installation script completes, follow the on-screen instructions to add the Homebrew installation to the path.
   - On macOS running on Apple Silicon, this is achieved with:

```
(echo; echo 'eval "$(/opt/homebrew/bin/brew shellenv)"') >> ~/.zprofile
source ~/.zprofile
```

   - On macOS running on Intel, use the command for Apple Silicon, but replace `/opt/homebrew/` with `/usr/local/`.

3. Use `brew` to install the required dependencies:

```
brew install cmake ninja gperf python3 python-tk ccache qemu dtc libmagic␣
↪wget openocd
```

4. Add the Homebrew Python folder to the path, in order to be able to execute `python` and `pip` as well `python3` and `pip3`.

```
(echo; echo 'export PATH="'$(brew --prefix)'/
↪opt/python/libexec/bin:$PATH"') >> ~/.zprofile
source ~/.zprofile
```

Windows

> **Note**
>
> Due to issues finding executables, the Zephyr Project doesn't currently support application flashing using the Windows Subsystem for Linux (WSL) (WSL).

Therefore, we don't recommend using WSL when getting started.

In modern version of Windows (10 and later) it is recommended to install the Windows Terminal application from the Microsoft Store. Instructions are provided for a `cmd.exe` or PowerShell command prompts.

These instructions rely on Windows' official package manager, winget. If using winget isn't an option, you can install dependencies from their respective websites and ensure the command line tools are on your *PATH environment variable*.

1. In modern Windows versions, winget is already pre-installed by default. You can verify that this is the case by typing `winget` in a terminal window. If that fails, you can then install winget.
2. Open a Command Prompt (`cmd.exe`) or PowerShell terminal window. To do so, press the Windows key, type `cmd.exe` or PowerShell and click on the result.
3. Use `winget` to install the required dependencies:

```
winget install Kitware.CMake Ninja-build.Ninja oss-winget.gperf␣
↪Python.Python.3.12 Git.Git oss-winget.dtc wget 7zip.7zip
```

4. Close the terminal window.

Note

You may need to add the 7zip installation folder to your `PATH`.

2.1.3 Get Zephyr and install Python dependencies

Next, clone Zephyr and its *modules* into a new *west* workspace. In the following instructions the name `zephyrproject` is used for the workspace, however in practice its name and location can be freely chosen. You'll also install Zephyr's additional Python dependencies in a Python virtual environment.

Ubuntu

1. Create a new virtual environment:

```
python3 -m venv ~/zephyrproject/.venv
```

2. Activate the virtual environment:

```
source ~/zephyrproject/.venv/bin/activate
```

Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

Note

Remember to activate the virtual environment every time you start working.

3. Install west:

```
pip install west
```

4. Get the Zephyr source code:

```
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

5. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

6. Install Python dependencies using `west packages`.

```
west packages pip --install
```

> **Note**
>
> This could downgrade or upgrade west itself.

macOS

1. Create a new virtual environment:

```
python3 -m venv ~/zephyrproject/.venv
```

2. Activate the virtual environment:

```
source ~/zephyrproject/.venv/bin/activate
```

Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

> **Note**
>
> Remember to activate the virtual environment every time you start working.

3. Install west:

```
pip install west
```

4. Get the Zephyr source code:

```
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

5. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

6. Install Python dependencies using `west packages`.

```
west packages pip --install
```

> **Note**
>
> This could downgrade or upgrade west itself.

Windows

1. Open a `cmd.exe` or PowerShell terminal window **as a regular user**
2. Create a new virtual environment:

   Batchfile

   ```
   cd %HOMEPATH%
   python -m venv zephyrproject\.venv
   ```

   PowerShell

   ```
   cd $Env:HOMEPATH
   python -m venv zephyrproject\.venv
   ```

3. Activate the virtual environment:

   > **Note**
   >
   > Python's virtual environment activation in PowerShell requires running a script itself, which needs to be allowed.
   >
   > ```
   > Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
   > ```

   Batchfile

   ```
   zephyrproject\.venv\Scripts\activate.bat
   ```

   PowerShell

   ```
   zephyrproject\.venv\Scripts\Activate.ps1
   ```

   Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

   > **Note**
   >
   > Remember to activate the virtual environment every time you start working.

4. Install west:

   ```
   pip install west
   ```

5. Get the Zephyr source code:

   ```
   west init zephyrproject
   cd zephyrproject
   west update
   ```

6. Export a *Zephyr CMake package*. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```
west zephyr-export
```

7. Install Python dependencies using `west packages`.

   Batchfile

   ```
   cmd /c zephyr\scripts\utils\west-packages-pip-install.cmd
   ```

   PowerShell

   ```
   python -m pip install @((west packages pip) -split ' ')
   ```

   Note

   This could downgrade or upgrade west itself.

2.1.4 Install the Zephyr SDK

The *Zephyr Software Development Kit (SDK)* contains toolchains for each of Zephyr's supported architectures, which include a compiler, assembler, linker and other programs required to build Zephyr applications.

For Linux, it also contains additional host tools, such as custom QEMU and OpenOCD builds that are used to emulate, flash and debug Zephyr applications.

Ubuntu

Install the Zephyr SDK using the `west sdk install`.

```
cd ~/zephyrproject/zephyr
west sdk install
```

Tip

Using the command options, you can specify the SDK installation destination and which architecture of toolchains to install. See `west sdk install --help` for details.

macOS

Install the Zephyr SDK using the `west sdk install`.

```
cd ~/zephyrproject/zephyr
west sdk install
```

Tip

Using the command options, you can specify the SDK installation destination and which architecture of toolchains to install. See `west sdk install --help` for details.

Windows

Install the Zephyr SDK using the `west sdk install`.

Batchfile

```
cd %HOMEPATH%\zephyrproject\zephyr
west sdk install
```

PowerShell

```
cd $Env:HOMEPATH\zephyrproject\zephyr
west sdk install
```

Tip

Using the command options, you can specify the SDK installation destination and which architecture of toolchains to install. See `west sdk install --help` for details.

Note

If you want to install Zephyr SDK without using the `west sdk` command, please see *Zephyr SDK installation*.

2.1.5 Build the Blinky Sample

Note

blinky is compatible with most, but not all, boards. If your board does not meet Blinky's blinky-sample-requirements, then hello_world is a good alternative.

If you are unsure what name west uses for your board, `west boards` can be used to obtain a list of all boards Zephyr supports.

Build the blinky with *west build*, changing `<your-board-name>` appropriately for your board:

Ubuntu

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

macOS

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

Windows

Batchfile

```
cd %HOMEPATH%\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

PowerShell

```
cd $Env:HOMEPATH\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

The `-p always` option forces a pristine build, and is recommended for new users. Users may also use the `-p auto` option, which will use heuristics to determine if a pristine build is required, such as when building another sample.

Note

A board may contain one or multiple SoCs, Also, each SoC may contain one or more CPU clusters. When building for such boards it is necessary to specify the SoC or CPU cluster for which the sample must be built. For example to build blinky for the cpuapp core on the nrf5340dk the board must be provided as: `nrf5340dk/nrf5340/cpuapp`. See also *Board terminology* for more details.

2.1.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there's a power switch. If in doubt about what to do, check your board's page in boards.

Then flash the sample using *west flash*:

```
west flash
```

Note

You may need to install additional *host tools* required by your board. The `west flash` command will print an error if any required dependencies are missing.

Note

When using Linux, you may need to configure udev rules the first time of using a debug probe. Please also see *Setting udev rules*.

If you're using blinky, the LED will start to blink as shown in this figure:

Fig. 1: Phytec reel_board running blinky

2.1.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples

- Learn about *Application Development* and the *west* tool
- Find out about west's *flashing and debugging* features, or more about *Flashing and Hardware Debugging* in general
- Check out *Beyond the Getting Started Guide* for additional setup alternatives and ideas
- Discover *Resources* for getting help from the Zephyr community

2.1.8 Troubleshooting Installation

Here are some tips for fixing some issues related to the installation process.

Double Check the Zephyr SDK Variables When Updating

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set. See *Updating the Zephyr SDK toolchain* for more information.

For more information about these environment variables in Zephyr, see *Important Environment Variables*.

2.1.9 Asking for Help

You can ask for help on a mailing list or on Discord. Please send bug reports and feature requests to GitHub.

- **Mailing Lists**: users@lists.zephyrproject.org is usually the right list to ask for help. Search archives and sign up here.
- **Discord**: You can join with this Discord invite.
- **GitHub**: Use GitHub issues for bugs and feature requests.

How to Ask

Important

Please search this documentation and the mailing list archives first. Your question may have an answer there.

Don't just say "this isn't working" or ask "is this working?". Include as much detail as you can about:

1. What you want to do
2. What you tried (commands you typed, etc.)
3. What happened (output of each command, etc.)

Use Copy/Paste

Please **copy/paste text** instead of taking a picture or a screenshot of it. Text includes source code, terminal commands, and their output.

Doing this makes it easier for people to help you, and also helps other users search the archives. Unnecessary screenshots exclude vision impaired developers; some are major Zephyr contributors. Accessibility has been recognized as a basic human right by the United Nations.

When copy/pasting more than 5 lines of computer text into Discord or Github, create a snippet using three backticks to delimit the snippet.

2.2 Beyond the Getting Started Guide

The *Getting Started Guide* gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.

2.2.1 Python and pip

Python 3 and its package manager, pip[1], are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the `--user` flag to the `pip3` command when installing new packages. This is documented throughout the instructions. See Installing Packages in the Python Packaging User Guide for more information about pip[1], including information on -\-user.

- On Linux, make sure `~/.local/bin` is at the front of your *PATH environment variable*, or programs installed with `--user` won't be found. Installing with `--user` avoids conflicts between pip and the system package manager, and is the default on Debian-based distributions.
- On macOS, Homebrew disables -\-user.
- On Windows, see the Installing Packages information on `--user` if you require using this option.

On all operating systems, pip's `-U` flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the scripts/requirements.txt file to see if a specific Python package version is expected.)

2.2.2 Advanced Platform Setup

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

Install Linux Host Dependencies

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

Note

If you're working behind a corporate firewall, you'll likely need to configure a proxy for accessing the internet, if you haven't done so already. While some tools use the environment

[1] pip is Python's package installer. Its `install` command first tries to reuse packages and package dependencies already installed on your computer. If that is not possible, `pip install` downloads them from the Python Package Index (PyPI) on the Internet.
The package versions requested by Zephyr's `requirements.txt` may conflict with other requirements on your system, in which case you may want to set up a virtualenv for Zephyr development.

variables `http_proxy` and `https_proxy` to get their proxy settings, some use their own configuration files, most notably `apt` and `git`.

Update Your Operating System Ensure your host system is up to date.

Ubuntu

```
sudo apt-get update
sudo apt-get upgrade
```

Fedora

```
sudo dnf upgrade
```

Clear Linux

```
sudo swupd update
```

Arch Linux

```
sudo pacman -Syu
```

Install Requirements and Dependencies Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils␣
↪file \
  make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

Fedora

```
sudo dnf group install development-tools c-development
sudo dnf install cmake ninja-build gperf dfu-util dtc wget which \
  python3-pip python3-tkinter xz file python3-devel SDL2-devel
```

Clear Linux

```
sudo swupd bundle-add c-basic dev-utils dfu-util dtc \
  os-core-dev python-basic python3-basic python3-tcl
```

The Clear Linux focus is on *native* performance and security and not cross-compilation. For that reason it uniquely exports by default to the *environment* of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for *all users on the system*. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in `/usr/share/defaults/etc/profile`.

Arch Linux

```
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
    python-pip python-setuptools python-wheel tk xz file make which
```

CMake A *recent CMake version* is required. Check what version you have by using `cmake --version`. If you have an older version, there are several ways of obtaining a more recent one:

- On Ubuntu, you can follow the instructions for adding the kitware third-party apt repository to get an updated version of cmake using apt.
- Download and install a packaged cmake from the CMake project site. (Note this won't uninstall the previous version of cmake.)

  ```
  cd ~
  wget␣
  ↪https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_64.sh
  chmod +x cmake-3.21.1-Linux-x86_64.sh
  sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
  hash -r
  ```

  The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.
- Download and install from the pre-built binaries provided by the CMake project itself in the CMake Downloads page. For example, to install version 3.21.1 in `~/bin/cmake`:

  ```
  mkdir $HOME/bin/cmake && cd $HOME/bin/cmake
  wget␣
  ↪https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_64.sh
  yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
  echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:\$PATH" >>
  ↪$HOME/.zephyrrc
  ```
- Use `pip3`:

  ```
  pip3 install --user cmake
  ```

  Note this won't uninstall the previous version of cmake and will install the new cmake into your ~/.local/bin folder so you'll need to add ~/.local/bin to your PATH. (See *Python and pip* for details.)
- Check your distribution's beta or unstable release package library for an update.
- On Ubuntu you can also use snap to get the latest version available:

  ```
  sudo snap install cmake
  ```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `whereis cmake` to find other installed versions.)

DTC (Device Tree Compiler) A *recent DTC version* is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the *Zephyr SDK* by installing it.

Python A *modern Python 3 version* is required. Check what version you have by using `python3 --version`.

If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution's package manager channels if one is available.

Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

Install the Zephyr Software Development Kit (SDK) The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

To install the SDK, follow the Linux steps from the Zephyr SDK installation guide.

Building on Linux without the Zephyr SDK The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides prebuilt host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as described in the *Toolchains* section.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the *ZEPHYR_SDK_INSTALL_DIR* environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the *ZEPHYR_SDK_INSTALL_DIR* environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

macOS alternative setup instructions

Important note about Gatekeeper Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open *System Preferences* ▸ *Security and Privacy* ▸ *Privacy* and then scroll down to "Developer Tools". Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does **not** apply to executables installed with Homebrew, since those are automatically un-quarantined by `brew` itself. This is however relevant for most *Toolchains*.

Additional notes for MacPorts users While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install `rust` and `cargo` for the Python dependencies to install correctly.

Windows alternative setup instructions

Windows 10 WSL (Windows Subsystem for Linux) If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the *Zephyr SDK* without setting up a virtual machine.

Warning

Windows 10 version 1803 has an issue that will cause CMake to not work properly and is fixed in version 1809 (and later). More information can be found in Zephyr Issue 10420.

1. Install the Windows Subsystem for Linux (WSL).

   Note

   For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the "About your PC" section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator's Update.

2. Follow the Ubuntu instructions in the *Install Linux Host Dependencies* document.

2.2.3 Install a Toolchain

Zephyr binaries are compiled and linked by a *toolchain* comprised of a cross-compiler and related tools which are different from the compiler and tools used for developing software that runs natively on your host operating system.

You can install the *Zephyr SDK* to get toolchains for all supported architectures, or install an *alternate toolchain* recommended by the SoC vendor or a specific board (check your specific board-level documentation).

You can configure the Zephyr build system to use a specific toolchain by setting *environment variables* such as `ZEPHYR_TOOLCHAIN_VARIANT` to a supported value, along with additional variable(s) specific to the toolchain variant.

2.2.4 Updating the Zephyr SDK toolchain

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set.

- If the variables are not set, the latest compatible version of Zephyr SDK will be selected by default. Proceed to next step without making any changes.
- If `ZEPHYR_TOOLCHAIN_VARIANT` is set, the corresponding toolchain will be selected at build time. Zephyr SDK is identified by the value `zephyr`. If the `ZEPHYR_TOOLCHAIN_VARIANT` environment variable is not `zephyr`, then either unset it or change its value to `zephyr` to make sure Zephyr SDK is selected.
- If the `ZEPHYR_SDK_INSTALL_DIR` environment variable is set, it will override the default lookup location for Zephyr SDK. If you install Zephyr SDK to one of the *recommended locations*, you can unset this variable. Otherwise, set it to your chosen install location.

For more information about these environment variables in Zephyr, see *Important Environment Variables*.

2.2.5 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the GitHub zephyr repo. External modules used by Zephyr are found in the parent GitHub Zephyr project. Because of these dependencies, it's convenient to use the Zephyr-created *west* tool to fetch and manage the Zephyr and external module source code. See *Basics* for more details.

Once your development tools are installed, use *West (Zephyr's meta-tool)* to create, initialize, and download sources from the zephyr and external module repos. We'll use the name `zephyrproject`, but you can choose any name that does not contain a space anywhere in the path.

```
west init zephyrproject
cd zephyrproject
west update
```

The `west update` command fetches and keeps *Modules (External projects)* in the `zephyrproject` folder in sync with the code in the local zephyr repo.

Warning

You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the `zephyr` repository, switch branches in it, or perform a `git bisect` inside of it.

Keeping Zephyr updated

To update the Zephyr project source code, you need to get the latest changes via `git`. Afterwards, run `west update` as mentioned in the previous paragraph. Additionally, check for updated or added Python dependencies.

Linux/macOS

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
west packages pip --install
```

Windows

Batchfile

```
:: replace zephyrproject with the path you gave west init
cd zephyrproject\zephyr
git pull
west update
cmd /c scripts\utils\west-packages-pip-install.cmd
```

PowerShell

```
# replace zephyrproject with the path you gave west init
cd zephyrproject\zephyr
git pull
west update
python -m pip install @((west packages pip) -split ' ')
```

2.2.6 Export Zephyr CMake package

The *Zephyr CMake Package* can be exported to CMake's user package registry if it has not already been done as part of *Getting Started Guide*.

2.2.7 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable foo_BOARD_ALIAS=bar replaces BOARD=foo with BOARD=bar and
# sets BOARD_ALIAS=foo in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk/nrf51822)
set(pca10056_BOARD_ALIAS nrf52840dk/nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in *ZEPHYR_BOARD_ALIASES*. This enables use of aliases `pca10028` in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

2.2.8 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native application with native_sim. Additional information about building applications can be found in the *Building an Application* section.

Build Blinky

Let's build the blinky sample application.

Zephyr applications are built to run on specific hardware, called a "board"[2]. We'll use the Phytec reel_board here, but you can change the `reel_board` build target to another value if you have a different board. See boards or run `west boards` from anywhere inside the `zephyrproject` directory for a list of supported boards.

1. Go to the zephyr repository:

   ```
   cd zephyrproject/zephyr
   ```

2. Build the blinky sample for the `reel_board`:

   ```
   # From the root of the zephyr repository
   west build -b reel_board samples/basic/blinky
   ```

The main build products will be in `build/zephyr`; `build/zephyr/zephyr.elf` is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

The other sample applications in the samples folder are documented in samples.

> **Note**
>
> If you want to reuse an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See *Run an Application* and your specific board's documentation in boards for additional details.

[2] This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr's driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a "board," even though that doesn't always make perfect sense in context.

Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you've installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:

```
wget -O 60-openocd.rules␣
↪https://sf.net/p/openocd/code/ci/master/tree/contrib/60-openocd.rules?format=raw
sudo cp 60-openocd.rules /etc/udev/rules.d
```

- or copy the rules file from the Zephyr SDK folder:

```
sudo cp $
↪{ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/openocd/contrib/60-openoc
↪/etc/udev/rules.d
```

Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation (boards) for further information if needed.

Run the Application in QEMU

On Linux and macOS, you can run Zephyr applications via emulation on your host system using QEMU when targeting either the x86 or ARM Cortex-M3 architectures. (QEMU is included with the Zephyr SDK installation.)

On Windows, you need to install QEMU manually from Download QEMU. After installation, add path to QEMU installation folder to PATH environment variable. To enable QEMU in Test Runner (Twister) on Windows, *set the environment variable* `QEMU_BIN_PATH` to the path of QEMU installation folder.

For example, you can build and run the hello_world sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type `Ctrl-a`, then `x`.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

Run a Sample Application natively (Linux)

You can compile some samples to run as host programs on Linux. See native_sim for more information. On 64-bit host operating systems, you need to install a 32-bit C library, or build targeting native_sim/native/64.

First, build Hello World for `native_sim`.

```
# From the root of the zephyr repository
west build -b native_sim samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press `Ctrl-C` to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as gdb or valgrind.

2.3 Environment Variables

Various pages in this documentation refer to setting Zephyr-specific environment variables. This page describes how.

2.3.1 Setting Variables

Option 1: Just Once

To set the environment variable `MY_VARIABLE` to `foo` for the lifetime of your current terminal window:

Linux/macOS

```
export MY_VARIABLE=foo
```

Windows

```
set MY_VARIABLE=foo
```

Warning

This is best for experimentation. If you close your terminal window, use another terminal window or tab, restart your computer, etc., this setting will be lost forever.

Using options 2 or 3 is recommended if you want to keep using the setting.

Option 2: In all Terminals

Linux/macOS

Add the `export MY_VARIABLE=foo` line to your shell's startup script in your home directory. For Bash, this is usually `~/.bashrc` on Linux or `~/.bash_profile` on macOS. Changes in these startup scripts don't affect shell instances already started; try opening a new terminal window to get the new settings.

Windows

You can use the `setx` program in `cmd.exe` or the third-party RapidEE program.

To use `setx`, type this command, then close the terminal window. Any new `cmd.exe` windows will have `MY_VARIABLE` set to `foo`.

```
setx MY_VARIABLE foo
```

To install RapidEE, a freeware graphical environment variable editor, using Chocolatey in an Administrator command prompt:

```
choco install rapidee
```

You can then run `rapidee` from your terminal to launch the program and set environment variables. Make sure to use the "User" environment variables area – otherwise, you have to run RapidEE as administrator. Also make sure to save your changes by clicking the Save button at top left before exiting. Settings you make in RapidEE will be available whenever you open a new terminal window.

Option 3: Using `zephyrrc` files

Choose this option if you don't want to make the variable's setting available to all of your terminals, but still want to save the value for loading into your environment when you are using Zephyr.

Linux/macOS

Zephyr supports multiple locations for your `zephyrrc` file, following the XDG Base Directory Specification when possible. Create a zephyrrc file in one of the following locations (they will be checked in order):

1. `$XDG_CONFIG_HOME/zephyr/zephyrrc`
2. `$HOME/.config/zephyr/zephyrrc`
3. `$HOME/.zephyrrc`

Add this line to the file in your preferred location:

```
export MY_VARIABLE=foo
```

To get this value back into your current terminal environment, **you must run** `source zephyr-env.sh` from the main `zephyr` repository. Among other things, this script sources your `zephyrrc` (the first one it finds from the list of locations above).

The value will be lost if you close the window, etc.; run `source zephyr-env.sh` again to get it back.

Windows

Add the line `set MY_VARIABLE=foo` to the file `%userprofile%\zephyrrc.cmd` using a text editor such as Notepad to save the value.

To get this value back into your current terminal environment, **you must run** `zephyr-env.cmd` in a `cmd.exe` window after changing directory to the main `zephyr` repository. Among other things, this script runs `%userprofile%\zephyrrc.cmd`.

The value will be lost if you close the window, etc.; run `zephyr-env.cmd` again to get it back.

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your *PATH* environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.2 Zephyr Environment Scripts

You can use the zephyr repository scripts `zephyr-env.sh` (for macOS and Linux) and `zephyr-env.cmd` (for Windows) to load Zephyr-specific settings into your current terminal's environment. To do so, run this command from the zephyr repository:

Linux/macOS

```
source zephyr-env.sh
```

Windows

```
zephyr-env.cmd
```

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.3 Important Environment Variables

Some *Important Build System Variables* can also be set in the environment. Here is a description of some of these important environment variables. This is not a comprehensive list.

`BOARD`
: See *Important Build System Variables*.

`CONF_FILE`
: See *Important Build System Variables*.

`SHIELD`
: See *Shields*.

`ZEPHYR_BASE`
: See *Important Build System Variables*.

`EXTRA_ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_BOARD_ALIASES`
: See *Board Aliases*

The following additional environment variables are significant when configuring the *toolchain* used to build Zephyr applications.

`ZEPHYR_SDK_INSTALL_DIR`
: Path where Zephyr SDK is installed.

`ZEPHYR_TOOLCHAIN_VARIANT`
: The name of the toolchain to use.

`{TOOLCHAIN}_TOOLCHAIN_PATH`
: Path to the toolchain specified by *ZEPHYR_TOOLCHAIN_VARIANT*. For example, if `ZEPHYR_TOOLCHAIN_VARIANT=llvm`, use `LLVM_TOOLCHAIN_PATH`. (Note the capitalization when forming the environment variable name.)

You might need to update some of these variables when you *update the Zephyr SDK toolchain*.

Emulators and boards may also depend on additional programs. The build system will try to locate those programs automatically, but may rely on additional CMake or environment variables to do so. Please consult your emulator's or board's documentation for more information. The following environment variables may be useful in such situations:

`PATH`
: `PATH` is an environment variable used on Unix-like or Microsoft Windows operating systems to specify a set of directories where executable programs are located.

2.4 Application Development

Note

In this document, we'll assume:

- your **application directory**, <app>, is something like <home>/zephyrproject/app
- its **build directory** is <app>/build

These terms are defined below. On Linux/macOS, <home> is equivalent to ~. On Windows, it's %userprofile%.

Keeping your application inside the workspace (<home>/zephyrproject) makes it easier to use `west build` and other commands with it. (You can put your application anywhere as long as *ZEPHYR_BASE* is set appropriately, though.)

2.4.1 Overview

Zephyr's build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the Zephyr source code. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.

The main zephyr repository contains Zephyr's source code, configuration files, and build system. You also likely have installed various *Modules (External projects)* alongside the zephyr repository, which provide third party source code integration.

The files in the **application directory** link Zephyr and any modules with the application. This directory contains all application-specific files, such as application-specific configuration files and source code.

Here are the files in a simple Zephyr application:

```
<app>
├── CMakeLists.txt
├── app.overlay
├── prj.conf
├── VERSION
└── src
    └── main.c
```

These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.

- **app.overlay**: This is a devicetree overlay file that specifies application-specific changes which should be applied to the base devicetree for any board you build for. The purpose of devicetree overlays is usually to configure something about the hardware used by the application.

  The build system looks for `app.overlay` by default, but you can add more devicetree overlays, and other default files are also searched for.

  See *Devicetree* for more information about devicetree.

- **prj.conf**: This is a Kconfig fragment that specifies application-specific values for one or more Kconfig options. These application settings are merged with other settings to produce the final configuration. The purpose of Kconfig fragments is usually to configure the software features used by the application.

  The build system looks for `prj.conf` by default, but you can add more Kconfig fragments, and other default files are also searched for.

  See *Kconfig Configuration* below for more information.

- **VERSION**: A text file that contains several version information fields. These fields let you manage the lifecycle of the application and automate providing the application version when signing application images.

  See *Application version management* for more information about this file and how to use it.

- **main.c**: A source code file. Applications typically contain source files written in C, C++, or assembly language. The Zephyr convention is to place them in a subdirectory of <app> named `src`.

Once an application has been defined, you will use CMake to generate a **build directory**, which contains the files you need to build the application and Zephyr, then link them together into a final binary you can run on your board. The easiest way to do this is with *west build*, but you can use CMake directly also. Application build artifacts are always generated in a separate build directory: Zephyr does not support "in-tree" builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

2.4.2 Application types

We distinguish three basic types of Zephyr application based on where <app> is located:

Application type	<app> location
repository	zephyr repository
workspace	west workspace where Zephyr is installed
freestanding	other locations

We'll discuss these more below. To learn how the build system supports each type, see *Zephyr CMake Package*.

Zephyr repository application

An application located within the `zephyr` source code repository in a Zephyr *west workspace* is referred to as a Zephyr repository application. In the following example, the hello_world sample is a Zephyr repository application:

```
zephyrproject/
├── .west/
│   └── config
└── zephyr/
```

(continues on next page)

(continued from previous page)

```
     ├── arch/
     ├── boards/
     ├── cmake/
     ├── samples/
     │    ├── hello_world/
     │    └── ...
     ├── tests/
     └── ...
```

Zephyr workspace application

An application located within a *workspace*, but outside the zephyr repository itself, is referred to as a Zephyr workspace application. In the following example, app is a Zephyr workspace application:

```
zephyrproject/
├─── .west/
│    └─── config
├─── zephyr/
├─── bootloader/
├─── modules/
├─── tools/
├─── <vendor/private-repositories>/
└─── applications/
     └── app/
```

Zephyr freestanding application

A Zephyr application located outside of a Zephyr *workspace* is referred to as a Zephyr freestanding application. In the following example, app is a Zephyr freestanding application:

```
<home>/
├─── zephyrproject/
│     ├─── .west/
│     │    └─── config
│     ├── zephyr/
│     ├── bootloader/
│     ├── modules/
│     └── ...
│
└─── app/
     ├── CMakeLists.txt
     ├── prj.conf
     └── src/
         └── main.c
```

2.4.3 Creating an Application

In Zephyr, you can either use a reference workspace application or create your application by hand.

Using a Reference Workspace Application

The example-application Git repository contains a reference *workspace application*. It is recommended to use it as a reference when creating your own application as described in the following sections.

The example-application repository demonstrates how to use several commonly-used features, such as:

- Custom *board ports*
- Custom *devicetree bindings*
- Custom *device drivers*
- Continuous Integration (CI) setup, including using *twister*
- A custom west *extension command*

Basic example-application Usage The easiest way to get started with the example-application repository within an existing Zephyr workspace is to follow these steps:

```
cd <home>/zephyrproject
git clone https://github.com/zephyrproject-rtos/example-application my-app
```

The directory name `my-app` above is arbitrary: change it as needed. You can now go into this directory and adapt its contents to suit your needs. Since you are using an existing Zephyr workspace, you can use `west build` or any other west commands to build, flash, and debug.

Advanced example-application Usage You can also use the example-application repository as a starting point for building your own customized Zephyr-based software distribution. This lets you do things like:

- remove Zephyr modules you don't need
- add additional custom repositories of your own
- override repositories provided by Zephyr with your own versions
- share the results with others and collaborate further

The example-application repository contains a `west.yml` file and is therefore also a west *manifest repository*. Use this to create a new, customized workspace by following these steps:

```
cd <home>
mkdir my-workspace
cd my-workspace
git clone https://github.com/zephyrproject-rtos/example-application␣
↪my-manifest-repo
west init -l my-manifest-repo
```

This will create a new workspace with the *T2 topology*, with `my-manifest-repo` as the manifest repository. The `my-workspace` and `my-manifest-repo` names are arbitrary: change them as needed.

Next, customize the manifest repository. The initial contents of this repository will match the example-application's contents when you clone it. You can then edit `my-manifest-repo/west.yml` to your liking, changing the set of repositories in it as you wish. See *Manifest Imports* for many examples of how to add or remove different repositories from your workspace as needed. Make any other changes you need to other files.

When you are satisfied, you can run:

```
west update
```

and your workspace will be ready for use.

If you push the resulting `my-manifest-repo` repository somewhere else, you can share your work with others. For example, let's say you push the repository to `https://git.example.com/my-manifest-repo`. Other people can then set up a matching workspace by running:

```
west init -m https://git.example.com/my-manifest-repo my-workspace
cd my-workspace
west update
```

From now on, you can collaborate on the shared software by pushing changes to the repositories you are using and updating `my-manifest-repo/west.yml` as needed to add and remove repositories, or change their contents.

Creating an Application by Hand

You can follow these steps to create a basic application directory from scratch. However, using the example-application repository or one of Zephyr's samples as a starting point is likely to be easier.

1. Create an application directory.

   For example, in a Unix shell or Windows `cmd.exe` prompt:

   ```
   mkdir app
   ```

   Warning

   Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path `C:\Users\YourName\app` will work, but `C:\Users\Your Name\app` will not.

2. Create your source code files.

   It's recommended to place all application source code in a subdirectory named `src`. This makes it easier to distinguish between project files and sources.

   Continuing the previous example, enter:

   ```
   cd app
   mkdir src
   ```

3. Place your application source code in the `src` sub-directory. For this example, we'll assume you created a file named `src/main.c`.

4. Create a file named `CMakeLists.txt` in the `app` directory with the following contents:

   ```
   cmake_minimum_required(VERSION 3.20.0)

   find_package(Zephyr)
   project(my_zephyr_app)

   target_sources(app PRIVATE src/main.c)
   ```

   Notes:

   - The `cmake_minimum_required()` call is required by CMake. It is also invoked by the Zephyr package on the next line. CMake will error out if its version is older than either the version in your `CMakeLists.txt` or the version number in the Zephyr package.
   - `find_package(Zephyr)` pulls in the Zephyr build system, which creates a CMake target named `app` (see *Zephyr CMake Package*). Adding sources to this target is how you include them in the build. The Zephyr package will define `Zephyr-Kernel` as a CMake project and enable support for the `C`, `CXX`, `ASM` languages.

- `project(my_zephyr_app)` defines your application's CMake project. This must be called after `find_package(Zephyr)` to avoid interference with Zephyr's `project(Zephyr-Kernel)`.
- `target_sources(app PRIVATE src/main.c)` is to add your source file to the app target. This must come after `find_package(Zephyr)` which defines the target. You can add as many files as you want with `target_sources()`.

5. Create at least one Kconfig fragment for your application (usually named `prj.conf`) and set Kconfig option values needed by your application there. See *Kconfig Configuration*. If no Kconfig options need to be set, create an empty file.
6. Configure any devicetree overlays needed by your application, usually in a file named `app.overlay`. See *Set devicetree overlays*.
7. Set up any other files you may need, such as *twister* configuration files, continuous integration files, documentation, etc.

2.4.4 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

Note

The variables **BOARD**, **CONF_FILE**, and **DTC_OVERLAY_FILE** can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the `west build` or `cmake` invocation via the `-D` command-line switch. If you have multiple overlay files, you should use quotations, `"file1.overlay;file2.overlay"`
- As *Environment Variables*.
- As a `set(<VARIABLE> <VALUE>)` statement in your `CMakeLists.txt`

- **ZEPHYR_BASE**: Zephyr base variable used by the build system. `find_package(Zephyr)` will automatically set this as a cached CMake variable. But `ZEPHYR_BASE` can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.
- **BOARD**: Selects the board that the application's build will use for the default configuration. See boards for built-in boards, and *Board Porting Guide* for information on adding board support.
- **CONF_FILE**: Indicates the name of one or more Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values.

  See *The Initial Configuration* for more information.
- **EXTRA_CONF_FILE**: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave **CONF_FILE** at its default value, but "mix in" some additional configuration options.
- **DTC_OVERLAY_FILE**: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See *Set devicetree overlays* for examples and *Introduction to devicetree* for information about devicetree and Zephyr.
- **EXTRA_DTC_OVERLAY_FILE**: Additional devicetree overlay files to use. Multiple files can be separated with semicolons. This can be useful to leave **DTC_OVERLAY_FILE** at its default value, but "mix in" some additional overlay files.
- **SHIELD**: see *Shields*

- **ZEPHYR_MODULES**: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See *Modules (External projects)* for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.
- **EXTRA_ZEPHYR_MODULES**: Like **ZEPHYR_MODULES**, except these will be added to the list of modules found via west, instead of replacing it.
- **FILE_SUFFIX**: Optional suffix for filenames that will be added to Kconfig fragments and devicetree overlays (if these files exists, otherwise will fallback to the name without the prefix). See *File Suffixes* for details.

Note

You can use a *Zephyr Build Configuration CMake packages* to share common settings for these variables.

2.4.5 Application CMakeLists.txt

Every application must have a `CMakeLists.txt` file. This file is the entry point, or top level, of the build system. The final `zephyr.elf` image contains both the application and the kernel libraries.

This section describes some of what you can do in your `CMakeLists.txt`. Make sure to follow these steps in order.

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

   ```
   set(BOARD qemu_x86)
   ```

   Refer to boards for more information on available boards.

   The Zephyr build system determines a value for **BOARD** by checking the following, in order (when a BOARD value is found, CMake stops looking further down the list):

   - Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don't try to run a build with a different **BOARD** value than you set during the build configuration step.
   - Any value given on the CMake command line (directly or indirectly via `west build`) using `-DBOARD=YOUR_BOARD` will be checked for and used next.
   - If an *environment variable* `BOARD` is set, its value will then be used.
   - Finally, if you set `BOARD` in your application `CMakeLists.txt` as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual `prj.conf`, add lines setting the **CONF_FILE** variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting **CONF_FILE** in a single place. For example:

   ```
   set(CONF_FILE "fragment_file1.conf")
   list(APPEND CONF_FILE "fragment_file2.conf")
   ```

   See *The Initial Configuration* for more information.

3. If your application uses devicetree overlays, you may need to set *DTC_OVERLAY_FILE*. See *Set devicetree overlays*.

4. If your application has its own kernel configuration options, create a `Kconfig` file in the same directory as your application's `CMakeLists.txt`.

See *the Kconfig section of the manual* for detailed Kconfig documentation.

An (unlikely) advanced use case would be if your application has its own unique configuration **options** that are set differently depending on the build configuration.

If you just want to set application specific **values** for existing Zephyr configuration options, refer to the `CONF_FILE` description above.

Structure your `Kconfig` file like this:

```
# SPDX-License-Identifier: Apache-2.0

mainmenu "Your Application Name"

# Your application configuration options go here

# Sources Kconfig.zephyr in the Zephyr root directory.
#
# Note: All 'source' statements work relative to the Zephyr root directory␣
↪(due
# to the $srctree environment variable being set to $ZEPHYR_BASE). If you want
# to 'source' relative to the current Kconfig file instead, use 'rsource' (or␣
↪a
# path relative to the Zephyr root).
source "Kconfig.zephyr"
```

Note

Environment variables in `source` statements are expanded directly, so you do not need to define an `option env="ZEPHYR_BASE"` Kconfig "bounce" symbol. If you use such a symbol, it must have the same name as the environment variable.

See *Kconfig extensions* for more information.

The `Kconfig` file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable `KCONFIG_ROOT` is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, **after any lines added from the steps above**:

```
find_package(Zephyr)
project(my_zephyr_app)
```

Note

`find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})` can be used if enforcing a specific Zephyr installation by explicitly setting the `ZEPHYR_BASE` environment variable should be supported. All samples in Zephyr supports the `ZEPHYR_BASE` environment variable.

6. Now add any application source files to the 'app' target library, each on their own line, like so:

```
target_sources(app PRIVATE src/main.c)
```

Below is a simple example `CMakeList.txt`:

```
set(BOARD qemu_x86)

find_package(Zephyr)
project(my_zephyr_app)

target_sources(app PRIVATE src/main.c)
```

The Cmake property HEX_FILES_TO_MERGE leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
    ${app_bootloader_hex}
    ${PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
    ${app_provision_hex})
```

2.4.6 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake Cache documentation.

2.4.7 Application Configuration

Application Configuration Directory

Zephyr will use configuration files from the application's configuration directory except for files with an absolute path provided by the arguments described earlier, for example CONF_FILE, EXTRA_CONF_FILE, DTC_OVERLAY_FILE, and EXTRA_DTC_OVERLAY_FILE.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable.

APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before find_package(Zephyr) then this folder is used a the application's configuration directory.
2. The application's source directory.

Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```
CONFIG_CPP=y
```

Looking at existing samples is a good way to get started.

See *Setting Kconfig configuration values* for detailed documentation on setting Kconfig configuration values. The *The Initial Configuration* section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See *Hardening Tool* for security information related with Kconfig options.

The other pages in the *Kconfig section of the manual* are also worth going through, especially if you planning to add new configuration options.

Experimental features Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked `[EXPERIMENTAL]` in their Kconfig title.

The `CONFIG_WARN_EXPERIMENTAL` setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option `CONFIG_FOO` is experimental, then enabling it and `CONFIG_WARN_EXPERIMENTAL` will print the following warning at CMake configure time when you build an application:

```
warning: Experimental symbol FOO is enabled.
```

Devicetree Overlays

See *Set devicetree overlays*.

File Suffixes

Zephyr applications might want to have a single code base with multiple configurations for different build/product variants which would necessitate different Kconfig options and devicetree configuration. In order to better configure this, Zephyr provides a **`FILE_SUFFIX`** option when configuring applications that can be automatically appended to filenames. This is applied to Kconfig fragments and board overlays but with a fallback so that if such files do not exist, the files without these suffixes will be used instead.

Given the following example project layout:

```
<app>
├── CMakeLists.txt
├── prj.conf
├── prj_mouse.conf
├── boards
│   ├── native_sim.overlay
│   └── qemu_cortex_m3_mouse.overlay
└── src
    └── main.c
```

- If this is built normally without `FILE_SUFFIX` being defined for `native_sim` then `prj.conf` and `boards/native_sim.overlay` will be used.
- If this is built normally without `FILE_SUFFIX` being defined for `qemu_cortex_m3` then `prj.conf` will be used, no application devicetree overlay will be used.
- If this is built with `FILE_SUFFIX` set to `mouse` for `native_sim` then `prj_mouse.conf` and `boards/native_sim.overlay` will be used (there is no `native_sim_mouse.overlay` file so it falls back to `native_sim.overlay`).
- If this is built with `FILE_SUFFIX` set to `mouse` for `qemu_cortex_m3` then `prj_mouse.conf` will be used and `boards/qemu_cortex_m3_mouse.overlay` will be used.

2.4.8 Application-Specific Code

Application-specific source code files are normally added to the application's `src` directory. If the application adds a large number of files the developer can group them into sub-directories under `src`, to whatever depth is needed.

Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

Third-party Library Code

It is possible to build library code outside the application's `src` directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the zephyr compiler options. The functions are documented and defined in cmake/modules/extensions.cmake and follow the naming convention `zephyr_get_<type>_<format>`.

The following variables will often need to be exported to the third-party build system.

- `CMAKE_C_COMPILER`, `CMAKE_AR`.
- `ARCH` and `BOARD`, together with several variables that identify the Zephyr kernel version.

samples/application_development/external_lib is a sample project that demonstrates some of these features.

2.4.9 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.

Like any other CMake-based system, the build process takes place *in two stages*. First, build files (also known as a buildsystem) are generated using the `cmake` command-line tool while specifying a generator. This generator determines the native build tool the buildsystem will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is *west*, Zephyr's meta-tool, which invokes `cmake` and the underlying build tool (`ninja` or `make`) behind the scenes, you can also choose to invoke `cmake` directly if you prefer. On Linux and macOS you can choose between the `make` and `ninja` generators (i.e. build tools), whereas on Windows you need to use `ninja`, since `make` is not supported on this platform. For simplicity we will use `ninja` throughout this guide, and if you choose to use `west build` to build your application know that it will default to `ninja` under the hood.

As an example, let's build the Hello World sample for the `reel_board`:

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild
```

On Linux and macOS, you can also build with `make` instead of `ninja`:

Using west:

- to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the *west build* documentation for an example.
- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`.

Using CMake directly:

```
# From the root of the zephyr repository
# Use cmake to configure a Make-based buildsystem:
cmake -Bbuild -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
make -Cbuild
```

Basics

1. Navigate to the application directory <app>.
2. Enter the following commands to build the application's `zephyr.elf` image for the board specified in the command-line parameters:

   Using west:

   ```
   west build -b <board>
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build

   # Use cmake to configure a Ninja-based buildsystem:
   cmake -GNinja -DBOARD=<board> ..

   # Now run the build tool on the generated build system:
   ninja
   ```

   If desired, you can build the application using the configuration settings specified in an alternate `.conf` file using the `CONF_FILE` parameter. These settings will override the settings in the application's `.config` file or its default `.conf` file. For example:

   Using west:

   ```
   west build -b <board> -- -DCONF_FILE=prj.alternate.conf
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build
   cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
   ninja
   ```

   As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting **`BOARD`** and **`CONF_FILE`** environment variables or by setting their values in your `CMakeLists.txt` using `set()` statements. Additionally, `west` allows you to *set a default board*.

Build Directory Contents

When using the Ninja generator a build directory looks like this:

```
<app>/build
├── build.ninja
├── CMakeCache.txt
├── CMakeFiles
├── cmake_install.cmake
├── rules.ninja
└── zephyr
```

The most notable files in the build directory are:

- `build.ninja`, which can be invoked to build the application.
- A `zephyr` directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running `ninja`, the following build output files will be written to the `zephyr` sub-directory of the build directory. (This is **not the Zephyr base directory**, which contains the Zephyr source code etc. and is described above.)

- `.config`, which contains the configuration settings used to build the application.

> **Note**
>
> The previous version of `.config` is saved to `.config.old` whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (`.o` files and `.a` files) containing compiled kernel and application code.
- `zephyr.elf`, which contains the final combined application and kernel binary. Other binary output formats, such as `.hex` and `.bin`, are also supported.

Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It's usually a good idea to rebuild and test after any major changes to the application's source files, CMakeLists.txt files, or configuration settings.

> **Important**
>
> The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn't rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<app>/build`.
2. Enter one of the following commands, depending on whether you want to use `west` or `cmake` directly to delete the application's generated files, except for the `.config` file that contains the application's current configuration information.

   ```
   west build -t clean
   ```

   or

   ```
   ninja clean
   ```

   Alternatively, enter one of the following commands to delete *all* generated files, including the `.config` files that contain the application's current configuration information for those board types.

   ```
   west build -t pristine
   ```

   or

```
ninja pristine
```

If you use west, you can take advantage of its capability to automatically *make the build folder pristine* whenever it is required.

3. Rebuild the application normally following the steps specified in *Building an Application* above.

Building for a board revision

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in *Create your board directory* for each revision.

To build for a particular revision, use `<board>@<revision>` or `<board>@<revision>/<qualifiers>` instead of plain `<board>` or `<board>/<qualifiers>`. For example:

Using west:

```
west build -b nrf9160dk@0.14.0/nrf9160/ns
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=nrf9160dk@0.14.0/nrf9160/ns ..
ninja
```

Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.

When targeting a board revision, the active revision will be printed at CMake configure time, like this:

```
-- Board: plank, Revision: 1.5.0
```

2.4.10 Run an Application

An application image can be run on a real board or emulated hardware.

Running on a Board

Most boards supported by Zephyr let you flash a compiled binary using the `flash` target to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in *Building an Application*.
2. Make sure your board is attached to your host computer. Usually, you'll do this via USB.
3. Run one of these console commands from the build directory, `<app>/build`, to flash the compiled Zephyr image and run it on your board:

   ```
   west flash
   ```

   or

   ```
   ninja flash
   ```

The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board's documentation for additional information on how to flash your board.

Note

When developing on Linux, it's common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board's documentation to see if this is necessary.

Running in an Emulator

Zephyr has built-in emulator support for QEMU. It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware.

Check out *Beyond the Getting Started Guide* for additional steps needed on Windows.

Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in *Building an Application*.

   For example, you could set `BOARD` to:

   - `qemu_x86` to emulate running on an x86-based board
   - `qemu_cortex_m3` to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, `<app>/build`, to run the Zephyr binary in QEMU:

   ```
   west build -t run
   ```

   or

   ```
   ninja run
   ```

3. Press `Ctrl A, X` to stop the application from running in QEMU.

   The application stops running and the terminal console prompt redisplays.

Each time you execute the run command, your application is rebuilt and run again.

Note

If the (Linux only) *Zephyr SDK* is installed, the `run` target will use the SDK's QEMU binary by default. To use another version of QEMU, *set the environment variable* `QEMU_BIN_PATH` to the path of the QEMU binary you want to use instead.

Note

You can choose a specific emulator by appending `_<emulator>` to your target name, for example `west build -t run_qemu` or `ninja run_qemu` for QEMU.

2.4.11 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them

to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:

```
boards/
soc/
CMakeLists.txt
prj.conf
README.rst
src/
```

where the `boards` directory hosts the board you are building for:

```
.
├── boards
│   └── vendor
│       └── my_custom_board
│           ├── doc
│           │   └── img
│           └── support
└── src
```

and the `soc` directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

Boards

Use the vendor name as the folder name (which must match the vendor prefix in dts/bindings/vendor-prefixes.txt if submitting upstream to Zephyr, or be `others` if it is not a vendor board) under `boards` for `my_custom_board`.

Documentation (under `doc/`) and support files (under `support/`) are optional, but will be needed when submitting to Zephyr.

The contents of `my_custom_board` should follow the same guidelines for any Zephyr board, and provide the following files:

```
my_custom_board_defconfig
my_custom_board.dts
my_custom_board.yaml
board.cmake
board.h
CMakeLists.txt
doc/
Kconfig.my_custom_board
Kconfig.defconfig
support/
```

Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the `-DBOARD_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DBOARD_ROOT=<path to boards> .
ninja -Cbuild
```

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the `BOARD_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `BOARD_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-board-root>)`. When using `-DBOARD_ROOT=<board-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Note

When using sysbuild, then `BOARD_ROOT` must defined in a module or in the sysbuild `CMakeLists.txt` file, see *Configuring sysbuild internal state* for details.

SOC Definitions

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

```
soc
└── st
    └── stm32
        ├── common
        └── stm32l0x
```

The file soc/Kconfig will create the top-level `SoC/CPU/Configuration Selection` menu in Kconfig.

Out of tree SoC definitions can be added to this menu using the `SOC_ROOT` CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu.

```
soc
└── st
    └── stm32
        └── stm32l0x
            ├── Kconfig
            ├── Kconfig.soc
            └── Kconfig.defconfig
```

The Kconfig files above may describe the SoC or load additional SoC Kconfig files.

An example of loading `stm32l0` specific Kconfig files in this structure:

```
soc
└── st
    └── stm32
        ├── Kconfig.soc
        └── stm32l0x
            └── Kconfig.soc
```

can be done with the following content in `st/stm32/Kconfig.soc`:

```
rsource "*/Kconfig.soc"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the `-DSOC_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to␣
↪boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DSOC_ROOT=<path to soc> -DBOARD_ROOT=
↪<path to boards> .
ninja -Cbuild
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.

See *Build settings* for information on setting SOC_ROOT in a module's `zephyr/module.yml` file.

Or you can define the `SOC_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `SOC_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>`. When using `-DSOC_ROOT=<soc-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree Definitions

Devicetree directory trees are found in `APPLICATION_SOURCE_DIR`, `BOARD_DIR`, and `ZEPHYR_BASE`, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```
include/
dts/common/
dts/arm/
dts/
dts/bindings/
```

Where 'arm' is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the `DTS_ROOT` CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_ROOT=<path to dts root>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -Cbuild
```

You can also define the variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `DTS_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>`. When using `-DDTS_ROOT=<dts-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a `DTS_ROOT` directory. By convention devicetree include files have a `.dtsi` extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the `DTS_EXTRA_CPPFLAGS` CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-
↪DTEST_ENABLE_FEATURE .
ninja -Cbuild
```

2.5 Debugging

2.5.1 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU_Debugger reference manuals.

In this quick reference, you'll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an ELF (Executable and Linkable Format) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is `zephyr.elf`. The name can be changed using `CONFIG_KERNEL_BIN_NAME`.

GDB server

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment. There are multiple ways to do this. Each way starts a QEMU instance with the processor halted at startup and with a GDB server instance listening for a connection.

Running QEMU directly You can run QEMU to listen for a "gdb connection" before it starts executing any code to debug it.

```
qemu -s -S <image>
```

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- `-S` Do not start CPU at startup; rather, you must type 'c' in the monitor.
- `-s` Shorthand for `-gdb tcp::1234`: open a GDB server on TCP port 1234.

Running QEMU via `ninja` Run the following inside the build directory of an application:

```
ninja debugserver
```

QEMU will write the console output to the path specified in **`${QEMU_PIPE}`** via CMake, typically `qemu-fifo` within the build directory. You may monitor this file during the run with **`tail -f qemu-fifo`**.

Running QEMU via `west` Run the following from your project root:

```
west build -t debugserver_qemu
```

QEMU will write the console output to the terminal from which you invoked **`west`**.

Configuring the gdbserver listening device The Kconfig option `CONFIG_QEMU_GDBSERVER_LISTEN_DEV` controls the listening device, which can be a TCP port number or a path to a character device. GDB releases 9.0 and newer also support Unix domain sockets.

If the option is unset, then the QEMU invocation will lack a `-s` or a `-gdb` parameter. You can then use the `QEMU_EXTRA_FLAGS` shell environment variable to pass in your own listen device configuration.

GDB client

Connect to the server by running **`gdb`** and giving these commands:

```
$ path/to/gdb path/to/zephyr.elf
(gdb) target remote localhost:1234
(gdb) dir ZEPHYR_BASE
```

> **Note**
>
> Substitute the correct *ZEPHYR_BASE* for your system.

You can use a local GDB configuration `.gdbinit` to initialize your GDB instance on every run. Your home directory is a typical location for `.gdbinit`, but you can configure GDB to load from other locations, including the directory from which you invoked **`gdb`**. This example file performs the same configuration as above:

```
target remote localhost:1234
dir ZEPHYR_BASE
```

Alternate interfaces GDB provides a curses-based interface that runs in the terminal. Pass the `--tui` option when invoking **`gdb`** or give the `tui enable` command within **`gdb`**.

Note

The GDB version on your development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

Finally, the command below connects to the GDB server using the DDD (Data Display Debugger), a graphical frontend for GDB. The following command loads the symbol table from the ELF binary file, in this instance, `zephyr.elf`.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute **gdb**. The command name might change depending on the toolchain you are using and your cross-development tools.

ddd may not be installed in your development system by default. Follow your system instructions to install it. For example, use **sudo apt-get install ddd** on an Ubuntu system.

Debugging

As configured above, when you connect the GDB client, the application will be stopped at system startup. You may set breakpoints, step through code, etc. as when running the application directly within **gdb**.

Note

gdb will not print the system console output as the application runs, unlike when you run a native application in GDB directly. If you just **continue** after connecting the client, the application will run, but nothing will appear to happen. Check the console output as described above.

2.5.2 Debug with Eclipse

Overview

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The GNU MCU Eclipse plug-ins provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

Set Up the Eclipse Development Environment

1. Download and install Eclipse IDE for C/C++ Developers.
2. In Eclipse, install the GNU MCU Eclipse plug-ins by opening the menu `Window->Eclipse Marketplace...`, searching for `GNU MCU Eclipse`, and clicking `Install` on the matching result.
3. Configure the path to the pyOCD GDB server by opening the menu `Window->Preferences`, navigating to `MCU`, and setting the `Global pyOCD Path`.

Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in *GNU Arm Embedded*.

2. Navigate to a folder outside of the Zephyr tree to build your application.

```
# On Windows
cd %userprofile%
```

> **Note**
>
> If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:
>
> "The build directory is a subdirectory of the source directory.
>
> This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory."

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the `-G"Eclipse CDT4 - Ninja"` argument. This will generate an Eclipse project description file, `.project`, in addition to the usual ninja build files.

   Using west:

```
west build -b frdm_k64f samples/synchronization -- -G"Eclipse CDT4 - Ninja"
```

   Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT4 - Ninja"␣
↪samples/synchronization
ninja -Cbuild
```

4. In Eclipse, import your generated project by opening the menu `File->Import...` and selecting the option `Existing Projects into Workspace`. Browse to your application build directory in the choice, `Select root directory:`. Check the box for your project in the list of projects found and click the `Finish` button.

Create a Debugger Configuration

1. Open the menu `Run->Debug Configurations...`.
2. Select `GDB PyOCD Debugging`, click the `New` button, and configure the following options:
   - In the Main tab:
     - Project: `my_zephyr_app@build`
     - C/C++ Application: `zephyr/zephyr.elf`
   - In the Debugger tab:
     - pyOCD Setup
       - Executable path: `$pyocd_path\$pyocd_executable`
       - Uncheck "Allocate console for semihosting"
     - Board Setup
       - Bus speed: 8000000 Hz
       - Uncheck "Enable semihosting"
     - GDB Client Setup
       - Executable path example (use your `GNUARMEMB_TOOLCHAIN_PATH`): `C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe`
   - In the SVD Path tab:

– File path: `<workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml`

> **Note**
>
> This is optional. It provides the SoC's memory-mapped register addresses and bit-fields to the debugger.

3. Click the Debug button to start debugging.

RTOS Awareness

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.

2.5.3 Debugging I2C communication

There is a possibility to log all or some of the I2C transactions done by the application. This feature is enabled by the Kconfig option `CONFIG_I2C_DUMP_MESSAGES`, but it uses the `LOG_DBG` function to print the contents so the `CONFIG_I2C_LOG_LEVEL_DBG` option must also be enabled.

The sample output of the dump looks like this:

```
D: I2C msg: io_i2c_ctrl7_port0, addr=50
D:    W      len=01: 00
D:    R Sr P len=08:
D: contents:
D: 43 42 41 00 00 00 00 00 |CBA.....
```

The first line indicates the I2C controller and the target address of the transaction. In above example, the I2C controller is named `io_i2c_ctrl7_port0` and the target device address is `0x50`

> **Note**
>
> the address, length and contents values are in hexadecimal, but lack the `0x` prefix

Next lines contain messages, both sent and received. The contents of write messages is always shown, while the content of read messages is controlled by a parameter to the function `i2c_dump_msgs_rw`. This function is available for use by user, but is also called internally by `i2c_transfer` API function with read content dump enabled. Before the length parameter, the header of the message is printed using abbreviations:

- W - write message
- R - read message
- Sr - restart bit
- P - stop bit

The above example shows one write message with byte `0x00` representing the address of register to read from the I2C target. After that the log shows the length of received message and following that, the bytes read from the target `43 42 41 00 00 00 00 00`. The content dump consist of both the hex and ASCII representation.

Filtering the I2C communication dump

By default, all I2C communication is logged between all I2C controllers and I2C targets. It may litter the log with unrelated devices and make it difficult to effectively debug the communication with a device of interest.

Enable the Kconfig option `CONFIG_I2C_DUMP_MESSAGES_ALLOWLIST` to create an allowlist of I2C targets to log. The allowlist of devices is configured using the devicetree, for example:

```
/ {
    i2c {
        display0: some-display@a {
            ...
        };
        sensor3: some-sensor@b {
            ...
        };
    };

    i2c-dump-allowlist {
        compatible = "zephyr,i2c-dump-allowlist";
        devices = < &display0 >, < &sensor3 >;
    };
};
```

The filters nodes are identified by the compatible string with `zephyr,i2c-dump-allowlist` value. The devices are selected using the `devices` property with phandles to the devices on the I2C bus.

In the above example, the communication with device `display0` and `sensor3` will be displayed in the log.

2.6 API Status and Guidelines

2.6.1 API Overview

The table lists Zephyr's APIs and information about them, including their current *stability level*. More details about API changes between major releases are available in the zephyr_release_notes.

The version column uses semantic version, and has the following expectations:

- Major version zero (0.y.z) is for initial development. Anything MAY change at any time. The public API SHOULD NOT be considered stable.
  - If minor version is up to one (0.1.z), API is considered *experimental*.
  - If minor version is larger than one (0.y.z | y > 1), API is considered *unstable*.
- Version 1.0.0 defines the public API. The way in which the version number is incremented after this release is dependent on this public API and how it changes.
  - APIs with major versions equal or larger than one (x.y.z | x >= 1) are considered *stable*.
  - All existing stable APIs in Zephyr will be start with version 1.0.0.
- Patch version Z (x.y.Z | x > 0) MUST be incremented if only backwards compatible bug fixes are introduced. A bug fix is defined as an internal change that fixes incorrect behavior.
- Minor version Y (x.Y.z | x > 0) MUST be incremented if new, backwards compatible functionality is introduced to the public API. It MUST be incremented if any public API functionality is marked as deprecated. It MAY be incremented if substantial new functionality or improvements are introduced within the private code. It MAY include patch level changes. Patch version MUST be reset to 0 when minor version is incremented.

- Major version X (x.Y.z | x > 0) MUST be incremented if a compatibility breaking change was made to the API.

Note

Version for existing APIs are initially set based on the current state of the APIs:

- 0.1.0 denotes an *experimental* API
- 0.8.0 denote an *unstable* API,
- and finally 1.0.0 indicates a *stable* APIs.

Changes to APIs in the future will require adapting the version following the guidelines above.

API	Version	Available in Zephyr Since
Audio		
Audio Codec Interface	0.2.0	v1.13.0
Digital Microphone Interface	0.1.0	v1.13.0
MIDI2 Universal MIDI Packet definitions	0.1.0	v4.1.0

2.6.2 API Lifecycle

Developers using Zephyr's APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr's APIs need to be able to introduce new APIs that aren't yet fully proven, and to potentially retire old APIs when they're no longer optimal or supported by the underlying platforms.

An up-to-date table of all APIs and their maturity level can be found in the *API Overview* page.

Experimental

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the Developer mailing list.

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)

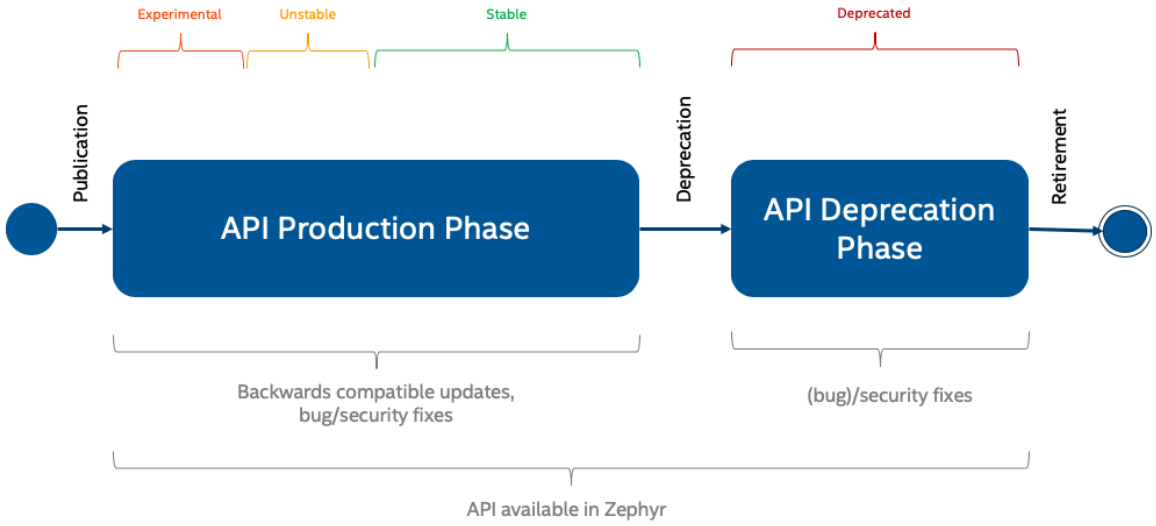

Fig. 2: API Life Cycle

- At least one sample using the new API (may only build on one single board)

When introducing a new and experimental API, mark the API version in the headers where the API is defined. An experimental API shall have a version where the minor version is up to one (0.1.z). (see *API Overview*)

Peripheral APIs (Hardware Related) When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the Architecture working group consisting of representatives from different vendors.

The API shall be promoted to `unstable` when it has at least two implementations on different hardware platforms.

Unstable

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

When the API changes status to unstable API, mark the API version in the headers where the API is defined. Unstable APIs shall have a version where the minor version is larger than one (0.y.z | y > 1). (see *API Overview*)

> **Note**
>
> Changes will not be announced.

Peripheral APIs (Hardware Related) The API shall be promoted from `experimental` to `unstable` when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs For hardware agnostic APIs, multiple applications using it are required to promote an API from `experimental` to `unstable`.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared `stable` after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
- Stable APIs can get backward compatible updates, bug fixes and security fixes at any time.

In order to declare an API `stable`, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the *API Overview* table
2. An email must be sent to the `devel` mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr Architecture meeting where, barring any objections, the Pull Request will be merged

When the API changes status to stable API, mark the API version in the headers where the API is defined. Stable APIs shall have a version where the major version is one or larger (x.y.z | x >= 1). (see *API Overview*)

Introducing breaking API changes A stable API, as described above, strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress, or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

A breaking API change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered a breaking API change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility, the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An *RFC issue* must be opened on GitHub with the following content:

   ```
   Title:     RFC: Breaking API Change: <subsystem>
   Contents:  - Problem Description:
                - Background information on why the change is required
              - Proposed Change (detailed):
                - Brief description of the API change
              - Detailed RFC:
                - Function call changes
                - Device Tree changes (source and bindings)
                - Kconfig option changes
              - Dependencies:
                - Impact to users of the API, including the steps required
                  to adapt out-of-tree users of the API to the change
   ```

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.

2. The RFC issue must be labeled with the GitHub `Breaking API Change` label
3. The RFC issue must be submitted for discussion in the next Zephyr Architecture meeting

4. An email must be sent to the `devel` mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr Architecture meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
  - Changes to the relevant API documentation
  - Changes to Device Tree source and bindings
- The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers
- An entry in the "API Changes" section of the release notes for the next upcoming release
- The labels `API`, `Breaking API Change` and `Release Notes`, as well as any others that are applicable
- The label `Architecture Review` if the RFC was not yet discussed and agreed upon in Zephyr Architecture meeting

Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting.

If the Pull Request is merged then an email must be sent to the `devel` and `user` mailing lists informing them of the change.

The API version shall be changed to signal backward incompatible changes. This is achieved by incrementing the major version (X.y.z | X > 1). It MAY also include minor and patch level changes. Patch and minor versions MUST be reset to 0 when major version is incremented. (see *API Overview*)

> **Note**
>
> Breaking API changes will be listed and described in the migration guide.

Deprecated

> **Note**
>
> Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the "API Changes" section of the release notes.

The following are the requirements for deprecating an existing API:

- Deprecation Time (stable APIs): 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 4.0, it will be ready to be removed in 4.2 at the earliest. There may be special circumstances, determined by the Architecture working group, where an API is deprecated sooner.
- What is required when deprecating:
  - Mark as deprecated. This can be done by using the compiler itself (`__deprecated` for function declarations and `__DEPRECATED_MACRO` for macro definitions), or by introducing a Kconfig option (typically one that contains the `DEPRECATED` word in it) that, when enabled, reverts the APIs back to their previous form
  - Document the deprecation
  - Include the deprecation in the "API Changes" of the release notes for the next upcoming release
  - Code using the deprecated API needs to be modified to remove usage of said API
  - The change needs to be atomic and bisectable
  - Add an entry in the corresponding release GitHub issue tracking removal of deprecated APIs. In this example in the one corresponding to the 4.2 release.

During the deprecation waiting period, the API will be in the `deprecated` state. The Zephyr maintainers will track usage of deprecated APIs on `docs.zephyrproject.org` and support developers migrating their code. Zephyr will continue to provide warnings:

- API documentation will inform users that the API is deprecated.
- Attempts to use a deprecated API at build time will log a warning to the console.

Retired

In this phase, the API is removed.

The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API: this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it's OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

If it's not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

2.6.3 Vendor-Specific API Placement Policy

Overview

This policy defines how vendor-specific hardware functionality must be contributed, structured, and exposed within the Zephyr Project. It ensures that Zephyr's public API surface remains stable, that vendor extensions do not bypass the standard API lifecycle, and that potential cross-vendor features have a clear path to evolve into generic driver classes.

Vendor-specific APIs must not be exposed as public Zephyr interfaces unless they meet the criteria required for inclusion in Zephyr's formal API lifecycle (experimental stable deprecated). Features that are inherently tied to a single SoC or vendor must remain encapsulated within the vendor's SoC directories.

This policy provides a consistent decision model for contributors and maintainers.

Guiding Principles

- **Public Zephyr APIs must not contain vendor-specific interfaces.**

  Interfaces placed under `include/zephyr/` are expected to evolve through the standard API lifecycle. Vendor-specific interfaces that cannot satisfy this evolution must not be exposed as public Zephyr APIs.

- **Prefer generic solutions over vendor-specific ones.**

  When a hardware feature applies to multiple vendors or might in the future it should be implemented as part of an existing driver class or as a new cross-vendor driver class.

- **Vendor-specific features must be encapsulated.**

  Vendor-only mechanisms should live within the vendor's platform namespace (SoCs, boards, etc.).

- **Evolution must remain possible.**

  Placement must not prevent later promotion of a vendor-specific implementation into a portable Zephyr driver class.

Decision Process

When adding new hardware functionality or vendor-specific behavior, contributors must follow the decision tree below, in the given order:

- **Does the feature logically extend an existing driver class?**

  If yes, extend the existing class; do not create a vendor-specific API.

- **Could the feature become a cross-vendor driver class?**

  If the hardware concept is not clearly unique to a single vendor, or resembles patterns likely to appear across multiple architectures, create a new driver class.

- **Is the functionality clearly vendor-specific and unlikely to generalize?**

  In this case, place both headers and implementations under:

  ```
  soc/<vendor>/..
  ```

  This ensures true encapsulation, long-term maintainability, and clean removal when an SoC is dropped.

  Vendor-specific code should be implemented in headers located under `soc/<vendor>/include` and code in `soc/<vendor>/common` or `soc/<vendor>/<series>`.

  Such interfaces would be private and/or internal to the vendor to support their specific hardware and will be scrutinized in order to avoid creating feature islands specific to vendors.

  Applications using these interfaces, given that they are internal and/or private to the vendor, shall expect no guarantees as to the lifecycle or backwards compatibility.

Allowed Locations Summary

1. When extending existing driver classes

- Where:

  ```
  include/zephyr/drivers/<class>.h
  drivers/<class>/
  ```

- Use when:

  The functionality fits or extends an existing class.

2. Vendor-specific extensions to existing driver classes

- Where:

```
include/zephyr/drivers/<class>/
drivers/<class>/
```

- Use when:

  The feature is a vendor-specific extension to an existing class, but the core concept is not unique to a single vendor and could be standardized in the future.

3. Create New Driver Class (Cross-Vendor)

- Where:

```
include/zephyr/drivers/<class>.h
drivers/<class>/
```

- Use when:

  The feature could reasonably apply to multiple vendors or evolve into a generic abstraction.

4. Vendor-Specific, SoC-Local Code (Default for Vendor-Unique Features)

- Where:

  Vendor-specific code should be implemented in headers located under `soc/<vendor>/include` and code in `soc/<vendor>/common` or `soc/<vendor>/<series>`.

- Use when:

  The feature is unique to a vendor or SoC and is not intended as a public API.

2.6.4 API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

All public API must be documented using Doxygen. See *Doxygen Style Guidelines* for details.

Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be `const struct device *dev`. For library functions it may be a pointer to another object that was referenced when the callback was provided.
- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.
- The final parameter should be a `void *user_data` pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing `user_data` as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is `gpio_callback`, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can accessed by the callback indirectly by `CONTAINER_OF`.

Examples

- The requirements of `k_timer_expiry_t` invoked when a system timer alarm fires are satisfied by:

```
void handle_timeout(struct k_timer *timer)
{ ... }
```

  The assumption here, as with `gpio_callback`, is that the timer is embedded in a structure reachable from `CONTAINER_OF` that can provide additional context to the callback.

- The requirements of `counter_alarm_callback_t` invoked when a counter device alarm fires are satisfied by:

```
void handle_alarm(const struct device *dev,
                  uint8_t chan_id,
                  uint32_t ticks,
                  void *user_data)
{ ... }
```

  This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the `counter_alarm_cfg` used to register the callback, depending on user needs.

Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include `capturing a timestamp` or `providing an alternative interface`. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.

In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for applications that don't need the capability.
- Function declarations that are available only when the option is enabled should be provided unconditionally. Add a note in the description that the function is available only when the specified feature is enabled, referencing the required Kconfig symbol by name. In the cases where the function is used but not enabled the definition of the function shall be excluded from compilation, so references to the unsupported API will result in a link-time error.
- Where code specific to the feature is isolated in a source file that has no other content that file should be conditionally included in `CMakeLists.txt`:

```
zephyr_sources_ifdef(CONFIG_MYFEATURE foo_funcs.c)
```

- Where code specific to the feature is part of a source file that has other content the feature-specific code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

See *Conditional code* for details on how to ensure conditional code is visible to Doxygen and included in the public API documentation.

Return Codes

Implementations of an API, for example an API for accessing a peripheral might implement only a subset of the functions that is required for minimal operation. A distinction is needed between

APIs that are not supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`.
- Optional APIs that are not supported by the hardware should be implemented and the return code in this case shall be `-ENOTSUP`.
- When an API is implemented, but the particular combination of options requested in the call cannot be satisfied by the implementation the call shall return `-ENOTSUP`. (For example, a request for a level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

2.6.5 API Terminology

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

reschedule
: if executing the function reaches a reschedule point

sleep
: if executing the function can cause the invoking thread to sleep

no-wait
: if a parameter to the function can prevent the invoking thread from trying to sleep

isr-ok
: if the function can be safely called and will have its specified effect whether invoked from interrupt or thread context

pre-kernel-ok
: if the function can be safely called before the kernel has been fully initialized and will have its specified effect when invoked from that context.

async
: if the function may return before the operation it initializes is complete (i.e. function return and operation completion are asynchronous)

supervisor
: if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

reschedule

The reschedule attribute is used on a function that can reach a *reschedule point* within its execution.

Details The significance of this attribute is that when a rescheduling function is invoked by a thread it is possible for that thread to be suspended as a consequence of a higher-priority thread being made ready. Whether the suspension actually occurs depends on the operation associated with the reschedule point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be suspended in any function.

Functions that are not **reschedule** may be invoked from either thread or interrupt context.

Functions that are **reschedule** may be invoked from thread context.

Functions that are **reschedule** but not **sleep** may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to *sleep*.

Explanation This attribute is of relevance specifically when considering applications that use only non-preemptible threads, because the kernel will not replace a running cooperative-only thread at a reschedule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require an invoking thread that would have to suspend, wait, or invoke `k_yield()` before it can complete its operation. This behavior may be mediated by **no-wait**.

Functions that are **sleep** are implicitly **reschedule**.

Functions that are **sleep** may be invoked from thread context.

Functions that are **sleep** may be invoked from interrupt and pre-kernel contexts if and only if invoked in **no-wait** mode.

no-wait

The no-wait attribute is used on a function that is also **sleep** to indicate that a parameter to the function can force an execution path that will not cause the invoking thread to sleep.

Explanation The paradigmatic case of a no-wait function is a function that takes a timeout, to which `K_NO_WAIT` can be passed. The semantics of this special timeout value are to execute the function's operation as long as it can be completed immediately, and to return an error code rather than sleep if it cannot.

It is use of the no-wait feature that allows functions like `k_sem_take()` to be invoked from ISRs, since it is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is synchronous.

Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

isr-ok

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

Explanation Any function that is not **sleep** is inherently **isr-ok**. Functions that are **sleep** are **isr-ok** if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally `-EWOULDBLOCK`).

Note that a function that is **no-wait** is safe to call from interrupt context only when the no-wait path is selected. **isr-ok** functions need not provide a no-wait path.

pre-kernel-ok

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.

Explanation This attribute is similar to **isr-ok** in function, but is intended for use by any API that is expected to be called in `DEVICE_DEFINE()` or `SYS_INIT()` calls that may be invoked with `PRE_KERNEL_1` or `PRE_KERNEL_2` initialization levels.

Generally a function that is **pre-kernel-ok** checks `k_is_pre_kernel()` when determining whether it can fulfill its required behavior. In many cases it would also check `k_is_in_isr()` so it can be **isr-ok** as well.

async

A function is **async** (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

Explanation Be aware that **async** is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is `spi_transceive_signal()`.

If a function is both **no-wait** and **async** then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

supervisor

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.

2.7 Language Support

2.7.1 C Language Support

C is a general-purpose low-level programming language that is widely used for writing code for embedded systems.

Zephyr is primarily written in C and natively supports applications written in the C language. All Zephyr API functions and macros are implemented in C and available as part of the C header files under the `include` directory, so writing Zephyr applications in C gives the developers access to the most features.

The `main()` function must have the return type of `int` as Zephyr applications run in a "hosted" environment as defined by the C standard. Applications must return zero (0) from main. All non-zero return values are reserved.

Language Standards

Zephyr does not target a specific version of the C standards; however, the Zephyr codebase makes extensive use of the features newly introduced in the 1999 release of the ISO C standard (ISO/IEC 9899:1999, hereinafter referred to as C99) such as those listed below, effectively requiring the use of a compiler toolchain that supports the C99 standard and above:

- inline functions
- standard boolean types (`bool` in `<stdbool.h>`)
- fixed-width integer types (`[u]intN_t` in `<stdint.h>`)
- designated initializers

- variadic macros
- `restrict` qualification

Additionally, some components or parts of them make use of features introduced in the C11 and C17 versions of the standard (ISO/IEC 9899:2011 and 9899:2018 respectively):

- _Generic keyword
- _Static_assert keyword

In summary, it is recommended to use a compiler toolchain that supports at least the C17 standard for developing with Zephyr. It is, however, important to note that some optional Zephyr components and external modules may make use of the C language features that have been introduced in more recent versions of the standards, in which case it will be necessary to use a more up-to-date compiler toolchain that supports such standards.

Standard Library

The C Standard Library is an integral part of any C program, and Zephyr provides the support for a number of different C libraries for the applications to choose from, depending on the compiler toolchain being used to build the application.

Common C library code Zephyr provides some C library functions that are designed to be used in conjunction with multiple C libraries. These either provide functions not available in multiple C libraries or are designed to replace functionality in the C library with code better suited for use in the Zephyr environment

Time function This provides an implementation of the standard C function, `time()`, relying on the Zephyr function, `sys_clock_gettime()`. This function can be enabled by selecting `COMMON_LIBC_TIME`.

Dynamic Memory Management The common dynamic memory management implementation can be enabled by selecting the `CONFIG_COMMON_LIBC_MALLOC` in the application configuration file.

The common C library internally uses the *kernel memory heap API* to manage the memory heap used by the standard dynamic memory management interface functions such as `malloc()` and `free()`.

The internal memory heap is normally located in the `.bss` section. When userspace is enabled, however, it is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads. The size of the internal memory heap is specified by the `CONFIG_COMMON_LIBC_MALLOC_ARENA_SIZE`.

The default heap size for applications using the common C library is zero (no heap). For other C library users, if there is an MMU present, then the default heap is 16kB. Otherwise, the heap uses all available memory.

There are also separate controls to select `calloc()` (`COMMON_LIBC_CALLOC`) and `reallocarray()` (`COMMON_LIBC_REALLOCARRAY`). Both of these are enabled by default as that doesn't impact memory usage in applications not using them.

The standard dynamic memory management interface functions implemented by the common C library are thread safe and may be simultaneously called by multiple threads. These functions are implemented in `lib/libc/common/source/stdlib/malloc.c`.

Minimal libc The most basic C library, named "minimal libc", is part of the Zephyr codebase and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems, primarily in the areas of string manipulation and display.

It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. It can also be used with a number of different toolchains.

The minimal libc implementation can be found in `lib/libc/minimal` in the main Zephyr tree.

Functions The minimal libc implements the minimal subset of the ISO/IEC 9899:2011 standard C library functions required to meet the needs of the Zephyr kernel, as defined by the *Coding Guidelines Rule A.4*.

Formatted Output The minimal libc does not implement its own formatted output processor; instead, it maps the C standard formatted output functions such as `printf` and `sprintf` to the `cbprintf()` function, which is Zephyr's own C99-compatible formatted output implementation.

For more details, refer to the *Formatted Output* OS service documentation.

Dynamic Memory Management The minimal libc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Error numbers Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the `errno.h` header file.

A subset of the error numbers defined in the POSIX errno.h specification and other de-facto standard sources have been added to the minimal libc.

A conscious effort is made in Zephyr to keep the values of the minimal libc error numbers consistent with the different implementations of the C standard libraries supported by Zephyr. The minimal libc `errno.h` is checked against that of the *Newlib* to ensure that the error numbers are kept aligned.

Below is a list of the error number definitions. For the actual numeric values please refer to errno.h.

Error numbers

Newlib Newlib is a complete C library implementation written for the embedded systems. It is a separate open source project and is not included in source code form with Zephyr. Instead, the *Zephyr SDK* includes a precompiled library for each supported architecture (`libc.a` and `libm.a`).

> **Note**
>
> Other 3rd-party toolchains, such as *GNU Arm Embedded*, also bundle the Newlib as a precompiled library.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Newlib. These hook functions are implemented in `lib/libc/newlib/libc-hooks.c` and translate the library internal system calls to the equivalent Zephyr API calls.

Types of Newlib The Newlib included in the *Zephyr SDK* comes in two versions: 'full' and 'nano' variants.

Full Newlib The Newlib full variant (`libc.a` and `libm.a`) is the most capable variant of the Newlib available in the Zephyr SDK, and supports almost all standard C library features. It is optimized for performance (prefers performance over code size) and its footprint is significantly larger than the nano variant.

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and de-selecting the `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Nano Newlib The Newlib nano variant (`libc_nano.a` and `libm_nano.a`) is the size-optimized version of the Newlib, and supports all features that the full variant supports except the new format specifiers introduced in C99, such as the `char`, `long long` type format specifiers (i.e. `%hhX` and `%llX`).

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Note that the Newlib nano variant is not available for all architectures. The availability of the nano variant is specified by the `CONFIG_HAS_NEWLIB_LIBC_NANO`.

Formatted Output Newlib supports all standard C formatted input and output functions, including `printf`, `fprintf`, `sprintf` and `sscanf`.

The Newlib formatted input and output function implementation supports all format specifiers defined by the C standard with the following exceptions:

- Floating point format specifiers (e.g. `%f`) require `CONFIG_NEWLIB_LIBC_FLOAT_PRINTF` and `CONFIG_NEWLIB_LIBC_FLOAT_SCANF` to be enabled.
- C99 format specifiers are not supported in the Newlib nano variant (i.e. `%hhX` for `char`, `%llX` for `long long`, `%jX` for `intmax_t`, `%zX` for `size_t`, `%tX` for `ptrdiff_t`).

Dynamic Memory Management Newlib implements an internal heap allocator to manage the memory blocks used by the standard dynamic memory management interface functions (for example, `malloc()` and `free()`).

The internal heap allocator implemented by the Newlib may vary across the different types of the Newlib used. For example, the heap allocator implemented in the Full Newlib (`libc.a` and `libm.a`) of the Zephyr SDK requests larger memory chunks to the operating system and has a significantly higher minimum memory requirement compared to that of the Nano Newlib (`libc_nano.a` and `libm_nano.a`).

The only interface between the Newlib dynamic memory management functions and the Zephyr-side libc hooks is the `sbrk()` function, which is used by the Newlib to manage the size of the memory pool reserved for its internal heap allocator.

The `_sbrk()` hook function, implemented in `libc-hooks.c`, handles the memory pool size change requests from the Newlib and ensures that the Newlib internal heap allocator memory pool size does not exceed the amount of available memory space by returning an error when the system is out of memory.

When userspace is enabled, the Newlib internal heap allocator memory pool is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads.

The amount of memory space available for the Newlib heap depends on the system configurations:

- When MMU is enabled (`CONFIG_MMU` is selected), the amount of memory space reserved for the Newlib heap is set by the size of the free memory space returned by the `k_mem_free_get()` function or the `CONFIG_NEWLIB_LIBC_MAX_MAPPED_REGION_SIZE`, whichever is the smallest.
- When MPU is enabled and the MPU requires power-of-two partition size and address alignment (`CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE` is set to a non-zero value), the amount of memory space reserved for the Newlib heap is set by the `CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE`.
- Otherwise, the amount of memory space reserved for the Newlib heap is equal to the amount of free (unallocated) memory in the SRAM region.

The standard dynamic memory management interface functions implemented by the Newlib are thread safe and may be simultaneously called by multiple threads.

Picolibc Picolibc is a complete C library implementation written for the embedded systems, targeting C17 (ISO/IEC 9899:2018) and POSIX 2018 (IEEE Std 1003.1-2017) standards. Picolibc is an external open source project which is provided for Zephyr as a module, and included as part of the *Zephyr SDK* in precompiled form for each supported architecture (`libc.a`).

> **Note**
>
> Picolibc is also available for other 3rd-party toolchains, such as *GNU Arm Embedded*.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Picolibc. These hook functions are implemented in lib/libc/picolibc/ and translate the library internal system calls to the equivalent Zephyr API calls.

Picolibc Module When built as a Zephyr module, there are several configuration knobs available to adjust the feature set in the library, balancing what the library supports versus the code size of the resulting functions. Because the standard C++ library must be compiled for the target C library, the Picolibc module cannot be used with applications which use the standard C++ library. Building the Picolibc module will increase the time it takes to compile the application.

The Picolibc module can be enabled by selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

When updating the Picolibc module to a newer version, the *toolchain-bundled Picolibc in the Zephyr SDK* must also be updated to the same version.

Toolchain Picolibc Starting with version 0.16, the Zephyr SDK includes precompiled versions of Picolibc for every target architecture, along with precompiled versions of libstdc++.

The toolchain version of Picolibc can be enabled by de-selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

For every release of Zephyr, the toolchain-bundled Picolibc and the *Picolibc module* are guaranteed to be in sync when using the *recommended version of Zephyr SDK*.

Building Without Toolchain bundled Picolibc For toolchain where there is no bundled Picolibc, it is still possible to use Picolibc by building it from source. Note that any restrictions mentioned in *Picolibc Module* still apply.

To build without toolchain bundled Picolibc, the toolchain must enable `CONFIG_PICOLIBC_SUPPORTED`. For example, this needs to be added to the toolchain Kconfig file:

```
config TOOLCHAIN_<name>_PICOLIBC_SUPPORTED
   def_bool y
   select PICOLIBC_SUPPORTED
```

By enabling `CONFIG_PICOLIBC_SUPPORTED`, the build system would automatically build Picolibc from source with its module when there is no toolchain bundled Picolibc.

Formatted Output Picolibc supports all standard C formatted input and output functions, including `printf()`, `fprintf()`, `sprintf()` and `sscanf()`.

Picolibc formatted input and output function implementation supports all format specifiers defined by the C17 and POSIX 2018 standards with the following exceptions:

- Floating point format specifiers (e.g. `%f`) require `CONFIG_PICOLIBC_IO_FLOAT`.
- Long long format specifiers (e.g. `%lld`) require `CONFIG_PICOLIBC_IO_LONG_LONG`. This option is automatically enabled with `CONFIG_PICOLIBC_IO_FLOAT`.

Printk, cbprintf and friends When using Picolibc, Zephyr formatted output functions are implemented in terms of stdio calls. This includes:

- printk, snprintk and vsnprintk
- cbprintf and cbvprintf
- fprintfcb, vfprintfcb, printfcb, vprintfcb, snprintfcb and vsnprintfcb

When using tagged args (`CONFIG_CBPRINTF_PACKAGE_SUPPORT_TAGGED_ARGUMENTS` and `CBPRINTF_PACKAGE_ARGS_ARE_TAGGED`), calls to cbpprintf will not use Picolibc, so formatting of output using those code will differ from Picolibc results as the cbprintf functions are not completely C/POSIX compliant.

Math Functions Picolibc provides full C17/IEEE STD 754-2019 support for float, double and long double math operations, except for long double versions of the Bessel functions.

Thread Local Storage Picolibc uses Thread Local Storage (TLS) (where supported) for data which is supposed to remain local to each thread, like `errno`. This means that TLS support is enabled when using Picolibc. As all TLS variables are allocated out of the thread stack area, this can affect stack size requirements by a few bytes.

C Library Local Variables Picolibc uses a few internal variables for things like heap management. These are collected in a dedicated memory partition called `z_libc_partition`. Applications using `CONFIG_USERSPACE` and memory domains must ensure that this partition is included in any domain active during Picolibc calls.

Dynamic Memory Management Picolibc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Formatted Output

C defines standard formatted output functions such as `printf` and `sprintf` and these functions are implemented by the C standard libraries.

Each C standard library has its own set of requirements and configurations for selecting the formatted output modes and capabilities. Refer to each C standard library documentation for more details.

Dynamic Memory Management

C defines a standard dynamic memory management interface (for example, `malloc()` and `free()`) and these functions are implemented by the C standard libraries.

While the details of the dynamic memory management implementation varies across different C standard libraries, all supported libraries must conform to the following conventions. Every supported C standard library shall:

- manage its own memory heap either internally or by invoking the hook functions (for example, `sbrk()`) implemented in `libc-hooks.c`.
- maintain the architecture- and memory region-specific alignment requirements for the memory blocks allocated by the standard dynamic memory allocation interface (for example, `malloc()`).
- allocate memory blocks inside the `z_malloc_partition` memory partition when userspace is enabled. See *Pre-defined Memory Partitions*.

For more details regarding the C standard library-specific memory management implementation, refer to each C standard library documentation.

Note

Native Zephyr applications should use the *memory management API* supported by the Zephyr kernel such as `k_malloc()` in order to take advantage of the advanced features that they offer.

C standard dynamic memory management interface functions such as `malloc()` should be used only by the portable applications and libraries that target multiple operating systems.

2.7.2 C++ Language Support

C++ is a general-purpose object-oriented programming language that is based on the C language.

Enabling C++ Support

Zephyr supports applications written in both C and C++. However, to use C++ in an application you must configure Zephyr to include C++ support by selecting the `CONFIG_CPP` in the application configuration file.

To enable C++ support, the compiler toolchain must also include a C++ compiler and the included compiler must be supported by the Zephyr build system. The *Zephyr SDK*, which includes the GNU C++ Compiler (part of GCC), is supported by Zephyr, and the features and their availability documented here assume the use of the Zephyr SDK.

The default C++ standard level (i.e. the language enforced by the compiler flags passed) for Zephyr apps is C++11. Other standards are available via kconfig choice, for example `CONFIG_STD_CPP98`. The oldest standard supported and tested in Zephyr is C++98.

When compiling a source file, the build system selects the C++ compiler based on the suffix (extension) of the files. Files identified with either a **cpp** or a **cxx** suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The C++ standard requires the `main()` function to have the return type of `int`. Your `main()` must be defined as `int main(void)` or `int main(int, char **)`. To use main with arguments the `CONFIG_BOOTARGS` option has to be selected. Zephyr ignores the return value from main. However, Applications must return zero (0). All non-zero return values are reserved.

Note

Do not use C++ for kernel, driver, or system initialization code.

Language Features

Zephyr currently provides only a subset of C++ functionality. The following features are *not* supported:

- Static global object destruction
- OS-specific C++ standard library classes (e.g. `std::thread`, `std::mutex`)

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Dynamic object management with the **new** and **delete** operators
- Exceptions

- RTTI (runtime type information)
- Standard Template Library (STL)

Static global object constructors are initialized after the drivers are initialized but before the application `main()` function. Therefore, use of C++ is restricted to application code.

In order to make use of the C++ exceptions, the `CONFIG_CPP_EXCEPTIONS` must be selected in the application configuration file.

Zephyr Minimal C++ Library

Zephyr minimal C++ library (`lib/cpp/minimal`) provides a minimal subset of the C++ standard library and application binary interface (ABI) functions to enable basic C++ language support. This includes:

- `new` and `delete` operators
- virtual function stub and vtables
- static global initializers for global constructors

The scope of the minimal C++ library is strictly limited to providing the basic C++ language support, and it does not implement any Standard Template Library (STL) classes and functions. For this reason, it is only suitable for use in the applications that implement their own (non-standard) class library and do not rely on the Standard Template Library (STL) components.

Any application that makes use of the Standard Template Library (STL) components, such as `std::string` and `std::vector`, must enable the C++ standard library support.

C++ Standard Library

The C++ Standard Library is a collection of classes and functions that are part of the ISO C++ standard (`std` namespace).

Zephyr does not include any C++ standard library implementation in source code form. Instead, it allows configuring the build system to link against the pre-built C++ standard library included in the C++ compiler toolchain.

To enable C++ standard library, select an applicable toolchain-specific C++ standard library type from the `CONFIG_LIBCPP_IMPLEMENTATION` in the application configuration file.

For instance, when building with the *Zephyr SDK*, the build system can be configured to link against the GNU C++ Library (`libstdc++.a`), which is a fully featured C++ standard library that provides all features required by the ISO C++ standard including the Standard Template Library (STL), by selecting `CONFIG_GLIBCXX_LIBCPP` in the application configuration file.

The following C++ standard libraries are supported by Zephyr:

- GNU C++ Library (`CONFIG_GLIBCXX_LIBCPP`)
- ARC MetaWare C++ Library (`CONFIG_ARCMWDT_LIBCPP`)

A Zephyr subsystem that requires the features from the full C++ standard library can select, from its config, `CONFIG_REQUIRES_FULL_LIBCPP`, which automatically selects a compatible C++ standard library unless the Kconfig symbol for a specific C++ standard library is selected.

Header files and incompatibilities between C and C++

To interact with each other, C and C++ must share code through header files: data structures, macros, static functions,... While C and C++ have a large overlap, they're different languages with known incompatibilities. C is not just a C++ subset. Standard levels (e.g.: "C+11") add another level of complexity as new features are often inspired by and copied from the other language but many years later and with subtle differences. Making things more complex, compilers often

offer early prototypes of features before they become standardized. Standards can have ambiguities interpreted differently by different compilers. Compilers can have bugs and these may need workarounds. To help with this, many projects restrict themselves to a limited number of toolchains. Zephyr does not.

These compatibility issues affect header files dis-proportionally. Not just because they have to be compatible between C and C++, but also because they end up being compiled in a surprisingly high number of other source files due to *indirect* inclusion and the lack of structure and headers organization that is typical in real-world projects. So, header files are exposed to a much larger variety of toolchains and project configurations. Adding more constraints, the Zephyr project has demanding policies with respect to code style, compiler warnings, static analyzers and standard compliance (e.g.: MISRA).

Put together, all these constraints can make writing header files very challenging. The purpose of this section is to document some best "header practices" and lessons learned in a Zephyr-specific context. While a lot of the information here is not Zephyr-specific, this section is not a substitute for knowledge of C/C++ standards, textbooks and other references.

Testing Fortunately, the Zephyr project has an extensive test and CI infrastructure that provides coverage baselines, catches issues early, enforces policies and maintains such combinatorial explosions under some control. The `tests/lib/cpp/cxx/` are very useful in this context because their `testcase.yaml` configuration lets `twister` iterate quickly over a range of `-std` parameters: `-std=c++98`, `-std=c++11`, etc.

Keep in mind unused macros are not compiled.

Designated initializers Initialization macros are common in header files as they help reduce boilerplate code. C99 added initialization of `struct` and `union` types by "designated" member names instead of a list of *bare* expressions. Some GCC versions support designated initializers even in their C90 mode.

When used at a simple level, designated initializers are less error-prone, more readable and more flexible. On the other hand, C99 allowed a surprisingly large and lax set of possibilities: designated initializers can be out of order, duplicated, "nested" (`.a.x =`), various other braces can be omitted, designated initializers and not can be mixed, etc.

Twenty years later, C++20 added designated initializers to C++ but in much more restricted way; partly because a C++ `struct` is actually a `class`. As described in the C++ proposal number P0329 (which compares with C) or in any complete C++ reference, a mix is not allowed and initializers must be in order (gaps are allowed).

Interestingly, the new restrictions in C++20 can cause `gcc -std=c++20` to fail to compile code that successfully compiles with `gcc -std=c++17`. For example, `gcc -std=c++17` and older allow the C-style mix of initializers and bare expressions. This fails to compile with using `gcc -std=c++20` *with the same GCC version*.

Recommendation: to maximize compatibility across different C and C++ toolchains and standards, designated initializers in Zephyr header files should follow all C++20 rules and restrictions. Non-designated, pre-C99 initialization offers more compatibility and is also allowed but designated initialization is the more readable and preferred code style. In any case, both styles must never be mixed in the same initializer.

Warning: successful compilation is not the end of the incompatibility story. For instance, the *evaluation order* of initializer expressions is unspecified in C99! It is the (expected) left-to-right order in C++20. Other standard revisions may vary. In doubt, do not rely on evaluation order (here and elsewhere).

Anonymous unions Anonymous unions (a.k.a. "unnamed" unions) seem to have been part of C++ from its very beginning. They were not officially added to C until C11. As usual, there are differences between C and C++. For instance, C supports anonymous unions only as a member of

an enclosing `struct` or `union`, empty lists `{ }` have always been allowed in C++ but they require C23, etc.

When initializing anonymous members, the expression can be enclosed in braces or not. It can be either designated or bare. For maximum portability, when initializing *anonymous unions*:

- Do *not* enclose *designated* initializers with braces. This is required by C++20 and above which perceive such braces as mixing bare expressions with (other) designated initializers and fails to compile.
- Do enclose *bare* expressions with braces. This is required by C. Maybe because C is laxer and allows many initialization possibilities and variations, so it may need such braces to disambiguate? Note C does allow omitting most braces in initializer expressions - but not in this particular case of initializing anonymous unions with bare expressions.

Some pre-C11 GCC versions support some form of anonymous unions. They unfortunately require enclosing their designated initializers with braces which conflicts with this recommendation. This can be solved with an `#ifdef __STDC_VERSION__` as demonstrated in Zephyr commit c15f029a7108 and the corresponding code review.

2.7.3 Rust Language Support

Rust is a modern systems programming language designed to provide memory safety, concurrency, and performance without sacrificing low-level control. It achieves this through a unique ownership model that eliminates common bugs like null pointer dereferencing and data races at compile time.

Rust's emphasis on safety and correctness makes it particularly well-suited for embedded systems and environments where reliability is critical. Additionally, Rust offers powerful abstractions without a runtime or garbage collector, allowing developers to write both high-level code and low-level hardware interactions with confidence and efficiency.

These attributes make Rust a strong choice for projects on Zephyr, where resource constraints and system stability are paramount.

Enabling Rust Support

In order to enable Rust support in a Zephyr application, a few things need to be done:

1. As Rust is currently an optional module, the module needs to be enabled. The easiest way to do this is with west:

   ```
   west config manifest.project-filter +zephyr-lang-rust
   west update
   ```

   This should cause the Rust language support to be placed in `modules/lang/rust` in your Zephyr workspace.

2. Enable Rust support, via `CONFIG_RUST` in the `prj.conf`. The easiest way to do this (as well as the CMake setup from the next step) is to start with one of the samples in modules/lang/rust/samples.

3. Configure the application's `CMakeLists.txt` file to support Rust. Again this is easiest to copy from a sample, but this will look something like:

   ```
   cmake_minimum_required(VERSION 3.20.0)

   find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})

   project(my_app)
   rust_cargo_application()
   ```

4. Create a `Cargo.toml` that describes how to build the Rust application. From the Hello World sample:

```
[package]
# This must be rustapp for now.
name = "rustapp"
version = "0.1.0"
edition = "2021"
description = "The description of my app"
license = "Apache-2.0 or MIT"

[lib]
crate-type = ["staticlib"]

[dependencies]
zephyr = "0.1.0"
log = "0.4.22"
```

   The only required dependency is `zephyr` which provides the zephyr crate that is used to interface with Zephyr.

5. Build as you would any other Zephyr application. Only a few targets currently support Rust (these can be seen in the modules/lang/rust/etc/platforms.txt file).

API Documentation

The API Documentation for the latest version in the module is kept on gh-pages.

This documentation is generated for a general target, with all features enabled. Once you have an application that is buildable, you can generate documentation specifically for your target:

```
west build -t rustdoc

...

Generated /
↪my/path/app/zephyr/build/doc/rust/target/riscv32i-unknown-none-elf/doc/rustapp/index.html
```

The path printed at the end can be opened in a browser. This top level docs will be for your application itself. Look for the 'zephyr' crate on the left side bar, and this will take you to the docs for Zephyr. This page will also generate local docs for any dependencies used by your application, directly or indirectly.

2.8 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

2.8.1 Optimizing for Footprint

Stack Sizes

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

`CONFIG_ISR_STACK_SIZE`
: Set to 2048 by default

`CONFIG_MAIN_STACK_SIZE`
: Set to 1024 by default

`CONFIG_IDLE_STACK_SIZE`
: Set to 320 by default

`CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
: Set to 1024 by default

`CONFIG_PRIVILEGED_STACK_SIZE`
: Set to 1024 by default, depends on userspace feature.

Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

```
CONFIG_GPIO=n
CONFIG_SPI=n
```

Various Debug/Informational Options

The following options output more information about the running application and provide means for debugging and error handling:

`CONFIG_BOOT_BANNER`
: This option can be disabled to save a few bytes.

`CONFIG_DEBUG`
: This option can be enabled for debug builds.

Note that the boot banner is enabled by default.

MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you'll lose advanced stack checking and support.

2.8.2 Optimization Tools

The available optimization tools let you analyse *Footprint and Memory Usage* and *Data Structures* using different build system targets.

Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis.

Some of the tools mentioned in this section are organizing their output based on the physical organization of the symbols. As some symbols might be external to the project's tree structure, or might lack metadata needed to display them by name, the following top-level containers are used to group such symbols:

- Hidden - The RAM and ROM reports list all processing symbols with no matching mapped files in the Hidden category.

  This means that the file for the listed symbol was not added to the metadata file, was empty, or was undefined. The tool was unable to get the name of the function for the given symbol nor identify where it comes from.

- No paths - The RAM and ROM reports list all processing symbols with relative paths in the No paths category.

  This means that the listed symbols cannot be placed in the tree structure of the report at an absolute path under one specific file. The tool was able to get the name of the function, but it was unable to identify where it comes from.

  > **Note**
  >
  > You can have multiple cases of the same function, and the No paths category will list the sum of these in one entry.

Build Target: ram_report List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `ram_report` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild ram_report
```

These commands will generate something similar to the output below:

```
Path                                                                                 Size    %     ␣

                                                            4637
```

Build Target: rom_report List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `rom_report` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world
```

(continues on next page)

(continued from previous page)

```
# Now run the build tool on the generated build system:
ninja -Cbuild rom_report
```

These commands will generate something similar to the output below:

```
Path                                                                  Size    %      ␣
↪Address

                                                                    21652
```

Build Targets: ram_plot/rom_plot Similar to the `ram_report` and `rom_report` build targets, these targets generate memory usage reports in a sunburst chart as a visual representation. A user can click on segments to navigate through the directory structures, and hover over segments to get more details.

Running the targets will first generate the CLI report and then open a browser window.

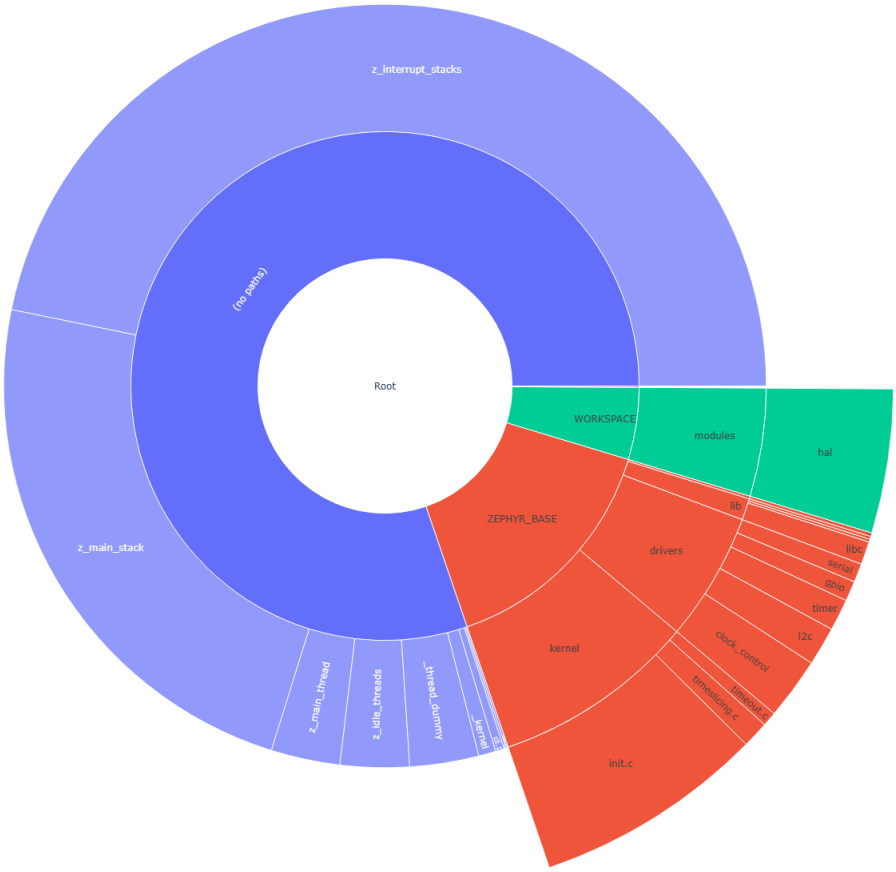
Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t ram_plot
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild ram_plot
```



And similarly for the ROM usage.

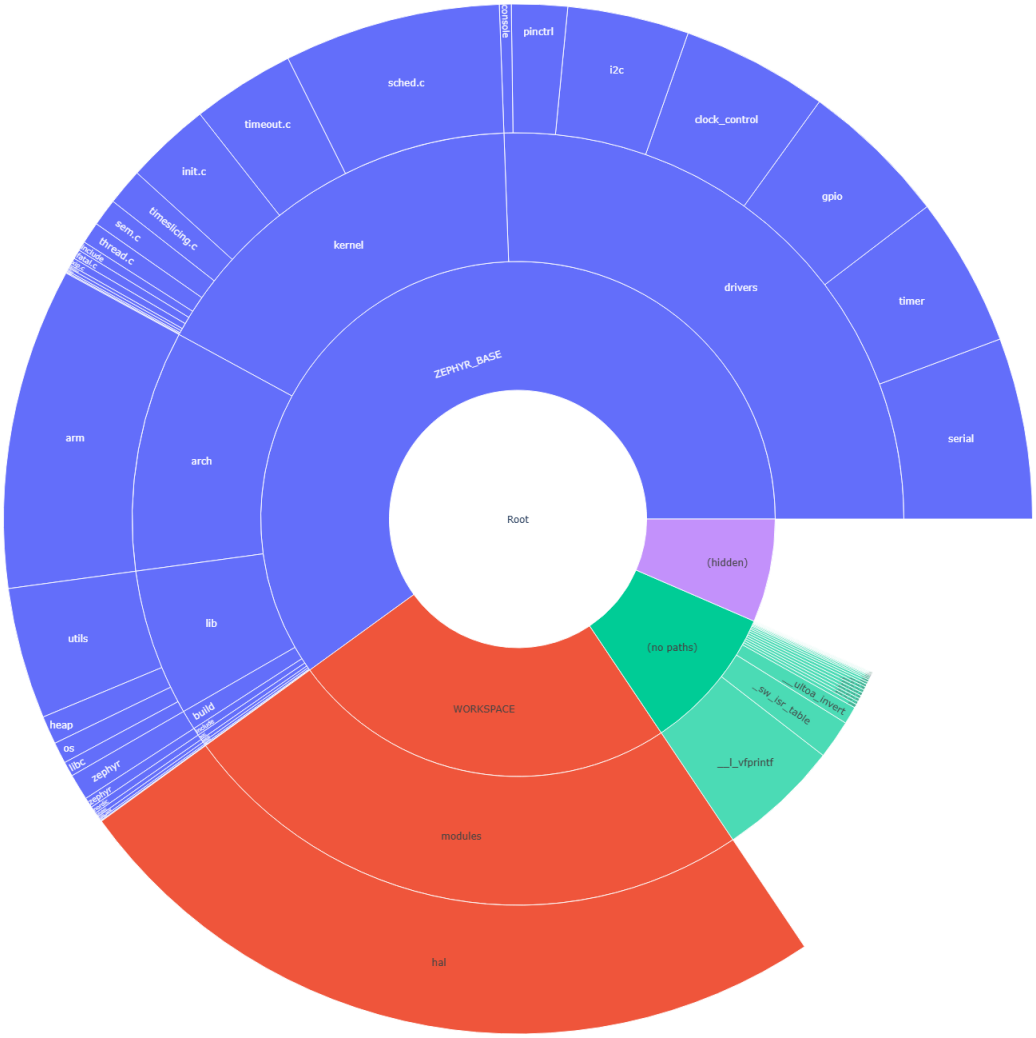
Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t rom_plot
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild rom_plot
```



Build Target: puncover This target uses a third-party tool called puncover which can be found at https://github.com/HBehrens/puncover. When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM, and stack usage.

Before you can use this target, install the puncover Python module:

```
pip3 install --user puncover
```

Warning

This is a third-party tool that might or might not be working at any given time. Please check the GitHub issues, and report new problems to the project maintainer.

After you installed the Python module, use `puncover` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

The puncover target will start a local web server on `localhost:5000` by default. The host IP and port the HTTP server runs on can be changed by setting the environment variables `PUNCOVER_HOST` and `PUNCOVER_PORT`.

To view worst-case stack usage analysis, build this with the `CONFIG_STACK_USAGE` enabled.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

Data Structures

Build Target: pahole Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from https://git.kernel.org/pub/scm/devel/pahole/pahole.git and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

Alternatively, you can get it from fedora:

```
sudo dnf install dwarves
```

After you installed the package, use `pahole` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild pahole
```

Pahole will generate something similar to the output below in the console:

```
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <375> [...]/zephyr/include/zephyr/sys/dlist.h:37 */
union {
        struct _dnode *            head;               /*     0     4 */
        struct _dnode *            next;               /*     0     4 */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <397> [...]/zephyr/include/zephyr/sys/dlist.h:36 */
struct _dnode {
        union {
                struct _dnode *    head;                 /*     0     4 */
                struct _dnode *    next;                 /*     0     4 */
        };                                               /*     0     4 */
        union {
                struct _dnode *    tail;                 /*     4     4 */
                struct _dnode *    prev;                 /*     4     4 */
        };                                               /*     4     4 */

        /* size: 8, cachelines: 1, members: 2 */
        /* last cacheline: 8 bytes */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <3b7> [...]/zephyr/include/zephyr/sys/dlist.h:41 */
union {
        struct _dnode *            tail;               /*     0     4 */
        struct _dnode *            prev;               /*     0     4 */
};
...
...
```

2.9 Flashing and Hardware Debugging

2.9.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr's west tool has built-in support for all of these in its `flash`, `debug`, `debugserver`, and `attach` commands, provided your board hardware supports them and your Zephyr board directory's `board.cmake` file declares that support properly. See *Building, Flashing and Debugging* for more information on these commands.

Black Magic Probe

Black Magic Probe (BMP) is an open-source debugging hardware incorporating GDB debug server functionality into the firmware. There is no need for a GDB server program, so there is no program equivalent to host-tool.

For more details, including usage instructions and supported targets, see *Black Magic Probe*.

SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using *west*. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
west flash [ -r bossac ] [ -p /dev/ttyX ] [ --erase ]
```

Note

By default, flashing with bossac will only erase the flash pages containing the flashed application, leaving other pages untouched. Should you wish to erase the entire flash of the target when flashing, pass the `--erase` parameter when flashing.

Flash configuration for devices:

With ROM bootloader

These devices don't need any special configuration. After building your application, just run `west flash` to flash the board.

Without ROM bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option set to `y` to instruct the build system to use these partitions for code relocation. This option can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_BOOTLOADER_BOSSA` Kconfig option set to `y`. This will automatically select the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option which instruct the build system to use these partitions for code relocation. The board `.defconfig` file should have `CONFIG_BOOTLOADER_BOSSA_ARDUINO` , `CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2` or the `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option set to `y` to select the right compatible SAM-BA bootloader mode. These options can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

Note

The `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

Typical flash layout and configuration For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and code_partition should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};

&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                boot_partition: partition@0 {
                        label = "sam-ba";
                        reg = <0x00000000 0x2000>;
                        read-only;
                };

                code_partition: partition@2000 {
                        label = "code";
                        reg = <0x2000 0x3a000>;
                        read-only;
                };

                /*
                * The final 16 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@3c000 {
                        label = "storage";
                        reg = <0x0003c000 0x00004000>;
                };
        };
};
```

A typical flash layout for devices with a ROM bootloader and storage partition is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};

&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;
```

(continues on next page)

(continued from previous page)

```
                code_partition: partition@0 {
                        label = "code";
                        reg = <0x0 0xF0000>;
                        read-only;
                };

                /*
                * The final 64 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@F0000 {
                        label = "storage";
                        reg = <0x000F0000 0x00100000>;
                };
        };
};
```

Enabling SAM-BA runner In order to instruct Zephyr west tool to use the SAM-BA bootloader the `board.cmake` file must have `include(${ZEPHYR_BASE}/boards/common/bossac.board.cmake)` entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.

More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- sam4e_xpro (ROM bootloader)
- adafruit_feather_m0_basic_proto (Adafruit UF2 bootloader)
- arduino_nano_33_iot (Arduino bootloader)
- arduino_nano_33_ble (Arduino legacy bootloader)

Enabling BOSSAC on Windows Native [Experimental] Zephyr SDK´s bossac is currently supported on Linux and macOS only. Windows support can be achieved by using the bossac version from BOSSA official releases. After installing using default options, the `bossac.exe` must be added to Windows PATH. A specific bossac executable can be used by passing the `--bossac` option, as follows:

```
west flash -r bossac --bossac="C:\Program Files (x86)\BOSSA\bossac.exe" --
↪bossac-port="COMx"
```

Note

WSL is not currently supported.

LinkServer Debug Host Tools

Linkserver is a utility for launching and managing GDB servers for NXP debug probes, which also provides a command-line target flash programming capabilities. Linkserver can be used with the NXP MCUXpresso for Visual Studio Code implementation, with custom debug configurations based on GNU tools or as part of a headless solution for continuous integration and test. LinkServer can be used with MCU-Link, LPC-Link2, LPC11U35-based and OpenSDA based standalone or on-board debug probes from NXP.

NXP recommends installing LinkServer by using NXP's MCUXpresso Installer. This method will also install the tools supporting the debug probes below, including NXP's MCU-Link and LPC-Scrypt tools.

LinkServer is compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*

To use LinkServer with West commands, the install folder should be added to the *PATH environment variable*. The default installation path to add is:

Linux

```
/usr/local/LinkServer
```

macOS

```
/Applications/LinkServer_<version>
```

Windows

```
c:\nxp\LinkServer_<version>
```

Supported west commands:

1. flash
2. debug
3. debugserver
4. attach

Notes:

1. Probes can be listed with LinkServer:

```
LinkServer probes
```

2. With multiple debug probes attached to the host, use the LinkServer west runner `--probe` option to pass the probe index.

```
west flash --runner=linkserver --probe=3
```

3. Device-specific settings can be overridden with the west runner for LinkServer with the option '–override'. May be used multiple times. The format is dictated by LinkServer, e.g.:

```
west flash --runner=linkserver --override /
↪device/memory/5/flash-driver=MIMXRT500_SFDP_MXIC_OSPI_S.cfx
```

4. LinkServer does not install an implicit breakpoint at the reset handler. If you would like to single step from the start of their application, you will need to add a breakpoint at `main` or the reset handler manually.

J-Link Debug Host Tools

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output

- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- *LPC-Link2 J-Link Onboard Debug Probe*
- *OpenSDA J-Link Onboard Debug Probe*
- *MCU-Link JLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in J-Link Supported Devices.

Download and install the J-Link Software and Documentation Pack to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

OpenOCD Debug Host Tools

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see Getting OpenOCD for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- *OpenSDA DAPLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in OpenOCD Supported Devices.

Note

On Linux, openocd is available though the Zephyr SDK. Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: OpenOCD Windows
- Copy bin and share dirs to `C:\Program Files\OpenOCD\`
- Add `C:\Program Files\OpenOCD\bin` to 'PATH' environment variable

pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the *Get Zephyr and install Python dependencies* step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in pyOCD Supported Devices.

Lauterbach TRACE32 Debug Host Tools

Lauterbach TRACE32 is a product line of microprocessor development tools, debuggers and real-time tracer with support for JTAG, SWD, NEXUS or ETM over multiple core architectures, including Arm Cortex-A/-R/-M, RISC-V, Xtensa, etc. Zephyr allows users to develop and program boards with Lauterbach TRACE32 support using *west*.

The runner consists of a wrapper around TRACE32 software, and allows a Zephyr board to execute a custom start-up script (Practice Script) for the different commands supported, including the ability to pass extra arguments from CMake. Is up to the board using this runner to define the actions performed on each command.

Install Lauterbach TRACE32 Software Download Lauterbach TRACE32 software from the Lauterbach TRACE32 download website (registration required) and follow the installation steps described in Lauterbach TRACE32 Installation Guide.

Flashing and Debugging Set the *environment variable* `T32_DIR` to the TRACE32 system directory. Then execute `west flash` or `west debug` commands to flash or debug the Zephyr application as detailed in *Building, Flashing and Debugging*. The `debug` command launches TRACE32 GUI to allow debug the Zephyr application, while the `flash` command hides the GUI and perform all operations in the background.

By default, the `t32` runner will launch TRACE32 using the default configuration file named `config.t32` located in the TRACE32 system directory. To use a different configuration file, supply the argument `--config CONFIG` to the runner, for example:

```
west flash --config myconfig.t32
```

For more options, run `west flash --context -r t32` to print the usage.

Zephyr RTOS Awareness To enable Zephyr RTOS awareness follow the steps described in Lauterbach TRACE32 Zephyr OS Awareness Manual.

NXP S32 Debug Probe Host Tools

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio for S32 Platform.

Download (registration required) NXP S32 Design Studio for S32 Platform and follow the S32 Design Studio for S32 Platform Installation User Guide to get the necessary debug host tools and associated USB device drivers.

Note that Zephyr RTOS-awareness support for the NXP S32 GDB server depends on the target device. Consult the product release notes for more information.

Supported west commands:

1. debug
2. debugserver
3. attach

Basic usage Before starting, add NXP S32 Design Studio installation directory to the system *PATH environment variable*. Alternatively, it can be passed to the runner on each invocation via `--s32ds-path` as shown below:

Linux

```
west debug --s32ds-path=/opt/NXP/S32DS.3.6
```

Windows

```
west debug --s32ds-path=C:\NXP\S32DS.3.6
```

If multiple S32 debug probes are connected to the host via USB, the runner will ask the user to select one via command line prompt before continuing. The connection string for the probe can be also specified when invoking the runner via `--dev-id=<connection-string>`. Consult NXP S32 debug probe user manual for details on how to construct the connection string. For example, if using a probe with serial ID `00:04:9f:00:ca:fe`:

```
west debug --dev-id='s32dbg:00:04:9f:00:ca:fe'
```

It is possible to pass extra options to the debug host tools via `--tool-opt`. When executing `debug` or `attach` commands, the tool options will be passed to the GDB client only. When executing `debugserver`, the tool options will be passed to the GDB server. For example, to load a Zephyr application to SRAM and afterwards detach the debug session:

```
west debug --tool-opt='--batch'
```

Requirements

- **S32 Design Studio version**: 3.6.0 or newer.
- **S32DebugProbe OS (firmware)**: 1.1.0 or newer.

S32 Debug Probe OS Upgrade Procedure Refer to the "Reprogramming S32 Debug Probe Firmware Images" chapter in the S32 Debug Probe User Guide to upgrade the OS of the S32DebugProbe.

probe-rs Debug Host Tools

probe-rs is an open-source embedded toolkit written in Rust. It provides out-of-the-box support for a variety of debug probes, including CMSIS-DAP, ST-Link, SEGGER J-Link, FTDI and built-in USB-JTAG interface on ESP32 devices.

Check probe-rs Installation for more setup details.

Check if your SoC is listed in probe-rs Supported Devices.

Renesas Flash Programmer (RFP) Host Tools

Renesas provides Renesas Flash Programmer as an official programming tool for Renesas boards using the Renesas standard boot firmware. It is available as a GUI and CLI.

For boards configured with the `rfp` west runner, the RFP CLI can be easily used to flash Zephyr.

Supported west commands:

1. flash

Once downloaded, if `rfp-cli` is not placed somewhere in your system PATH, you can pass the location to `rfp-cli` when flashing:

```
west flash --rfp-cli ~/Downloads/RFP_CLI_Linux_V31800_x64/linux-x64/rfp-cli
```

STM32CubeCLT Flash & Debug Host Tools

STMicroelectronics provides STM32CubeCLT as an official all-in-one toolset compatible with Linux®, macOS® and Windows®, allowing the use of STMicroelectronics proprietary tools within third-party development environments.

It notably provides a GDB debugging server (the *ST-LINK GDB Server*) that can be used to debug applications on STM32 boards thanks to on-board or external ST-LINK debug probes.

It is compatible with the following debug probes:

- *ST-LINK/V2-1 Onboard Debug Probe*
- Standalone ST-LINK-V2, ST-LINK-V3, and STLINK-V3PWR probes

Install STM32CubeCLT The easiest way to get the ST-LINK GDB Server is to install STM32CubeCLT from STMicroelectronics' website. A valid email address is needed to receive the downloading link.

Basic usage The ST-Link GDB Server can be used through the `west attach`, `west debug` or `west debugserver` commands to debug Zephyr applications.

```
west debug --runner stlink_gdbserver
```

Note

The STM32CubeProgrammer version contained in the STM32CubeCLT installation can also be used to flash applications. To do so, the dedicated *STM32CubeProgrammer runner* should be used instead of `stlink_gdbserver`, as done in the following example:

```
west flash --runner stm32cubeprogrammer
```

STM32CubeProgrammer Flash Host Tools

STMicroelectronics provides STM32CubeProgrammer (STM32CubeProg) as an official programming tool for STM32 boards on Linux®, macOS®, and Windows® operating systems.

It provides an easy-to-use and efficient environment for reading, writing, and verifying device memory through both the debug interface (JTAG and SWD) and the bootloader interface (UART and USB DFU, I2C, SPI, and CAN).

It offers a wide range of features to program STM32 internal memories (such as flash, RAM, and OTP) as well as external memories.

It also allows option programming and upload, programming content verification, and programming automation through scripting.

It is delivered in GUI (graphical user interface) and CLI (command-line interface) versions.

It is compatible with the following debug probes:

- *ST-LINK/V2-1 Onboard Debug Probe*
- *J-Link External Debug Probe*
- Standalone ST-LINK-V2, ST-LINK-V3, and STLINK-V3PWR probes

Install STM32CubeProgrammer The easiest way to get STM32CubeProgrammer is to download it from STMicroelectronics website. A valid email address is needed to receive the downloading link.

Alternatively, it can be installed as part of STM32CubeCLT all-in-one multi-OS command-line toolset which also includes GDB debugger client and server.

If you have STM32CubeIDE installed on your system, then STM32CubeProg is already present.

Basic usage STM32CubeProgrammer is setup as the default west runner for all active STM32 boards supported by Zephyr. It can be used through the `west flash` command to flash Zephyr applications.

```
west flash --runner stm32cubeprogrammer
```

For advanced usage via the GUI or CLI, check out the STM32CubeProgrammer User Manual.

UF2 Uploader

The uf2 runner supports flashing some boards using the UF2 (USB Flashing Format). UF2 is a user-friendly file format designed for drag-and-drop programming via a USB mass storage device.

It relies on the target device entering a special bootloader mode where it appears to the host as a USB mass storage device. Once in this mode, the application image can be uploaded by copying a `.uf2` file to the mounted volume.

```
west flash --runner uf2
```

If the UF2 volume is not automatically detected, you may need to manually specify the mount point using the `--device` option:

For more about the UF2 format and its tooling, see USB Flashing Format (UF2).

Realtek Bee Flash Programmer (MPCli) Host Tools

Realtek provides Realtek Flash Programmer (MPCli) as an official programming tool for the Bee series, supporting Linux, macOS, and Windows operating systems. MPCli enables In-System Programming (ISP) via a UART interface, eliminating the need for external programming hardware. On most official Bee-series evaluation boards, a built-in UART-to-USB converter is included for ready-to-use programming and logging.

After downloading the archive of MPCli, extract it and choose the version compatible with your operating system. Then, add the directory containing the `mpcli` executable to your system *PATH environment variable*.

Before starting, ensure your board is in download mode. Please refer to the board documentation at: Realtek Supported Boards

```
west flash [--runner mpcli] --port /dev/ttyX
```

2.9.2 Debug Probes

A *debug probe* is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as *tracing program execution*. For details on the related host software supported by Zephyr, see *Flash & Debug Host Tools*.

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP boards may use *OpenSDA*, *LPC-Link2*, or *MCU-Link*, probes depending on the microcontroller the debug probe firmware runs on. ST boards have the *ST-LINK probe*. Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their

respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

Debug Probes & Host Tools Compatibility Chart		Host Tools					
		J-Link Debug	**OpenO**	**pyOCD**	**NXP S32DS**	**NXP LinkServe**	**ST-LINK GDB Server**
Debug Probes	**J-Link External**	✓	✓				
	LPC-Link2 CMSIS-DAP					✓	
	LPC-Link2 J-Link	✓					
	MCU-Link CMSIS-DAP					✓	
	MCU-Link J-Link	✓					
	NXP S32 Debug Probe				✓		
	OpenSDA DAPLink		✓	✓		✓	
	OpenSDA J-Link	✓					
	ST-LINK/V2-1	✓	✓	*some STM32 boards*			✓

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

NXP Onboard Debug Probes

NXP boards may have one of several onboard debug probes. These probes include the *MCU-Link Onboard Debug Probe*, *LPC-LINK2 Onboard Debug Probe* and *OpenSDA Onboard Debug Probe*. Each of these probes is implemented as a secondary microcontroller present on the evaluation board. The specific debug probe type present on a given board can be determined based on the debug microcontroller SOC:

- LPC55S69: *MCU-Link Onboard Debug Probe*
- LPC4322: *LPC-LINK2 Onboard Debug Probe*
- MK20: *OpenSDA Onboard Debug Probe*

For example, the frdm_k64f board has an MK20 debug microcontroller, so this board uses the *OpenSDA Onboard Debug Probe*.

MCU-Link Onboard Debug Probe

The MCU-Link onboard debug probe uses an LPC55S69 SOC. This probe supports the following firmwares:

- *MCU-Link CMSIS-DAP Onboard Debug Probe* (default firmware)

- *MCU-Link JLink Onboard Debug Probe*

This probe is programmed using the MCU-Link host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

MCU-Link CMSIS-DAP Onboard Debug Probe This is the default firmware installed on MCU-Link debug probes. The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. In addition to debug probe functionality, the MCU-Link probes may also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. USB to UART, SPI and/or I2C interfaces (depending on MCU-Link type/implementation)
4. Energy measurements of the target MCU

This debug probe is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

Once the MCU-Link host tools are installed, the following steps are required to program the CMSIS-DAP firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_CMSIS` script, found in the installed MCU-Link `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

MCU-Link JLink Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

These probes do not have JLink firmware installed by default, and must be updated. Once the MCU-Link host tools are installed, the following steps are required to program the JLink firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_JLINK` script, found in the installed MCU-Link `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-LINK2 Onboard Debug Probe

The LPC-LINK2 onboard debug probe uses an LPC4322 SOC. This probe supports the following firmwares:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *LPC-Link2 J-Link Onboard Debug Probe*

- *LPC-Link2 DAPLink Onboard Debug Probe* (default firmware)

This probe is programmed using the LPCScrypt host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

LPC-LINK2 CMSIS DAP Onboard Debug Probe The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, as well as NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. As well as providing debug probe functionality, the LPC-Link2 probes also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. LPCSIO bridge that provides communication to I2C and SPI slave devices

This debug probe firmware is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

The probe may be updated to use CMSIS-DAP firmware with the following steps:

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_CMSIS` script, found in the installed LPCScrypt `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

Note

On some boards, the J-Link probe firmware will no longer power the board via the USB debug port. On these boards, an alternative method of powering the board must be used when this firmware is programmed.

LPC-Link2 J-Link Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

The probe may be updated to use the J-Link firmware with the following steps:

Note

Verify the firmware supports your board by visiting Firmware for LPCXpresso

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_JLINK` script, found in the installed LPCScrypt `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-Link2 DAPLink Onboard Debug Probe The LPC-Link2 DAPLink firmware is the default firmware shipped on LPC-Link2 based boards, but is not the recommended firmware. Users should update to the *LPC-LINK2 CMSIS DAP Onboard Debug Probe* firmware following the instructions provided above. For details on programming the DAPLink firmware, see NXP AN13206.

OpenSDA Onboard Debug Probe

The OpenSDA onboard debug probe is based on the NXP MK20 SOC. It features drag and drop programming supports, and supports the following debug firmwares:

- *OpenSDA DAPLink Onboard Debug Probe* (default firmware)
- *OpenSDA J-Link Onboard Debug Probe*

OpenSDA DAPLink Onboard Debug Probe This debug probe firmware is compatible with the following debug host tools:

- *pyOCD Debug Host Tools*
- *OpenOCD Debug Host Tools*
- *LinkServer Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides OpenSDA DAPLink Board-Specific Firmwares.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

OpenSDA J-Link Onboard Debug Probe This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides OpenSDA J-Link Generic Firmwares and OpenSDA J-Link Board-Specific Firmwares, where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you plug a USB into the board's USB debug port. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).

J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*
- *OpenOCD Debug Host Tools*

Install the debug host tools before you program the firmware.

ST-LINK/V2-1 Onboard Debug Probe

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- *OpenOCD Debug Host Tools*
- *J-Link Debug Host Tools*
- *STM32CubeCLT Flash & Debug Host Tools*

For some STM32 based boards, it is also compatible with:

- *pyOCD Debug Host Tools*

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More information about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: Segger over ST-Link

Flash and debug with ST-Link Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application `CMakeList.txt` file.

```
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner` (or `-r`) option.

```
west flash --runner jlink
```

To attach a debugger to your board and open up a debug console with `jlink`.

```
west debug --runner jlink
```

For more information about West and available options, see *West (Zephyr's meta-tool)*.

If you configured your Zephyr application to use Segger RTT console instead, open telnet:

```
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
shell>
```

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART_CONSOLE in menuconfig

Updating or restoring ST-Link firmware ST-Link firmware can be updated using STM32CubeProgrammer Tool. It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/
↪STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/FirmwareUpgrade/STLinkUpgrade.jar
↪-sn <board_uid>
```

Where board_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see *Test Runner (Twister)*.

OpenOCD Deprecates HLA ST-Link Interface OpenOCD has deprecated the legacy HLA interface used by ST-Link firmware in favor to the generic DAP interface in January 2024 (see OpenOCD deprecates ST-Link HLA Interface) in favor of the generic DAP interface. DAP interface is supported by ST-Link firmware since 2015 (from version v2j24).

Since OpenOCD deprecation, one using a recent OpenOCD tool (after release tag v0.12.0) may experience communication issues when the ST-Link adapter embeds a firmware prior version v2j24. In such case, it is recommended to update the ST-Link firmware (refer to *ST-LINK firmware*

update). If it is not possible to update the firmware, one may still use the old HLA interface by modifying its OpenOCD configuration script replacing (if applicable) the 2 below lines:

```
source [find interface/stlink-dap.cfg]
transport select dapdirect_swd
```

with the 2 following lines:

```
source [find interface/stlink-hla.cfg]
transport select hla_swd
```

NXP S32 Debug Probe

NXP S32 Debug Probe enables NXP S32 target system debugging via a standard debug port while connected to a developer's workstation via USB or remotely via Ethernet.

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio (S32DS) and NXP Automotive microcontrollers and processors. Install the debug host tools as in indicated in *NXP S32 Debug Probe Host Tools* before you program the firmware.

Black Magic Probe

The Black Magic Probe is an open-source hardware for debugging that is designed to be used with Black Magic Debug firmware. The firmware incorporates GDB Server so that you can connect directly from gdb to the target device.

Some of the STM32F103-based boards can run the Black Magic Debug firmware. See Black Magic Debug supported hardware.

2.10 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called *modules*. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the *module licensing requirements* and *contribution guidelines*. They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
- Silicon vendor Hardware Abstraction Layers (HALs)
- Cryptography libraries
- File Systems
- Inter-Process Communication (IPC) libraries

Additionally, in some cases modules (particularly vendor HALs) can contain references to optional *binary blobs*.

This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

2.10.1 Modules vs west projects

Zephyr modules, described in this page, are not the same as *west projects*. In fact, modules *do not require west* at all. However, when using modules *with west*, then the build system uses west in order to find modules.

In summary:

Modules are repositories that contain a `zephyr/module.yml` file, so that the Zephyr build system can pull in the source code from the repository. *West projects* are entries in the `projects:` section in the `west.yml` manifest file. West projects are often also modules, but not always. There are west projects that are not included in the final firmware image (eg. tools) and thus do not need to be modules. Modules are found by the Zephyr build system either via *west itself*, or via the *ZEPHYR_MODULES CMake variable*.

The contents of this page only apply to modules, and not to west projects in general (unless they are a module themselves).

2.10.2 Module Repositories

- All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
- The module repository codebase shall include a *module.yml* file in a `zephyr/` folder at the root of the repository.
- Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

> **Note**
>
> Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

- Module repositories names should be explicitly set in the `zephyr/module.yml` file.
- Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr_’ prefix.
- If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

> **Note**
>
> It is not required in module repositories to maintain a ‘master’ branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module’s main branch, which should be ‘zephyr’.

- Modules should expose all provided header files with an include pathname beginning with the module-name. (E.g., mcuboot should expose its `bootutil/bootutil.h` as “mcuboot/bootutil/bootutil.h”.)

Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

Requirements for allowed practices Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be *verifiable* by Zephyr CI and *mergeable* (e.g. with the *Rebase and merge*, or *Create a merge commit* option using Github UI). This ensures that the incoming changes are always **reviewable**, and the *downstream* module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

> **Note**
>
> Force-pushing to a module's main branch is not allowed.

Allowed practices The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

Updating modules with a diff from upstream: Upstream changes brought as a single *snapshot* commit (manual diff) in a pull request against the module's main branch, which may be merged using the *Rebase & merge* operation. This approach is simple and should be applicable to all modules with the downside of suppressing the upstream history in the module repository.

> **Note**
>
> The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

Updating modules by merging the upstream branch: Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull request using the *Create a merge commit* operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

2.10.3 Contributing to Zephyr modules

Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

Administrator: Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

Module owner: Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

- coordinate code reviewing in the module repository
- be the default assignee in pull-requests against the repository's main branch
- request additional collaborators to be added to the repository, as they see fit
- regularly synchronize the module repository with its upstream counterpart following the policies described in *Synchronizing with upstream*
- be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
- list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

> **Note**
>
> Module owners are not required to be Zephyr *Maintainers*.

Merger: The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.

Maintaining the module codebase

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module's codebase. The responsibility for keeping the module codebase up to date is shared between the **contributor** of such updates in Zephyr and the module **owner**. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.
- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is required to fix issues in the module's codebase that have not been caught by Zephyr pull request CI runs.

Contributing changes to modules

Submitting and merging changes directly to a module's codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

Submitting changes to modules describes in detail the process of contributing changes to module repositories.

Contribution guidelines Contributing to Zephyr modules shall follow the generic project *Contribution guidelines*.

Pull Requests: may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

Issue Reporting: GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

> **Note**
>
> It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the *Release Quality Criteria*.

2.10.4 Licensing requirements and policies

All source files in a module's codebase shall include a license header, unless the module repository has **main license file** that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

> **Note**
>
> Zephyr recommends conveying module licensing via individual license headers and main license files. This not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

License policies

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yml file) the default license that covers the module's codebase.

License checks License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

2.10.5 Documentation requirements

All Zephyr module repositories shall include an .rst file documenting:

- the scope and the purpose of the module
- how the module integrates with Zephyr
- the owner of the module repository
- synchronization information with the external project (commit, SHA, version etc.)
- licensing information as described in *Licensing requirements and policies*.

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

2.10.6 Testing requirements

All Zephyr modules should provide some level of **integration** testing, ensuring that the integration with Zephyr works correctly. Integration tests:

- may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
- should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
- shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

> **Note**
>
> New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.

> **Note**
>
> Vendor HALs are implicitly tested via Zephyr tests built or executed on target platforms, so they do not need to provide integration tests.

The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

2.10.7 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

- Lack of maintainership in the module
- Licensing changes in the external project
- Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

> **Note**
>
> Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.

2.10.8 Integrate modules in Zephyr build system

The build system variable **ZEPHYR_MODULES** is a CMake list of absolute paths to the directories containing Zephyr modules. These modules contain `CMakeLists.txt` and `Kconfig` files describing how to build and configure them, respectively. Module `CMakeLists.txt` files are added to the build using CMake's add_subdirectory() command, and the `Kconfig` files are included in the build's Kconfig menu tree.

If you have *west* installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use west to set **ZEPHYR_MODULES**. You can add additional modules to this list by setting the **EXTRA_ZEPHYR_MODULES** CMake variable or by adding a **EXTRA_ZEPHYR_MODULES** line to `.zephyrrc` (See the section on *Environment Variables* for more details). This can be useful if you want to keep the list of modules found with west and also add your own. If **EXTRA_ZEPHYR_MODULES** is set in multiple places, for example both as an environment variable and as a CMake variable, the final list of additional modules will be the merged result of all sources.

> **Note**
>
> If the module `FOO` is provided by *west* but also given with `-DEXTRA_ZEPHYR_MODULES=/<path>/foo` then the module given by the command line variable **EXTRA_ZEPHYR_MODULES** will take precedence. This allows you to use a custom version of `FOO` when building and still use other Zephyr modules provided by *west*. This can for example be useful for special test purposes.

If you want to permanently add modules to the zephyr workspace and you are using zephyr as your manifest repository, you can also add a west manifest file into the submanifests directory. See submanifests/README.txt for more details.

See *Basics* for more on west workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.

2.10.9 Module yaml file description

A module can be described using a file named `zephyr/module.yml`. The format of `zephyr/module.yml` is described in the following:

Module name

Each Zephyr module is given a name by which it can be referred to in the build system.

The name should be specified in the `zephyr/module.yml` file. This will ensure the module name is not changeable through user-defined directory names or `west` manifest files:

```
name: <name>
```

In CMake the location of the Zephyr module can then be referred to using the CMake variable ZEPHYR_<MODULE_NAME>_MODULE_DIR and the variable ZEPHYR_<MODULE_NAME>_CMAKE_DIR holds the location of the directory containing the module's CMakeLists.txt file.

Note

When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (_). As example, the module foo-bar must be referred to as ZEPHYR_FOO_BAR_MODULE_DIR in CMake and Kconfig.

Here is an example for the Zephyr module foo:

```
name: foo
```

Note

If the name field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in <workspace>/modules/bar will use bar as its module name if nothing is specified in zephyr/module.yml.

Module integration files (in-module)

Inclusion of build files, CMakeLists.txt and Kconfig, can be described as:

```
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The cmake: <cmake-directory> part specifies that <cmake-directory> contains the CMakeLists.txt to use. The kconfig: <directory>/Kconfig part specifies the Kconfig file to use. Neither is required: cmake defaults to zephyr, and kconfig defaults to zephyr/Kconfig.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the root directory of the module:

```
build:
  cmake: .
  kconfig: Kconfig
```

Sysbuild integration

Sysbuild is the Zephyr build system that allows for building multiple images as part of a single application, the sysbuild build process can be extended externally with modules as needed, for example to add custom build steps or add additional targets to a build. Inclusion of sysbuild-specific build files, CMakeLists.txt and Kconfig, can be described as:

```
build:
  sysbuild-cmake: <cmake-directory>
  sysbuild-kconfig: <directory>/Kconfig
```

The sysbuild-cmake: <cmake-directory> part specifies that <cmake-directory> contains the CMakeLists.txt to use. The sysbuild-kconfig: <directory>/Kconfig part specifies the Kconfig file to use.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the sysbuild directory of the module:

```
build:
  sysbuild-cmake: sysbuild
  sysbuild-kconfig: sysbuild/Kconfig
```

The module description file `zephyr/module.yml` can also be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a *Module integration files (external)*.

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  sysbuild-cmake-ext: True
  sysbuild-kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

Vulnerability monitoring

The module description file `zephyr/module.yml` can be used to improve vulnerability monitoring.

If your module needs to track vulnerabilities using an external reference (e.g your module is forked from another repository), you can use the `security` section. It contains the field `external-references` that contains a list of references that needs to be monitored for your module. The supported formats are:

- CPE (Common Platform Enumeration)
- PURL (Package URL)

```
security:
  external-references:
    - <module-related-cpe>
    - <an-other-module-related-cpe>
    - <module-related-purl>
```

A real life example for `mbedTLS` module could look like this:

```
security:
  external-references:
    - cpe:2.3:a:arm:mbed_tls:3.5.2:*:*:*:*:*:*:*
    - pkg:github/Mbed-TLS/mbedtls@V3.5.2
```

Note

CPE field must follow the CPE 2.3 schema provided by NVD. PURL field must follow the PURL specification provided by Github.

Build system integration

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.

Zephyr modules In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

Additionally, `ZEPHYR_<MODULE_NAME>_MODULE` and `ZEPHYR_<MODULE_NAME>_MODULE_BLOBS` (in case the module declares blobs) symbols are automatically generated for available modules. These can be used e.g. to declare dependencies from other Kconfig symbols which depend on the module or blobs from the module. To satisfy compliance checking when building Zephyr without the

module present, it's recommended for the module to have default definitions for these symbols in its respective Kconfig file under `modules/` in the Zephyr main tree.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```
if(ZEPHYR_FOO_MODULE_DIR)
  # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```
source "$(ZEPHYR_FOO_MODULE_DIR)/some/Kconfig"
```

During CMake processing of each Zephyr module, the following variables are also available:

- the current module's name: `${ZEPHYR_CURRENT_MODULE_NAME}`
- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's `CMakeLists.txt` directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```
include(${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the `SYSCALL_INCLUDE_DIRS` list.

Sysbuild modules In both Kconfig and CMake, the variable `SYSBUILD_CURRENT_MODULE_DIR` contains the absolute path to the sysbuild module. In CMake, `SYSBUILD_CURRENT_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a sysbuild module:

- In CMake: use `${SYSBUILD_CURRENT_MODULE_DIR}` for the module's top level directory, and `${SYSBUILD_CURRENT_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(SYSBUILD_CURRENT_MODULE_DIR)` for the module's top level directory

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig`:

```
source "$(SYSBUILD_CURRENT_MODULE_DIR)/some/Kconfig"
```

The module can source additional CMake files using these variables. For example:

```
include(${SYSBUILD_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

Sysbuild modules hooks Sysbuild provides an infrastructure which allows a sysbuild module to define a function which will be invoked by sysbuild at a pre-defined point in the CMake flow.

Functions invoked by sysbuild:

- `<module-name>_pre_cmake(IMAGES <images>)`: This function is called for each sysbuild module before CMake configure is invoked for all images.
- `<module-name>_post_cmake(IMAGES <images>)`: This function is called for each sysbuild module after CMake configure has completed for all images.
- `<module-name>_pre_domains(IMAGES <images>)`: This function is called for each sysbuild module before domains yaml is created by sysbuild.
- `<module-name>_post_domains(IMAGES <images>)`: This function is called for each sysbuild module after domains yaml has been created by sysbuild.

arguments passed from sysbuild to the function defined by a module:

- `<images>` is the list of Zephyr images that will be created by the build system.

If a module `foo` want to provide a post CMake configure function, then the module's sysbuild `CMakeLists.txt` file must define function `foo_post_cmake()`.

To facilitate naming of functions, the module name is provided by sysbuild CMake through the `SYSBUILD_CURRENT_MODULE_NAME` CMake variable when loading the module's sysbuild `CMakeLists.txt` file.

Example of how the `foo` sysbuild module can define `foo_post_cmake()`:

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "IMAGES" ${ARGN})

  message("Invoking ${CMAKE_CURRENT_FUNCTION}. Images: ${POST_CMAKE_IMAGES}")
endfunction()
```

Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the `depends` field.

```
build:
  depends:
    - <module>
```

Here is an example for the Zephyr module `foo` that is dependent on the Zephyr module `bar` to be present in the build system:

```
name: foo
build:
  depends:
    - bar
```

This example will ensure that `bar` is present when `foo` is included into the build system, and it will also ensure that `bar` is processed before `foo`.

Module integration files (external)

Module integration files can be located externally to the Zephyr module itself. The `MODULE_EXT_ROOT` variable holds a list of roots containing integration files located externally to Zephyr modules.

Module integration files in Zephyr The Zephyr repository contain `CMakeLists.txt` and `Kconfig` build files for certain known Zephyr modules.

Those files are located under

```
<ZEPHYR_BASE>
└── modules
    └── <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

Module integration files in a custom location You can create a similar `MODULE_EXT_ROOT` for additional modules, and make those modules known to Zephyr build system.

Create a `MODULE_EXT_ROOT` with the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE_EXT_ROOT` list using the module description file `zephyr/module.yml`, see *Build settings*.

Note

`ZEPHYR_BASE` is always added as a `MODULE_EXT_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation your own `MODULE_EXT_ROOT`.

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.

To include a module's CMake file, set the variable ZEPHYR_<MODULE_NAME>_CMAKE_DIR to the path containing the CMake file.

To include a module's Kconfig file, set the variable ZEPHYR_<MODULE_NAME>_KCONFIG to the path to the Kconfig file.

The following is an example on how to add support the FOO module.

Create the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── foo
        ├── CMakeLists.txt
        └── Kconfig
```

and inside the modules.cmake file, add the following content

```
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG   ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

Module integration files (zephyr/module.yml) The module description file zephyr/module.yml can be used to specify that the build files, CMakeLists.txt and Kconfig, are located in a *Module integration files (external)*.

Build files located in a MODULE_EXT_ROOT can be described as:

```
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

Build settings

It is possible to specify additional build settings that must be used when including the module into the build system.

All root settings are relative to the root of the module.

Build settings supported in the module.yml file are:

- board_root: Contains additional boards that are available to the build system. Additional boards must be located in a <board_root>/boards folder.
- dts_root: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a <dts_root>/dts folder.
- snippet_root: Contains additional snippets that are available for use. These snippets must be defined in snippet.yml files underneath the <snippet_root>/snippets folder. For example, if you have snippet_root: foo, then you should place your module's snippet.yml files in <your-module>/foo/snippets or any nested subdirectory.
- soc_root: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a <soc_root>/soc folder.
- arch_root: Contains additional architectures that are available to the build system. Additional architectures must be located in a <arch_root>/arch folder.
- module_ext_root: Contains CMakeLists.txt and Kconfig files for Zephyr modules, see also *Module integration files (external)*.

- `sca_root`: Contains additional *SCA* tool implementations available to the build system. Each tool must be located in `<sca_root>/sca/<tool>` folder. The folder must contain a `sca.cmake`.

Example of a `module.yaml` file containing additional roots, and the corresponding file system layout.

```
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:

```
<zephyr-module-root>
├── arch
├── boards
├── dts
├── modules
└── soc
```

Twister (Test Runner)

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```
build:
  cmake: .
samples:
  - samples
tests:
  - tests
boards:
  - boards
```

Binary Blobs

Zephyr supports fetching and using *binary blobs*, and their metadata is contained entirely in `zephyr/module.yml`. This is because a binary blob must always be associated with a Zephyr module, and thus the blob metadata belongs in the module's description itself.

Binary blobs are fetched using *west blobs*. If `west` is *not used*, they must be downloaded and verified manually.

The `blobs` section in `zephyr/module.yml` consists of a sequence of maps, each of which has the following entries:

- `path`: The path to the binary blob, relative to the `zephyr/blobs/` folder in the module repository
- `sha256`: SHA-256 checksum of the binary blob file
- `type`: The *type of binary blob*. Currently limited to `img` or `lib`
- `version`: A version string

- `license-path`: Path to the license file for this blob, relative to the root of the module repository
- `url`: URL that identifies the location the blob will be fetched from, as well as the fetching scheme to use
- `description`: Human-readable description of the binary blob
- `doc-url`: A URL pointing to the location of the official documentation for this blob

The following entries may also be present:

- `click-through`: A boolean indicating if a click-through license must be accepted to download this blob
- `size`: Size of the blob in bytes. May be required by some fetchers
- `fetcher`: The method used to download the blob. If not set, the method is inferred from the URL

Package manager dependencies

Zephyr modules can describe dependencies available from package managers, currently only `pip` is supported.

A west extension command `west packages <manager>` is available to list dependencies for Zephyr and present modules that leverage this feature in their `module.yml` file. Run `west help packages` for more details.

Python pip Calling `west packages pip` lists requirement files for Zephyr and modules. Passing `--install` installs these if there's an active virtual environment.

The following example demonstrates a `zephyr/module.yml` file with some requirement files in the `scripts` directory of the module.

```
package-managers:
  pip:
    requirement-files:
      - scripts/requirements-build.txt
      - scripts/requirements-doc.txt
```

External Runners

If a module has out of tree boards that require custom *runners*, then it can add a list to its `zephyr/module.yml` file, for example:

```
runners:
  - file: scripts/my-runner.py
```

Each file entry is imported when executing `west flash` or `west debug` and subclasses of the `ZephyrBinaryRunner` are registered for use.

Module Inclusion

Using West If west is installed and `ZEPHYR_MODULES` is not already set, the build system finds all the modules in your *west installation* and uses those. It does this by running *west list* to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.

Each project in the `west list` output is tested like this:

- If the project contains a file named `zephyr/module.yml`, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no `zephyr/module.yml`), the build system looks for `zephyr/CMakeLists.txt` and `zephyr/Kconfig` files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to **ZEPHYR_MODULES**.

Without West If you don't have west installed or don't want the build system to use it to find Zephyr modules, you can set **ZEPHYR_MODULES** yourself using one of the following options. Each of the directories in the list must contain either a `zephyr/module.yml` file or the files `zephyr/CMakeLists.txt` and `Kconfig`, as described in the previous section.

1. At the CMake command line, like this:

```
cmake -DZEPHYR_MODULES=<path-to-module1>[;<path-to-module2>[...]] ...
```

2. At the top of your application's top level `CMakeLists.txt`, like this:

```
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...])
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

   If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

```
# Put this in a file with a name like "zephyr-modules.cmake"
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2>
  CACHE STRING "pre-cached modules")
```

   You can tell the build system to use this file by adding `-C zephyr-modules.cmake` to your CMake command line.

Not using modules If you don't have west installed and don't specify **ZEPHYR_MODULES** yourself, then no additional modules are added to the build. You will still be able to build any applications that don't require code or Kconfig options defined in an external repository.

2.10.10 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as `DNM` (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Drafts reduce noise by not automatically notifying anyone until marked as "Ready for review". Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.

Process for submitting a new module

Please follow the process in *Submission and review process* and obtain the TSC approval to integrate the external source code as a module

If the request is approved, a new repository will created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named `zephyr`.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described *here*, and then add a new entry to the west.yml with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the *contribution guidelines* and *expectations*.
2. Submit a pull request changing the entry referencing the module into the west.yml of the main Zephyr tree with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

2.11 West (Zephyr's meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`[1]. West is developed in its own repository.

[1] Zephyr is an English name for the Latin Zephyrus, the ancient Greek god of the west wind.

West's built-in commands provide a multiple repository management system with features inspired by Google's Repo tool and Git submodules. West is also "pluggable": you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like `git` and `docker`, the top-level `west` command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

2.11.1 Installing west

West is written in Python 3 and distributed through PyPI. Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

> **Note**
>
> See *Python and pip* for additional clarification on using the `--user` switch.

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to *clone the Zephyr repositories*.

Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When west is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be on the `PATH` *environment variable*). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use west's Python APIs directly. See west-apis for details.

Enabling shell completion

West currently supports shell completion in the following shells:

- bash
- zsh
- fish
- powershell (board qualifiers only)

In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced. Using the completion scripts:

bash

One-time setup:

```
source <(west completion bash)
```

Permanent setup:

```
west completion bash > ~/west-completion.bash; echo "source ~/
↪west-completion.bash" >> ~/.bashrc
```

zsh

One-time setup:

```
source <(west completion zsh)
```

Permanent setup:

```
west completion zsh > "${fpath[1]}/_west"
```

fish

One-time setup:

```
west completion fish | source
```

Permanent setup:

```
west completion fish > $HOME/.config/fish/completions/west.fish
```

powershell

One-time setup:

```
west completion powershell | Out-String | Invoke-Expression
```

Permanent setup:

```
Set-ExecutionPolicy RemoteSigned -Scope CurrentUser
New-item -type file -force $PROFILE
west completion powershell > $HOME/west-completion.ps1
(Add-Content -Path $PROFILE -Value ". '{$HOME/west-completion.ps1}'")
```

2.11.2 West Release Notes

v1.5.0

Major changes:

- Add support for auto-caching. Pass the `--auto-cache <directory>` argument to `west update`.

Other changes:

- Allow combining `--name-cache` and `--path-cache` for `west update`.
- Document default revision value in the manifest schema.

Bug fixes:

- Allow empty or missing manifest projects list.

- Make `manifest.group-filter` list order deterministic when freezing or resolving manifest files.

v1.4.0

Changes:

- Allow appending data to configuration strings. To append to a value for `<name>`, type: `west config -a <name> <value>`.
- Add `--untracked` argument option to `west manifest`. Run `west manifest --untracked` in a workspace to print all files and directories that are not tracked or managed by west.
- Add `--inactive` argument option to `west list` to support printing inactive projects.
- Support `--active-only` argument option for the `west manifest --resolve` and `west manifest --freeze` commands. This allows freezing workspaces with active project or group filters.

API changes:

- `west.manifest.Manifest` methods `as_dict()`, `as_frozen_dict()`, `as_yaml()` and `as_frozen_yaml()` now have an optional `active_only` argument (defaults to `False`) to return an object containing all projects or only the active ones.

v1.3.0

Major changes:

- Added support for *West aliases* commands.
- Adopt the pyproject TOML specification for packaging.

Other changes:

- Add cache support for submodules.
- Decode manifest files as UTF-8 by default.
- Pass unknown arguments for `west diff` and `west status` to underlying `git` commands.
- Added `--manifest` argument to `west diff` to allow comparing the current workspace to the manifest revisions.
- Environment variables can be used with west forall The following are defined:
  - `WEST_PROJECT_NAME`
  - `WEST_PROJECT_PATH`
  - `WEST_PROJECT_ABSPATH`
  - `WEST_PROJECT_REVISION`
  - `WEST_PROJECT_URL`
  - `WEST_PROJECT_REMOTE`
- Added support for early argument `-q/--quiet` to reduce verbosity.
- Added `-o/--clone-opt` argument to `west init` to pass to `git clone`.
- Support Python 3.13 and drop support for Python 3.8.
- Prevent manifests from having projects in the `.west` directory.
- Add NTFS workarounds and `--rename-delay` for `west init`.
- Print a stack trace when calling die in debug `-vvv`.

Bug fixes:

- Use `'backslashreplace'` not to crash on malformed UTF from subprocess.
- Fix handling in `west diff` for repositories with merge conflicts. Additionally improve error printing and handle `git diff` return codes.
- Fix `--freeze` and `--resolve` for the `west manifest` command when git submodules are used.

v1.2.0

Major changes:

- New `west grep` command for running a "grep tool" in your west workspace's repositories. Currently, `git grep`, ripgrep, and standard `grep` are supported grep tools.

  To run this command to get `git grep foo` results from all cloned, active repositories, run:

  ```
  west grep foo
  ```

  Here are some other examples for running different grep commands with `west grep`:

`git grep --untracked`	`west grep --untracked foo`
`ripgrep`	`west grep --tool ripgrep foo`
`grep --recursive`	`west grep --tool grep foo`

  To switch the default grep tool in your workspace, run the appropriate command in this table:

`ripgrep`	`west config grep.tool ripgrep`
`grep`	`west config grep.tool grep`

  For more details, run `west help grep`.

Other changes:

- The manifest file format now supports a `description` field in each `projects:` element. See *Projects* for examples.
- `west list --format` now accepts `{description}` in the format string, which prints the project's `description:` value.
- `west compare` now always prints information about *The manifest-rev branch*.

Bug fixes:

- `west init` aborts if the destination directory already exists.

API changes:

- `west.commands.WestCommand` methods `check_call()` and `check_output()` now take any kwargs that can be passed on to the underlying subprocess function.
- `west.commands.WestCommand.run_subprocess()`: new wrapper around `subprocess.run()`. This could not be named `run()` because `WestCommand` already had a method by this name.
- `west.commands.WestCommand` methods `dbg()`, `inf()`, `wrn()`, and `err()` now all take an `end` kwarg, which is passed on to the call to `print()`.
- `west.manifest.Project` now has a `description` attribute, which contains the parsed value of the `description:` field in the manifest data.

v1.1.0

Major changes:

- `west compare`: new command that compares the state of the workspace against the manifest.
- Support for a new `manifest.project-filter` configuration option. See *Built-in Configuration Options* for details. The `west manifest --freeze` and `west manifest --resolve` commands currently cannot be used when this option is set. This restriction can be removed in a later release.
- Project names which contain comma (`,`) or whitespace now generate warnings. These warnings are errors if the new `manifest.project-filter` configuration option is set. The warnings may be promoted to errors in a future major version of west.

Other changes:

- `west forall` now takese a `--group` argument that can be used to restrict the command to only run in one or more groups. Run `west help forall` for details.
- All west commands will now output log messages from west API modules at warning level or higher. In addition, the `--verbose` argument to west can be used once to include informational messages, or twice to include debug messages, from all commands.

Bug fixes:

- Various improvements to error messages, debug logging, and error handling.

API changes:

- `west.manifest.Manifest.is_active()` now respects the `manifest.project-filter` configuration option's value.

v1.0.1

Major changes:

- Manifest schema version "1.0" is now available for use in this release. This is identical to the "0.13" schema version in terms of features, but can be used by applications that do not wish to use a "0.x" manifest "version:" field. See *Version* for details on this feature.

Bug fixes:

- West no longer exits with a successful error code when sent an interrupt signal. Instead, it exits with a platform-specific error code and signals to the calling environment that the process was interrupted.

v1.0.0

Major changes in this release:

- The west-apis are now declared stable. Any breaking changes will be communicated by a major version bump from v1.x.y to v2.x.y.
- West v1.0 no longer works with the Zephyr v1.14 LTS releases. This LTS has long been obsoleted by Zephyr v2.7 LTS. If you need to use Zephyr v1.14, you must use west v0.14 or earlier.
- Like the rest of Zephyr, west now requires Python v3.8 or later
- West commands no longer accept abbreviated command line arguments. For example, you must now specify `west update --keep-descendants` instead of using an abbreviation like `west update --keep-d`. This is part of a change applied to all of Zephyr's Python scripts' command-line interfaces. The abbreviations were causing problems in practice when commands were updated to add new options with similar names but different behavior to existing ones.

Other changes:

- All built-in west functions have stopped using `west.log`
- `west update`: new `--submodule-init-config` option. See commit 9ba92b05 for details.

Bug fixes:

- West extension commands that failed to load properly sometimes dumped stack. This has been fixed and west now prints a sensible error message in this case.
- `west config` now fails on malformed configuration option arguments which lack a `.` in the option name

API changes:

- The west package now contains the metadata files necessary for some static analyzers (such as mypy) to auto-detect its type annotations. See commit d9f00e24 for details.
- the deprecated `west.build` module used for Zephyr v1.14 LTS compatibility was removed
- the deprecated `west.cmake` module used for Zephyr v1.14 LTS compatibility was removed
- the `west.log` module is now deprecated. This module uses global state, which can make it awkward to use it as an API which multiple different python modules may rely on.
- The west-apis-commands module got some new APIs which lay groundwork for a future change to add a global verbosity control to a command's output, and work to remove global state from the `west` package's API:
  - New `west.commands.WestCommand.__init__()` keyword argument: `verbosity`
  - New `west.commands.WestCommand` property: `color_ui`
  - New `west.commands.WestCommand` methods, which should be used to print output from extension commands instead of writing directly to sys.stdout or sys.stderr: `inf()`, `wrn()`, `err()`, `die()`, `banner()`, `small_banner()`
  - New `west.commands.VERBOSITY` enum

v0.14.0

Bug fixes:

- West commands that were run with a bad local configuration file dumped stack in a confusing way. This has been fixed and west now prints a sensible error message in this case.
- A bug in the way west looks for the zephyr repository was fixed. The bug itself usually appeared when running an extension command like `west build` in a new workspace for the first time; this used to fail (just for the first time, not on subsequent command invocations) unless you ran the command in the workspace's top level directory.
- West now prints sensible error messages when the user lacks permission to open the manifest file instead of dumping stack traces.

API changes:

- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module
- The `west.manifest.MalformedConfig` exception type has been moved to the west.configuration module
- The `west.configuration.Configuration` class now raises `MalformedConfig` instead of `RuntimeError` in some cases

v0.13.1

Bug fix:

- When calling west.manifest.Manifest.from_file() when outside of a workspace, west again falls back on the ZEPHYR_BASE environment variable to locate the workspace.

v0.13.0

New features:

- You can now associate arbitrary user data with the manifest repository itself in the `manifest: self: userdata:` value, like so:

```
manifest:
  self:
    userdata: <any YAML value can go here>
```

Bug fixes:

- The path to the manifest repository reported by west could be incorrect in certain circumstances detailed in [issue #572](https://github.com/zephyrproject-rtos/west/issues/572). This has been fixed as part of a larger overhaul of path handling support in the `west.manifest` API module.
- The `west.Manifest.ManifestProject.__repr__` return value was fixed

API changes:

- `west.configuration.Configuration`: new object-oriented interface to the current configuration. This reflects the system, global, and workspace-local configuration values, and allows you to read, write, and delete configuration options from any or all of these locations.
- `west.commands.WestCommand`:
  - `config`: new attribute, returns a `Configuration` object or aborts the program if none is set. This is always usable from within extension command `do_run()` implementations.
  - `has_config`: new boolean attribute, which is `True` if and only if reading `self.config` will abort the program.
- The path handling in the `west.manifest` package has been overhauled in a backwards-incompatible way. For more details, see commit [56cfe8d1d1](https://github.com/zephyrproject-rtos/west/commit/56cfe8d1d1f3c9b45de3e793c738acd62db52aca).
- `west.manifest.Manifest.validate()`: this now returns the validated data as a Python dict. This can be useful if the value passed to this function was a str, and the dict is desired.
- `west.manifest.Manifest`: new:
  - path attributes `abspath`, `posixpath`, `relative_path`, `yaml_path`, `repo_path`, `repo_posixpath`
  - `userdata` attribute, which contains the parsed value from `manifest: self: userdata:`, or is None
  - `from_topdir()` factory method
- `west.manifest.ManifestProject`: new `userdata` attribute, which also contains the parsed value from `manifest: self: userdata:`, or is None
- `west.manifest.ManifestImportFailed`: the constructor can now take any value; this can be used to reflect failed imports from a *map* or other compound value.
- Deprecated configuration APIs:

The following APIs are now deprecated in favor of using a `Configuration` object. Usually this will be done via `self.config` from a `WestCommand` instance, but this can be done directly by instantiating a `Configuration` object for other usages.

- `west.configuration.config`
- `west.configuration.read_config`
- `west.configuration.update_config`
- `west.configuration.delete_config`

v0.12.0

New features:

- West now works on the MSYS2 platform.
- West manifest files can now contain arbitrary user data associated with each project. See *Repository user data* for details.

Bug fixes:

- The `west list` command's `{sha}` format key has been fixed for the manifest repository; it now prints `N/A` ("not applicable") as expected.

API changes:

- The `west.manifest.Project.userdata` attribute was added to support project user data.

v0.11.1

New features:

- `west status` now only prints output for projects which have a nonempty status.

Bug fixes:

- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `\`. These invalid characters are now rejected.

  Note: if you need to place a project within a subdirectory of the workspace topdir, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base:`, use `repo-path:`. See *Projects* for examples.
- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See issue #522 for details.
- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.
- `west update --fetch=smart` (`smart` is the default) now correctly skips fetches for project revisions which are lightweight tags (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

Other changes:

- The fix for issue #522 mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, "pseudo-branches" like GitHub's `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to `--manifest-rev`. Users must now fetch and check out such revisions manually after running `west init`.

API changes:

- `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in issue #523.
- `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

v0.11.0

New features:

- `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` *Configuration* options. These can be used to optimize the speed of the update.
- `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

Bug fixes:

- `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

Other changes:

- the west-apis-manifest module has fixed docstrings for the Project class

v0.10.1

New features:

- The *west init* command's `--manifest-rev` (`--mr`) option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

v0.10.0

New features:

- The `name` key in a project's *submodules list* is now optional.

Bug fixes:

- West now checks that the manifest schema version is one of the explicitly allowed values documented in *Version*. The old behavior was just to check that the schema version was newer than the west version where the `manifest: version:` key was introduced. This incorrectly allowed invalid schema versions, like `0.8.2`.

Other changes:

- A manifest file's `group-filter` is now propagated through an `import`. This is a change from how west v0.9.x handled this. In west v0.9.x, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

  Starting with west v0.10.0, the group filter lists from imported manifests are also imported. For details, see *Group Filters and Imports*.

  The new behavior will take effect if `manifest: version:` is not given or is at least `0.10`. The old behavior is still available in the top level manifest file only with an explicit `manifest: version: 0.9`. See *Version* for more information on schema versions.

  See west pull request #482 for the motivation for this change and additional context.

v0.9.1

Bug fixes:

- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:

- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

v0.9.0

Warning

The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

Warning

Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:

- West manifests now support *Git Submodules in Projects*. This allows you to clone Git submodules into a west project repository in addition to the project repository itself.
- West manifests now support *Project Groups*. Project groups can be enabled and disabled to determine what projects are "active", and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
- `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.
- Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active.

  These commands also now support `--all` arguments to include all projects, even inactive ones.
- `west list` now supports a `{groups}` format string key in its `--format` argument.

Bug fixes:

- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see commit 36f3f91e for details.
- A manifest file with an empty `manifest: self: path:` value is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l .` command was fixed; see issue #435.

API changes:

- added `west.manifest.Manifest.is_active()`

- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

Other changes:

- The *Manifest Imports* feature now supports the terms `allowlist` and `blocklist` instead of `whitelist` and `blacklist`, respectively.

  The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

v0.8.0

This is a feature release which changes the manifest schema by adding support for a `path-prefix:` key in an `import:` mapping, along with some other features and fixes.

- Manifest import mappings now support a `path-prefix:` key, which places the project and its imported repositories in a subdirectory of the workspace. See *Example 3.4: Import into a subdirectory* for an example.
- The west command line application can now also be run using `python3 -m west`. This makes it easier to run west under a particular Python interpreter without modifying the *PATH* environment variable.
- *west manifest –path* prints the absolute path to west.yml
- `west init` now supports an `--mf foo.yml` option, which initializes the workspace using `foo.yml` instead of `west.yml`.
- `west list` now prints the manifest repository's path using the `manifest.path` *configuration option*, which may differ from the `self: path:` value in the manifest data. The old behavior is still available, but requires passing a new `--manifest-path-from-yaml` option.
- Various Python API changes; see west-apis for details.

v0.7.3

This is a bugfix release.

- Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

v0.7.2

This is a bugfix and minor feature release.

- Filter out duplicate extension commands brought in by manifest imports
- Fix `west.Manifest.get_projects()` when finding the manifest repository by path

v0.7.1

This is a bugfix and minor feature release.

- `west update --stats` now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.
- `west topdir` always prints a POSIX style path
- minor console output changes

v0.7.0

The main user-visible feature in west 0.7 is the *Manifest Imports* feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a "west installation" has been renamed to "west workspace" in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a *schema version*.
- The "west config" command can now be run outside of a workspace, e.g. to run `west config --global section.key value` to set a configuration option's value globally.
- There is a new *west topdir* command, which prints the root directory of the current west workspace.
- The `west -vv init` command now prints the git operations being performed, and their results.
- The restriction that no project can be named "manifest" is now enforced; the name "manifest" is reserved for the manifest repository, and is usable as such in commands like `west list manifest`, instead of `west list path-to-manifest-repository` being the only way to say that
- It's no longer an error if there is no project named "zephyr". This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- west.build and west.cmake: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.
- west.commands:
  - WestCommand.requires_installation: deprecated; use requires_workspace instead
  - WestCommand.requires_workspace: new
  - WestCommand.has_manifest: new
  - WestCommand.manifest: this is now settable
- west.configuration: callers can now identify the workspace directory when reading and writing configuration files
- west.log:
  - msg(): new
- west.manifest:
  - The module now uses the standard logging module instead of west.log
  - QUAL_REFS_WEST: new
  - SCHEMA_VERSION: new
  - Defaults: removed
  - Manifest.as_dict(): new
  - Manifest.as_frozen_yaml(): new
  - Manifest.as_yaml(): new

  - Manifest.from_file() and from_data(): these factory methods are more flexible to use and less reliant on global state
  - Manifest.validate(): new
  - ManifestImportFailed: new
  - ManifestProject: semi-deprecated and will likely be removed later.
  - Project: the constructor now takes a topdir argument
  - Project.format() and its callers are removed. Use f-strings instead.
  - Project.name_and_path: new
  - Project.remote_name: new
  - Project.sha() now captures stderr
  - Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but it is part of the language specification as of Python 3.7.

v0.6.3

This point release fixes an error in the behavior of the deprecated `west.cmake` module.

v0.6.2

This point release fixes an error in the behavior of `west update --fetch=smart`, introduced in v0.6.1.

All v0.6.1 users must upgrade.

v0.6.1

Warning

Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The *west update* command has a new `--fetch` command line flag and `update.fetch` *configuration option*. The default value, "smart", skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The *west manifest* command also handles errors better.
- The *west list* command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.

- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the `--mr` argument needed to be the entire 40 character SHA if it wasn't a branch or a tag.

The developer-visible changes to the west-apis are:

- west.log.banner(): new
- west.log.small_banner(): new
- west.manifest.Manifest.get_projects(): new
- west.manifest.Project.is_cloned(): new
- west.commands.WestCommand instances can now access the parsed Manifest object via a new self.manifest property during the do_run() call. If read, it returns the Manifest object or aborts the command if it could not be parsed.
- west.manifest.Project.git() now has a capture_stderr kwarg

v0.6.0

- No separate bootstrapper

  In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation clone. See Multiple Repository Management in the v1.14 documentation for more details.

  This is similar to how Google's Repo tool works, and lets west iterate quickly at first. It caused confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

  From v0.6.x onwards, all of the core west commands and helper classes are part of the west package distributed via PyPI. This eliminates complexity and makes it possible to import west modules from anywhere in the system, not just extension commands.

- The `selfupdate` command still exists for backwards compatibility, but now simply exits after printing an error message.
- Manifest syntax changes
  - A west manifest file's `projects` elements can now specify their fetch URLs directly, like so:

    ```
    manifest:
      projects:
        - name: example-project-name
          url: https://github.com/example/example-project
    ```

    Project elements with `url` attributes set in this way may not also have `remote` attributes.
  - Project names must be unique: this restriction is needed to support future work, but was not possible in west v0.5.x because distinct projects may have URLs with the same final pathname component, like so:

    ```
    manifest:
      remotes:
        - name: remote-1
          url-base: https://github.com/remote-1
        - name: remote-2
          url-base: https://github.com/remote-2
      projects:
        - name: project
          remote: remote-1
          path: remote-1-project
    ```

(continues on next page)

(continued from previous page)

```
    - name: project
      remote: remote-2
      path: remote-2-project
```

These manifests can now be written with projects that use `url` instead of `remote`, like so:

```
manifest:
  projects:
    - name: remote-1-project
      url: https://github.com/remote-1/project
    - name: remote-2-project
      url: https://github.com/remote-2/project
```

- The `west list` command now supports a `{sha}` format string key
- The default format string for `west list` was changed to `"{name:12} {path:28} {revision:40} {url}"`.
- The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
- Incompatible API changes were made to west's APIs. Further changes are expected until API stability is declared in west v1.0.
  - The `west.manifest.Project` constructor's `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  - `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The *sections* kwargs in the `west.manifest.Manifest` factory methods and constructor were also removed.
  - The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The west v0.5.x documentation is available as part of the Zephyr's v1.14 documentation.

West's main features in v0.5.x are:

- Multiple repository management using Git repositories, including self-update of west itself
- Hierarchical configuration files
- Extension commands

Versions Before v0.5.x

Tags in the west repository before v0.5.x are prototypes which are of historical interest only.

2.11.3 Troubleshooting West

This page covers common issues with west and how to solve them.

`west update` fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```
west -v update
```

The output includes Git commands run by west and their outputs. Look for something like this:

```
=== updating your_project (path/to/your/project):
west.manifest: your_project: checking if cloned
[...other west.manifest logs...]
--- your_project: fetching, need revision SOME_SHA
west.manifest: running 'git fetch ...␣
↪https://github.com/your-username/your_project ...' in /some/directory
```

The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/path/to/your/project`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you're behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

"'west' is not recognized as an internal or external command, operable program or batch file.'

On Windows, this means that either west is not installed, or your *PATH* environment variable does not contain the directory where pip installed `west.exe`.

First, make sure you've installed west; see *Installing west*. Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your *PATH*. (This *PATH* change should have been done for you when you installed Python and pip, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.
2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

   Important

   Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your *PATH* using a command like this:

   ```
   setx PATH "%PATH%;C:\foo\python\python38\scripts"
   ```

   Do not just copy/paste this command. The `scripts` directory location will be different on your system.

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

"invalid choice: 'build'" (or 'flash', etc.)

If you see an unexpected error like this when trying to run a Zephyr extension command (like *west flash*, *west build*, etc.):

```
$ west build [...]
west: error: argument <command>: invalid choice: 'build' (choose from 'init',␣
↪[...])

$ west flash [...]
west: error: argument <command>: invalid choice: 'flash' (choose from 'init',␣
↪[...])
```

The most likely cause is that you're running the command outside of a *west workspace*. West needs to know where your workspace is to find *Extensions*.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the `zephyrproject` directory you created when you *got started*).

   For example, create your build directory inside the workspace, or run `west flash --build-dir YOUR_BUILD_DIR` from inside the workspace.

2. Set the *ZEPHYR_BASE environment variable* and re-run the west extension command. If set, west will use *ZEPHYR_BASE* to find your workspace.

If you're unsure whether a command is built-in or an extension, run `west help` from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
  init:                 create a west workspace
  [...]

other built-in commands:
  help:                 get help for west or a command
  [...]

extension commands from project manifest (path: zephyr):
  build:                compile a Zephyr application
  flash:                flash and run a binary on a board
  [...]
```

"invalid choice: 'post-init'"

If you see this error when running `west init`:

```
west: error: argument <command>: invalid choice: 'post-init'
(choose from 'init', 'update', 'list', 'manifest', 'diff',
'status', 'forall', 'config', 'selfupdate', 'help')
```

Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the `-U` option for `pip3 install` as shown in *Installing west*.

2. Back up any contents of `zephyrproject/.west/config` that you want to save. (If you don't have any configuration options set, it's safe to skip this step.)
3. Completely remove the `zephyrproject/.west` directory (if you don't, you will get the "already in a workspace" error message discussed next).
4. Run `west init` again.

2.11.4 Basics

This page introduces west's basic concepts and provides references to further reading.

West's built-in commands allow you to work with *projects* (Git repositories) under a common *workspace* directory.

West works in the following manner: the `west init` command creates the *west workspace*, and clones the *manifest repo*, while the `west update` command initially clones, and later updates, the *projects* listed in the manifest in the workspace.

Example workspace

If you've followed the *Getting Started Guide*, your local *west workspace*, which in this case is the folder named `zephyrproject` as well as all its subfolders, looks like this:

```
zephyrproject/                # west topdir
├── .west/                    # marks the location of the topdir
│   └── config                # per-workspace local configuration file
│
│   # The manifest repository, never modified by west after creation:
├── zephyr/                   # .git/ repo
│   ├── west.yml              # manifest file
│   └── [... other files ...]
│
│   # Projects managed by west:
├── modules/
│   └── lib/
│       └── zcbor/            # .git/ project
├── tools/
│   └── net-tools/            # .git/ project
└── [ ... other projects ...]
```

Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in *Workspaces*.

topdir
: Above, `zephyrproject` is the name of the workspace's top level directory, or *topdir*. (The name `zephyrproject` is just an example – it could be anything, like `z`, `my-zephyr-workspace`, etc.)

  You'll typically create the topdir and a few other files and directories using *west init*.

.west directory
: The topdir contains the `.west` directory. When west needs to find the topdir, it searches for `.west`, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the *ZEPHYR_BASE* environment variable as a fallback if that fails).

configuration file
: The file `.west/config` is the workspace's *local configuration file*.

manifest repository
: Every west workspace contains exactly one *manifest repository*, which is a Git repository containing a *manifest file*. The location of the manifest repository is given by the *manifest.path configuration option* in the local configuration file.

  For upstream Zephyr, `zephyr` is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See *Topologies supported* for information on other options, and *West Manifests* for details on the manifest file format.

manifest file
: The manifest file is a YAML file that defines *projects*, which are the additional Git repositories in the workspace managed by west. The manifest file is named `west.yml` by default; this can be overridden using the `manifest.file` local configuration option.

  You use the *west update* command to update the workspace's projects based on the contents of the manifest file.

projects
: Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, `zcbor` and `net-tools` are projects.

  By default, the Zephyr *build system* uses west to get the locations of all the projects in the workspace, so any code they contain can be used as *Modules (External projects)*. Note however that modules and projects *are conceptually different*.

extensions
: Any repository known to west (either the manifest repository or any project repository) can define *Extensions*. Extensions are extra west commands you can run when using that workspace.

  The zephyr repository uses this feature to provide Zephyr-specific commands like *west build*. Defining these as extensions keeps west's core agnostic to the specifics of any workspace's Zephyr version, etc.

ignored files
: A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except `.west`, the manifest repository, and the projects specified in the manifest file.

west init and west update

The two most important workspace-related commands are `west init` and `west update`.

`west init` basics This command creates a west workspace.

> **Important**
>
> West doesn't change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

You will typically run it once, like this:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the topdir, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from https://github.com/zephyrproject-rtos/zephyr, placing it into `zephyrproject/zephyr`

3. Check out the `v2.5.0` git tag in your local zephyr clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see *west init*.

`west update` basics This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

Important

Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

The `west update` command reads the manifest file's contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see *west update*.

Other built-in commands

See *Built-in commands*.

Zephyr Extensions

See the following pages for information on Zephyr's extension commands:

- *Building, Flashing and Debugging*
- *Signing Binaries*
- *Additional Zephyr extension commands*
- *Enabling shell completion*

Troubleshooting

See *Troubleshooting West*.

2.11.5 Built-in commands

This page describes west's built-in commands, some of which were introduced in *Basics*, in more detail.

Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, `west diff` shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as `west list`, `west forall`, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run `west <command> -h` (e.g. `west init -h`).

west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

Option 1: to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given `directory`, creating a new `.west` inside this directory. You can give the manifest URL using the `-m` switch, the initial revision to check out using `--mr`, and the location of the manifest file within the repository using `--mf`.

For example, running:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into `zp/zephyr`, and check out the `v1.14.0` release. This command creates `zp/.west`, and set the `manifest.path` *configuration option* to `zephyr` to record the location of the manifest repository in the workspace. The default manifest file location is used.

The `-m` option defaults to `https://github.com/zephyrproject-rtos/zephyr`. The `--mf` option defaults to `west.yml`. Since west v0.10.1, west will use the default branch in the manifest repository unless the `--mr` option is used to override it. (In prior versions, `--mr` defaulted to `master`.)

If no `directory` is given, the current working directory is used.

Option 2: to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates `.west` **next to** `directory` in the file system, and sets `manifest.path` to `directory`.

As above, `--mf` defaults to `west.yml`.

Reconfiguring the workspace:

If you change your mind later, you are free to change `manifest.path` and `manifest.file` using *west config* after running `west init`. Just be sure to run `west update` afterwards to update your workspace to match the new manifest file.

west update

```
west update [-f {always,smart}] [-k] [-r]
            [--group-filter FILTER] [--stats] [PROJECT ...]
```

Which projects are updated:

By default, this command parses the manifest file, usually `west.yml`, and updates each project specified there. If your manifest uses *project groups*, then only the active projects are updated.

To operate on a subset of projects only, give PROJECT argument(s). Each PROJECT is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

Project update procedure:

For each project that is updated, this command:

1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's `revision` field in the manifest, and fetches it from the remote if it is not already available locally
3. Sets the project's *manifest-rev* branch to the commit specified by the revision in the previous step
4. Checks out `manifest-rev` in the local working copy as a detached HEAD (see *west update detached HEADs* for details about this choice)
5. If the manifest file specifies a *submodules* key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, `west update` will not fetch project `revision` values which are Git SHAs or tags that are already available locally. This is the behavior when the `-f` (`--fetch`) option has its default value, `smart`. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use `-f always` or set the `update.fetch` *configuration option* to `always`. SHAs may be given as unique prefixes as long as they are acceptable to Git[1].

If the project `revision` is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), `west update` always fetches, regardless of `-f` and `update.fetch`.

Some branch names might look like short SHAs, like `deadbeef`. West treats these like SHAs. You can disambiguate by prefixing the `revision` value with `refs/heads/`, e.g. `revision: refs/heads/deadbeef`.

For safety, `west update` uses `git checkout --detach` to check out a detached `HEAD` at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached `HEAD` checked out by west, then git will warn you that you've left behind some commits which are no longer referred to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running `west update`.

If you would rather rebase any locally checked out branches instead, use the `-r` (`--rebase`) option.

If you would like `west update` to keep local branches checked out as long as they point to commits that are descendants of the new `manifest-rev`, use the `-k` (`--keep-descendants`) option.

Note

`west update --rebase` will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with `git`, or you can use `git -C <project_path> rebase --abort` to ignore incoming changes for the moment.

With a clean working tree, a plain `west update` never fails because it does not try to hold on to your commits and simply leaves them aside.

`west update --keep-descendants` offers an intermediate option that never fails either but does not treat all projects the same:

[1] West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain `west update` does;
- in all other projects where no rebase or merge is needed it keeps your branches in place.

One-time project group manipulation:

The `--group-filter` option can be used to change which project groups are enabled or disabled for the duration of a single `west update` command. See *Project Groups* for details on the project group feature.

The `west update` command behaves as if the `--group-filter` option's value were appended to the `manifest.group-filter` *configuration option*.

For example, running `west update --group-filter=+foo,-bar` would behave the same way as if you had temporarily appended the string `"+foo,-bar"` to the value of `manifest.group-filter`, run `west update`, then restored `manifest.group-filter` to its original value.

Note that using the syntax `--group-filter=VALUE` instead of `--group-filter VALUE` avoids issues parsing command line options if you just want to disable a single group, e.g. `--group-filter=-bar`.

Submodule update procedure:

If a project in the manifest has a `submodules` key, the submodules are updated as follows, depending on the value of the `submodules` key.

If the project has `submodules: true`, west first synchronizes the project's submodules with:

```
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has `submodules: <list-of-submodules>`. In this case, west synchronizes the project's submodules with:

```
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```

The `git submodule sync` commands are skipped if the `update.sync-submodules` *Configuration* option is false.

Other project commands

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west compare`: compare the state of the workspace against the manifest
- `west diff`: run `git diff` in local project repositories
- `west forall`: run an arbitrary command in local project repositories
- `west grep`: search for patterns in local project repositories
- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See *Manifest Command*.
- `west status`: run `git status` in local project repositories

Other built-in commands

Finally, here is a summary of other built-in commands.

- `west config`: get or set *configuration options*
- `west topdir`: print the top level directory of the west workspace
- `west help`: get help about a command, or print information about all commands in the workspace, including *Extensions*

2.11.6 Workspaces

This page describes the *west workspace* concept introduced in *Basics* in more detail.

The `manifest-rev` branch

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time *west update* was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is **dangerous** to check it out or otherwise modify it yourself. For instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

Note

West does not create a `manifest-rev` branch in the manifest repository, since west does not manage the manifest repository's branches or revisions.

The `refs/west/*` Git refs

West also reserves all Git refs that begin with `refs/west/` (such as `refs/west/foo`) for itself in local project repositories. Unlike `manifest-rev`, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.

Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The `west update` command essentially runs `git fetch YOUR_PROJECT_URL` when a project's `manifest-rev` branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the credential helpers built in to Git. Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running `west update` without having to enter your password, as well as how to troubleshoot issues.

Fetching via HTTPS On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work "out of the box" on Windows after you have done it once.

In general, you can store your credentials on disk using the "store" git credential helper. See the git-credential-store manual page for details.

To use this helper for all the repositories in your workspace, run:

```
west forall -c "git config credential.helper store"
```

To use this helper on just the projects `foo` and `bar`, run:

```
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```
git config --global credential.helper store
```

On GitHub, you can set up a personal access token to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

You can use the Git credential store to authenticate with a GitHub PAT (Personal Access Token) like so:

```
echo "https://x-access-token:$GH_TOKEN@github.com" >> ~/.git-credentials
```

If you don't want to store any credentials on the file system, you can store them in memory temporarily using git-credential-cache instead.

If you setup fetching via SSH, you can use Git URL rewrite feature. The following command instructs Git to use SSH URLs for GitHub instead of HTTPS ones:

```
git config --global url."git@github.com:".insteadOf "https://github.com/"
```

Fetching via SSH If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using ssh-agent.

On GitHub, see Connecting to GitHub with SSH for details on configuration and key creation.

Project locations

Projects can be located anywhere inside the workspace, but they may not "escape" it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the topdir. However, projects must have paths inside the workspace.

You may replace a project's repository directory within the workspace with a symbolic link to elsewhere on your computer, but west will not do this for you.

Topologies supported

The following are example source code topologies supported by west.

- T1: star topology, zephyr is the manifest repository
- T2: star topology, a Zephyr application is the manifest repository
- T3: forest topology, freestanding manifest repository

T1: Star topology, zephyr is the manifest repository

- The zephyr repository acts as the central repository and specifies its *Modules (External projects)* in its `west.yml`
- Analogy with existing mechanisms: Git submodules with zephyr as the super-project

This is the default. See *Workspace concepts* for how mainline Zephyr is an example of this topology.

T2: Star topology, application is the manifest repository

- Useful for those focused on a single application
- A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its `west.yml`. This includes the zephyr repository and any modules.
- Analogy with existing mechanisms: Git submodules with the application as the super-project, zephyr and other projects as submodules

A workspace using this topology looks like this:

```
west-workspace/
|
├── application/         # .git/     |
|   ├── CMakeLists.txt                |
|   ├── prj.conf                      |  never modified by west
|   ├── src/                          |
|   |   └── main.c                    |
|   └── west.yml         # main manifest with optional import(s) and override(s)
|                                     |
├── modules/
|   └── lib/
|       └── zcbor/       # .git/ project from either the main manifest or some␣
↪import.
|
└── zephyr/              # .git/ project
    └── west.yml         # This can be partially imported with lower precedence or␣
↪ignored.
                         # Only the 'manifest-rev' version can be imported.
```

Here is an example `application/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:

```
# Example T2 west.yml, using manifest imports.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
```

(continues on next page)

(continued from previous page)

```
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
  self:
    path: application
```

You can still selectively "override" individual Zephyr modules if you use `import:` in this way; see *Example 1.3: Downstream of a Zephyr release, with module fork* for an example.

Another way to do the same thing is to copy/paste `zephyr/west.yml` to `application/west.yml`, adding an entry for the zephyr project itself, like this:

```
# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
    # ... other Zephyr modules go here ...
  self:
    path: application
```

(The `west-commands` is there for *Building, Flashing and Debugging* and other Zephyr-specific *Extensions*. It's not necessary when using `import`.)

The main advantage to using `import` is not having to track the revisions of imported projects separately. In the above example, using `import` means Zephyr's *module* versions are automatically determined from the `zephyr/west.yml` revision, instead of having to be copy/pasted (and maintained) on their own.

T3: Forest topology

- Useful for those supporting multiple independent applications or downstream distributions with no "central" repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same "level"
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
├── app1/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── app2/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
```

(continues on next page)

(continued from previous page)

```
|   └── src/
|       └── main.c
├── manifest-repo/      # .git/ never modified by west
|   └── west.yml        # main manifest with optional import(s) and override(s)
├── modules/
|   └── lib/
|       └── zcbor/      # .git/ project from either the main manifest or
|                       #       from some import
|
└── zephyr/             # .git/ project
    └── west.yml        # This can be partially imported with lower precedence or␣
↪ignored.
                        # Only the 'manifest-rev' version can be imported.
```

Here is an example T3 `manifest-repo/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules, then add the `app1` and `app2` projects:

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
    - name: app2
      revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
  self:
    path: manifest-repo
```

You can also do this "by hand" by copy/pasting `zephyr/west.yml` as shown *above* for the T2 topology, with the same caveats.

Not supported: workspace topdir as .git repository

Some users have asked for support making the workspace *topdir* a git repository, like this example:

```
my-workspace/                   # workspace topdir
├── .git/                       # puts the entire workspace in a git repository
├── .west/                      # marks the location of the topdir
└── [ ... other projects ...]
```

This is **not** an officially supported topology. As a design decision, west assumes that the workspace topdir itself is not a git repository.

You may be able to make something like this "work" for yourself and your own goals. However, future versions of west might contain changes which can "break" your setup.

2.11.7 West Manifests

This page contains detailed information about west's multiple repository model, manifest files, and the `west manifest` command. For API documentation on the `west.manifest` module, see west-apis-manifest. For a more general introduction and command overview, see *Basics*.

Multiple Repository Model

West's view of the repositories in a *west workspace*, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr's use of west):

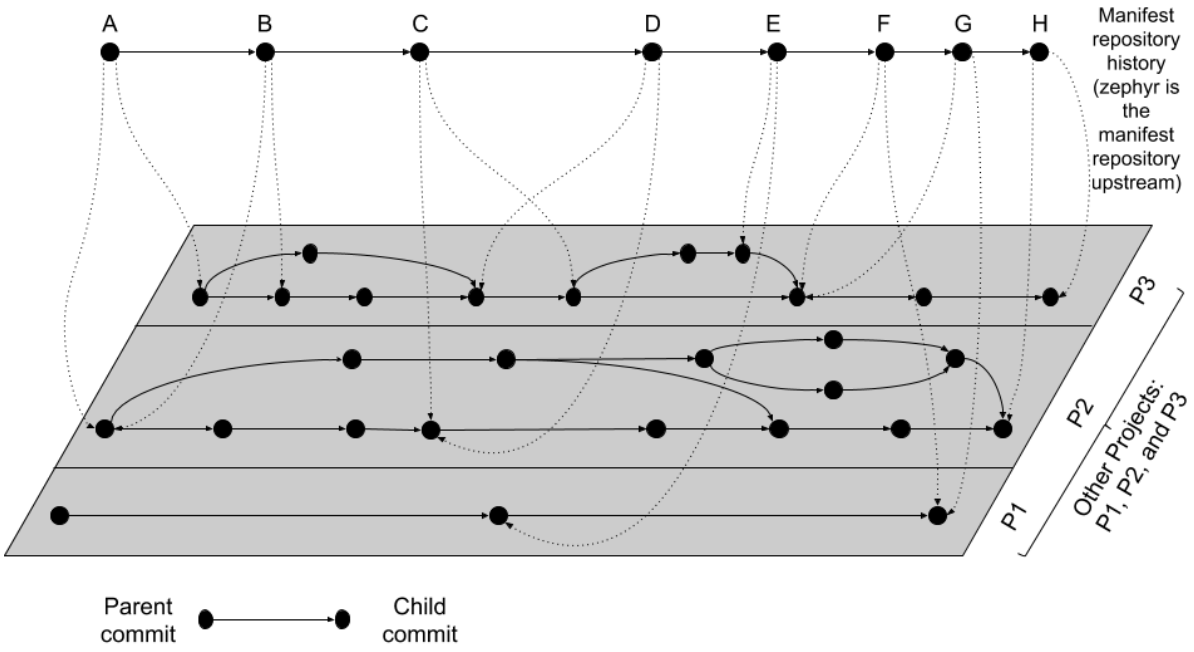


Fig. 3: West multi-repo history

The history of the manifest repository is the line of Git commits which is "floating" on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.

The commits in the manifest repository (again, for upstream Zephyr this is the zephyr repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like `P1` between manifest repository commits `D` and `E`) and removed (`P2` between the same manifest repository commits)
- Project and manifest repository histories don't have to move forwards or backwards together:
  - `P2` stays the same from `A` → `B`, as do `P1` and `P3` from `F` → `G`.
  - `P3` moves forward from `A` → `B`.
  - `P3` moves backward from `C` → `D`.

One use for moving backward in project history is to "revert" a regression by going back to a revision before it was introduced.

- Project repository commits can be "skipped": `P3` moves forward multiple commits in its history from `B → C`.
- In the above diagram, no project repository has two revisions "at the same time": every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.

Manifest Files

West manifests are YAML files. Manifests have a top-level `manifest` section with some subsections, like this:

```
manifest:
  remotes:
    # short names for project URLs
  projects:
    # a list of projects managed by west
  defaults:
    # default project attributes
  self:
    # configuration related to the manifest repository itself,
    # i.e. the repository containing west.yml
  version: "<schema-version>"
  group-filter:
    # a list of project groups to enable or disable
```

In YAML terms, the manifest file contains a mapping, with a `manifest` key. Any other keys and their contents are ignored (west v0.5 also required a `west` key, but this is ignored starting with v0.6).

The manifest contains subsections, like `defaults`, `remotes`, `projects`, and `self`. In YAML terms, the value of the `manifest` key is also a mapping, with these "subsections" as keys. As of west v0.10, all of these "subsection" keys are optional.

The `projects` value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the `remotes` section, which can be used to save typing in the `projects` list.

Remotes The `remotes` subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each `remotes` element has a name and a "URL base". These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```
manifest:
  # ...
  remotes:
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

The `remotes` keys and their usage are in the following table.

Table 2: remotes keys

Key	Description
name	Mandatory; a unique name for the remote.
url-base	A prefix that is prepended to the fetch URL for each project with this remote.

Above, two remotes are given, with names remote1 and remote2. Their URL bases are respectively https://git.example.com/base1 and https://git.example.com/base2. You can use SSH URL bases as well; for example, you might use git@example.com:base1 if remote1 supported Git over SSH as well. Anything acceptable to Git will work.

Projects The projects subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system. Note that west projects *are different from modules*.

Here is an example. We'll assume the remotes given above.

```
manifest:
  # [... same remotes as above...]
  projects:
    - name: proj1
      description: the first example project
      remote: remote1
      path: extra/project-1
    - name: proj2
      description: |
        A multi-line description of the second example
        project.
      repo-path: my-path
      remote: remote2
      revision: v1.3
    - name: proj3
      url: https://github.com/user/project-three
      revision: abcde413a111
```

In this manifest:

- proj1 has remote remote1, so its Git fetch URL is https://git.example.com/base1/proj1. The remote url-base is appended with a / and the project name to form the URL.

  Locally, this project will be cloned at path extra/project-1 relative to the west workspace's root directory, since it has an explicit path attribute with this value.

  Since the project has no revision specified, master is used by default. The current tip of this branch will be fetched and checked out as a detached HEAD when west next updates this project.

- proj2 has a remote and a repo-path, so its fetch URL is https://git.example.com/base2/my-path. The repo-path attribute, if present, overrides the default name when forming the fetch URL.

  Since the project has no path attribute, its name is used by default. It will be cloned into a directory named proj2. The commit pointed to by the v1.3 tag will be checked out when west updates the project.

- proj3 has an explicit url, so it will be fetched from https://github.com/user/project-three.

  Its local path defaults to its name, proj3. Commit abcde413a111 will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the `defaults` subsection; it will be described next.

Table 3: projects elements keys

Key(s)	Description
`name`	Mandatory; a unique name for the project. The name cannot be one of the reserved values "west" or "manifest". The name must be unique in the manifest file.
`description`	Optional, an informational description of the project. Added in west v1.2.0.
`remote`, `url`	Mandatory (one of the two, but not both). If the project has a `remote`, that remote's `url-base` will be combined with the project's `name` (or `repo-path`, if it has one) to form the fetch URL instead. If the project has a `url`, that's the complete fetch URL for the remote Git repository. If the project has neither, the `defaults` section must specify a `remote`, which will be used as the project's remote. Otherwise, the manifest is invalid.
`repo-path`	Optional. If given, this is concatenated on to the remote's `url-base` instead of the project's `name` to form its fetch URL. Projects may not have both `url` and `repo-path` attributes.
`revision`	Optional. The Git revision that `west update` should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the `revision` value from the `defaults` subsection will be used if present. A project revision can be a branch, tag, or SHA. The default `revision` is `master` if not otherwise specified. Using `HEAD~0`[1] as the `revision` will cause west to keep the current state of the project.
`path`	Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project's `name` is used as a directory name.
`clone-depth`	Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the `revision` is a branch or tag.
`west-commands`	Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named `west-commands.yml` by convention. See *Extensions* for details.
`import`	Optional. If `true`, imports projects from manifest files in the given repository into the current manifest. See *Manifest Imports* for details.
`groups`	Optional, a list of groups the project belongs to. See *Project Groups* for details.
`submodules`	Optional. You can use this to make `west update` also update Git submodules defined by the project. See *Git Submodules in Projects* for details.
`userdata`	Optional. The value is an arbitrary YAML value. See *Repository user data*.

Defaults The `defaults` subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using `defaults` is:

```
manifest:
  defaults:
    remote: remote1
    revision: v1.3
```

(continues on next page)

[1] In git, HEAD is a reference, whereas HEAD~<n> is a valid revision but not a reference. West fetches references, such as refs/heads/main or HEAD, and commits not available locally, but will not fetch commits if they are already available. HEAD~0 is resolved to a specific commit that is locally available, and therefore west will simply checkout the locally available commit, identified by HEAD~0.

(continued from previous page)

```
remotes:
  - name: remote1
    url-base: https://git.example.com/base1
  - name: remote2
    url-base: https://git.example.com/base2

projects:
  - name: proj1
    description: the first example project
    path: extra/project-1
    revision: master
  - name: proj2
    description: |
      A multi-line description of the second example
      project.
    repo-path: my-path
    remote: remote2
  - name: proj3
    url: https://github.com/user/project-three
    revision: abcde413a111
```

The available `defaults` keys and their usage are in the following table.

Table 4: defaults keys

Key	Description
`remote`	Optional. This will be used for a project's `remote` if it does not have a `url` or `remote` key set.
`revision`	Optional. This will be used for a project's `revision` if it does not have one set. If not given, the default is `master`.

Self The `self` subsection can be used to control the manifest repository itself.

As an example, let's consider this snippet from the zephyr repository's `west.yml`:

```
manifest:
  # ...
  self:
    path: zephyr
    west-commands: scripts/west-commands.yml
```

This ensures that the zephyr repository is cloned into path `zephyr`, though as explained above that would have happened anyway if cloning from the default manifest URL, `https://github.com/zephyrproject-rtos/zephyr`. Since the zephyr repository does contain extension commands, its `self` entry declares the location of the corresponding `west-commands.yml` relative to the repository root.

The available `self` keys and their usage are in the following table.

Table 5: self keys

Key	Description
path	Optional. The path `west init` should clone the manifest repository into, relative to the west workspace topdir. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is `https://git.example.com/project-repo`, the manifest repository would be cloned to the directory `project-repo`.
west-commands	Optional. This is analogous to the same key in a project sequence element.
import	Optional. This is also analogous to the `projects` key, but allows importing projects from other files in the manifest repository. See *Manifest Imports*.

Version The `version` subsection declares that the manifest file uses features which were introduced in some version of west. Attempts to load the manifest with older versions of west will fail with an error message that explains the minimum required version of west which is needed.

Here is an example:

```
manifest:
  # Marks that this file uses version 0.10 of the west manifest
  # file format.
  #
  # An attempt to load this manifest file with west v0.8.0 will
  # fail with an error message saying that west v0.10.0 or
  # later is required.
  version: "0.10"
```

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section.

Here is a table with the valid `version` values, along with information about the manifest file features that were introduced in that version.

version	New features
"0.7"	Initial support for the version feature. All manifest file features that are not otherwise mentioned in this table were introduced in west v0.7.0 or earlier.
"0.8"	Support for import: path-prefix: (*Option 3: Mapping*)
"0.9"	**Use of west v0.9.x is discouraged.** This schema version is provided to allow users to explicitly request compatibility with west *v0.9.0*. However, west *v0.10.0* and later have incompatible behavior for features that were introduced in west v0.9.0. You should ignore version "0.9" if possible.
"0.10"	Support for: • submodules: in projects: (*Git Submodules in Projects*) • manifest: group-filter:, and groups: in projects: (*Project Groups*) • The import: feature now supports allowlist: and blocklist:; these are respectively recommended as replacements for older names as part of a general Zephyr-wide inclusive language change. The older key names are still supported for backwards compatibility. (*Manifest Imports*, *Option 3: Mapping*)
"0.12"	Support for userdata: in projects: (*Repository user data*)
"0.13"	Support for self: userdata: (*Repository user data*)
"1.0"	Identical to "0.13", but available for use by users that do not wish to use a "0.x" version field.
"1.2"	Support for description: in projects: (*Projects*)

Note

Versions of west without any new features in the manifest file format do not change the list of valid version values. For example, version: "0.11" is **not** valid, because west v0.11.x did not introduce new manifest file format features.

Quoting the version value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it's best to include them. Always use quotes if you're not sure.

If you do not include a version in your manifest, each new release of west assumes that it should try to load it using the features that were available in that release. This may result in error messages that are harder to understand if that version of west is too old to load the manifest.

Group-filter See *Project Groups*.

Active and Inactive Projects

Projects defined in the west manifest can be *inactive* or *active*. The difference is that an inactive project is generally ignored by west. For example, west update will not update inactive projects, and west list will not print information about them by default. As another example, any *Manifest Imports* in an inactive project will be ignored by west.

There are two ways to make a project inactive:

1. Using the manifest.project-filter configuration option. If a project is made active or inactive using this option, then the rules related to making a project inactive using its groups: are ignored. That is, if a regular expression in manifest.project-filter applies to a project, the project's groups have no effect on whether it is active or inactive.

   See the entry for this option in *Built-in Configuration Options* for details.

2. Otherwise, if a project has groups, and they are all disabled, then the project is inactive.

   See the following section for details.

Project Groups

You can use the `groups` and `group-filter` keys briefly described *above* to place projects into groups, and to enable or disable groups.

For example, this lets you run a `west forall` command only on the projects in the group by using `west forall --group`. This can also let you make projects inactive; see the previous section for more information on inactive projects.

The next section introduces project groups. The following section describes *Enabled and Disabled Project Groups*. There are some basic examples in *Project Group Examples*. Finally, *Group Filters and Imports* provides a simplified overview of how `group-filter` interacts with the *Manifest Imports* feature.

Groups Basics The `groups:` and `group-filter:` keys appear in the manifest like this:

```
manifest:
  projects:
    - name: some-project
      groups: ...
  group-filter: ...
```

The `groups` key's value is a list of group names. Group names are strings.

You can enable or disable project groups using `group-filter`. Projects whose groups are all disabled, and which are not otherwise made active by a `manifest.project-filter` configuration option, are inactive.

For example, in this manifest fragment:

```
manifest:
  projects:
    - name: project-1
      groups:
        - groupA
    - name: project-2
      groups:
        - groupB
        - groupC
    - name: project-3
```

The projects are in these groups:

- `project-1`: one group, named `groupA`
- `project-2`: two groups, named `groupB` and `groupC`
- `project-3`: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, `foo-bar` and `foo+bar` are valid groups, but `-foobar` and `+foobar` are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both `import:` and `groups:`. (This is necessary to avoid some pathological edge cases.)

Enabled and Disabled Project Groups All project groups are enabled by default. You can enable or disable groups in both your manifest file and *Configuration*.

Within a manifest file, `manifest: group-filter:` is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, `groupA` is enabled in this manifest fragment:

```
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See *Group Filters and Imports* for more information.

To disable a group, prefix its name with a dash (-). For example, `groupA` and `groupB` are disabled in this manifest fragment:

```
manifest:
  group-filter: [-groupA,-groupB]
```

Note

Since `group-filter` is a YAML list, you could have written this fragment as follows:

```
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

In addition to the manifest file, you can control which groups are enabled and disabled using the `manifest.group-filter` configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with `+`. To disable a group, add its name prefixed with `-`. For example, setting `manifest.group-filter` to `+groupA,-groupB` enables `groupA`, and disables `groupB`.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the `manifest.group-filter` configuration option is appended to the `manifest: group-filter:` list from YAML, with "last entry wins" semantics.

Project Group Examples This section contains example situations involving project groups and active projects. The examples use both `manifest: group-filter:` YAML lists and `manifest.group-filter` configuration lists, to show how they work together.

Note that the `defaults` and `remotes` data in the following manifests isn't relevant except to make the examples complete and self-contained.

Note

In all of the examples that follow, the `manifest.project-filter` option is assumed to be unset.

Example 1: no disabled groups The entire manifest file is:

```
manifest:
  projects:
```

(continues on next page)

(continued from previous page)

```
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
    - name: baz

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (`foo`, `bar`, and `baz`) are active. Note that there is no way to make project `baz` inactive, since it has no groups.

Example 2: Disabling one group via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Since `groupA` is disabled, project `foo` is inactive. Project `bar` is active, because `groupB` is enabled.

Example 3: Disabling multiple groups via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
```

(continues on next page)

(continued from previous page)

```
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Both `foo` and `bar` are inactive, because all of their groups are disabled.

Example 4: Disabling a group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA` (you can ensure this by running `west config manifest.group-filter -- -groupA`; the extra `--` is required so the argument parser does not treat `-groupA` as a command line option `-g` with value `roupA`).

Project `foo` is inactive because `groupA` has been disabled by the `manifest.group-filter` configuration option. Project `bar` is active because `groupB` is enabled.

Example 5: Overriding a disabled group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
```

(continues on next page)

(continued from previous page)

```
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA` (you can ensure this by running `west config manifest.group-filter +groupA`).

In this case, `groupA` is enabled: the `manifest.group-filter` configuration option has higher precedence than the `manifest: group-filter: [-groupA]` content in the manifest file.

Therefore, projects `foo` and `bar` are both active.

Example 6: Overriding multiple disabled groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA,+groupB` (you can ensure this by running `west config manifest.group-filter "+groupA,+groupB"`).

In this case, both `groupA` and `groupB` are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects `foo` and `bar` are both active.

Example 7: Disabling multiple groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
```

(continues on next page)

(continued from previous page)

```
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA,-groupB` (you can ensure this by running `west config manifest.group-filter -- "-groupA,-groupB"`).

In this case, both `groupA` and `groupB` are disabled.

Therefore, projects `foo` and `bar` are both inactive.

Group Filters and Imports This section provides a simplified description of how the `manifest: group-filter:` value behaves when combined with *Manifest Imports*. For complete details, see *Manifest Import Details*.

Warning

The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining `group-filter` with `import` in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its `group-filter` are also disabled in your manifest
- you can override this in your manifest file's `manifest: group-filter:` value, your workspace's `manifest.group-filter` configuration option, or both

Here are some examples.

Example 1: no overrides You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only `child` and `project-2` are active in the resolved manifest.

The `unstable` group is disabled in `child/west.yml`, and that is not overridden in `parent/west.yml`. Therefore, the final `group-filter` for the resolved manifest is `[-unstable]`.

Since `project-1` and `project-3` are in the `unstable` group and are not in any other group, they are inactive.

Example 2: overriding an imported `group-filter` via manifest You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only the `child`, `project-1`, and `project-3` projects are active.

The `[-unstable]` group filter in `child/west.yml` is overridden in `parent/west.yml`, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same `parent/west.yml` file disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` is `[+unstable,-optional]`.

Example 3: overriding an imported `group-filter` via configuration You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the `child`, `project-1`, and `project-3` projects are active.

The `-unstable` group filter in `child/west.yml` is overridden in the `manifest.group-filter` configuration option, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same configuration option disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` and the `manifest.group-filter` configuration option is `[+unstable,-optional]`.

Git Submodules in Projects

You can use the `submodules` keys briefly described *above* to force `west update` to also handle any Git submodules configured in project's git repository. The `submodules` key can appear inside `projects`, like this:

```
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The `submodules` key can be a boolean or a list of mappings. We'll describe these in order.

Option 1: Boolean This is the easiest way to use `submodules`.

If `submodules` is `true` as a `projects` attribute, `west update` will recursively update the project's Git submodules whenever it updates the project itself. If it's `false` or missing, it has no effect.

For example, let's say you have a source code repository `foo`, which has some submodules, and you want `west update` to keep all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules: true
    - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

Option 2: List of mappings The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent west project, as shown in the output of `git submodule status`. The `name` key is optional and not used by west for now; it's not passed to `git submodule` commands either. The `name` key was briefly mandatory in west version 0.9.0, but was made optional in 0.9.1.

For example, let's say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules:
        - path: path/to/foo-first-sub
        - name: foo-second-sub
          path: path/to/foo-second-sub
    - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

Repository user data

West versions v0.12 and later support an optional `userdata` key in projects.

West versions v0.13 and later supports this key in the `manifest: self:` section.

It is meant for consumption by programs that require user-specific project metadata. Beyond parsing it as YAML, west itself ignores the value completely.

The key's value is arbitrary YAML. West parses the value and makes it accessible to programs using west-apis as the `userdata` attribute of the corresponding `west.manifest.Project` object.

Example manifest fragment:

```
manifest:
  projects:
    - name: foo
    - name: bar
      userdata: a-string
    - name: baz
      userdata:
        key: value
  self:
    userdata: blub
```

Example Python usage:

```
manifest = west.manifest.Manifest.from_file()

foo, bar, baz = manifest.get_projects(['foo', 'bar', 'baz'])

foo.userdata # None
bar.userdata # 'a-string'
```

(continues on next page)

(continued from previous page)

```
baz.userdata # {'key': 'value'}
manifest.userdata # 'blub'
```

Manifest Imports

You can use the `import` key briefly described above to include projects from other manifest files in your `west.yml`. This key can be either a `project` or `self` section attribute:

```
manifest:
  projects:
    - name: some-project
      import: ...
  self:
    import: ...
```

You can use a "self: import:" to load additional files from the repository containing your `west.yml`. You can use a "project: ... import:" to load additional files defined in that project's Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in `self`
2. your `west.yml` file
3. imported files in `projects`

During resolution, west ignores projects which have already been defined in other files. For example, a project named `foo` in your `west.yml` makes west ignore other projects named `foo` imported from your `projects` list.

The `import` key can be a boolean, path, mapping, or sequence. We'll describe these in order, using examples:

- *Boolean*
  - *Example 1.1: Downstream of a Zephyr release*
  - *Example 1.2: "Rolling release" Zephyr downstream*
  - *Example 1.3: Downstream of a Zephyr release, with module fork*
- *Relative path*
  - *Example 2.1: Downstream of a Zephyr release with explicit path*
  - *Example 2.2: Downstream with directory of manifest files*
  - *Example 2.3: Continuous Integration overrides*
- *Mapping with additional configuration*
  - *Example 3.1: Downstream with name allowlist*
  - *Example 3.2: Downstream with path allowlist*
  - *Example 3.3: Downstream with path blocklist*
  - *Example 3.4: Import into a subdirectory*
- *Sequence of paths and mappings*
  - *Example 4.1: Downstream with sequence of manifest files*
  - *Example 4.2: Import order illustration*

A more *formal description* of how this works is last, after the examples.

Troubleshooting Note If you're using this feature and find west's behavior confusing, try *resolving your manifest* to see the final results after imports are done.

Option 1: Boolean This is the easiest way to use `import`.

If `import` is `true` as a `projects` attribute, west imports projects from the `west.yml` file in that project's root directory. If it's `false` or missing, it has no effect. For example, this manifest would import `west.yml` from the `p1` git repository at revision `v1.0`:

```
manifest:
  # ...
  projects:
    - name: p1
      revision: v1.0
      import: true    # Import west.yml from p1's v1.0 git tag
    - name: p2
      import: false   # Nothing is imported from p2.
    - name: p3        # Nothing is imported from p3 either.
```

It's an error to set `import` to either `true` or `false` inside `self`, like this:

```
manifest:
  # ...
  self:
    import: true  # Error
```

Example 1.1: Downstream of a Zephyr release You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don't want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:

```
my-downstream/
├── .west/                    # west directory
├── zephyr/                   # mainline zephyr repository
│   └── west.yml              # the v1.14.1 version of this file is imported
├── modules/                  # modules from mainline zephyr
│   ├── hal/
│   └── [...other directories..]
├── [ ... other projects ...]  # other mainline repositories
└── my-repo/                  # your downstream repository
    ├── west.yml              # main manifest importing zephyr/west.yml v1.14.1
    └── [...other files..]
```

You can do this with the following `my-repo/west.yml`:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: true
```

You can then create the workspace on your computer like this, assuming `my-repo` is hosted at `https://git.example.com/my-repo`:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

After `west init`, `my-downstream/my-repo` will be cloned.

After `west update`, all of the projects defined in the `zephyr` repository's `west.yml` at revision `v1.14.1` will be cloned into `my-downstream` as well.

You can add and commit any code to `my-repo` you please at this point, including your own Zephyr applications, drivers, etc. See *Application Development*.

Example 1.2: "Rolling release" Zephyr downstream This is similar to *Example 1.1: Downstream of a Zephyr release*, except we'll use `revision: main` for the zephyr repository:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
```

You can create the workspace in the same way:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

This time, whenever you run `west update`, the special *manifest-rev* branch in the `zephyr` repository will be updated to point at a newly fetched `main` branch tip from the URL https://github.com/zephyrproject-rtos/zephyr.

The contents of `zephyr/west.yml` at the new `manifest-rev` will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that running `west update` will not produce reproducible results, since the remote `main` branch can change every time you run it.

It's also important to understand that west **ignores your working tree's** `zephyr/west.yml` entirely when resolving imports. West always uses the contents of imported manifests as they were committed to the latest `manifest-rev` when importing from a project.

You can only import manifest from the file system if they are in your manifest repository's working tree. See *Example 2.2: Downstream with directory of manifest files* for an example.

Example 1.3: Downstream of a Zephyr release, with module fork This manifest is similar to the one in *Example 1.1: Downstream of a Zephyr release*, except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` *module* which was included in that release

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
```

(continues on next page)

(continued from previous page)

```
      url-base: https://github.com/zephyrproject-rtos
    - name: my-remote
      url-base: https://git.example.com
  projects:
    - name: hal_nordic         # higher precedence
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true             # imported projects have lower precedence

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
  # ...
  - name: hal_nordic           # lower precedence, values ignored
    path: modules/hal/nordic
    revision: another-sha
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`

In other words, when your top-level manifest defines a project, like `hal_nordic`, west will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the `path: modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See *Resolving Manifests* for troubleshooting advice if this gets confusing in practice.

When you run `west update`, west will:

- update zephyr's `manifest-rev` to point at the `v2.0.0` tag
- import `zephyr/west.yml` at that `manifest-rev`
- locally check out the `v2.0.0` revisions for all zephyr projects except `hal_nordic`
- update `hal_nordic` to `my-sha` instead of `another-sha`

Option 2: Relative path The `import` value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the `projects` or `self` repository the `import` key appears in.

Here is an example:

```
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
```

(continues on next page)

(continued from previous page)

```
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of `project-1/west.yml` at `manifest-rev`, which points at tag `v1.0` after running `west update`
- any YAML files in the directory tree `project-2/p2-manifests` at the latest commit in the `main` branch, as fetched by `west update`, sorted by file name
- YAML files in `submanifests` in your manifest repository, as they appear on your file system, sorted by file name

Notice how `projects` imports get data from Git using `manifest-rev`, while `self` imports get data from your file system. This is because as usual, west leaves version control for your manifest repository up to you.

Example 2.1: Downstream of a Zephyr release with explicit path This is an explicit way to write an equivalent manifest to the one in *Example 1.1: Downstream of a Zephyr release*.

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: west.yml
```

The setting `import: west.yml` means to use the file `west.yml` inside the `zephyr` project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not `west.yml`.

Example 2.2: Downstream with directory of manifest files Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:

```
my-repo/
├── submanifests
│   ├── 01-libraries.yml
│   ├── 02-vendor-hals.yml
│   └── 03-applications.yml
└── west.yml
```

You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository's `main` branch instead of using a fixed revision.

Here's how:

```
# my-repo/west.yml:
manifest:
```

(continues on next page)

(continued from previous page)

```
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

Note

The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported *before* `my-repo/west.yml` and `zephyr/west.yml`. In general, an `import` in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see *Resolving Manifests* for troubleshooting advice.

This may seem strange, but it allows you to redefine projects "after the fact", as we'll see in the next example.

Example 2.3: Continuous Integration overrides Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer's forks instead of your mainline development trees, to see if the changes all work well together.

Starting with *Example 2.2: Downstream with directory of manifest files*, the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:

```
# my-repo/submanifests/00-ci.yml:
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
      url: https://github.com/a-developer/application
      revision: another-pull-request-branch
```

The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer's branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

Option 3: Mapping The `import` key can also contain a mapping with the following keys:

- `file`: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- `name-allowlist`: Optional. If present, a name or sequence of project names to include.
- `path-allowlist`: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with pathlib. Note that this means case sensitivity is platform specific.
- `name-blocklist`: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- `path-blocklist`: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.
- `path-prefix`: Optional (new in v0.8.0). If given, this will be prepended to the project's path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

Example 3.1: Downstream with name allowlist Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn't want to use all the mainline projects, however. We'll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```
# mainline west.yml:
manifest:
  projects:
    - name: mainline-app                # included
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                        # included
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        name-allowlist:
          - mainline-app
          - lib2
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
```

(continues on next page)

(continued from previous page)

```
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
    - name: mainline-app                    # imported
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib2                            # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
```

If an allowlist had not been used, the `lib` project from the mainline manifest would have been imported.

Example 3.2: Downstream with path allowlist Here is an example showing how to allowlist mainline's libraries only, using `path-allowlist`.

```
# mainline west.yml:
manifest:
  projects:
    - name: app
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib                   # included
      url: https://git.example.com/mainline/lib
    - name: lib2
      path: libraries/lib2                  # included
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-allowlist: libraries/*
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```yaml
manifest:
  projects:
    - name: lib                          # imported
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                         # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

Example 3.3: Downstream with path blocklist Here's an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you're targeting, and keep everything else.

```yaml
# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
    - name: hal_foo
      path: modules/hals/foo     # excluded
    - name: hal_bar
      path: modules/hals/bar     # excluded
    - name: hal_baz
      path: modules/hals/baz     # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-blocklist: modules/hals/*
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

An equivalent manifest in a single file would be:

```yaml
manifest:
  defaults:
    remote: mainline
```

(continues on next page)

(continued from previous page)

```
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app                  # imported
    - name: lib                  # imported
      path: libraries/lib
    - name: lib2                 # imported
      path: libraries/lib2
    - name: mainline
      repo-path: https://git.example.com/mainline/manifest
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

Example 3.4: Import into a subdirectory You want to import a manifest and its projects, placing everything into a subdirectory of your *west workspace*.

For example, suppose you want to import this manifest from project `foo`, adding this project and its projects `bar` and `baz` to your workspace:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz
```

Instead of importing these into the top level workspace, you want to place all three project repositories in an `external-code` subdirectory, like this:

```
workspace/
└── external-code/
    ├── foo/
    ├── bar/
    └── baz/
```

You can do this using this manifest:

```
manifest:
  projects:
    - name: foo
      url: https://git.example.com/foo
      import:
        path-prefix: external-code
```

An equivalent manifest in a single file would be:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
```

(continues on next page)

(continued from previous page)

```
    - name: example
      url-base: https://git.example.com
  projects:
    - name: foo
      path: external-code/foo
    - name: bar
      path: external-code/bar
    - name: baz
      path: external-code/baz
```

Option 4: Sequence The `import` key can also contain a sequence of files, directories, and mappings.

Example 4.1: Downstream with sequence of manifest files This example manifest is equivalent to the manifest in *Example 2.2: Downstream with directory of manifest files*, with a sequence of explicitly named files.

```
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
    import:
      - submanifests/01-libraries.yml
      - submanifests/02-vendor-hals.yml
      - submanifests/03-applications.yml
```

Example 4.2: Import order illustration This more complicated example shows the order that west imports manifest files:

```
# my-repo/west.yml
manifest:
  # ...
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
    import:
      - submanifests/libraries.yml
      - submanifests/vendor-hals.yml
      - submanifests/applications.yml
  defaults:
    remote: my-remote
```

For this example, west resolves imports in this order:

1. the listed files in `my-repo/submanifests` are first, in the order they occur (e.g. `libraries.yml` comes before `applications.yml`, since this is a sequence of files), since the `self: import:` is always imported first

2. `my-repo/west.yml` is next (with projects `my-library` etc. as long as they weren't already defined somewhere in `submanifests`)
3. `zephyr/west.yml` is after that, since that's the first `import` key in the `projects` list in `my-repo/west.yml`
4. files in `another-manifest-repo/submanifests` are last (sorted by file name), since that's the final project `import`

Manifest Import Details This section describes how west resolves a manifest file that uses `import` a bit more formally.

Overview The `import` key can appear in a west manifest's `projects` and `self` sections. The general case looks like this:

```
# Top-level manifest file.
manifest:
  projects:
    - name: foo
      import:
        ... # import-1
    - name: bar
      import:
        ... # import-2
    # ...
    - name: baz
      import:
        ... # import-N
  self:
    import:
      ... # self-import
```

Import keys are optional. If any of `import-1`, `...`, `import-N` are missing, west will not import additional manifest data from that project. If `self-import` is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a `projects` list, which is produced by combining the `projects` defined in the top-level file with those defined in imported files
- a set of extension commands, which are drawn from the `west-commands` keys in the top-level file and any imported files
- a `group-filter` list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from `self-import` are imported first.
2. The top-level manifest file's definitions are handled next.
3. Manifests from `import-1`, ..., `import-N`, are imported in that order.

When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose `file` is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.

The following sections describe these outcomes.

Projects This section describes how the final `projects` list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if `import-1` contains a project named `bar`, that is ignored, because the top-level `west.yml` has already defined a project by that name.

The contents of files named by `import-1` through `import-N` are imported from Git at the latest `manifest-rev` revisions in their projects. These revisions can be updated to the values `rev-1` through `rev-N` by running `west update`. If any `manifest-rev` reference is missing or out of date, `west update` also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project `P`, must be up to date in order for west to update `P` itself. For example, this means `west update P` would update `manifest-rev` in the `baz` project if `baz/west.yml` defines `P`, as well as updating the `manifest-rev` branch in the local git clone of `P`. Confusingly, updating `baz` may result in the removal of `P` from `baz/west.yml`, which "should" cause `west update P` to fail with an unrecognized project!

For this reason, it's not possible to run `west update P` if `P` is defined in an imported manifest; you must update this project along with all the others with a plain `west update`.

By default, west won't fetch any project data over the network if a project's revision is a SHA or tag which is already available locally, so updating the extra projects shouldn't take too much time unless it's really needed. See the documentation for the *update.fetch* configuration option for more information.

Extensions All extension commands defined using `west-commands` keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a `west-commands:` definition in its `self:` section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

Group filters The resolved manifest has a `group-filter` value which is the result of concatenating the `group-filter` values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final `group-filter`.

In other words, let:

- the submanifest resolved from `self-import` have group filter `self-filter`
- the top-level manifest file have group filter `top-filter`
- the submanifests resolved from `import-1` through `import-N` have group filters `filter-1` through `filter-N` respectively

The final resolved `group-filter` value is then `filterN + ... + filter-2 + filter-1 + top-filter + self-filter`, where `+` here refers to list concatenation.

Important

The order that filters appear in the above list matters.

The last filter element in the final concatenated list "wins" and determines if the group is enabled or disabled.

For example, in `[-foo] + [+foo]`, group `foo` is *enabled*. However, in `[+foo] + [-foo]`, group `foo` is *disabled*.

For simplicity, west and this documentation may elide concatenated group filter elements which are redundant using these rules. For example, `[+foo] + [-foo]` could be written more simply as `[-foo]`, for the reasons given above. As another example, `[-foo] + [+foo]` could be written as the empty list `[]`, since all groups are enabled by default.

Manifest Command

The `west manifest` command can be used to manipulate manifest files. It takes an action, and action-specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run `west manifest --help` for full details on all options.

Resolving Manifests The `--resolve` action outputs a single manifest file equivalent to your current manifest and all its *imported manifests*:

```
west manifest --resolve [-o outfile]
```

The main use for this action is to see the "final" manifest contents after performing any `imports`.

To print detailed information about each imported manifest file and how projects are handled during manifest resolution, set the maximum verbosity level using `-v`:

```
west -v manifest --resolve
```

Freezing Manifests The `--freeze` action outputs a frozen manifest:

```
west manifest --freeze [-o outfile]
```

A "frozen" manifest is a manifest file where every project's revision is a SHA. You can use `--freeze` to produce a frozen manifest that's equivalent to your current manifest file. The `-o` option specifies an output file; if not given, standard output is used.

Validating Manifests The `--validate` action either succeeds if the current manifest file is valid, or fails with an error:

```
west manifest --validate
```

The error message can help diagnose errors.

Here, "invalid" means that the syntax of the manifest file doesn't follow the rules documented on this page.

If your manifest is valid but it's not working the way you want it to, turning up the verbosity with `-v` is a good way to get detailed information about what decisions west made about your manifest, and why:

```
west -v manifest --validate
```

Get the manifest path The `--path` action prints the path to the top level manifest file:

```
west manifest --path
```

The output is something like `/path/to/workspace/west.yml`. The path format depends on your operating system.

2.11.8 Configuration

This page documents west's configuration file system, the `west config` command, and configuration options used by built-in commands. For API documentation on the `west.configuration` module, see west-apis-configuration.

West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the `manifest` section has option `path` set to `zephyr`. Another way to say the same thing is that `manifest.path` is `zephyr` in this file.

There are three types of configuration file:

1. **System**: Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
   - Linux: `/etc/westconfig`
   - macOS: `/usr/local/etc/westconfig`
   - Windows: `%PROGRAMDATA%\west\config`
2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
   - All platforms: the default is `.westconfig` in the user's home directory.
   - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.
   - Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.
3. **Local**: Settings in this file affect west's behavior for the current *west workspace*. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if `color.ui` is `true` in the system's configuration file, but `false` in the workspace's, then the final value is `false`. Similarly, settings in the user configuration file override system settings, and so on.

west config

The built-in `config` command can be used to get and set configuration values. You can pass `west config` the options `--system`, `--global`, or `--local` to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to `--local`, and reads show the final value after applying overrides.

Some examples for common uses follow; run `west config -h` for detailed help, and see *Built-in Configuration Options* for more details on built-in options.

To set `manifest.path` to `some-other-manifest`:

```
west config manifest.path some-other-manifest
```

Doing the above means that commands like `west update` will look for the *west manifest* inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr`.)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
west config --global color.ui false
```

To undo the above change:

```
west config --global color.ui true
```

Built-in Configuration Options

The following table documents configuration options supported by west's built-in commands. Configuration options supported by Zephyr's extension commands are documented in the pages for those commands.

Option	Description
`alias.ALIAS`	String. If non-empty the `<ALIAS>` can be used as a west command. See *West aliases*.
`color.ui`	Boolean. If `true` (the default), then west output is colorized when stdout is a terminal.
`commands.allow_extensions`	Boolean, default `true`, disables *Extensions* if `false`
`grep.color`	String, default empty. Set this to `never` to disable `west grep` color output. If set, `west grep` passes the value to the grep tool's `--color` option.
`grep.tool`	String, one of `"git-grep"` (default), `"ripgrep"`, or `"grep"`. The grep tool that `west grep` should use.
`grep.<TOOL>-args`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-args` is an example configuration option. If set, arguments that `west grep` should pass to the corresponding grep tool. Run `west help grep` for details.
`grep.<TOOL>-path`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-path` is an example configuration option. The path to the corresponding tool that `west grep` should use instead of searching for the command. Run `west help grep` for details.
`manifest.file`	String, default `west.yml`. Relative path from the manifest repository root directory to the manifest file used by `west init` and other commands which parse the manifest.
`manifest.group-filter`	String, default empty. A comma-separated list of project groups to enable and disable within the workspace. Prefix enabled groups with `+` and disabled groups with `-`. For example, the value `"+foo,-bar"` enables group `foo` and disables `bar`. See *Project Groups*.
`manifest.path`	String, relative path from the *west workspace* root directory to the manifest repository used by `west update` and other commands which parse the manifest. Set locally by `west init`.

`manifest.project-filter`	Comma-separated list of strings.
	The option's value is a comma-separated list of regular expressions, each prefixed with `+` or `-`, like this:
	`+re1,-re2,-re3`
	Project names are matched against each regular expression (`re1`, `re2`, `re3`, ...) in the list, in order. If the entire project name matches the regular expression, that element of the list either deactivates or activates the project. The project is deactivated if the element begins with `-`. The project is activated if the element begins with `+`. (Project names cannot contain `,` if this option is used, so the regular expressions do not need to contain a literal `,` character.)
	If a project's name matches multiple regular expressions in the list, the result from the last regular expression is used. For example, if `manifest.project-filter` is:
	`-hal_.*,+hal_foo`
	Then a project named `hal_bar` is inactive, but a project named `hal_foo` is active.
	If a project is made inactive or active by a list element, the project is active or not regardless of whether any or all of its groups are disabled. (This is currently the only way to make a project that has no groups inactive.)
	Otherwise, i.e. if a project does not match any regular expressions in the list, it is active or inactive according to the usual rules related to its groups (see *Project Group Examples* for examples in that case).
	Within an element of a `manifest.project-filter` list, leading and trailing whitespace are ignored. That means these example values are equivalent:
	`+foo,-bar`
	`+foo , -bar`
	Any empty elements are ignored. That means these example values are equivalent:

2.11.9 West aliases

West allows to add alias commands to the local, global or system configuration files. These aliases make it easy to add shortcuts for frequently used, or hard to memorize commands for ease of development.

Similar to how `git` aliases work, the alias command is replaced with the alias' full text and parsed as a new shell argument list (using the Python function shlex.split() internally to split the value). This enables adding argument parameters as they were passed to the original command. Spaces are considered argument separators; use proper escaping if arguments shouldn't be split.

To add a new alias simply call the `west config` command:

```
west config alias.mylist "list -f '{name} {revision}'"
```

To list aliases, use `west help` *some_alias*.

Recursive aliases are allowed as an alias command can contain other aliases, effectively building more complex but easy-to-remember commands.

It is possible to override an existing command, for example to pass default arguments:

```
west config alias.update "update -o=--depth=1 -n"
```

Warning

Overriding/shadowing other or built-in commands is an advanced use case, it can lead to strange side-effects and should be done with great care.

Examples

Add `west run` and `west menuconfig` shortcuts to your global configuration to call `west build` with the corresponding CMake targets:

```
west config --global alias.run "build --pristine=never --target run"
west config --global alias.menuconfig "build --pristine=never --target menuconfig"
```

Create an alias for the sample you are actively developing with additional options:

```
west config alias.sample "build -b native_sim samples/hello_world -t run -- -
↪DCONFIG_ASSERT=y"
```

Override `west update` to check a local cache:

```
west config alias.update "update --path-cache $HOME/.cache/zephyrproject"
```

Automatically exclude the 32-bit native simulator target when running *Twister* via west. This is especially useful when running on hosts systems without a 32-bit host C library (i.e. Linux/AArch64):

```
west config alias.twister "twister --exclude-platform native_sim/native"
```

2.11.10 Extensions

West is "pluggable": you can add your own commands to west without editing its source code. These are called **west extension commands**, or just "extensions" for short. Extensions show up in the `west --help` output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to *build, flash, and debug* and the *ones described here*, are extensions. That's why help for them shows up like this in `west --help`:

```
extension commands from project manifest (path: zephyr):
  completion:           display shell completion scripts
  boards:               display information about supported boards
  shields:              display list of supported shields
  build:                compile a Zephyr application
  twister:              west twister wrapper
  sign:                 sign a Zephyr binary for bootloader chain-loading
  flash:                flash and run a binary on a board
  debug:                flash and interactively debug a Zephyr application
  debugserver:          connect to board and launch a debug server
  attach:               interactively debug a board
  ...
```

See `zephyr/scripts/west-commands.yml` and the `zephyr/scripts/west_commands` directory for the implementation details.

Disabling Extension Commands

To disable support for extension commands, set the `commands.allow_extensions` *configuration* option to `false`. To set this globally for whenever you run west, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular *west workspace* with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by west unless the commands are explicitly run. See below for details.

Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a `west-commands.yml` file.
3. Make sure the `west-commands.yml` file is referenced in the *west manifest*.

Note that west ignores extension commands whose names are the same as a built-in command.

Step 1: Implement Your Command Create a Python file to contain your command implementation (see the west project metadata on the west PyPI page for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your *west manifest*, or the manifest repository itself. This file must contain a subclass of the `west.commands.WestCommand` class. This class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of `WestCommand`, with implementations for all the abstract methods. For more details on the west APIs you can use, see west-apis.

```
'''my_west_extension.py

Basic example of a west extension.'''
```

(continues on next page)

(continued from previous page)

```
from textwrap import dedent             # just for nicer code indentation

from west.commands import WestCommand  # your extension must subclass this

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name',  # gets stored as self.name
            '', # ignored self.help, will not be required by future west versions
            # self.description:
            description=dedent('''
            A multi-line description of my-command.

            You can split this up into multiple paragraphs and they'll get
            reflowed for you. You can also pass
            formatter_class=argparse.RawDescriptionHelpFormatter when calling
            parser_adder.add_parser() below if you want to keep your line
            endings.'''))

    def do_add_parser(self, parser_adder):
        # This is a bit of boilerplate, which allows you full control over the
        # type of argparse handling you want. The "parser_adder" argument is
        # the return value of an argparse.ArgumentParser.add_subparsers() call.
        parser = parser_adder.add_parser(self.name,
                                         description=self.description)

        # Add some example options using the standard argparse module API.
        parser.add_argument('-o', '--optional', help='an optional argument')
        parser.add_argument('required', help='a required argument')

        return parser           # gets stored as self.parser

    def do_run(self, args, unknown):
        # This gets called when the user runs the command, e.g.:
        #
        #   $ west my-command-name -o FOO BAR
        #   --optional is FOO
        #   required is BAR
        self.inf('--optional is', args.optional)
        self.inf('required is', args.required)
```

You can ignore the second argument to `do_run()` (`unknown` above), as `WestCommand` will reject unknown arguments by default. If you want to be passed a list of unknown arguments instead, add `accepts_unknown_args=True` to the `super().__init__()` arguments.

Step 2: Add or Update Your `west-commands.yml` You now need to add a `west-commands.yml` file to your project which describes your extension to west.

Here is an example for the above class definition, assuming it's in `my_west_extension.py` at the project root directory:

```
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
```

(continues on next page)

(continued from previous page)

```
        class: MyCommand
        help: one-line help for what my-command-name does
```

The top level of this YAML file is a map with a `west-commands` key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the `class` value defaults to the same thing as `name`).

Some information in this file is redundant with definitions in the Python code. This is because west won't import `my_west_extension.py` until the user runs `west my-command-name`, since:

- It allows users to run `west update` with a manifest from an untrusted source, then use other west commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.
- It's a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the `west-commands.yml` file to get the basic information it needs to display information about your extension to the user in `west --help` output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your `west-commands.yml` will look something like this:

```
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
  - file: another_file.py
    commands:
      - name: command2
        help: another cool west extension
      - name: a-third-command
        class: ThirdCommand
        help: a third command in the same file as command2
```

Above:

- `my_west_extension.py` defines extension `my-command-name` with class `MyCommand`
- `another_file.py` defines two extensions:
  1. `command2` with class `command2`
  2. `a-third-command` with class `ThirdCommand`

See the file `west-commands-schema.yml` in the west repository for a schema describing the contents of a `west-commands.yml`.

Step 3: Update Your Manifest Finally, you need to specify the location of the `west-commands.yml` you just edited in your west manifest. If your extension is in a project, add it like this:

```
manifest:
   # [... other contents ...]

   projects:
     - name: your-project
       west-commands: path/to/west-commands.yml
     # [... other projects ...]
```

Where `path/to/west-commands.yml` is relative to the root of the project. Note that the name `west-commands.yml`, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest's `self` section, like this:

```
manifest:
  # [... other contents ...]

  self:
    west-commands: path/to/west-commands.yml
```

That's it; you can now run `west my-command-name`. Your command's name, help, and the project which contains its code will now also show up in the `west --help` output. If you share the updated repositories with others, they'll be able to use it, too.

2.11.11 Building, Flashing and Debugging

Zephyr provides several *west extension commands* for building, flashing, and interacting with Zephyr programs running on a board: `build`, `flash`, `debug`, `debugserver` and `attach`.

For information on adding board support for the flashing and debugging commands, see *Flash and debug support* in the board porting guide.

Building: `west build`

> **Tip**
>
> Run `west build -h` for a quick overview.

The `build` command helps you build Zephyr applications from source. You can use *west config* to configure its behavior.

Its default behavior tries to "do what you mean":

- If there is a Zephyr build directory named `build` in your current working directory, it is incrementally re-compiled. The same is true if you run `west build` from a Zephyr build directory.
- Otherwise, if you run `west build` from a Zephyr application's source directory and no build directory is found, a new one is created and the application is compiled in it.

Basics The easiest way to use `west build` is to go to an application's root directory (i.e. the folder containing the application's `CMakeLists.txt`) and then run:

```
west build -b <BOARD>
```

Where `<BOARD>` is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: `cmake -DBOARD=<BOARD>`.

> **Tip**
>
> You can use the *west boards* command to list all supported boards.

A build directory named `build` will be created, and the application will be compiled there after `west build` runs CMake to create a build system in that directory. If `west build` finds an existing

build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with `--cmake`.

You don't need to use the `--board` option if you've already got an existing build directory; `west build` can figure out the board from the CMake cache. For new builds, the `--board` option, *BOARD* environment variable, or `build.board` configuration option are checked (in that order).

Sysbuild (multi-domain builds) *Sysbuild (System build)* can be used to create a multi-domain build system combining multiple images for a single or multiple boards.

Use `--sysbuild` to select the *Sysbuild (System build)* build infrastructure with `west build` to build multiple domains.

More detailed information regarding the use of sysbuild can be found in the *Sysbuild (System build)* guide.

Tip

The `build.sysbuild` configuration option can be enabled to tell `west build` to default build using sysbuild. `--no-sysbuild` can be used to disable sysbuild for a specific build.

`west build` will build all domains through the top-level build folder of the domains specified by sysbuild.

A single domain from a multi-domain project can be built by using `--domain` argument.

Examples Here are some `west build` usage examples, grouped by area.

Forcing CMake to Run Again To force a CMake re-run, use the `--cmake` (or `-c`) option:

```
west build -c
```

Setting a Default Board To configure `west build` to build for the `reel_board` by default:

```
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn't have to be `reel_board`.)

Setting Source and Build Directories To set the application source directory explicitly, give its path as a positional argument:

```
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use `--build-dir` (or `-d`):

```
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from `build`, use the `build.dir-fmt` configuration option. This lets you name build directories using format strings, like this:

```
west config build.dir-fmt "build/{board}/{app}"
```

With the above, running `west build -b reel_board samples/hello_world` will use build directory `build/reel_board/hello_world`. See *Configuration Options* for more details on this option.

Setting the Build System Target To specify the build system target to run, use `--target` (or `-t`).

For example, on host platforms with QEMU, you can use the `run` target to build and run the hello_world sample for the emulated qemu_x86 board in one command:

```
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use `-t` to list all build system targets:

```
west build -t help
```

As a final example, to use `-t` to run the `pristine` target, which deletes all the files in the build directory:

```
west build -t pristine
```

Pristine Builds A *pristine* build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the `--pristine=always` (or `-p=always`) option.

Giving `--pristine` or `-p` without a value has the same effect as giving it the value `always`. For example, these commands are equivalent:

```
west build -p -b reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` makes no attempt to detect if the build directory needs to be made pristine. This can lead to errors if you do something like try to reuse a build directory for a different `--board`.

Using `--pristine=auto` makes `west build` detect some of these situations and make the build directory pristine before trying the build.

Tip

You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` *Configuration Options* for details.

Verbose Builds To print the CMake and compiler commands run by `west build`, use the global west verbosity option, `-v`:

```
west -v build -b reel_board samples/hello_world
```

One-Time CMake Arguments To pass additional arguments to the CMake invocation performed by `west build`, pass them after a `--` at the end of the command line.

Important

Passing additional CMake arguments like this forces `west build` to re-run the CMake build configuration step, even if a build system has already been generated. This will make incremental builds slower (but still much faster than building from scratch).

After using `--` once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

> Alternatively, make your CMake arguments permanent as described in the next section; it will not slow down incremental builds.

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
west build -b reel_board -- -G'Unix Makefiles'
```

To use Unix Makefiles and set CMAKE_VERBOSE_MAKEFILE to ON:

```
west build -b reel_board -- -G'Unix Makefiles' -DCMAKE_VERBOSE_MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set *DTC_OVERLAY_FILE* to `enable-modem.overlay`, using that file as a *devicetree overlay*:

```
west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
west build -- -DEXTRA_CONF_FILE=file.conf
```

Permanent CMake Arguments The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option. Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` **tries to avoid generating a new build system if one is present** in your build directory. Therefore, you need to either delete any existing build directories or do a *pristine build* after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable **CMAKE_EXPORT_COMPILE_COMMANDS**, you can run:

```
west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, *west config* would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable **CMAKE_VERBOSE_MAKEFILE**, so CMake always produces a verbose build system:

```
west config build.cmake-args -- -DCMAKE_VERBOSE_MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function shlex.split() internally to split the value).

For example, to enable both **CMAKE_EXPORT_COMPILE_COMMANDS** and **CMAKE_VERBOSE_MAKEFILE**:

```
west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -
↪DCMAKE_VERBOSE_MAKEFILE=ON"
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOSE_MAKEFILE ON CACHE BOOL "")
```

Then run:

```
west config build.cmake-args "-C ~/my-cache.cmake"
```

See the cmake(1) manual page and the set() command documentation for more details.

Build tool arguments Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (*the default*) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```
west build -o=-dexplain
```

As another example, to pass `--keep-going` to `make`:

```
west build -o=--keep-going
```

Note that using `-o=--foo` instead of `-o --foo` is required to prevent `--foo` from being treated as a `west build` option.

Build parallelism By default, `ninja` uses all of your cores to build, while `make` uses only one. You can control this explicitly with the `-j` option supported by both tools.

For example, to build with 4 cores:

```
west build -o=-j4
```

The `-o` option is described further in the previous section.

Build a single domain In a multi-domain build with hello_world and MCUboot, you can use `--domain hello_world` to only build this domain:

```
west build --sysbuild --domain hello_world
```

The `--domain` argument can be combined with the `--target` argument to build the specific target for the target, for example:

```
west build --sysbuild --domain hello_world --target help
```

Use a snippet See *Using Snippets*.

Configuration Options You can *configure* `west build` using these options.

Option	Description
build.board	String. If given, this the board used by *west build* when --board is not given and BOARD is unset in the environment.
build.board_warn	Boolean, default true. If false, disables warnings when west build can't figure out the target board.
build.cmake-args	String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See *Permanent CMake Arguments*.
build.dir-fmt	String, default build. The build folder format string, used by west whenever it needs to create or locate a build folder. The currently available arguments are: • west_topdir: The absolute path to the west workspace, as returned by the west_topdir command • board: The board name • source_dir: Path to the CMake source directory, relative to the current working directory. If the current working directory is inside the source directory, this is an empty string. If no source directory is specified, it defaults to current working directory. E.g. if west build ../app is run from <west_topdir>/app1, source_dir resolves to ../app (which is the relative path to the current working dir). • source_dir_workspace: Path to the source directory, relative to west_topdir (if it is inside the workspace). Otherwise, it is relative to the filesystem root (/ on Unix, respectively C:/ on Windows). E.g. if west build ../app is run from <west_topdir>/app1, source_dir resolves to app (which is the relative path to the west workspace dir). • app: The name of the source directory.
build.generator	String, default Ninja. The CMake Generator to use to create a build system. (To set a generator for a single build, see the *above example*)
build.guess-dir	String, instructs west whether to try to guess what build folder to use when build.dir-fmt is in use and not enough information is available to resolve the build folder name. Can take these values: • never (default): Never try to guess, bail out instead and require the user to provide a build folder with -d. • runners: Try to guess the folder when using any of the 'runner' commands. These are typically all commands that invoke an external tool, such as flash and debug.
build.pristine	String. Controls the way in which west build may clean the build folder before building. Can take the following values: • never (default): Never automatically make the build folder pristine. • auto: west build will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory). • always: Always make the build folder pristine before building, if a build system is present.
build.sysbuild	Boolean, default false. If true, build application using the sysbuild infrastructure.

Flashing: west flash

> **Tip**
>
> Run `west flash -h` for additional help.

Basics From a Zephyr build directory, re-build the binary and flash it to your board:

```
west flash
```

Without options, the behavior is the same as `ninja flash` (or `make flash`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west flash --build-dir path/to/build/directory
```

If you don't specify the build directory, `west flash` searches for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west flash` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports flashing with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West flashes your board with `nrfjprog` by default, but it also supports JLink, you can override the default with:

```
west flash --runner jlink
```

You can override the default flash runner at build time by using the `BOARD_FLASH_RUNNER` CMake variable, and the debug runner with `BOARD_DEBUG_RUNNER`.

For example:

```
# Set the default runner to "jlink", overriding the board's
# usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See *One-Time CMake Arguments* and *Permanent CMake Arguments* for more information on setting CMake arguments.

See *Configuration Options* below for more information on the `runner` library used by West. The list of runners which support flashing can be obtained with `west flash -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```
west flash --hex-file path/to/some/other.hex
```

The `west flash -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to flashing. For example, some runners support an `--erase` flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west flash --context
```

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west flash -H` just prints a list of runners. You can use `west flash -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west flash -H -r jlink
```

Multi-domain flashing When a *Sysbuild (multi-domain builds)* folder is detected, then `west flash` will flash all domains in the order defined by sysbuild.

It is possible to flash the image from a single domain in a multi-domain project by using `--domain`.

For example, in a multi-domain build with hello_world and MCUboot, you can use the `--domain hello_world` domain to only flash only the image from this domain:

```
west flash --domain hello_world
```

Configuration Options You can *configure* `west flash` using these options.

Option	Description
`flash.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west flash.

Debugging: `west debug`, `west debugserver`

Tip

Run `west debug -h` or `west debugserver -h` for additional help.

Basics From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
west debugserver
```

Without options, the behavior is the same as `ninja debug` and `ninja debugserver` (or `make debug`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west debug` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West debugs your board with `pyocd-gdbserver` by default, but it also supports JLink, you can override the default with:

```
west debug --runner jlink
west debugserver --runner jlink
```

See *Configuration Options* below for more information on the `runner` library used by West. The list of runners which support debugging can be obtained with `west debug -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.

For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

```
west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf
```

The `west debug -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west debug --context
```

(The command `west debugserver --context` will print the same output.)

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west debug -H` just prints a list of runners. You can use `west debug -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west debug -H -r jlink
```

Multi-domain debugging `west debug` can only debug a single domain at a time. When a *Sysbuild (multi-domain builds)* folder is detected, `west debug` will debug the `default` domain specified by sysbuild.

The default domain will be the application given as the source directory. See the following example:

```
west build --sysbuild path/to/source/directory
```

For example, when building `hello_world` with MCUboot using sysbuild, `hello_world` becomes the default domain:

```
west build --sysbuild samples/hello_world
```

So to debug `hello_world` you can do:

```
west debug
```

or:

```
west debug --domain hello_world
```

If you wish to debug MCUboot, you must explicitly specify MCUboot as the domain to debug:

```
west debug --domain mcuboot
```

Configuration Options You can *configure* `west debug` and *configure* `west debugserver` using these options.

Option	Description
`debug.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west debug.
`debugserver.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west debugserver.

Flash and debug runners

The flash and debug commands use Python wrappers around various *Flash & Debug Host Tools*. These wrappers are all defined in a Python library at scripts/west_commands/runners. Each wrapper is called a *runner*. Runners can flash and/or debug Zephyr programs.

The central abstraction within this library is `ZephyrBinaryRunner`, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of `ZephyrBinaryRunner`. `ZephyrBinaryRunner` is available in the `runners.core` module; individual runner implementations are in other submodules, such as `runners.nrfjprog`, `runners.openocd`, etc.

Running Robot Framework tests: `west robot`

> **Tip**
>
> Run `west robot -h` for additional help.

Basics Currently the command supports only one runner which is using `renode-test`, (essentially a wrapper for running Robot tests in Renode), but can be easily extended by adding other runners.

From a Zephyr build directory, to run a Robot test suite:

```
west robot --runner=renode-robot --testsuite path/to/testsuite.robot
```

This will run all tests from testsuite.robot and print output provided by Robot Framework.

To pass additional parameters to Renode use `--renode-robot-args` switch. For example to show Renode logs in addition to Robot Framework's output:

> west robot –runner=renode-robot –testsuite path/to/testsuite.robot –renode-robot-arg="–show-log"

Runner-Specific Overrides To view all of the available options for the Robot runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west robot --runner=renode-robot --context
```

To view all available options "renode-test" runner supports, use:

```
west robot --runner=renode-robot --renode-robot-help
```

Simulating a board with: `west simulate`

Basics Currently the command supports only one runner which is using Renode, but can be easily extended by adding other runners.

From a Zephyr build directory, to run the built binary:

```
west simulate --runner=renode
```

This will start Renode and configure simulation based on a default `.resc` script for the current platform with the zephyr.elf file loaded by default. The simulation then can be started by typing "start" or "s" in Renode's Monitor. This can also be done by passing a command to Renode, using an argument provided by the runner:

> west simulate –runner=renode –renode-command start

To pass an argument to Renode itself, for example to start Renode in console mode instead of a separate window:

> west simulate –runner=renode –renode-arg="–console"

From that point on Renode can be used normally in both console and window modes. For details on using Renode see Renode - documentation.

Runner-Specific Overrides To view all of the available options supported by the runners, as well as their usage information, use `--context` (or `-H`):

```
west simulate --runner=renode --context
```

To view all available options Renode supports, use:

```
west simulate --runner=renode --renode-help
```

Out of tree runners

Zephyr modules can have external runners discovered by adding python files in their *module.yml*. Create an external runner class by inheriting from `ZephyrBinaryRunner` and implement all abstract methods.

> **Note**
>
> Support for custom out-of-tree runners makes the `runners.core` module part of the public API and backwards incompatible changes need to undergo the *deprecation process*.

Hacking

This section documents the `runners.core` module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing `runners` module, and imported from `runners/__init__.py`.

Note

The test cases in scripts/west_commands/tests add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

Zephyr binary runner core interfaces

This provides the core ZephyrBinaryRunner class meant for public use, as well as some other helpers for concrete runner classes.

`class runners.core.BuildConfiguration(build_dir: str)`

This helper class provides access to build-time configuration.

Configuration options can be read as if the object were a dict, either object['CONFIG_FOO'] or object.get('CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

`getboolean(option)`

If a boolean option is explicitly set to y or n, returns its value. Otherwise, falls back to False.

`class runners.core.DeprecatedAction(option_strings, dest, nargs=None, const=None, default=None, type=None, choices=None, required=False, help=None, metavar=None)`

`class runners.core.FileType(*values)`

`exception runners.core.MissingProgram(program)`

FileNotFoundError subclass for missing program dependencies.

No significant changes from the parent FileNotFoundError; this is useful for explicitly signaling that the file in question is a program that some class requires to proceed.

The filename attribute contains the missing program.

`class runners.core.NetworkPortHelper`

Helper class for dealing with local IP network ports.

`get_unused_ports(starting_from)`

Find unused network ports, starting at given values.

starting_from is an iterable of ports the caller would like to use.

The return value is an iterable of ports, in the same order, using the given values if they were unused, or the next sequentially available unused port otherwise.

Ports may be bound between this call's check and actual usage, so callers still need to handle errors involving returned ports.

class runners.core.**RunnerCaps**(*commands: set[str] = <factory>*, *dev_id: bool = False*, *mult_dev_ids: bool = False*, *flash_addr: bool = False*, *erase: bool = False*, *reset: bool = False*, *reset_types: bool = False*, *reset_types_supported: list[str] | None = None*, *extload: bool = False*, *tool_opt: bool = False*, *file: bool = False*, *hide_load_files: bool = False*, *rtt: bool = False*, *dry_run: bool = False*, *skip_load: bool = False*, *batch_debug: bool = False*)

This class represents a runner class's capabilities.

Each capability is represented as an attribute with the same name. Flag attributes are True or False.

Available capabilities:

- commands: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach', 'simulate', 'robot', 'rtt'}.
- dev_id: whether the runner supports device identifiers, in the form of an -i, –dev-id option. This is useful when the user has multiple debuggers connected to a single computer, in order to select which one will be used with the command provided.
- mult_dev_ids: whether the runner supports multiple device identifiers for a single operation, allowing for bulk flashing of devices.
- flash_addr: whether the runner supports flashing to an arbitrary address. Default is False. If true, the runner must honor the –dt-flash option.
- erase: whether the runner supports an –erase option, which does a mass-erase of the entire addressable flash on the target before flashing. On multi-core SoCs, this may only erase portions of flash specific the actual target core. (This option can be useful for things like clearing out old settings values or other subsystem state that may affect the behavior of the zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can't be sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)
- reset: whether the runner supports a –reset option, which resets the device after a flash operation is complete.
- reset_types: whether the runner supports a –reset-type=x option, which specifies a runner specific value for selecting a specific type of reset to use when resetting the device.
- reset_types_supported: a list of values allowed to be passed with the –reset-type option. If the list of supported reset types is dynamic/device specific, this should be omitted, allowing any value to be set and passed directly to the underlying tool. In addition to these, each runner implementation must always be ready to accept *None* in a runner-specific fashion. For user-friendliness, it is recommended to place first in the list the value which has the behavior identical or most similar to *None*.
- extload: whether the runner supports a –extload option, which must be given one time and is passed on to the underlying tool that the runner wraps.
- tool_opt: whether the runner supports a –tool-opt (-O) option, which can be given multiple times and is passed on to the underlying tool that the runner wraps.
- file: whether the runner supports a –file option, which specifies exactly the file that should be used to flash, overriding any default discovered in the build directory.
- hide_load_files: whether the elf/hex/bin file arguments should be hidden.
- rtt: whether the runner supports SEGGER RTT. This adds a –rtt-address option.
- skip_load: whether the runner supports the –load/–no-load option, which allows skipping the load of image on target before starting a debug session (this option only affects the 'debug' command)

class runners.core.**RunnerConfig**(*build_dir: str*, *board_dir: str*, *elf_file: str | None*, *exe_file: str | None*, *hex_file: str | None*, *bin_file: str | None*, *uf2_file: str | None*, *mot_file: str | None*, *file: str | None*, *file_type: FileType | None = FileType.OTHER*, *gdb: str | None = None*, *openocd: str | None = None*, *openocd_search: list[str] = []*, *rtt_address: int | None = None*)

Runner execution-time configuration.

This is a common object shared by all runners. Individual runners can register specific configuration options using their do_add_parser() hooks.

bin_file: str | None

class runners.core.**SysbuildConfiguration**(*build_dir: str*)

This helper class provides access to sysbuild-time configuration.

Configuration options can be read as if the object were a dict, either object['SB_CONFIG_FOO'] or object.get('SB_CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

class runners.core.**ZephyrBinaryRunner**(*cfg:* RunnerConfig)

Abstract superclass for binary runners (flashers, debuggers).

Note: this class's API has changed relatively rarely since it as added, but it is not considered a stable Zephyr API, and may change without notice.

With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have a Zephyr firmware binary permanently installed on the device for running) and debugged (have a breakpoint debugger and program loader on a host workstation attached to a running target).

This is supported by four top-level commands managed by the Zephyr build system:

- 'flash': flash a previously configured binary to the board, start execution on the target, then return.
- 'debug': connect to the board via a debugging protocol, program the flash, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits.
- 'debugserver': connect via a board-specific debugging protocol, then reset and halt the target. Ensure the user is now able to connect to a debug server with symbol tables loaded from the binary.
- 'attach': connect to the board via a debugging protocol, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits. Unlike 'debug', this command does not program the flash.

This class provides an API for these commands. Every subclass is called a 'runner' for short. Each runner has a name (like 'pyocd'), and declares commands it can handle (like 'flash'). Boards (like 'nrf52dk/nrf52832') declare which runner(s) are compatible with them to the Zephyr build system, along with information on how to configure the runner to work with the board.

The build system will then place enough information in the build directory to create and use runners with this class's create() method, which provides a command line argument parsing API. You can also create runners by instantiating subclasses directly.

In order to define your own runner, you need to:

1. Define a ZephyrBinaryRunner subclass, and implement its abstract methods. You may need to override capabilities().
2. Make sure the Python module defining your runner class is imported, e.g. by editing this package's __init__.py (otherwise, get_runners() won't work).
3. Give your runner's name to the Zephyr build system in your board's board.cmake.

Additional advice:

- If you need to import any non-standard-library modules, make sure to catch ImportError and defer complaints about it to a RuntimeError if one is missing. This avoids affecting users that don't require your runner, while still making it clear what went wrong to users that do require it that don't have the necessary modules installed.
- If you need to ask the user something (e.g. using input()), do it in your create() classmethod, not do_run(). That ensures your __init__() really has everything it needs to call do_run(), and also avoids calling input() when not instantiating within a command line application.
- Use self.logger to log messages using the standard library's logging API; your logger is named "runner.<your-runner-name()>"

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common add_parser() (and runner-specific do_add_parser() it delegates to), and provide a way to create instances of themselves from a RunnerConfig and parsed runner-specific arguments via create().

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the run() method.

`classmethod add_parser`(*parser*)

Adds a sub-command parser for this runner.

The given object, parser, is a sub-command parser from the argparse module. For more details, refer to the documentation for argparse.ArgumentParser.add_subparsers().

The lone common optional argument is:

- –dt-flash (if the runner capabilities includes flash_addr)

Runner-specific options are added through the do_add_parser() hook.

`classmethod args_from_previous_runner`(*previous_runner*, *args: Namespace*)

Update arguments from a previously created runner.

This is intended for propagating relevant user responses between multiple runs of the same runner, for example a JTAG serial number.

`property build_conf:` *BuildConfiguration*

Get a BuildConfiguration for the build directory.

`call`(*cmd: list[str]*, ***kwargs*) → int

Subclass subprocess.call() wrapper.

Subclasses should use this method to run command in a subprocess and get its return code, rather than using subprocess directly, to keep accurate debug logs.

`classmethod capabilities`() → *RunnerCaps*

Returns a RunnerCaps representing this runner's capabilities.

This implementation returns the default capabilities.

Subclasses should override appropriately if needed.

`cfg`

RunnerConfig for this instance.

`check_call`(*cmd: list[str]*, ***kwargs*)

Subclass subprocess.check_call() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`check_output`(*cmd: list[str]*, ***kwargs*) → bytes

Subclass subprocess.check_output() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`classmethod create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Create an instance from command-line arguments.

- `cfg`: runner configuration (pass to superclass __init__)
- `args`: arguments parsed from execution environment, as specified by `add_parser()`.

`classmethod dev_id_help`() → str

Get the ArgParse help text for the –dev-id option.

`abstractmethod classmethod do_add_parser`(*parser*)

Hook for adding runner-specific options.

`abstractmethod classmethod do_create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Hook for instance creation from command line arguments.

`abstractmethod do_run`(*command: str*, ***kwargs*)

Concrete runner; run() delegates to this. Implement in subclasses.

In case of an unsupported command, raise a ValueError.

`dry_run`

log commands instead of executing them. Can be set by subclasses

`ensure_output`(*output_type: str*) → None

Ensure self.cfg has a particular output artifact.

For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors out if it's missing or undefined.

Parameters
`output_type` – string naming the output type

`classmethod extload_help`() → str

Get the ArgParse help text for the –extload option.

`static flash_address_from_build_conf`(*build_conf:* BuildConfiguration)

If CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CONFIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS + CONFIG_FLASH_LOAD_OFFSET.

`static get_flash_address`(*args: Namespace*, *build_conf:* BuildConfiguration, *default: int = 0*) → int

Helper method for extracting a flash address.

If args.dt_flash is true, returns the address obtained from ZephyrBinaryRunner.flash_address_from_build_conf(build_conf).

Otherwise (when args.dt_flash is False), the default value is returned.

`get_rtt_address`() → int | None

Helper method for extracting a the RTT control block address.

If args.rtt_address was supplied, returns that.

Otherwise, attempt to locate an rtt block in the elf file. If this is not found, None is returned

`static get_runners`() → list[type[*ZephyrBinaryRunner*]]

Get a list of all currently defined runner classes.

`logger`

logging.Logger for this instance.

`abstractmethod classmethod name`() → str

Return this runner's user-visible name.

When choosing a name, pick something short and lowercase, based on the name of the tool (like openocd, jlink, etc.) or the target architecture/board (like xtensa etc.).

`popen_ignore_int`(*cmd: list[str]*, ***kwargs*) → Popen

Spawn a child command, ensuring it ignores SIGINT.

The returned subprocess.Popen object must be manually terminated.

`static require`(*program: str*, *path: str | None = None*) → str
Require that a program is installed before proceeding.

Parameters

- `program` – name of the program that is required, or path to a program binary.
- `path` – PATH where to search for the program binary. By default check on the system PATH.

If `program` is an absolute path to an existing program binary, this call succeeds. Otherwise, try to find the program by name on the system PATH or in the given PATH, if provided.

If the program can be found, its path is returned. Otherwise, raises MissingProgram.

`run`(*command: str*, ***kwargs*)
Runs command ('flash', 'debug', 'debugserver', 'attach').

This is the main entry point to this runner.

`run_client`(*client*, ***kwargs*)
Run a client that handles SIGINT.

`run_server_and_client`(*server*, *client*, ***kwargs*)
Run a server that ignores SIGINT, and a client that handles it.

This routine portably:

- creates a Popen object for the `server` command which ignores SIGINT
- runs `client` in a subprocess while temporarily ignoring SIGINT
- cleans up the server after the client exits.
- the keyword arguments, if any, will be passed down to both server and client subprocess calls

It's useful to e.g. open a GDB server and client.

`run_telnet_client`(*host: str*, *port: int*, *active_sock=None*) → None
Run a telnet client for user interaction.

`static sram_address_from_build_conf`(*build_conf:* BuildConfiguration)
return CONFIG_SRAM_BASE_ADDRESS.

`property sysbuild_conf: SysbuildConfiguration`
Get a SysbuildConfiguration for the sysbuild directory.

`property thread_info_enabled: bool`
Returns True if self.build_conf has CONFIG_DEBUG_THREAD_INFO enabled.

`classmethod tool_opt_help`() → str
Get the ArgParse help text for the –tool-opt option.

Doing it By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the binaries output by the build system. These will be named something like `zephyr/zephyr.elf`, `zephyr/zephyr.hex`, etc., depending on your board's build system integration. These binaries may be flashed to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course also be accomplished using the usual targets provided by Zephyr's build system (in fact, that's how these commands do it).

2.11.12 Signing Binaries

The `west sign` *extension* command can be used to sign a Zephyr application binary for consumption by a bootloader using an external tool. In some configurations, `west sign` is also used to invoke an external, post-processing tool that "stitches" the final components of the image together. Run `west sign -h` for command line help.

rimage

rimage configuration uses an approach that does not rely on Kconfig or CMake but on *west config*, similar to *Permanent CMake Arguments*.

Signing involves a number of "wrapper" scripts stacked on top of each other: `west flash` invokes `west build` which invokes `cmake` and `ninja` which invokes `west sign` which invokes `imgtool` or `rimage`. As long as the signing parameters desired are the default ones and fairly static, these indirections are not a problem. On the other hand, passing `imgtool` or `rimage` options through all these layers can causes issues typical when the layers don't abstract anything. First, this usually requires boilerplate code in each layer. Quoting whitespace or other special characters through all the wrappers can be difficult. Reproducing a lower `west sign` command to debug some build-time issue can be very time-consuming: it requires at least enabling and searching verbose build logs to find which exact options were used. Copying these options from the build logs can be unreliable: it may produce different results because of subtle environment differences. Last and worst: new signing feature and options are impossible to use until more boilerplate code has been added in each layer.

To avoid these issues, `rimage` parameters can bet set in `west config`. Here's a `workspace/.west/config` example:

```
[sign]
# Not needed when invoked from CMake
tool = rimage

[rimage]
# Quoting is optional and works like in Unix shells
# Not needed when rimage can be found in the default PATH
path = "/home/me/zworkspace/build-rimage/rimage"

# Not needed when using the default development key
extra-args = -i 4 -k 'keys/key argument with space.pem'
```

In order to support quoting, values are parsed by Python's `shlex.split()` like in *One-Time CMake Arguments*.

The `extra-args` are passed directly to the `rimage` command. The example above has the same effect as appending them on command line after `--` like this: `west sign --tool rimage -- -i 4 -k 'keys/key argument with space.pem'`. In case both are used, the command-line arguments go last.

silabs_commander

The `silabs_commander` tool is used to apply sign or MIC or encrypt binaries for Silicon Labs devices. It can be invoked either by `west sign` when the `sign.tool` configuration is set to `silabs_commander` or by `west build` if `CONFIG_SIWX91X_SIGN_KEY` or `CONFIG_SIWX91X_MIC_KEY` is set.

If one of `CONFIG_SIWX91X_SIGN_KEY` or `CONFIG_SIWX91X_MIC_KEY` is set, `west flash` will automatically flash the signed version of the binary.

`silabs_commander` require Simplicity Commander to be install on the host. The provisionning of the key on the device is described in UG574 SiWx917 SoC Manufacturing Utility User Guide.

2.11.13 Additional Zephyr extension commands

This page documents miscellaneous *Zephyr Extensions*.

Listing boards: `west boards`

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
west boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
west boards -f "{arch}:{name}"
```

Additional help about the formatting options can be found by running:

```
west boards -h
```

Shell completion scripts: `west completion`

The `completion` extension command outputs shell completion scripts that can then be used directly to enable shell completion for the supported shells.

It currently supports the following shells:

- bash
- zsh
- fish
- powershell (board qualifiers only)

Additional instructions are available in the command's help:

```
west help completion
```

Installing CMake packages: `west zephyr-export`

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in. `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application CMakeLists.txt files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See share/zephyr-package/cmake for details.

Software bill of materials: `west spdx`

This command generates SPDX 2.2 or 2.3 tag-value documents, creating relationships from source files to the corresponding generated build files. `SPDX-License-Identifier` comments in source files are scanned and filled into the SPDX documents.

To use this command:

1. Pre-populate a build directory `BUILD_DIR` like this:

   ```
   west spdx --init -d BUILD_DIR
   ```

   This step ensures the build directory contains CMake metadata required for SPDX document generation.

2. Enable `CONFIG_BUILD_OUTPUT_META` in your project.

3. Build your application using this pre-created build directory, like so:

   ```
   west build -d BUILD_DIR [...]
   ```

4. Generate SPDX documents using this build directory:

   ```
   west spdx -d BUILD_DIR
   ```

   By default, this generates SPDX 2.3 documents. To generate SPDX 2.2 documents instead:

   ```
   west spdx -d BUILD_DIR --spdx-version 2.2
   ```

> **Note**
>
> When building with *Sysbuild (System build)*, make sure you target the actual application which you want to generate the SBOM for. For example, if the application is named `hello_world`:
>
> ```
> west spdx --init  -d BUILD_DIR/hello_world
> west build -d BUILD_DIR/hello_world
> west spdx -d BUILD_DIR/hello_world
> ```

This generates the following SPDX bill-of-materials (BOM) documents in `BUILD_DIR/spdx/`:

- `app.spdx`: BOM for the application source files used for the build
- `zephyr.spdx`: BOM for the specific Zephyr source code files used for the build
- `build.spdx`: BOM for the built output files
- `modules-deps.spdx`: BOM for modules dependencies. Check *modules* for more details.

Each file in the bill-of-materials is scanned, so that its hashes (SHA256 and SHA1) can be recorded, along with any detected licenses if an `SPDX-License-Identifier` comment appears in the file.

Copyright notices are extracted using the third-party **`reuse`** tool from the REUSE group. When found, these notices are added to SPDX documents as `FileCopyrightText` fields.

> **Note**
>
> Copyright extraction uses heuristics that may not capture complete notice text, so `FileCopyrightText` content is best-effort. This aligns with SPDX specification recommendations.

SPDX Relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

`west spdx` accepts these additional options:

- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See SPDX specification clause 6 for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of `BUILD_DIR/spdx/`.
- `--spdx-version {2.2,2.3}`: specifies which SPDX specification version to use. Defaults to `2.3`. SPDX 2.3 includes additional fields like `PrimaryPackagePurpose` that are not available in SPDX 2.2.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.

  This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.
- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, `sdk.spdx`, which lists header files included from the SDK.

Warning

The generation of SBOM documents for the `native_sim` platform is currently not supported.

Working with binary blobs: `west blobs`

The `blobs` command allows users to interact with *binary blobs* declared in one or more *modules* via their *module.yml* file.

The `blobs` command has three sub-commands, used to list, fetch or clean (i.e. delete) the binary blobs themselves.

You can list binary blobs while specifying the format of the output:

```
west blobs list -f '{module}: {type} {path}'
```

For the full set of variables available in `-f/--format` run `west blobs -h`.

Fetching blobs works in a similar manner:

```
west blobs fetch
```

Note that, as described in *the modules section*, fetched blobs are stored in a `zephyr/blobs/` folder relative to the root of the corresponding module repository.

As does deleting them:

```
west blobs clean
```

Additionally the tool allows you to specify the modules you want to list, fetch or clean blobs for by typing the module names as a command-line parameter.

The argument `--allow-regex` can be passed `west blobs fetch` to restrict the specific blobs that are fetched, by passing a regular expression:

```
# For example, only download esp32 blobs, skip the other variants
west blobs fetch hal_espressif --allow-regex 'lib/esp32/.*'
```

An auto-cache directory can be provided via the `--auto-cache` cli argument or via the `blobs.auto-cache` config option. When enabled, the auto-cache directory is automatically populated whenever a blob is missing and downloaded.

One or more additional cache directories (separated by `;`) can be provided in `--cache-dirs` cli argument or `blobs.cache-dirs` config option.

`west blobs fetch` searches all configured cache directories (including the auto-cache) for a matching blob filename. Cached files may be stored either under their original filename or with a SHA-256 suffix (`<filename>.<sha>`). If found, the blob is copied from the cache to the blob path; otherwise it is downloaded from its url to the blob path.

Twister wrapper: `west twister`

This command is a wrapper for *twister*.

Twister can then be invoked via west as follows:

```
west twister -help
west twister -T tests/ztest/base
```

Working with binary descriptors: `west bindesc`

The `bindesc` command allows users to read *binary descriptors* of executable files. It currently supports `.bin`, `.hex`, `.elf` and `.uf2` files as input.

You can search for a specific descriptor in an image, for example:

```
west bindesc search KERNEL_VERSION_STRING build/zephyr/zephyr.bin
```

You can search for a custom descriptor by type and ID, for example:

```
west bindesc custom_search STR 0x200 build/zephyr/zephyr.bin
```

You can dump all of the descriptors in an image using:

```
west bindesc dump build/zephyr/zephyr.bin
```

You can extract the descriptor data area of the image to a file using:

```
west bindesc extract
```

You can list all known standard descriptor names using:

```
west bindesc list
```

You can print the offset of the descriptors inside the image using:

```
west bindesc get_offset
```

Indexing the sources with GNU Global: `west gtags`

Important

You must install the `gtags` and `global` programs provided by GNU Global to use this command.

The `west gtags` command lets you create a GNU Global tags file for the entire west workspace:

```
west gtags
```

This will create a tags file named `GTAGS` in the workspace *topdir* (it will also create other Global-related metadata files named `GPATH` and `GRTAGS` in the same place).

You can then run the `global` command anywhere inside the workspace to search for symbol locations using this tags file.

For example, to search for definitions of the `arch_system_halt()` function, starting from the `zephyr/drivers` directory:

```
$ cd zephyr/drivers
$ global -x arch_system_halt
arch_system_halt   65 ../arch/arc/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  455 ../arch/arm64/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  137 ../arch/nios2/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   18 ../arch/posix/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   17 ../arch/x86/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  126 ../arch/xtensa/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   21 ../kernel/fatal.c FUNC_NORETURN __weak void␣
↪arch_system_halt(unsigned int reason)
```

This prints the search symbol, the line it is defined on, a relative path to the file it is defined in, and the line itself, for all places where the symbol is defined.

Additional tips:

- This can also be useful to search for vendor HAL function definitions.
- See the `global` command's manual page for more information on how to use this tool.
- You should run `global`, **not** `west global`. There is no need for a separate `west global` command since `global` already searches for the `GTAGS` file starting from your current working directory. This is why you need to run `global` from inside the workspace.

Working with patches: `west patch`

The `patch` command allows users to apply patches to Zephyr or Zephyr modules in a controlled manner that makes automation and tracking easier for external applications that use the *T2 star topology*. The *patches.yml* file stores metadata about patch files and fills-in the gaps between official Zephyr releases, so that users can easily see the status of any upstreaming efforts, and determine which patches to drop before upgrading to the next Zephyr release.

There are several sub-commands available to manage patches for Zephyr or other modules in the workspace:

- `apply`: apply patches listed in `patches.yml`
- `clean`: remove all patches that have been applied, and reset to the manifest checkout state
- `list`: list all patches in `patches.yml`
- `gh-fetch`: fetch patches from a GitHub pull request

```
west-workspace/
└── application/
   ...
```

(continues on next page)

(continued from previous page)

```
   ├── west.yml
   └── zephyr
       ├── module.yml
       ├── patches
       │   ├── bootloader
       │   │   └── mcuboot
       │   │       └── my-tweak-for-mcuboot.patch
       │   └── zephyr
       │       └── my-zephyr-change.patch
       └── patches.yml
```

In this example, the *west manifest* file, `west.yml`, would pin to a specific Zephyr revision (e.g. `v4.1.0`) and apply patches against that revision of Zephyr and the specific revisions of other modules used in the application. However, this application needs two changes in order to meet requirements; one for Zephyr and another for MCUBoot.

```
patches:

    merge-commit: 1234567890abcdef1234567890abcdef12345678
    merge-date: 2025-05-06
    apply-command: git apply
    comments: |
      A change to mcuboot that has been merged already. We can remove this
      patch when we are ready to upgrade to the next Zephyr release.
```

Patches can easily be applied in an automated manner. For example:

```
west init -m <manifest repo> <workspace>
cd <workspace>
west update
west patch apply
```

When it is time to update to a newer version of Zephyr, the `west.yml` file can be updated to point at the next Zephyr release, e.g. `v4.2.0`. Patches that are no longer needed, like `my-tweak-for-mcuboot.patch` in the example above, can be removed from `patches.yml` and from the external application repository, and then the following commands can be run.

```
west patch clean
west update
west patch apply --roll-back # roll-back all patches if one does not apply cleanly
```

If a patch needs to be reworked, remember to update the `patches.yml` file with the new SHA256 checksum.

```
sha256sum zephyr/patches/zephyr/my-zephyr-change.patch
7d57ca78d5214f422172cc47fed9d0faa6d97a0796c02485bff0bf29455765e9
```

It is also possible to use `west patch gh-fetch` to fetch patches from a GitHub pull request and automatically create or update the `patches.yml` file. This can be useful when the author already has a number of changes captured in existing upstream pull requests.

```
west patch gh-fetch --owner zephyrproject-rtos --repo zephyr --pull-request
↪<pr-number> \
  --module zephyr --split-commits
```

The above command will create the directory and file structure below, which includes patches for each individual commit associated with the given pull request.

```
zephyr
├── patches
│   ├── first-commit-from-pr.patch
│   ├── second-commit-from-pr.patch
│   └── third-commit-from-pr.patch
└── patches.yml
```

Working with the Zephyr SDK: `west sdk`

The `west sdk` command is a Zephyr-specific west command used to list and install the Zephyr SDK and its toolchains.

Listing SDKs and toolchains To list installed Zephyr SDKs as well as available SDK releases and toolchains, run:

```
west sdk list
```

This command shows:

- Installed SDK versions
- Available SDK releases
- Toolchains included in each SDK

Installing the Zephyr SDK To install the Zephyr SDK, run:

```
west sdk install
```

This command may run in interactive mode and prompt for SDK or toolchain selection. When specific toolchains are provided via `--toolchains`, the command runs non-interactively, which is recommended for automation.

To install specific toolchains only, use the `--toolchains` option:

```
west sdk install --toolchains arm-zephyr-eabi riscv64-zephyr-elf
```

If you are unsure which toolchains you need, run `west sdk list` first to see the available options and avoid downloading unnecessary toolchains, which can save gigabytes of disk space and download time.

2.11.14 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of *Design Constraints* were identified to avoid the common pitfalls of tools of this kind.

Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

Rationale for a custom tool

Some of west's features are similar to those provided by Git Submodules and Google's repo.

Existing tools were considered during west's initial design and development. None were found suitable for Zephyr's requirements. In particular, these were examined in detail:

- Google repo
  - Does not cleanly support using zephyr as the manifest repository (**R4**)
  - Python 2 only
  - Does not play well with Windows
  - Assumes Gerrit is used for code review
- Git submodules
  - Does not fully support **R1**, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support **R3**, since downstream copies would need to either delete or replace submodule definitions
  - Does not support continuous tracking of the latest `HEAD` in external repositories (**R4**)
  - Requires hardcoding of the paths/locations of the external repositories

Multiple Git Repositories

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

- Clean separation of Zephyr original code and imported projects and libraries
- Avoidance of license incompatibilities between original and imported code
- Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
- Safety and security certifications
- Enforcement of modularization of the components
- Out-of-tree development based on subsets of the supported boards and SoCs

See *Basics* for information on how west workspaces manage multiple git repositories.

Design Constraints

West is:

- **Optional**: it is always *possible* to drop back to "raw" command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be *convenient* to do so, however. (If all of west's features were already conveniently available, there would be no reason to develop it.)
- **Compatible with CMake**: building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.
- **Cross-platform**: West is written in Python 3, and works on all platforms supported by Zephyr.
- **Usable as a Library**: whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named `west`; its libraries are implemented as subpackages.
- **Conservative about features**: no features will be accepted without strong and compelling motivation.
- **Clearly specified**: West's behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening "under the hood" when using west.

See Zephyr issue #6205 and for more details and discussion.

`west update` detached HEADs

The use of detached git `HEAD` revisions documented in the *update procedure* confuses and even frustrates some users.

Specifically, users often ask why `west update` doesn't leave existing local branches checked out by default.

This section explains why `west update` behaves the way it does by default, and mentions some other options you have for managing projects that you modified locally.

Two core requirements for `west update` are:

1. safety: the command should not lose any of the user's work
2. determinism: two users running `west update` on the same manifest should get the exact same *workspace* contents

Using detached HEADs helps preserve safety. As documented in the update procedure, using `git checkout --detach` on the updated project to get a detached `HEAD` is a generally safe operation that won't lose the user's work:

- if your work is all safely committed in a local git branch, that branch will be left as-is (see the `git help checkout` output for details)
- if you have uncommitted work, it will be safely kept in your working tree by git if that's possible
- if that's not possible, the entire command will fail, and you can decide what to do with your work before re-running `west update`

Detached HEADs also help ensure determinism:

- Checking out exactly the project revision that's specified in your manifest file is needed to make sure your workspace's files match what's specified in the main manifest. If west did not check out the manifest revision by default, your workspace could be invisibly different from what you would expect given the contents of the manifest files in your working copy. Even worse, the way it was different would depend on exactly what was in your branch before you ran `west update`.
- There is a subtle interaction with *Manifest Imports*. If your project itself has one or more manifest files that are being imported by `west update`, then west needs to check out those files into the working tree so it can resolve the entire imported manifest. If `west update` left a branch checked out in your project, the manifest files in your working tree could be out of date. If west then used those out-of-date files to finish the import, the process could fail unexpectedly or produce other nondeterministic results.

West does not check out the *manifest-rev* branch directly for reasons explained in the documentation for that branch.

This default behavior was chosen a long time ago and it's too late to change it now, since users are depending on it. However, there are other ways to run `west update` if this default doesn't work for you. To learn more, run `west help update` and read the `checked out branch behavior` option group text. For example:

- if you're actively writing some code in your project and you want to keep it up to date after potential changes in the upstream manifest, use `west update --rebase`
- if you've got some local code you'd like to keep around as long as the upstream revision for your project hasn't moved on to something newer, use `west update --keep-descendants`

You can use *West aliases* if you want to set up a shorter way to type one of these commands in your workspace. You can also contribute new options to this option group by sending a pull request to:

https://github.com/zephyrproject-rtos/west

2.11.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work "by hand" to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main zephyr repository, and keeping them up to date
- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

Note

If you have previously installed west and want to stop using it, uninstall it first:

```
pip3 uninstall west
```

Otherwise, Zephyr's build system will find it and may try to use it.

Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the *west manifest* file inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml,
# and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -Bbuild -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -Cbuild
```

When building with west installed, the Zephyr build system will use it to set *ZEPHYR_MODULES*.

If you don't have west installed and your application does not need any of these repositories, the build will still work.

If you don't have west installed and your application *does* need one of these repositories, you must set **ZEPHYR_MODULES** yourself as shown above.

See *Modules (External projects)* for more details.

Similarly, if your application requires binary blobs and you are not using west, you will need to download and place those blobs in the right places instead of using `west blobs`. See *Binary Blobs* for more details.

Flashing and Debugging

Running build system targets like `ninja flash`, `ninja debug`, etc. is just a call to the corresponding *west command*. For example, `ninja flash` calls `west flash`[1]. If you don't have west installed on your system, running those targets will fail. You can of course still flash and debug using any *Flash & Debug Host Tools* which work for your board (and which those west commands wrap).

If you want to use these build system targets but do not want to install west on your system using `pip`, it is possible to do so by manually creating a *west workspace*:

```
# cd into zephyrproject if not already there
git clone https://github.com/zephyrproject-rtos/west.git .west/west
```

Then create a file `.west/config` with the following contents:

[1] Note that `west build` invokes `ninja`, among other tools. There's no recursive invocation of either `west` or `ninja` involved by default, however, as `west build` does not invoke `ninja flash`, `debug`, etc. The one exception is if you specifically run one of these build system targets with a command line like `west build -t flash`. In that case, west is run twice: once for `west build`, and in a subprocess, again for `west flash`. Even in this case, `ninja` is only run once, as `ninja flash`. This is because these build system targets depend on an up to date build of the Zephyr application, so it's compiled before `west flash` is run.

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

After that, and in order for `ninja` to be able to invoke `west` to flash and debug, you must specify the west directory. This can be done by setting the environment variable `WEST_DIR` to point to `zephyrproject/.west/west` before running CMake to set up a build directory.

For details on west's Python APIs, see west-apis.

2.12 Testing

2.12.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

Creating a test suite

Using Ztest to create a test suite is as easy as calling the `ZTEST_SUITE`. The macro accepts the following arguments:

- `suite_name` - The name of the suite. This name must be unique within a single binary.
- `ztest_suite_predicate_t` - An optional predicate function to allow choosing when the test will run. The predicate will get a pointer to the global state passed in through `ztest_run_all()` and should return a boolean to decide if the suite should run.
- `ztest_suite_setup_t` - An optional setup function which returns a test fixture. This will be called and run once per test suite run.
- `ztest_suite_before_t` - An optional before function which will run before every single test in this suite.
- `ztest_suite_after_t` - An optional after function which will run after every single test in this suite.
- `ztest_suite_teardown_t` - An optional teardown function which will run at the end of all the tests in the suite.

Below is an example of a test suite using a predicate:

```
#include <zephyr/ztest.h>
#include "test_state.h"

static bool predicate(const void *global_state)
{
     return ((const struct test_state*)global_state)->x == 5;
}

ZTEST_SUITE(alternating_suite, predicate, NULL, NULL, NULL, NULL);
```

Adding tests to a suite

There are 5 macros used to add a test to a suite, they are:

- `ZTEST (suite_name, test_name)` - Which can be used to add a test by `test_name` to a given suite by `suite_name`.
- `ZTEST_P (suite_name, test_name)` - Add a parameterized test to a given suite by specifying the `suite_name` and `test_name`. You can then access the passed parameter within the body of the test using the `data` pointer.
- `ZTEST_USER (suite_name, test_name)` - Which behaves the same as `ZTEST`, only that when `CONFIG_USERSPACE` is enabled, then the test will be run in a userspace thread.
- `ZTEST_F (suite_name, test_name)` - Which behaves the same as `ZTEST`, only that the test function will already include a variable named `fixture` with the type `<suite_name>_fixture`.
- `ZTEST_USER_F (suite_name, test_name)` - Which combines the fixture feature of `ZTEST_F` with the userspace threading for the test.

Test fixtures Test fixtures can be used to help simplify repeated test setup operations. In many cases, tests in the same suite will require some initial setup followed by some form of reset between each test. This is achieved via fixtures in the following way:

```
#include <zephyr/ztest.h>

struct my_suite_fixture {
     size_t max_size;
     size_t size;
     uint8_t buff[1];
};

static void *my_suite_setup(void)
{
     /* Allocate the fixture with 256 byte buffer */
   struct my_suite_fixture *fixture = malloc(sizeof(struct my_suite_fixture) +␣
↪255);

     zassume_not_null(fixture, NULL);
     fixture->max_size = 256;

     return fixture;
}

static void my_suite_before(void *f)
{
     struct my_suite_fixture *fixture = (struct my_suite_fixture *)f;
     memset(fixture->buff, 0, fixture->max_size);
     fixture->size = 0;
}

static void my_suite_teardown(void *f)
{
   free(f);
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, my_suite_before, NULL,␣
↪my_suite_teardown);

ZTEST_F(my_suite, test_feature_x)
{
     zassert_equal(0, fixture->size);
```

(continues on next page)

(continued from previous page)

```
	zassert_equal(256, fixture->max_size);
}
```

Using memory allocated by a test fixture in a userspace thread, such as during execution of `ZTEST_USER` or `ZTEST_USER_F`, requires that memory to be declared userspace accessible. This is because the fixture memory is owned and initialized by kernel space. The Ztest framework provides the `ZTEST_DMEM` and `ZTEST_BMEM` macros for use of such user/kernel space shared memory.

Advanced features

Test result expectations Some tests were made to be broken. In cases where the test is expected to fail or skip due to the nature of the code, it's possible to annotate the test as such. For example:

```
#include <zephyr/ztest.h>

ZTEST_SUITE(my_suite, NULL, NULL, NULL, NULL, NULL);

ZTEST_EXPECT_FAIL(my_suite, test_fail);
ZTEST(my_suite, test_fail)
{
  /** This will fail the test */
  zassert_true(false, NULL);
}

ZTEST_EXPECT_SKIP(my_suite, test_skip);
ZTEST(my_suite, test_skip)
{
  /** This will skip the test */
  zassume_true(false, NULL);
}
```

In this example, the above tests should be marked as failed and skipped respectively. Instead, Ztest will mark both as passed due to the expectation.

Test rules Test rules are a way to run the same logic for every test and every suite. There are a lot of cases where you might want to reset some state for every test in the binary (regardless of which suite is currently running). As an example, this could be to reset mocks, reset emulators, flush the UART, etc.:

```
#include <zephyr/fff.h>
#include <zephyr/ztest.h>

#include "test_mocks.h"

DEFINE_FFF_GLOBALS;

DEFINE_FAKE_VOID_FUN(my_weak_func);

static void fff_reset_rule_before(const struct ztest_unit_test *test, void␣
↪*fixture)
{
	ARG_UNUSED(test);
	ARG_UNUSED(fixture);

	RESET_FAKE(my_weak_func);
```

(continues on next page)

(continued from previous page)

```
}

ZTEST_RULE(fff_reset_rule, fff_reset_rule_before, NULL);
```

A custom `test_main` While the Ztest framework provides a default `test_main()` function, it's possible that some applications will want to provide custom behavior. This is particularly true if there's some global state that the tests depend on and that state either cannot be replicated or is difficult to replicate without starting the process over. For example, one such state could be a power sequence. Assuming there's a board with several steps in the power-on sequence a test suite can be written using the `predicate` to control when it would run. In that case, the `test_main()` function can be written as follows:

```
#include <zephyr/ztest.h>

#include "my_test.h"

void test_main(void)
{
     struct power_sequence_state state;

     /* Only suites that use a predicate checking for phase == PWR_PHASE_0 will␣
↪run. */
     state.phase = PWR_PHASE_0;
     ztest_run_all(&state, false, 1, 1);

     /* Only suites that use a predicate checking for phase == PWR_PHASE_1 will␣
↪run. */
     state.phase = PWR_PHASE_1;
     ztest_run_all(&state, false, 1, 1);

     /* Only suites that use a predicate checking for phase == PWR_PHASE_2 will␣
↪run. */
     state.phase = PWR_PHASE_2;
     ztest_run_all(&state, false, 1, 1);

     /* Check that all the suites in this binary ran at least once. */
     ztest_verify_all_test_suites_ran();
}
```

Quick start - Integration testing

A simple working base is located at samples/subsys/testsuite/integration. To make a test application for the **bar** component of **foo**, you should copy the sample folder to `tests/foo/bar` and edit files there adjusting for your test application's purposes.

To build and execute all applicable test scenarios defined in your test application use the *Twister* tool, for example:

```
./scripts/twister -T tests/foo/bar/
```

To select just one of the test scenarios, run Twister with `--scenario` command:

```
./scripts/twister --scenario tests/foo/bar/your.test.scenario.name
```

In the command line above `tests/foo/bar` is the path to your test application and `your.test.scenario.name` references a test scenario defined in `testcase.yaml` file, which is like `sample.testing.ztest` in the boilerplate test suite sample.

See *Twister test project diagram* for more details on how Twister deals with Ztest application.

The sample contains the following files:

CMakeLists.txt

```
# SPDX-License-Identifier: Apache-2.0

cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
project(integration)

 */

#include <zephyr/ztest.h>

ZTEST_SUITE(framework_tests, NULL, NULL, NULL, NULL, NULL);

/**
 * @brief Test Asserts
 *
 * This test verifies various assert macros provided by ztest.
 *
 */
ZTEST(framework_tests, test_assert)
{
        zassert_true(1, "1 was false");
        zassert_false(0, "0 was true");
        zassert_is_null(NULL, "NULL was not NULL");
        zassert_not_null("foo", "\"foo\" was NULL");
        zassert_equal(1, 1, "1 was not equal to 1");
        zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
}
```

- *Listing Tests*
- *Skipping Tests*

A test application may consist of multiple test suites that either can be testing functionality or APIs. Functions implementing a test case should follow the guidelines below:

- Test cases function names should be prefixed with **test_**
- Test cases should be documented using doxygen
- Test case function names should be unique within the section or component being tested

For example:

```
/**
 * @brief Test Asserts
 *
 * This test case verifies the zassert_true macro.
 */
ZTEST(my_suite, test_assert)
{
        zassert_true(1, "1 was false");
}
```

Listing Tests Tests (test applications) in the Zephyr tree consist of many test scenarios that run as part of a project and test similar functionality, for example an API or a feature. The `twister` script can parse the test scenarios, suites and cases in all test applications or a subset of them, and can generate reports on a granular level, i.e. if test cases have passed or failed or if they were blocked or skipped.

Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by running:

```
./scripts/twister --list-tests -T tests/kernel
```

Skipping Tests Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using `ztest_test_skip()` or `Z_TEST_SKIP_IFDEF`. If the test runs, it needs to report either a pass or fail. For example:

```
#ifdef CONFIG_TEST1
ZTEST(common, test_test1)
{
     zassert_true(1, "true");
}
#else
ZTEST(common, test_test1)
{
     ztest_test_skip();
}
#endif

ZTEST(common, test_test2)
{
```

(continues on next page)

(continued from previous page)

```
    Z_TEST_SKIP_IFDEF(CONFIG_BUGxxxxx);
    zassert_equal(1, 0, NULL);
}

ZTEST_SUITE(common, NULL, NULL, NULL, NULL, NULL);
```

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

To setup unit tests you have to add a CMakeLists.txt, a testcases.yml and a prj.conf to the directory containing the unit test source files. The resulting binary from this directory is built using -DBOARD=unit_testing. When twister is invoked the script zephyr/scripts/pylib/twister/twisterlib/testplan.py filters out all testcases.yml in which type: unit is not set. Only unit tests are executed with a firmware build with BOARD=unit_testing.

Note

Unit tests are run as **native** applications on the host and are therefore subject to similar limitations as documented for the POSIX architecture. Running unit tests is therefore only supported for Linux. To run unit tests on Windows or macOS it is necessary to use containers or Virtual Machines running a Linux guest. Follow the same instructions as for the POSIX Arch dependencies.

CMakeLists.txt In order to declare the unit tests present in a source folder, you need to add the relevant source files to the `testbinary` target from the CMake unittest component. See a minimal example below:

```
cmake_minimum_required(VERSION 3.20.0)

project(app)
find_package(Zephyr COMPONENTS unittest REQUIRED HINTS $ENV{ZEPHYR_BASE})
target_sources(testbinary PRIVATE main.c)
```

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

testcases.yaml You have to set the value for the key "type" to "unit" in the testcase.yaml

```
tests:
  testscenario.testsuite:
    tags: your_tag
    type: unit
```

prj.conf For unit tests this contains usually only

```
CONFIG_ZTEST=y
```

If your unit tests require additional libraries (e.g. math-lib) you will have to add them either via the CMakeLists.txt or in the testcase.yaml:

```
tests:
  testscenario.testsuite:
    tags: your_tag
    type: unit
    extra_args:
      - EXTRA_LDFLAGS="-lm"
```

Examples of unit tests can be found in the tests/unit/ folder.

Best practices for declaring the test suite

twister and other validation tools need to obtain the list of test cases that a Zephyr *ztest* test image will expose.

Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test application. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every test case as passed, failed, blocked, or skipped. Reporting on only the high-level test application, particularly when tests do too many things, is too vague.

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?

  If C pre-processing or building fails because of any issue, then we won't be able to tell the subcases.

- Why not declare them in the YAML test configuration?

  A separate test case description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

Stress test framework

Zephyr stress test framework (Ztress) provides an environment for executing user functions in multiple priority contexts. It can be used to validate that code is resilient to preemptions. The framework tracks the number of executions and preemptions for each context. Execution can have various completion conditions like timeout, number of executions or number of preemptions.

The framework is setting up the environment by creating the requested number of threads (each on different priority), optionally starting a timer. For each context, a user function (different for each context) is called and then the context sleeps for a randomized amount of system ticks. The framework is tracking CPU load and adjusts sleeping periods to achieve higher CPU load. In order to increase the probability of preemptions, the system clock frequency should be relatively high. The default 100 Hz on QEMU x86 is much too low and it is recommended to increase it to 100 kHz.

The stress test environment is setup and executed using `ZTRESS_EXECUTE` which accepts a variable number of arguments. Each argument is a context that is specified by `ZTRESS_TIMER` or

ZTRESS_THREAD macros. Contexts are specified in priority descending order. Each context specifies completion conditions by providing the minimum number of executions and preemptions. When all conditions are met and the execution has completed, an execution report is printed and the macro returns. Note that while the test is executing, a progress report is periodically printed.

Execution can be prematurely completed by specifying a test timeout (ztress_set_timeout()) or an explicit abort (ztress_abort()).

User function parameters contains an execution counter and a flag indicating if it is the last execution.

The example below presents how to setup and run 3 contexts (one of which is k_timer interrupt handler context). Completion criteria is set to at least 10000 executions of each context and 1000 preemptions of the lowest priority context. Additionally, the timeout is configured to complete after 10 seconds if those conditions are not met. The last argument of each context is the initial sleep time which will be adjusted throughout the test to achieve the highest CPU load.

```
ztress_set_timeout(K_MSEC(10000));
ZTRESS_EXECUTE(ZTRESS_TIMER(foo_0, user_data_0, 10000,␣
↪Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_1, user_data_1, 10000, 0,␣
↪Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_2, user_data_2, 10000, 1000,␣
↪Z_TIMEOUT_TICKS(20)));
```

Configuration Static configuration of Ztress contains:

- CONFIG_ZTRESS_MAX_THREADS - number of supported threads.
- CONFIG_ZTRESS_STACK_SIZE - Stack size of created threads.
- CONFIG_ZTRESS_REPORT_PROGRESS_MS - Test progress report interval.

API reference

Running tests

Ztest testing macros

Assertions These macros will instantly fail the test if the related assertion fails. When an assertion fails, it will print the current file, line and function, alongside a reason for the failure and an optional message. If the config CONFIG_ZTEST_ASSERT_VERBOSE is 0, the assertions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassert_equal(buf->ref, 2, "Invalid refcount")`:

```
Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref␣
↪not equal to 2)
Aborted at unit test function
```

Ztest assertion macros

Expectations These macros will continue test execution if the related expectation fails and subsequently fail the test at the end of its execution. When an expectation fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message but continue executing the test. If the config CONFIG_ZTEST_ASSERT_VERBOSE is 0, the expectations will only print the file and line numbers, reducing the binary size of the test.

For example, if the following expectations fail:

```
zexpect_equal(buf->ref, 2, "Invalid refcount");
zexpect_equal(buf->ref, 1337, "Invalid refcount");
```

The output will look something like:

```
START - test_get_single_buffer
    Expectation failed at main.c:62: test_get_single_buffer: Invalid refcount␣
↪(buf->ref not equal to 2)
    Expectation failed at main.c:63: test_get_single_buffer: Invalid refcount␣
↪(buf->ref not equal to 1337)
 FAIL - test_get_single_buffer in 0.0 seconds
```

Ztest expectation macros

Assumptions These macros will instantly skip the test or suite if the related assumption fails. When an assumption fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assumptions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassume_equal(buf->ref, 2, "Invalid refcount")`:

Ztest assumption macros

Ztress

Ztest ztress macros

Mocking via FFF Zephyr has integrated with FFF for mocking. See FFF for documentation. To use it, include the relevant header:

```
#include <zephyr/fff.h>
```

Zephyr provides several FFF-based fake drivers which can be used as either stubs or mocks. Fake driver instances are configured via *Devicetree* and *Configuration System (Kconfig)*. See the following devicetree bindings for more information:

- `zephyr,fake-can`
- `zephyr,fake-eeprom`

Zephyr also has defined extensions to FFF for simplified declarations of fake functions. See *FFF Extensions*.

Customizing Test Output

Customization is enabled by setting `CONFIG_ZTEST_TC_UTIL_USER_OVERRIDE` to "y" and adding a file `tc_util_user_override.h` with your overrides.

Add the line `zephyr_include_directories(my_folder)` to your project's `CMakeLists.txt` to let Zephyr find your header file during builds.

See the file subsys/testsuite/include/zephyr/tc_util.h to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

```
#ifndef SOMETHING
#define SOMETHING <default implementation>
#endif /* SOMETHING */
```

Shuffling Test Sequence

By default the tests are sorted and ran in alphanumerical order. Test cases may be dependent on this sequence. Enable `CONFIG_ZTEST_SHUFFLE` to randomize the order. The output from the test will display the seed for failed tests. For native simulator builds you can provide the seed as an argument to twister with `--seed`.

Repeating Tests

By default the tests are executed once. The test cases and test suites may be executed multiple times. Enable `CONFIG_ZTEST_REPEAT` to execute the tests multiple times. By default the multiplication factors are 3, which means every test suite is executed 3 times and every test case is executed 3 times. This can be changed by the `CONFIG_ZTEST_SUITE_REPEAT_COUNT` and `CONFIG_ZTEST_TEST_REPEAT_COUNT` Kconfig options.

Test Selection

For tests built for native simulator, use command line arguments to list or select tests to run. The test argument expects a comma separated list of `suite::test` . You can substitute the test name with an `*` to run all tests within a suite.

For example

```
$ zephyr.exe -list
$ zephyr.exe -test=
↪"fixture_tests::test_fixture_pointer,framework_tests::test_assert_mem_equal"
$ zephyr.exe -test="framework_tests::*"
```

FFF Extensions

FFF extensions

2.12.2 Test Runner (Twister)

Twister scans for the set of test applications in the git repository and attempts to execute them. By default, it tries to build each test application on boards marked as default in the board definition file.

The default options will build the majority of the test applications on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

Because of the limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one `-v` option, twister's console output shows for every test application how the test is run (qemu, native_sim, etc.) or whether the binary was just built. The resultant *status* of a test is likewise reported in the `twister.json` and other report files. There are a few reasons why twister only builds a test and doesn't run it:

- The test is marked as `build_only: true` in its `.yaml` configuration file.
- The test configuration has defined a `harness` but you don't have it or haven't set it up.
- The target device is not connected and not available for flashing
- You or some higher level automation invoked twister with `--build-only`.

To run the script in the local tree, follow the steps below:

Linux

```
$ source zephyr-env.sh
$ ./scripts/twister
```

Windows

```
zephyr-env.cmd
python .\scripts\twister
```

If you have a system with a large number of cores and plenty of free storage space, you can build and run all possible tests using the following options:

Linux

```
$ ./scripts/twister --all --enable-slow
```

Windows

```
python .\scripts\twister --all --enable-slow
```

This will build for all available boards and run all applicable tests in a simulated (for example QEMU) environment.

If you want to run tests on one or more specific platforms, you can use the `--platform` option, it is a platform filter for testing, with this option, test suites will only be built/run on the platforms specified. This option also supports different revisions of one same board, you can use `--platform board@revision` to test on a specific revision.

The list of command line options supported by twister can be viewed using:

Linux

```

                [--alt-config-root ALT_CONFIG_ROOT]
                ...

positional arguments:
  extra_test_args       Additional args following a '--' are passed to the
                        test binary

options:
  -h, --help            show this help message and exit
  -G, --integration     Run integration tests
  --emulation-only      Only build and run emulation platforms
  --simulation {mdb-nsim,nsim,renode,qemu,tsim,armfvp,xt-sim,native,custom,simics}
                        Selects which simulation to use. Must match one of the
                        names defined in the board's manifest. If multiple
                        simulator are specified in the selected board and this
                        argument is not passed, then the first simulator is
                        selected.
  --device-testing      Test on device directly. Specify the serial device to
                        use with the --device-serial option.
  --pre-script PRE_SCRIPT
                        specify a pre script. This will be executed before
                        device handler open serial port and invoke runner.
  --device-serial DEVICE_SERIAL
                        Serial device for accessing the board (e.g.,
                        /dev/ttyACM0)
  --device-serial-baud DEVICE_SERIAL_BAUD
                        Serial device baud rate (default 115200)
  --device-serial-pty DEVICE_SERIAL_PTY
                        Script for controlling pseudoterminal. Twister
                        believes that it interacts with a terminal when it
                        actually interacts with the script. E.g "twister
                        --device-testing --device-serial-pty <script>
```

(continues on next page)

(continued from previous page)

```
  --generate-hardware-map GENERATE_HARDWARE_MAP
                        Probe serial devices connected to this platform and
                        create a hardware map file to be used with --device-
                        testing
  --hardware-map HARDWARE_MAP
                        Load hardware map from a file. This will be used for
                        testing on hardware that is listed in the file.
  --persistent-hardware-map
                        With --generate-hardware-map, tries to use persistent
                        names for serial devices on platforms that support
                        this feature (currently only Linux).
  --device-flash-with-test
                        Add a test case timeout to the flash operation timeout
                        when flash operation also executes test case on the
                        platform.
  --device-flash-timeout DEVICE_FLASH_TIMEOUT
                        Set timeout for the device flash operation in seconds.
  --flash-before        Flash device before attaching to serial port. This is
                        useful for devices that share the same port for
                        programming and serial console, or use soft-USB, where
                        flash must come first. Also, it skips reading
                        remaining logs from the old image run.
  --flash-command FLASH_COMMAND
                        Instead of 'west flash', uses a custom flash command
                        to flash when running with --device-testing. Supports
                        comma-separated argument list, the script is also
                        passed a --build-dir flag with the build directory as
                        an argument, and a --board-id flag with the board or
                        probe id if available.
  --west-flash [WEST_FLASH]
                        Comma separated list of additional flags passed to
                        west when running with --device-testing. E.g "twister
                        --device-testing --device-serial /dev/ttyACM0 --west-
                        flash="--board-id=foobar,--erase" will translate to
                        "west flash -- --board-id=foobar --erase"
  --west-runner WEST_RUNNER
                        Uses the specified west runner instead of default when
                        running with --west-flash. E.g "twister --device-
                        testing --device-serial /dev/ttyACM0 --west-flash
                        --west-runner=pyocd" will translate to "west flash
                        --runner pyocd"
  --west-flash-cmd {flash,debug}
                        Uses the specified west command. twister will use
                        flash if not set E.g "twister --device-testing
                        --device-serial /dev/ttyACM0 --west-flash-cmd="flash"
                        will translate to "west flash ..."
  -a ARCH, --arch ARCH  Arch filter for testing. Takes precedence over
                        --platform. If unspecified, test all arches. Multiple
                        invocations are treated as a logical 'or' relationship
  --vendor VENDOR       Vendor filter for testing
  -p PLATFORM, --platform PLATFORM
                        Platform filter for testing. This option may be used
                        multiple times. Test suites will only be built/run on
                        the platforms specified. If this option is not used,
                        then platforms marked as default in the platform
                        metadata file will be chosen to build and test.
```

(continues on next page)

(continued from previous page)

```
  -P EXCLUDE_PLATFORM, --exclude-platform EXCLUDE_PLATFORM
                        Exclude platforms and do not build or run any tests on
                        those platforms. This option can be called multiple
                        times.
  --platform-pattern PLATFORM_PATTERN
                        Platform regular expression filter for testing. This
                        option may be used multiple times. Test suites will
                        only be built/run on the platforms matching the
                        specified patterns. If this option is not used, then
                        platforms marked as default in the platform metadata
                        file will be chosen to build and test.
  --test-pattern TEST_PATTERN
                        Run only the tests matching the specified pattern. The
                        pattern can include regular expressions.
  --filter {buildable,runnable}
                        Filter tests to be built and executed. By default
                        everything is built and if a test is runnable
                        (emulation or a connected device), it is run. This
                        option allows for example to only build tests that can
                        actually be run. Runnable is a subset of buildable.
  -t TAG, --tag TAG     Specify tags to restrict which tests to run by tag
                        value. Default is to not do any tag filtering.
                        Multiple invocations are treated as a logical 'or'
                        relationship.
  -e EXCLUDE_TAG, --exclude-tag EXCLUDE_TAG
                        Specify tags of tests that should not run. Default is
                        to run all tests with all tags.
  -K, --force-platform  Force testing on selected platforms, even if they are
                        excluded in the test configuration (testcase.yaml).
  --ignore-platform-key
                        Do not filter based on platform key
  --level LEVEL         Test level to be used. By default, no levels are used
                        for filtering and do the selection based on existing
                        filters.
  -b, --build-only      Only build the code, do not attempt to run the code on
                        targets.
  --prep-artifacts-for-testing
                        Generate artifacts for testing, do not attempt to run
                        the code on targets.
  --package-artifacts PACKAGE_ARTIFACTS
                        Package artifacts needed for flashing in a file to be
                        used with --test-only
  --test-only           Only run device tests with current artifacts, do not
                        build the code
  --timeout-multiplier TIMEOUT_MULTIPLIER
                        Globally adjust tests timeouts by specified
                        multiplier. The resulting test timeout would be
                        multiplication of test timeout value, board-level
                        timeout multiplier and global timeout multiplier (this
                        parameter)
  --pytest-args PYTEST_ARGS
                        Pass additional arguments to the pytest subprocess.
                        This parameter will extend the pytest_args from the
                        harness_config in YAML file.
  --ctest-args CTEST_ARGS
                        Pass additional arguments to the ctest subprocess.
```

(continues on next page)

(continued from previous page)

```
                      This parameter will extend the ctest_args from the
                      harness_config in YAML file.
  --enable-valgrind   Run binary through valgrind and check for several
                      memory access errors. Valgrind needs to be installed
                      on the host. This option only works with host binaries
                      such as those generated for the native_sim
                      configuration and is mutual exclusive with --enable-
                      asan.
  --enable-asan       Enable address sanitizer to check for several memory
                      access errors. Libasan needs to be installed on the
                      host. This option only works with host binaries such
                      as those generated for the native_sim configuration
                      and is mutual exclusive with --enable-valgrind.
  -A BOARD_ROOT, --board-root BOARD_ROOT
                      Directory to search for board configuration files. All
                      .yaml files in the directory will be processed. The
                      directory should have the same structure in the main
                      Zephyr tree: boards/<vendor>/<board_name>/
  --allow-installed-plugin
                      Allow to use pytest plugin installed by pip for pytest
                      tests.
  -B SUBSET, --subset SUBSET
                      Only run a subset of the tests, 1/4 for running the
                      first 25%, 3/5 means run the 3rd fifth of the total.
                      This option is useful when running a large number of
                      tests on different hosts to speed up execution time.
  --shuffle-tests     Shuffle test execution order to get randomly
                      distributed tests across subsets. Used only when
                      --subset is provided.
  --shuffle-tests-seed SHUFFLE_TESTS_SEED
                      Seed value for random generator used to shuffle tests.
                      If not provided, seed in generated by system. Used
                      only when --shuffle-tests is provided.
  -c, --clobber-output  Cleaning the output directory will simply delete it
                      instead of the default policy of renaming.
  --cmake-only        Only run cmake, do not build or run.
  --test-config TEST_CONFIG
                      Path to file with plans and test configurations.
  --disable-suite-name-check
                      Disable extended test suite name verification at the
                      beginning of Ztest test. This option could be useful
                      for tests or platforms, which from some reasons cannot
                      print early logs.
  --enable-lsan       Enable leak sanitizer to check for heap memory leaks.
                      Libasan needs to be installed on the host. This option
                      only works with host binaries such as those generated
                      for the native_sim configuration and when --enable-
                      asan is given.
  --enable-ubsan      Enable undefined behavior sanitizer to check for
                      undefined behaviour during program execution. It uses
                      an optional runtime library to provide better error
                      diagnostics. This option only works with host binaries
                      such as those generated for the native_sim
                      configuration.
  --force-color       Always output ANSI color escape sequences even when
                      the output is redirected (not a tty)
```

(continues on next page)

(continued from previous page)

```
  --force-toolchain     Do not filter based on toolchain, use the set
                        toolchain unconditionally
  -i, --inline-logs     Upon test failure, print relevant log data to stdout
                        instead of just a path to it.
  -j JOBS, --jobs JOBS  Number of jobs for building, defaults to number of CPU
                        threads, overcommitted by factor 2 when --build-only.
  -l, --all             Build/test on all platforms. Any --platform arguments
                        ignored.
  --log-file FILENAME   Specify a file where to save logs.
  -M [{pass,all}], --runtime-artifact-cleanup [{pass,all}]
                        Cleanup test artifacts. The default behavior is 'pass'
                        which only removes artifacts of passing tests. If you
                        wish to remove all artificats including those of
                        failed tests, use 'all'.
  --keep-artifacts KEEP_ARTIFACTS
                        Keep specified artifacts when cleaning up at runtime.
                        Multiple invocations are possible.
  -n, --no-clean        Re-use the outdir before building. Will result in
                        faster compilation since builds will be incremental.
  --aggressive-no-clean
                        Re-use the outdir before building and do not re-run
                        cmake. Will result in much faster compilation since
                        builds will be incremental. This option might result
                        in build failures and inconsistencies if dependencies
                        change or when applied on a significantly changed code
                        base. Use on your own risk. It is recommended to only
                        use this option for local development and when testing
                        localized change in a subsystem.
  --detailed-test-id    Compose each test Suite name from its configuration
                        path (relative to root) and the appropriate Scenario
                        name using PATH_TO_TEST_CONFIG/SCENARIO_NAME schema.
  --no-detailed-test-id
                        Don't prefix each test Suite name with its
                        configuration path, so it is the same as the
                        appropriate Scenario name.
  --detailed-skipped-report
                        Generate a detailed report with all skipped test cases
                        including those that are filtered based on testsuite
                        definition.
  -O OUTDIR, --outdir OUTDIR
                        Output directory for logs and binaries. Default is
                        'twister-out' in the current directory. This directory
                        will be cleaned unless '--no-clean' is set. The '--
                        clobber-output' option controls what cleaning does.
  -o REPORT_DIR, --report-dir REPORT_DIR
                        Output reports containing results of the test run into
                        the specified directory. The output will be both in
                        JSON and JUNIT format (twister.json and twister.xml).
  --overflow-as-errors  Treat RAM/SRAM overflows as errors.
  --report-filtered     Include filtered tests in the reports.
  --platform-reports    Create individual reports for each platform.
  --quarantine-list FILENAME
                        Load list of test scenarios under quarantine. The
                        entries in the file need to correspond to the test
                        scenarios names as in corresponding tests .yaml files.
                        These scenarios will be skipped with quarantine as the
```

(continues on next page)

(continued from previous page)

```
                        reason.
  --quarantine-verify   Use the list of test scenarios under quarantine and
                        run them to verify their current status.
  --quit-on-failure     quit twister once there is build / run failure
  --report-name REPORT_NAME
                        Create a report with a custom name.
  --report-summary [REPORT_SUMMARY]
                        Show failed/error report from latest run. Default
                        shows all items found. However, you can specify the
                        number of items (e.g. --report-summary 15). It also
                        works well with the --outdir switch.
  --report-suffix REPORT_SUFFIX
                        Add a suffix to all generated file names, for example
                        to add a version or a commit ID.
  --report-all-options  Show all command line options applied, including
                        defaults, as environment.options object in
                        twister.json. Default: show only non-default settings.
  --retry-failed RETRY_FAILED
                        Retry failing tests again, up to the number of times
                        specified.
  --retry-interval RETRY_INTERVAL
                        Retry failing tests after specified period of time.
  --retry-build-errors  Retry build errors as well.
  -S, --enable-slow     Execute time-consuming test cases that have been
                        marked as 'slow' in testcase.yaml. Normally these are
                        only built.
  --enable-slow-only    Execute time-consuming test cases that have been
                        marked as 'slow' in testcase.yaml only. This also set
                        the option --enable-slow
  --seed SEED           Seed for native_sim pseudo-random number generator
  --short-build-path    Create shorter build directory paths based on symbolic
                        links. The shortened build path will be used by CMake
                        for generating the build system and executing the
                        build. Use this option if you experience build
                        failures related to path length, for example on
                        Windows OS. This option can be used only with '--
                        ninja' argument (to use Ninja build generator).
  --timestamps          Print all messages with time stamps.
  -u, --no-update       Do not update the results of the last run. This option
                        is only useful when reusing the same output directory
                        of twister, for example when re-running failed tests
                        with --only-failed or --no-clean. This option is for
                        debugging purposes only.
  -v, --verbose         Call multiple times to increase verbosity.
  -ll {NOTSET,DEBUG,INFO,WARNING,ERROR,CRITICAL}, --log-level
↪{NOTSET,DEBUG,INFO,WARNING,ERROR,CRITICAL}
                        Select the threshold event severity for which you'd
                        like to receive logs in console. Default is INFO.
  -W, --disable-warnings-as-errors
                        Do not treat warning conditions as errors.
  -X FIXTURE, --fixture FIXTURE
                        Specify a fixture that a board might support.
  -x EXTRA_ARGS, --extra-args EXTRA_ARGS
                        Extra CMake cache entries to define when building test
                        cases. May be called multiple times. The key-value
                        entries will be prefixed with -D before being passed
```

(continues on next page)

(continued from previous page)

```
                        to CMake. E.g "twister -x=USE_CCACHE=0" will translate
                        to "cmake -DUSE_CCACHE=0" which will ultimately
                        disable ccache.
  -y, --dry-run         Create the filtered list of test cases, but don't
                        actually run them. Useful if you're just interested in
                        the test plan generated for every run and saved in the
                        specified output directory (testplan.json).
  --alt-config-root ALT_CONFIG_ROOT
                        Alternative test configuration root/s. When a test is
                        found, Twister will check if a test configuration file
                        exist in any of the alternative test configuration
                        root folders. For example, given
                        $test_root/tests/foo/testcase.yaml, Twister will use
                        $alt_config_root/tests/foo/testcase.yaml if it exists

Test case selection:

  Artificially long but functional example:
      $ ./scripts/twister -v     \
        --testsuite-root tests/ztest/base    \
        --testsuite-root tests/kernel   \
        --test      tests/ztest/base/testing.ztest.verbose_0  \
        --test      tests/kernel/fifo/fifo_api/kernel.fifo

     "kernel.fifo.poll" is one of the test section names in
                                  __/fifo_api/testcase.yaml

  -F FILENAME, --load-tests FILENAME
                        Load a list of tests and platforms to be run from a
                        JSON file ('testplan.json' schema).
  -T TESTSUITE_ROOT, --testsuite-root TESTSUITE_ROOT
                        Base directory to recursively search for test cases.
                        All testcase.yaml files under here will be processed.
                        May be called multiple times. Defaults to the
                        'samples/' and 'tests/' directories at the base of the
                        Zephyr tree.
  -f, --only-failed     Run only those tests that failed the previous twister
                        run invocation.
  -s TEST, --test TEST, --scenario TEST
                        Run only the specified test suite scenario. These are
                        named by 'path/relative/to/Zephyr/base/section.subsect
                        ion_in_testcase_yaml', or just 'section.subsection'
                        identifier. With '--testsuite-root' option the
                        scenario will be found faster.
  --sub-test SUB_TEST   Recursively find sub-test functions (test cases) and
                        run the entire test scenario (section.subsection)
                        where they were found, including all sibling test
                        functions. Sub-tests are named by: 'section.subsection
                        _in_testcase_yaml.ztest_suite.ztest_without_test_prefi
                        x'. Example_1: 'kernel.fifo.fifo_api_1cpu.fifo_loop'
                        where 'kernel.fifo' is a test scenario name
                        (section.subsection) and 'fifo_api_1cpu.fifo_loop' is
                        a Ztest 'suite_name.test_name'. Example_2:
                        'debug.coredump.logging_backend' is a standalone test
                        scenario name. Note: This selection mechanism works
```

(continues on next page)

(continued from previous page)

```
                        only for Ztest suite and test function names in the
                        source files which are not generated by macro-
                        substitutions.
  -N, --ninja           Use the Ninja generator with CMake. (This is the
                        default)
  -k, --make            Use the unix Makefile generator with CMake.

Test plan reporting:
  Report the composed test plan details and exit (dry-run).

  -E FILENAME, --save-tests FILENAME
                        Write a list of tests and platforms to be run to
                        FILENAME file and stop execution. The resulting file
                        will have the same content as 'testplan.json'.
  --list-tests          List of all sub-test functions recursively found in
                        all --testsuite-root arguments. The output is
                        flattened and reports detailed sub-test names without
                        their directories. Note: sub-test names can share the
                        same test scenario identifier prefix
                        (section.subsection) even if they are from different
                        test projects.
  --test-tree           Output the test plan in a tree form.
  --list-tags           List all tags occurring in selected tests.

Memory footprint:
  Collect and report ROM/RAM size footprint for the test instance images built.

  --create-rom-ram-report
                        Generate detailed json reports with ROM/RAM symbol
                        sizes for each test image built using additional build
                        option `--target footprint`.
  --footprint-report [{all,ROM,RAM}]
                        Select which memory area symbols' data to collect as
                        'footprint' property of each test suite built, and
                        report in 'twister_footprint.json' together with the
                        relevant execution metadata the same way as in
                        `twister.json`. Implies '--create-rom-ram-report' to
                        generate the footprint data files. No value means
                        'all'. Default: None
  --enable-size-report  Collect and report ROM/RAM section sizes for each test
                        image built.
  --footprint-from-buildlog
                        Take ROM/RAM sections footprint summary values from
                        the 'build.log' instead of 'objdump' results used
                        otherwise.Requires --enable-size-report or one of the
                        baseline comparison modes.Warning: the feature will
                        not work correctly with sysbuild.
  -m, --last-metrics    Compare footprints to the previous twister invocation
                        as a baseline running in the same output directory.
                        Implies --enable-size-report option.
  --compare-report COMPARE_REPORT
                        Use this report file as a baseline for footprint
                        comparison. The file should be of 'twister.json'
                        schema. Implies --enable-size-report option.
  --show-footprint      With footprint comparison to a baseline, log ROM/RAM
                        section deltas.
```

(continues on next page)

```
  -H FOOTPRINT_THRESHOLD, --footprint-threshold FOOTPRINT_THRESHOLD
                        With footprint comparison to a baseline, warn the user
                        for any of the footprint metric change which is
                        greater or equal to the specified percentage value.
                        Default is 5.0 for 5.0% delta from the new footprint
                        value. Use zero to warn on any footprint metric
                        increase.
  -D, --all-deltas      With footprint comparison to a baseline, warn on any
                        footprint change, increase or decrease. Implies
                        --footprint-threshold=0
  -z FILENAME, --size FILENAME
                        Ignore all other command line options and just produce
                        a report to stdout with ROM/RAM section sizes on the
                        specified binary images.

Code coverage:
  Build with code coverage support, collect code coverage statistics executing␣
↪tests, compose code coverage report at the end.
  Effective for devices with 'HAS_COVERAGE_SUPPORT'.

  --enable-coverage     Enable code coverage collection using gcov.
  -C, --coverage        Generate coverage reports. Implies --enable-coverage
                        to collect the coverage data first.
  --gcov-tool GCOV_TOOL
                        Path to the 'gcov' tool to use for code coverage
                        reports. By default it will be chosen in the following
                        order: using ZEPHYR_TOOLCHAIN_VARIANT ('llvm': from
                        LLVM_TOOLCHAIN_PATH), gcov installed on the host - for
                        'native' or 'unit' platform types, using
                        ZEPHYR_SDK_INSTALL_DIR.
  --coverage-basedir COVERAGE_BASEDIR
                        Base source directory for coverage report.
  --coverage-platform COVERAGE_PLATFORM
                        Platforms to run coverage reports on. This option may
                        be used multiple times. Default to what was selected
                        with --platform.
  --coverage-tool {lcov,gcovr}
                        Tool to use to generate coverage reports (gcovr -
                        default).
  --coverage-formats COVERAGE_FORMATS
                        Output formats to use for generated coverage reports
                        as a comma-separated list without spaces. Valid
                        options for 'gcovr' tool are:
                        html,xml,csv,txt,coveralls,sonarqube (html - default).
                        Valid options for 'lcov' tool are: html,lcov
                        (html,lcov - default).
  --coverage-per-instance
                        Compose individual coverage reports for each test
                        suite when coverage reporting is enabled; it might run
                        in addition to the default aggregation mode which
                        produces one coverage report for all executed test
                        suites. Default: False
  --disable-coverage-aggregation
                        Don't aggregate coverage report statistics for all the
                        test suites selected to run with enabled coverage.
                        Requires another reporting mode to be active
                        (`--coverage-per-instance`) to have at least one of
```

(continues on next page)

(continued from previous page)

```
                        these reporting modes. Default: False
```

Windows

```
python .\scripts\twister --help
```

Board Configuration

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
  - spi
  - gpio
  - usb_device
  - watchdog
  - can
  - pwm
testing:
  default: true
```

identifier:
A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

name:
The actual name of the board as it appears in marketing material.

type:
Type of the board or configuration, currently we support 2 types: mcu, qemu

simulation:
Simulator(s) used to simulate the platform, e.g. qemu.

```
simulation:
  - name: qemu
  - name: armfvp
    exec: FVP_Some_Platform
  - name: custom
    exec: AnotherBinary
```

By default, tests will be executed using the first entry in the simulation array. Another simulation can be selected with `--simulation <simulation_name>`. The `exec` attribute is optional. If it is set but the required simulator is not available, the tests will be built only. If it is not set and the required simulator is not available the tests will fail to run. The simulation name must match one of the element of `SUPPORTED_EMU_PLATFORMS`.

arch:
Architecture of the board

toolchain:
The list of supported toolchains that can build this board. This should match one of the values used for *ZEPHYR_TOOLCHAIN_VARIANT* when building on the command line

ram:
Available RAM on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 128KB.

flash:
Available FLASH on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 512KB.

supported:
A list of features this board supports. This can be specified as a single word feature or as a variant of a feature class. For example:

```
supported:
  - pci
```

This indicates the board does support PCI. You can make a test scenario build or run only on such boards, or:

```
supported:
  - netif:eth
  - sensor:bmi16
```

A test scenario can depend on 'eth' to only test ethernet or on 'netif' to run on any board with a networking interface.

testing:
testing relating keywords to provide best coverage for the features of this board.

binaries:
A list of custom binaries to be kept for device testing.

default: [True|False]:
This is a default board, it will tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

ignore_tags:
Do not attempt to build (and therefore run) tests marked with this list of tags.

only_tags:
Only execute tests with this list of tags on a specific platform.

timeout_multiplier: <float> (default 1)
Multiply each test scenario timeout by specified ratio. This option allows to tune timeouts only for required platform. It can be useful in case naturally slow platform I.e.:

HW board with power-efficient but slow CPU or simulation platform which can perform instruction accurate simulation but does it slowly.

flash_before: [True|False] (default False)
For pytest/shell harness hardware testing, flash the device before opening the serial port. This prevents serial port disconnection issues during flashing on some boards (e.g., those with USB CDC that reset during flash operations).

env:
A list of environment variables. Twister will check if all these environment variables are set, and otherwise skip this platform. This allows the user to define a platform which should be used, for example, only if some required software or hardware is present, and to signal that presence to twister using these environment variables.

Tests

Tests are detected by the presence of a `testcase.yaml` or a `sample.yaml` files in the application's project directory. This test application configuration file may contain one or more entries in the `tests:` section each identifying a Test Scenario.

Test application configurations are written using the YAML syntax and share the same structure as samples.

A Test Scenario is a set of conditions and variables defined in a Test Scenario entry, under which a set of Test Suites will be built and executed.

A Test Suite is a collection of Test Cases which are intended to be used to test a software program to ensure it meets certain requirements. The Test Cases in a Test Suite are either related or meant to be executed together.

Test Scenario, Test Suite, and Test Case names must follow to these basic rules:

1. The format of the Test Scenario identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [_=]) consisting of multiple sections delimited with a dot (`.`).
2. Each Test Scenario identifier shall start with a section name followed by a subsection names delimited with a dot (`.`). For example, a test scenario that covers semaphores in the kernel shall start with `kernel.semaphore`.
3. All Test Scenario identifiers within a Test Configuration (`testcase.yaml` file) need to be unique. For example a `testcase.yaml` file covering semaphores in the kernel can have:
   - `kernel.semaphore`: For general semaphore tests
   - `kernel.semaphore.stress`: Stress testing semaphores in the kernel.
4. The full canonical name of a Test Suite is: `<Test Application Project path>/<Test Scenario identifier>`
5. Depending on the Test Suite implementation, its Test Case identifiers consist of **at least three sections** delimited with a dot (`.`):
   - **Ztest tests**: a Test Scenario identifier from the corresponding `testcase.yaml` file, a Ztest suite name, and a Ztest test name: `<Test Scenario identifier>.<Ztest suite name>.<Ztest test name>`
   - **Standalone tests and samples**: a Test Scenario identifier from the corresponding `testcase.yaml` (or `sample.yaml`) file where the last section signifies the standalone Test Case name, for example: `debug.coredump.logging_backend`.

The `--no-detailed-test-id` command line option modifies the above rules in this way:

1. A Test Suite name has only `<Test Scenario identifier>` component. Its Application Project path can be found in `twister.json` report as `path:` property.

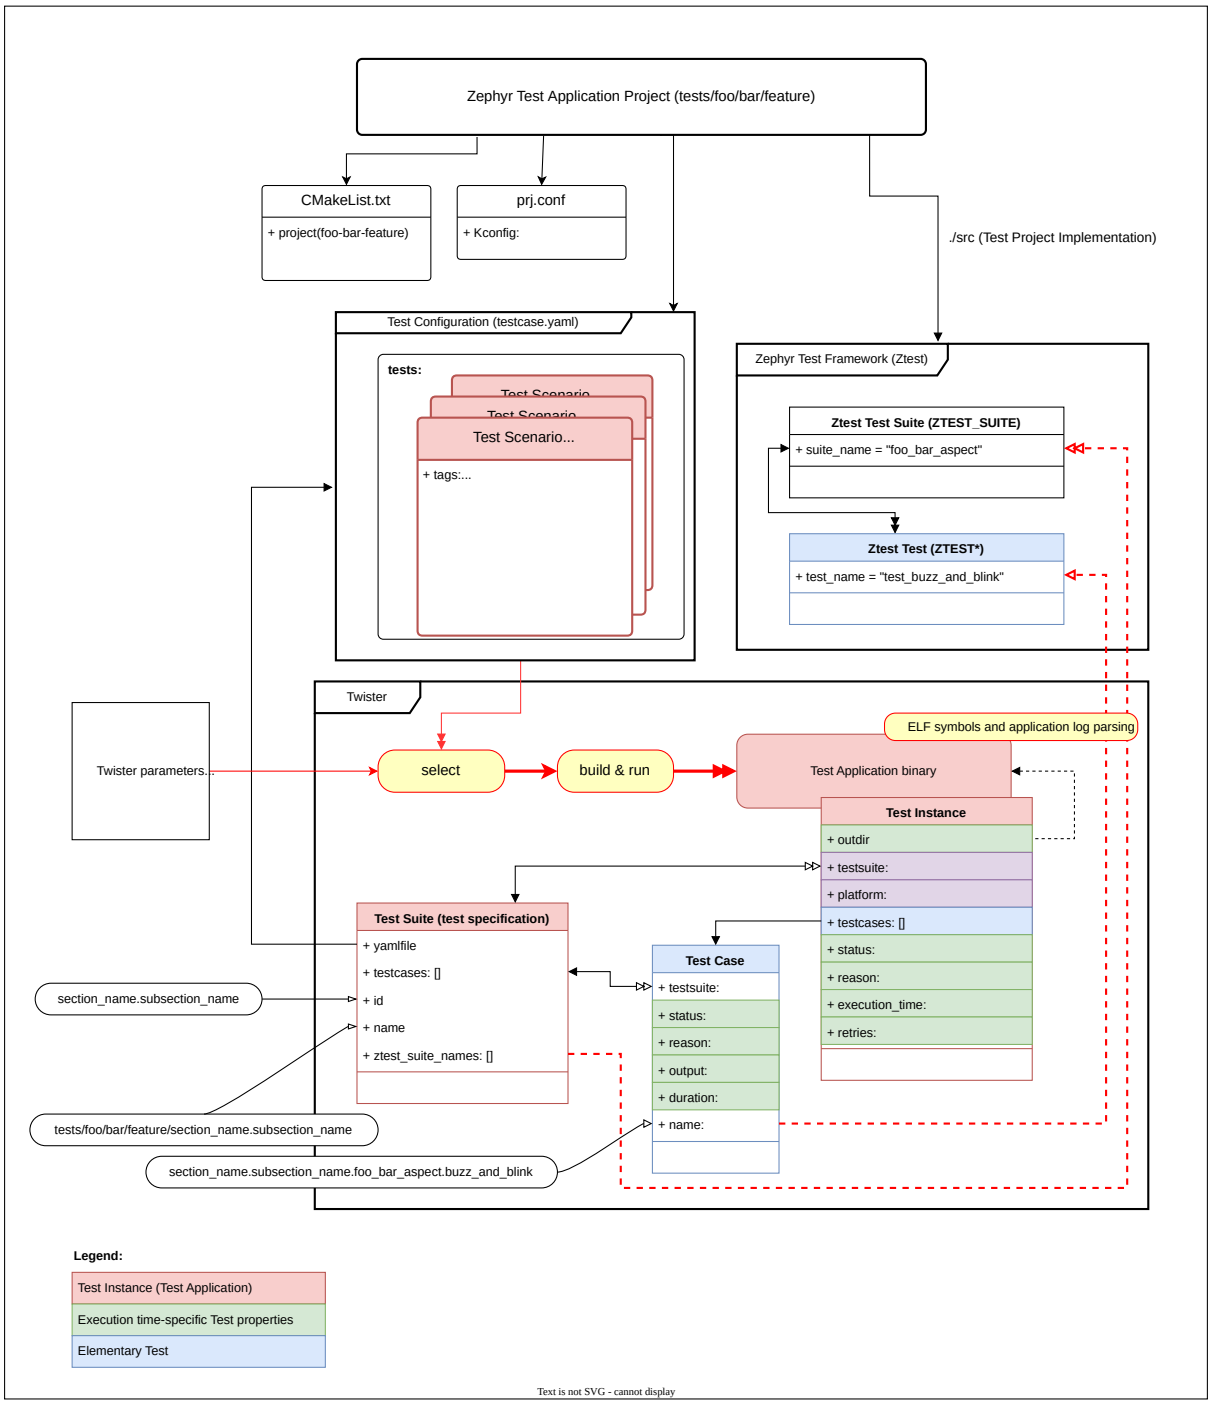

Fig. 4: Twister and a Test application project.

2. With short Test Suite names in this mode, all corresponding Test Scenario names must be unique for the Twister execution scope.

The following is an example test configuration with a few options that are explained in this document.

```
tests:
  bluetooth.gatt:
    build_only: true
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
  bluetooth.gatt.br:
    build_only: true
    extra_args: CONF_FILE="prj_br.conf"
    filter: not CONFIG_DEBUG
    platform_exclude: up_squared
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
```

A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application
tests:
  sample.basic.hello_world:
    build_only: true
    tags: tests
    min_ram: 16
  sample.basic.hello_world.singlethread:
    build_only: true
    extra_args: CONF_FILE=prj_single.conf
    filter: not CONFIG_BT
    tags: tests
    min_ram: 16
```

A Test Scenario entry in the `tests:` YAML dictionary has its Test Scenario identifier as a key.

Each Test Scenario entry in the Test Application configuration can define the following key/value pairs:

tags: <list of tags> (required)
A set of string tags for the test scenario. Usually pertains to functional domains but can be anything. Command line invocations of this script can filter the set of tests to run based on tag.

skip: <True|False> (default False)
skip test scenario unconditionally. This can be used for broken tests for example.

slow: <True|False> (default False)
Don't run this test scenario unless `--enable-slow` or `--enable-slow-only` was passed in on the command line. Intended for time-consuming test scenarios that are only run under certain circumstances, like daily builds. These test scenarios are still compiled.

extra_args: <list of extra arguments>
Extra arguments to pass to build tool when building or running the test scenario.

Using namespacing, it is possible to apply extra_args only to some hardware. Currently architectures/platforms/simulation are supported:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_args:
      - arch:x86:CONFIG_ADC_ASYNC=y
      - platform:qemu_x86:CONFIG_DEBUG=y
      - platform:mimxrt1060_evk:SHIELD=rk043fn66hs_ctg
      - simulation:qemu:CONFIG_MPU=y
```

extra_configs: <list of extra configurations>
Extra configuration options to be merged with a main prj.conf when building or running the test scenario. For example:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - CONFIG_ADC_ASYNC=y
```

Using namespacing, it is possible to apply a configuration only to some hardware. Currently both architectures and platforms are supported:

```
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - arch:x86:CONFIG_ADC_ASYNC=y
      - platform:qemu_x86:CONFIG_DEBUG=y
```

build_only: <True|False> (default False)
If true, twister will not try to run the test even if the test is runnable on the platform.

This keyword is reserved for tests that are used to test if some code actually builds. A `build_only` test is not designed to be run in any environment and should not be testing any functionality, it only verifies that the code builds.

This option is often used to test drivers and the fact that they are correctly enabled in Zephyr and that the code builds, for example sensor drivers. Such test shall not be used to verify the functionality of the driver.

build_on_all: <True|False> (default False)
If true, attempt to build test scenario on all available platforms. This is mostly used in CI for increased coverage. Do not use this flag in new tests.

depends_on: <list of features>
A board or platform can announce what features it supports, this option will enable the test only those platforms that provide this feature.

levels: <list of levels>
Test levels this test should be part of. If a level is present, this test will be selectable using the command line option `--level <level name>`

min_ram: <integer>
estimated minimum amount of RAM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

min_flash: <integer>
estimated minimum amount of ROM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

timeout: <number of seconds>
Length of time to run test before automatically killing it. Default to 60 seconds.

arch_allow: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should only be run for.

arch_exclude: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should not run on.

vendor_allow: <list of vendors>
Set of platform vendors that this test scenario should only be run for. The vendor is defined as part of the board definition. Boards associated with this vendors will be included. Other boards, including those without a vendor will be excluded.

vendor_exclude: <list of vendors>
Set of platform vendors that this test scenario should not run on. The vendor is defined as part of the board. Boards associated with this vendors will be excluded.

platform_allow: <list of platforms>
Set of platforms that this test scenario should only be run for. Do not use this option to limit testing or building in CI due to time or resource constraints, this option should only be used if the test or sample can only be run on the allowed platform and nothing else.

integration_platforms: <YML list of platforms/boards>
This option limits the scope to the listed platforms when twister is invoked with the `--integration` option. Use this instead of platform_allow if the goal is to limit scope due to timing or resource constraints.

integration_toolchains: <YML list of toolchain variants>
This option expands the scope to all the listed toolchains variants and adds another vector of testing where desired. By default, test configurations are generated based on the toolchain configured in the environment:

test scenario -> platforms1 -> toolchain1 test scenario -> platforms2 -> toolchain1

When a platform supports multiple toolchains that are available during the twister run, it is possible to expand the test configurations to include additional tests for each toolchain. For example, if a platform supports toolchains `toolchain1` and `toolchain2`, and the test scenario includes:

```
integration_toolchains:
  - toolchain1
  - toolchain2
```

the following configurations are generated:

test scenario -> platforms1 -> toolchain1 test scenario -> platforms1 -> toolchain2 test scenario -> platforms2 -> toolchain1 test scenario -> platforms2 -> toolchain2

> **Note**
> This functionality is evaluated always and is not limited to the `--integration` option.

platform_exclude: <list of platforms>
Set of platforms that this test scenario should not run on.

extra_sections: <list of extra binary sections>
When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr binary unless they are named here. They will not be included in the size calculation.

sysbuild: <True|False> (default False)
Build the project using sysbuild infrastructure. Only the main project's generated device-tree and Kconfig will be used for filtering tests. on device testing must use the hardware map, or west flash to load the images onto the target. The `--erase` option of west flash is not supported with this option. Usage of unsupported options will result in tests requiring sysbuild support being skipped.

harness: <string>
A harness keyword in the `testcase.yaml` file identifies a Twister harness needed to run a test successfully. A harness is a feature of Twister and implemented by Twister, some harnesses are defined as placeholders and have no implementation yet.

A harness can be seen as the handler that needs to be implemented in Twister to be able to evaluate if a test passes criteria. For example, a keyboard harness is set on tests that require keyboard interaction to reach verdict on whether a test has passed or failed, however, Twister lack this harness implementation at the moment.

Supported harnesses:

- ztest
- test
- console
- pytest
- gtest
- robot
- ctest
- shell
- power
- display_capture

See *Harnesses* for more information.

platform_key: <list of platform attributes>
Often a test needs to only be built and run once to qualify as passing. Imagine a library of code that depends on the platform architecture where passing the test on a single platform for each arch is enough to qualify the tests and code as passing. The platform_key attribute enables doing just that.

For example to key on (arch, simulation) to ensure a test is run once per arch and simulation (as would be most common):

```
platform_key:
  - arch
  - simulation
```

Adding platform (board) attributes to include things such as soc name, soc family, and perhaps sets of IP blocks implementing each peripheral interface would enable other interesting uses. For example, this could enable building and running SPI tests once for each unique IP block.

harness_config: <harness configuration options>
Extra harness configuration options to be used to select a board and/or for handling generic Console with regex matching. Config can announce what features it supports. This option will enable the test to run on only those platforms that fulfill this external dependency.

fixture: <expression>
Specify a test scenario dependency on an external device(e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on `fixture` keyword. Some sample fixture names are i2c_hts221, i2c_bme280, i2c_FRAM, ble_fw and gpio_loop.

Only one fixture can be defined per test scenario and the fixture name has to be unique across all tests in the test suite.

ztest_suite_repeat: <int> (default 1)
This parameter specifies the number of times the entire test suite should be repeated.

ztest_test_repeat: <int> (default 1)
This parameter specifies the number of times each individual test within the test suite should be repeated.

ztest_test_shuffle: <True|False> (default False)
This parameter indicates whether the order of the tests within the test suite should be shuffled. When set to `true`, the tests will be executed in a random order.

The following is an example yaml file with robot harness_config options.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
```

It can be more than one test suite using a list.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite:
        - [robot file path 1]
        - [robot file path 2]
        - [robot file path n]
```

One or more options can be passed to robotframework.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
      robot_option:
        - --exclude tag
        - --stop-on-error
```

filter: <expression>
Filter whether the test scenario should be run by evaluating an expression against an environment containing the following values:

```
{ ARCH : <architecture>,
  PLATFORM : <platform>,
  <all CONFIG_* key/value pairs in the test's generated defconfig>,
  *<env>: any environment variable available
}
```

Twister will first evaluate the expression to find if a "limited" cmake call, i.e. using package_helper cmake script, can be done.

Existence of "dt_*" entries indicates devicetree is needed. Refer to *Devicetree Filtering Expressions* for detailed description of the different DT expressions available.

Existence of "CONFIG*" entries indicates kconfig is needed. If there are no other types of entries in the expression a filtration can be done without creating a complete build system. If there are entries of other types a full cmake is required.

The grammar for the expression language is as follows:

```
expression : expression 'and' expression
           | expression 'or' expression
           | 'not' expression
           | '(' expression ')'
           | symbol '==' constant
           | symbol '!=' constant
           | symbol '<' NUMBER
           | symbol '>' NUMBER
           | symbol '>=' NUMBER
           | symbol '<=' NUMBER
           | symbol 'in' list
           | symbol ':' STRING
           | symbol
           ;

list : '[' list_contents ']';

list_contents : constant (',' constant)*;

constant : NUMBER | STRING;
```

For the case where `expression ::= symbol`, it evaluates to `true` if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

- or (left associative)
- and (left associative)
- not (right associative)
- all comparison operators (non-associative)

`arch_allow`, `arch_exclude`, `platform_allow`, `platform_exclude` are all syntactic sugar for these expressions. For instance:

```
arch_exclude = x86 arc
```

Is the same as:

```
filter = not ARCH in ["x86", "arc"]
```

The `:` operator compiles the string argument as a regular expression, and then returns a true value only if the symbol's value in the environment matches. For example, if `CONFIG_SOC="stm32f107xc"` then

```
filter = CONFIG_SOC : "stm.*"
```

Would match it.

required_snippets: <list of needed snippets>

Snippets are supported in twister for test scenarios that require them. As with normal applications, twister supports using the base zephyr snippet directory and test application directory for finding snippets. Listed snippets will filter supported tests for boards (snippets must be compatible with a board for the test to run on them, they are not optional).

The following is an example yaml file with 2 required snippets.

```
tests:
  snippet.example:
    required_snippets:
      - cdc-acm-console
      - user-snippet-example
```

required_applications: <list of required applications> (default empty)

Specify a list of test applications that must be built before current test can run. It enables sharing of built applications between test scenarios, allowing tests to access build artifacts from other applications.

Each required application entry supports: - `name`: Test scenario identifier (required) - `platform`: Target platform (optional, defaults to current test's platform)

Required applications must be available in the source tree (specified with `-T` and/or `-s` options). When reusing build directories (e.g., with `--no-clean`), Twister can find required applications in the current build directory.

How it works:

- Twister builds the required applications first
- The main test application waits for required applications to complete
- Build directories of required applications are made available to the test harness
- For pytest harness, build directories are passed via `--required-build` arguments and accessible through the `required_build_dirs` fixture

Example configuration:

```
tests:
  sample.required_app_demo:
    harness: pytest
    required_applications:
      - name: sample.shared_app
      - name: sample.basic.helloworld
        platform: native_sim
  sample.shared_app:
    build_only: true
```

Limitations: Not supported with `--subset` or `--runtime-artifact-cleanup` options.

expect_reboot: <True|False> (default False)

Notify twister that the test scenario is expected to reboot while executing. When enabled, twister will suppress warnings about unexpected multiple runs of a testsuite or testcase.

The set of test scenarios that actually run depends on directives in the test scenario filed and options passed in on the command line. If there is any confusion, running with `-v` or examining the discard report (`twister_discard.csv`) can help show why particular test scenarios were skipped.

Metrics (such as pass/fail state and binary size) for the last code release are stored in `scripts/release/twister_last_release.csv`. To update this, pass the `--all --release` options.

To load arguments from a file, add + before the file name, e.g., `+file_name`. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

Devicetree Filtering Expressions Expressions starting with "dt_*" are used to filter boards based on specific devicetree properties, such as compatibles, aliases, node labels, node properties, chosen nodes, etc. when selecting test scenarios.

> **Note**
>
> The source code for these expressions can be found at scripts/pylib/twister/expr_parser.py.

Expressions

`dt_compat_enabled(compat)`

Purpose:
Checks if any DT node with the specified compatible string (`compat`) is enabled.

Parameters:

- `compat`: The compatible string to match.

`dt_alias_exists(alias)`

Purpose:
Checks if any DT node with the specified alias exists and is enabled.

Parameters:

- `alias`: The alias (defined in `aliases` node) to match.

`dt_enabled_alias_with_parent_compat(alias, compat)`

Purpose:
Checks if the DT has an enabled alias node whose parent has the specified compatible string. Useful for nodes like `gpio-leds` child nodes, which may not have their own compatible.

Parameters:

- `alias`: The alias (defined in `aliases` node) to match.
- `compat`: The parent node's compatible string to match.

`dt_label_with_parent_compat_enabled(label, compat)`

Purpose:
Checks if a DT node with the specified label exists, is enabled, and its parent has the specified compatible string.

Parameters:

- `label`: The node label to match.
- `compat`: The parent node's compatible string to match.

`dt_chosen_enabled(chosen)`

Purpose:
Checks if a DT chosen property with the specified name exists and the node assigned to it is enabled.

Parameters:

- `chosen`: The name of the chosen property.

`dt_nodelabel_enabled(label)`

Purpose:
Checks if a DT node with the specified label exists and is enabled.

Parameters:

- `label`: The node label to match.

`dt_nodelabel_prop_enabled(label, prop)`

Purpose:
Checks if a DT node with the specified label exists, is enabled, and has the specified property with a non-empty value.

Parameters:

- `label`: The node label to match.
- `prop`: The node's property to check.

`dt_node_has_prop(node_id, prop)`

Purpose:
Checks if a DT node (specified by alias or path) has the specified property, regardless of its status. Useful for nodes that do not have a status, like `zephyr,user` node.

Parameters:

- `node_id`: The node alias (defined in `aliases` node) or node path to match.
- `prop`: The node's property to check.

Usage These expressions are used in Twister's test scenarios filtering logic to select boards that match specific DT conditions. For example:

```
tests:
  - test: my_test
    filter: dt_compat_enabled("my-compat-string")
```

The test scenario `my_test` will only build for boards where a DT node with `my-compat-string` is enabled.

Harnesses

Harnesses `ztest`, `gtest` and `console` are based on parsing of the output and matching certain phrases. `ztest` and `gtest` harnesses look for pass/fail/etc. frames defined in those frameworks.

Some widely used harnesses that are not supported yet:

- keyboard
- net
- bluetooth

The following is an example yaml file with a few harness_config options.

```
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
  tags: sensor
  harness: console
  harness_config:
```

(continues on next page)

(continued from previous page)

```
    type: multi_line
    ordered: false
    regex:
      - "Temperature:(.*)C"
      - "Relative Humidity:(.*)%"
    fixture: i2c_hts221
tests:
  test:
    tags: sensors
    depends_on: i2c
```

Ctest

ctest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to `ctest` e.g.: `ctest_args: ['--repeat until-pass:5']`. Note that `--ctest-args` can be passed multiple times to pass several arguments to the ctest.

Gtest Use `gtest` harness if you've already got tests written in the gTest framework and do not wish to update them to zTest.

Pytest The *pytest harness* is used to execute pytest test suites in the Zephyr test. The following options apply to the pytest harness:

pytest_root: <list of pytest testpaths> (default pytest)
Specify a list of pytest directories, files or subtests that need to be executed when a test scenario begins to run. The default pytest directory is `pytest`. After the pytest run is finished, Twister will check if the test scenario passed or failed according to the pytest report. As an example, a list of valid pytest roots is presented below:

```
harness_config:
  pytest_root:
    - "pytest/test_shell_help.py"
    - "../shell/pytest/test_shell.py"
    - "/tmp/test_shell.py"
    - "~/tmp/test_shell.py"
    - "$ZEPHYR_BASE/samples/subsys/testsuite/pytest/shell/pytest/test_shell.py
↪"
    - "pytest/test_shell_help.py::test_shell2_sample"  # select pytest subtest
    - "pytest/test_shell_help.py::test_shell2_sample[param_a]"  # select␣
↪pytest parametrized subtest
```

pytest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to `pytest` e.g.: `pytest_args: ['-k=test_method', '--log-level=DEBUG']`. Note that `--pytest-args` can be passed multiple times to pass several arguments to the pytest.

pytest_dut_scope: <function|class|module|package|session> (default function)

The scope for which `dut` and `shell` pytest fixtures are shared. If the scope is set to `function`, DUT is launched for every test case in python script. For `session` scope, DUT is launched only once.

The following is an example yaml file with pytest harness_config options, default pytest_root name "pytest" will be used if pytest_root not specified. please refer the examples in samples/subsys/testsuite/pytest/.

```
common:
  harness: pytest
tests:
  pytest.example.directories:
    harness_config:
      pytest_root:
        - pytest_dir1
        - $ENV_VAR/samples/test/pytest_dir2
  pytest.example.files_and_subtests:
    harness_config:
      pytest_root:
        - pytest/test_file_1.py
        - test_file_2.py::test_A
        - test_file_2.py::test_B[param_a]
```

Console The `console` harness tells Twister to parse a test's text output for a regex defined in the test's YAML file.

The following options are currently supported:

type: <one_line|multi_line> (required)
Depends on the regex string to be matched

regex: <list of regular expressions> (required)
Strings with regular expressions to match with the test's output to confirm the test runs as expected.

ordered: <True|False> (default False)
Check the regular expression strings in orderly or randomly fashion

record: <recording options> (optional)

regex: <list of regular expressions> (required)
Regular expressions with named subgroups to match data fields found in the test instance's output lines where it provides some custom data for further analysis. These records will be written into the build directory `recording.csv` file as well as `recording` property of the test suite object in `twister.json`.

With several regular expressions given, each of them will be applied to each output line producing either several different records from the same output line, or different records from different lines, or similar records from different lines.

The .CSV file will have as many columns as there are fields detected in all records; missing values are filled by empty strings.

For example, to extract three data fields `metric`, `cycles`, `nanoseconds`:

```
record:
  regex:
    - "(?P<metric>.*):(?P<cycles>.*) cycles, (?P<nanoseconds>.*) ns"
```

merge: <True|False> (default False)
Allows to keep only one record in a test instance with all the data fields extracted by the regular expressions. Fields with the same name will be put into lists ordered as their appearance in recordings. It is possible for such multi value fields to have different number of values depending on the regex rules and the test's output.

as_json: <list of regex subgroup names> (optional)
Data fields, extracted by the regular expressions into named subgroups, which will be additionally parsed as JSON encoded strings and written into `twister.json` as nested `recording` object properties. The corresponding `recording.csv` columns will contain JSON strings as-is.

Using this option, a test log can convey layered data structures passed from the test image for further analysis with summary results, traces, statistics, etc.

For example, this configuration:

```
record:
  regex: "RECORD:(?P<type>.*):DATA:(?P<metrics>.*)"
  as_json: [metrics]
```

when matched to a test log string:

```
RECORD:jitter_drift:DATA:{"rollovers":0, "mean_us":1000.0}
```

will be reported in `twister.json` as:

```
"recording":[
    {
            "type":"jitter_drift",
            "metrics":{
                "rollovers":0,
                "mean_us":1000.0
            }
    }
]
```

Robot The `robot` harness is used to execute Robot Framework test suites in the Renode simulation framework.

robot_testsuite: <robot file path> (default empty)
Specify one or more paths to a file containing a Robot Framework test suite to be run.

robot_option: <robot option> (default empty)
One or more options to be send to robotframework.

Power The `power` harness is used to measure and validate the current consumption. It integrates with 'pytest' to perform automated data collection and analysis using a hardware power monitor.

The harness executes the following steps:

1. Initializes a power monitoring device (e.g., `stm_powershield`) via the `PowerMonitor` abstract interface.
2. Starts current measurement for a defined `measurement_duration`.
3. Collects raw current waveform data.
4. Uses a peak detection algorithm to segment data into defined execution phases based on power transitions.
5. Computes RMS current values for each phase using a utility function.
6. Compares the computed values with user-defined expected RMS values.

```
harness: power
harness_config:
  fixture: pm_probe
  power_measurements:
    element_to_trim: 100
    min_peak_distance: 40
    min_peak_height: 0.008
    peak_padding: 40
```

(continues on next page)

(continued from previous page)

```
measurement_duration: 6
num_of_transitions: 4
expected_rms_values: [56.0, 4.0, 1.2, 0.26, 140]
tolerance_percentage: 20
```

- **elements_to_trim** – Number of samples to discard at the start of measurement to eliminate noise.
- **min_peak_distance** – Minimum distance between detected current peaks (helps detect distinct transitions).
- **min_peak_height** – Minimum current threshold to qualify as a peak (in amps).
- **peak_padding** – Number of samples to extend around each detected peak.
- **measurement_duration** – Total time (in seconds) to record current data.
- **num_of_transitions** – Expected number of power state transitions in the DUT during test execution.
- **expected_rms_values** – Target RMS values for each identified execution phase (in milliamps).
- **tolerance_percentage** – Allowed deviation percentage from the expected RMS values.

Display capture The `display_capture` harness is used to verify display driver functionality by capturing and analyzing display output using a camera. It integrates with pytest to perform automated visual testing using video fingerprints.

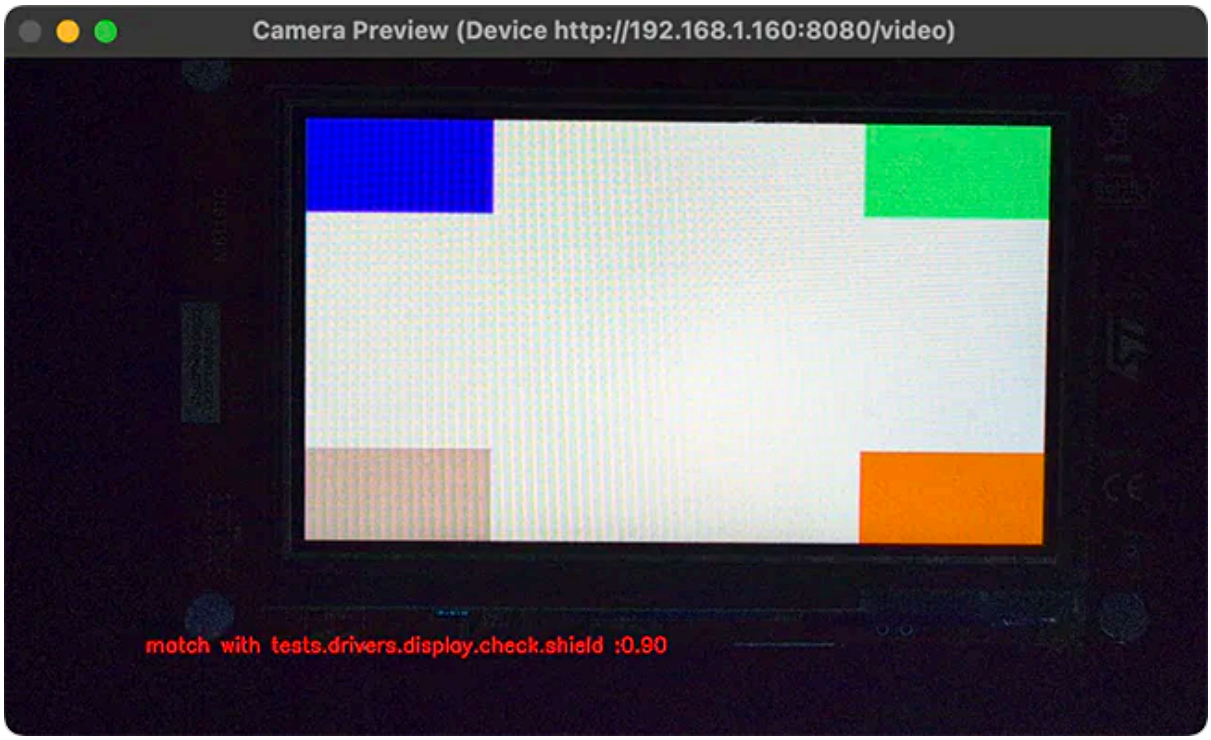

Fig. 5: Window being displayed for a “compare” run where fingerprint is a 90% match with the reference.

Hardware setup The display capture harness requires:

- UVC compatible camera with at least 2 megapixels (e.g., 1080p resolution)

- Light-blocking enclosure or black curtain to ensure consistent lighting
- PC host with camera connection for capturing display output
- DUT connected to the same PC for flashing and serial console access

Configuration The harness uses a YAML configuration file that defines camera settings, test parameters, and video signature analysis options. A typical configuration is shown below:

Listing 1: display_config.yaml

```yaml
case_config:
  device_id: 0
  res_x: 1280
  res_y: 720
  fps: 30
  run_time: 20
tests:
  timeout: 30
  prompt: "screen starts"
  expect: ["tests.drivers.display.check.shield"]
plugins:
  - name: signature
    module: plugins.signature_plugin
    class: VideoSignaturePlugin
    status: enable
    config:
      operations: "compare"  # or "generate"
      metadata:
        name: "tests.drivers.display.check.shield"
        platform: "frdm_mcxn947"
      directory: "./fingerprints"
      duration: 100
      method: "combined"
      threshold: 0.65
      phash_weight: 0.35
      dhash_weight: 0.25
      histogram_weight: 0.2
      edge_ratio_weight: 0.1
      gradient_hist_weight: 0.1
```

- `case_config` - This section defines to the general camera settings and duration of the test.
  - `device_id` - The camera device ID (defaults to 0). Any valid OpenCV camera identifier, which can be:
    - An integer for local cameras (use 0 for the first camera, 1 for the second, etc).
    - A device path string such as `/dev/video0` on Linux.
    - An IP video stream URL such as `rtsp://192.168.1.100:8554/stream` for network cameras.
  - `res_x` - The horizontal resolution of the camera (integer, defaults to 1280).
  - `res_y` - The vertical resolution of the camera (integer, defaults to 720).
  - `fps` - The frames per second of the camera (integer, defaults to 30).
  - `run_time` - The duration of the test in seconds (integer, defaults to 20).
- `test` - This section contains the test configuration for device interaction.

  - timeout - Maximum time in seconds to wait for the prompt to appear on the device UART output (integer, defaults to 30).
  - prompt - The string pattern to wait for in the device UART output before starting the display capture. This can be a regular expression (string, defaults to uart:~$).
  - expect - A list of expected test result strings that must match the results returned by the application. The test passes if the captured results match this list (list of strings, defaults to ['PASS']).

- plugins - This section contains the configuration for the plugins processing the camera frames. Only the VideoSignaturePlugin plugin is currently supported, and it takes the following configuration options:
  - operations - The operation to perform when running the test (string). Must be set to either generate to capture fingerprints or compare to compare the captured fingerprints with the reference fingerprints.
  - metadata - Metadata information for fingerprint identification (optional).
    * name - Test case name identifier (string).
    * platform - Target platform identifier (string).
  - directory - The directory where the fingerprints are stored (string, defaults to ./fingerprints).
  - duration - The number of frames to analyze (integer). More frames takes longer but generate more accurate fingerprints).
  - method - The method used to generate display fingerprints (string, defaults to combined). Must be set to either of the following values: phash, dhash, histogram, or combined.

    phash (Perceptual Hash)
    Captures overall visual structure and layout. Best for detecting major rendering issues, e.g. UI elements being positioned incorrectly.

    dhash (Difference Hash)
    Detects brightness patterns and gradients. Sensitive to contrast changes, e.g. brightness or contrast problems.

    histogram (Color Histogram)
    Analyzes color distribution. Fast at detecting obvious color problems, e.g. color swap bugs.

    combined (recommended method)
    Weights all methods together (see *method*_weight option below) for robust comparison. Provides balanced detection of both major and subtle visual issues.
  - threshold - The similarity score above which it is considered that there is a match between the reference and the captured fingerprints (optional float, defaults to 0.65).
  - phash_weight - The weight for the phash method (optional float, defaults to 0.35)
  - dhash_weight - The weight for the dhash method (optional float, defaults to 0.25)
  - histogram_weight - The weight for the histogram method (optional float, defaults to 0.2)
  - gradient_hist_weight - The weight for the gradient histogram method (optional float, defaults to 0.1)
  - edge_ratio_weight - The weight for the edge ratio method (optional float, defaults to 0.1)

The configuration file path is specified in the test's testcase.yaml via the display_capture_config harness configuration option using the DISPLAY_TEST_DIR environment variable:

```
harness: display_capture
harness_config:
  pytest_dut_scope: session
  fixture: fixture_display
  display_capture_config: "${DISPLAY_TEST_DIR}/display_config.yaml"
```

Workflow First, generate **reference fingerprints** for a known-good display output:

```
# Build and flash the display test
west build -b <board> tests/drivers/display/display_check
west flash

# Configure for fingerprint generation mode by setting the 'operations' field to
↪'generate'
# in the configuration file.

# Generate fingerprints
export DISPLAY_TEST_DIR=<path-to-config-directory>
scripts/twister --device-testing --hardware-map map.yml \
    -T tests/drivers/display/display_check/
```

Fingerprints are stored in the directory specified in the `directory` field of the configuration file, and organized by test name and platform as defined in the `metadata` field of the configuration file.

Once the fingerprints have been generated, you can run the test(s) again, this time in **comparison mode**:

```
# Set the 'operations' field to 'compare' in the configuration file.

export DISPLAY_TEST_DIR=<path-to-fingerprints-parent-directory>
scripts/twister --device-testing --hardware-map map.yml \
    -T tests/drivers/display/display_check/
```

The harness compares captured video against reference fingerprints using the configured signature methods and thresholds. If the similarity score between reference and captured fingerprints exceeds the configured `threshold`, the test passes.

Note

- The test name in the DUT's `testcase.yaml` must match the `name` field in the fingerprint's metadata configuration.
- Multiple fingerprints can be stored in one directory for comprehensive validation, though this increases comparison time.
- Fingerprints are specific to both the test scenario and platform.

Bsim Harness `bsim` is implemented in limited way - it helps only to copy the final executable (`zephyr.exe`) from build directory to BabbleSim's `bin` directory (`${BSIM_OUT_PATH}/bin`).

This action is useful to allow BabbleSim's tests to directly run after. By default, the executable file name is (with dots and slashes replaced by underscores): `bs_<platform_name>_<test_path>_<test_scenario_name>`. This name can be overridden with the `bsim_exe_name` option in `harness_config` section.

bsim_exe_name: <string>
If provided, the executable filename when copying to BabbleSim's bin directory, will be

bs_<platform_name>_<bsim_exe_name> instead of the default based on the test path and scenario name.

Shell The shell harness is used to execute shell commands and parse the output and utilizes the pytest framework and the pytest harness of twister.

The following options apply to the shell harness:

shell_commands: <list of pairs of commands and their expected output> (default empty)
Specify a list of shell commands to be executed and their expected output. For example:

```
harness_config:
  shell_commands:
  - command: "kernel cycles"
    expected: "cycles: .* hw cycles"
  - command: "kernel version"
    expected: "Zephyr version .*"
  - command: "kernel sleep 100"
```

If expected output is not provided, the command will be executed and the output will be logged.

shell_commands_file: <string> (default empty)
Specify a file containing test parameters to be used in the test. The file should contain a list of commands and their expected output. For example:

```
- command: "mpu mtest 1"
  expected: "The value is: 0x.*"
- command: "mpu mtest 2"
  expected: "The value is: 0x.*"
```

If no file is specified, the shell harness will use the default file `test_shell.yml` in the test directory. `shell_commands` will take precedence over `shell_commands_file`.

Selecting platform scope

One of the key features of Twister is its ability to decide on which platforms a given test scenario should run. This behavior has its roots in Twister being developed as a test runner for Zephyr's CI. With hundreds of available platforms and thousands of tests, the testing tools should be able to adapt the scope and select/filter out what is relevant and what is not.

Twister always prepares an initial list of platforms in scope for a given test, based on command line arguments and the *test's configuration*. Then, platforms that don't fulfill the conditions required in the configuration yaml (e.g. minimum ram) are filtered out from the scope. Using `--force-platform` allows to override filtering caused by `platform_allow`, `platform_exclude`, `arch_allow` and `arch_exclude` keys in test configuration files.

Command line arguments define the initial scope in the following way:

- `-p/--platform <platform_name>` (can be used multiple times): only platforms passed with this argument;
- `-l/--all`: all available platforms;
- `-G/--integration`: all platforms from an `integration_platforms` list in a given test configuration file. If a test has no `integration_platforms` *"scope presumption"* will happen;
- No scope argument: *"scope presumption"* will happen.

"Scope presumption": A list of Twister's *default platforms* is used as the initial list. If nothing is left after the filtration, the `platform_allow` list is used as the initial scope.

Managing tests timeouts

There are several parameters which control tests timeouts on various levels:

- `timeout` option in each test scenario. See *here* for more details.
- `timeout_multiplier` option in board configuration. See *here* for more details.
- `--timeout-multiplier` twister option which can be used to adjust timeouts in exact twister run. It can be useful in case of simulation platform as simulation time may depend on the host speed & load or we may select different simulation method (i.e. cycle accurate but slower one), etc...

Overall test scenario timeout is a multiplication of these three parameters.

Running in Integration Mode

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the `--integration` option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the test configuration file (`testcase.yaml` and `sample.yaml`).

Running tests on custom emulator

Apart from the already supported QEMU and other simulated environments, Twister supports running any out-of-tree custom emulator defined in the board's `board.cmake`. To use this type of simulation, add the following properties to `custom_board/custom_board.yaml`:

```
simulation:
  - name: custom
    exec: <name_of_emu_binary>
```

This tells Twister that the board is using a custom emulator called `<name_of_emu_binary>`, make sure this binary exists in the PATH.

Then, in `custom_board/board.cmake`, set the supported emulation platforms to `custom`:

```
set(SUPPORTED_EMU_PLATFORMS custom)
```

Finally, implement the `run_custom` target in `custom_board/board.cmake`. It should look something like this:

```
add_custom_target(run_custom
  COMMAND
  <name_of_emu_binary to invoke during 'run'>
  <any args to be passed to the command, i.e. ${BOARD}, ${APPLICATION_BINARY_DIR}/
↪zephyr/zephyr.elf>
  WORKING_DIRECTORY ${APPLICATION_BINARY_DIR}
  DEPENDS ${logical_target_for_zephyr_elf}
  USES_TERMINAL
  )
```

Running Tests on Hardware

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.

Executing tests on a single device To use this feature on a single connected device, run twister with the following new options:

Linux

```
scripts/twister --device-testing --device-serial /dev/ttyACM0 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

Windows

```
python .\scripts\twister --device-testing --device-serial COM1 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

The `--device-serial` option denotes the serial device the board is connected to. This needs to be accessible by the user running twister. You can run this on only one board at a time, specified using the `--platform` option. If the platform supports multiple serial ports, you can provide `--device-serial` multiple times, and it will be passed to the pytest harness. Alternatively you can use the hardware map, see *multi-core testing* for more details

The `--device-serial-baud` option is only needed if your device does not run at 115200 baud.

To support devices without a physical serial port, use the `--device-serial-pty` option. In this cases, log messages are captured for example using a script. In this case you can run twister with the following options:

Linux

```
scripts/twister --device-testing --device-serial-pty "script.py" \
-p intel_adsp/cavs25 -T tests/kernel
```

Windows

Note

Not supported on Windows OS

The script is user-defined and handles delivering the messages which can be used by twister to determine the test execution status.

The `--device-flash-timeout` option allows to set explicit timeout on the device flash operation, for example when device flashing takes significantly large time.

The `--device-flash-with-test` option indicates that on the platform the flash operation also executes a test scenario, so the flash timeout is increased by a test scenario timeout.

Executing tests on multiple devices To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details such as the serial device, baud and their IDs if available. Run the following command to produce the hardware map:

Linux

```
./scripts/twister --generate-hardware-map map.yml
```

Windows

```
python .\scripts\twister --generate-hardware-map map.yml
```

The generated hardware map file (map.yml) will have the list of connected devices, for example:

Linux

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: 000683759358
  platform: unknown
  product: J-Link
  runner: unknown
  serial: /dev/cu.usbmodem0006837593581
```

Windows

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM1
- connected: true
  id: 000683759358
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM2
```

Any options marked as `unknown` need to be changed and set with the correct values, in the above example the platform names, the products and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a reel_board and an nrf52840dk/nrf52840:

Linux

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
  baud: 9600
```

Windows

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: COM1
```

(continues on next page)

(continued from previous page)

```
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: COM2
  baud: 9600
```

The baud entry is only needed if not running at 115200.

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map

Linux

```
./scripts/twister --device-testing --hardware-map map.yml -T samples/hello_world/
```

Windows

```
python .\scripts\twister --device-testing --hardware-map map.yml -T␣
↪samples\hello_world
```

The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

Note

Currently only boards with support for pyocd, nrfjprog, jlink, openocd, or dediprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

Hardware map allows to set `--device-flash-timeout` and `--device-flash-with-test` command line options as `flash-timeout` and `flash-with-test` fields respectively. These hardware map values override command line options for the particular platform.

Serial PTY support using `--device-serial-pty` can also be used in the hardware map:

```
- connected: true
  id: None
  platform: intel_adsp/cavs25
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
```

The runner_params field indicates the parameters you want to pass to the west runner. For some boards the west runner needs some extra parameters to work. It is equivalent to following west and twister commands.

Linux

```
west flash --remote-host remote_host_ip_addr --key /path/to/key.pem

twister -p intel_adsp/cavs25 --device-testing --device-serial-pty script.py
--west-flash="--remote-host=remote_host_ip_addr,--key=/path/to/key.pem"
```

Windows

Note

Not supported on Windows OS

Note

For serial PTY, the "–generate-hardware-map" option cannot scan it out and generate a correct hardware map automatically. You have to edit it manually according to above example. This is because the serial port of the PTY is not fixed and being allocated in the system at runtime.

If west is not available or does not know how to flash your system, a custom flash command can be specified using the `flash-command` flag. The script is called with a `--build-dir` with the path of the current build, as well as a `--board-id` flag to identify the specific device when multiple are available in a hardware map.

Linux

```
twister -p npcx9m6f_evb --device-testing --device-serial /dev/ttyACM0
--flash-command './custom_flash_script.py,--flag,"complex, argument"'
```

Windows

Note

python .scriptstwister -p npcx9m6f_evb –device-testing –device-serial COM1 –flash-command 'custom_flash_script.py,–flag,"complex, argument"'

Would result in calling `./custom_flash_script.py --build-dir <build directory> --board-id <board identification> --flag "complex, argument"`.

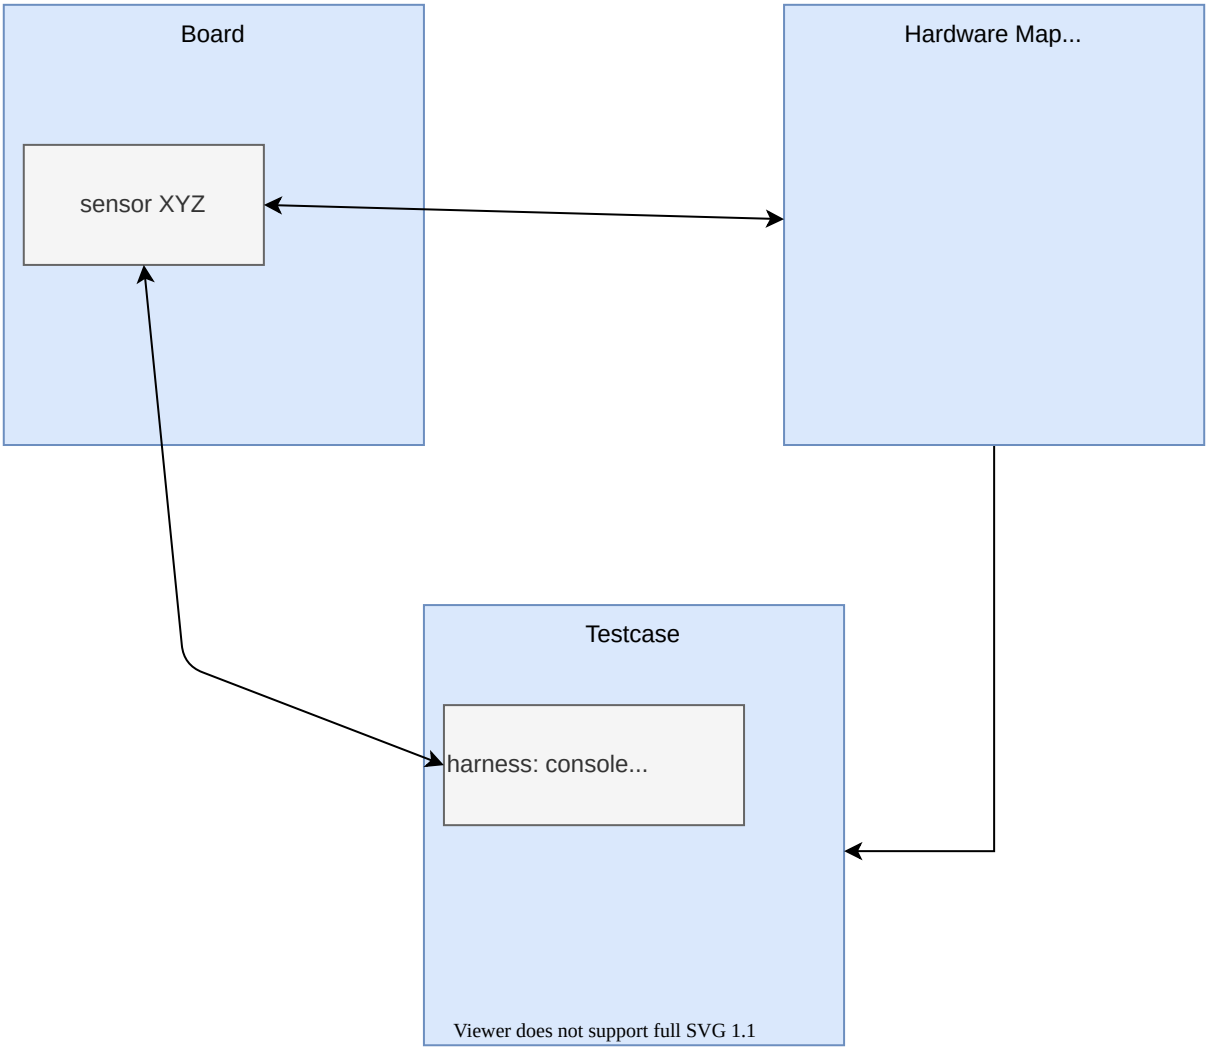
Fixtures Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A test scenario can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:

```
- connected: true
  fixtures:
    - gpio_loopback
  id: 0240000026334e450015400f5e0e000b4eb1000097969900
  platform: frdm_k64f
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/ttyACM9
```

When running `twister` with `--device-testing`, the configured fixture in the hardware map file will be matched to test scenarios requesting the same fixtures and these tests will be executed

on the boards that provide this fixture.



Fixtures can also be provided via twister command option `--fixture`, this option can be used multiple times and all given fixtures will be appended as a list. And the given fixtures will be assigned to all boards, this means that all boards set by current twister command can run those test scenarios which request the same fixtures.

Some fixtures allow for configuration strings to be appended, separated from the fixture name by a `:`. Only the fixture name is matched against the fixtures requested by test scenarios.

Notes It may be useful to annotate board descriptions in the hardware map file with additional information. Use the `notes` keyword to do this. For example:

```
- connected: false
  fixtures:
    - gpio_loopback
  id: 000683290670
  notes: An nrf5340dk/nrf5340 is detected as an nrf52840dk/nrf52840 with no serial
    port, and three serial ports with an unknown platform.  The board id of the␣
↪serial
    ports is not the same as the board id of the development kit.  If you␣
↪regenerate
    this file you will need to update serial to reference the third port, and␣
↪platform
```

(continues on next page)

(continued from previous page)

```
    to nrf5340dk/nrf5340/cpuapp or another supported board target.
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: jlink
  serial: null
```

Overriding Board Identifier When (re-)generated the hardware map file will contain an `id` keyword that serves as the argument to `--board-id` when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The `probe_id` keyword overrides the `id` keyword for this purpose. For example:

```
- connected: false
  id: 0229000005d9ebc60000000000000000000000000097969905
  platform: mimxrt1060_evk
  probe_id: 000609301751
  product: DAPLink CMSIS-DAP
  runner: jlink
  serial: null
```

Using Single Board For Multiple Variants

The `platform` attribute can be a list of names or a string with names separated by spaces. This allows to run tests for different platform variants on the same physical board, without re-configuring the hardware map file for each variant. For example:

```
- connected: true
  id: '001234567890'
  platform:
  - nrf5340dk/nrf5340/cpuapp
  - nrf5340dk/nrf5340/cpuapp/ns
  product: J-Link
  runner: nrfjprog
  serial: /dev/ttyACM1
```

Multi-Core testing support Twister supports testing multi-core applications where different cores use separate UART interfaces. This feature works only with the pytest harness (`harness: pytest`). Generated hardware map should contain multiple entries for the same physical device, each representing a different core connection. For example:

```
- connected: true
  id: 001234567890
  serial: /dev/ttyACM0
- connected: true
  id: 001234567890
  platform:
  - nrf54l15dk/nrf54l15/cpuapp
  product: J-Link
  runner: nrfutil
  serial: /dev/ttyACM1
```

Both instances share the same device ID but have different serial ports, allowing tests to interact with multiple cores simultaneously. Each connection is handled independently with separate log files.

Quarantine Twister allows user to provide configuration files defining a list of tests or platforms to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument `--quarantine-list <PATH_TO_QUARANTINE_YAML>` to a twister call. Multiple quarantine files can be used. The current status of tests on the quarantine list can also be verified by adding `--quarantine-verify` to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml is a sequence of dictionaries. Each dictionary must have at least one of the following keys: `scenarios`, `platforms`, `architectures` or `simulations`. A combination of these entries is allowed. An optional `comment` entry can be used to provide more details (e.g., a link to a reported issue). These comments will also be added to the output reports.

When quarantining a class of tests or many scenarios in a single testsuite or when dealing with multiple issues within a subsystem, it is possible to use regular expressions, for example, **kernel.*** would quarantine all kernel tests.

An example of entries in a quarantine yaml:

```
- scenarios:
    - sample.basic.helloworld
  comment: "Link to the issue:␣
↪https://github.com/zephyrproject-rtos/zephyr/pull/33287"

- scenarios:
    - kernel.common
    - kernel.common.(misra|tls)
    - kernel.common.nano64
  platforms:
    - .*_cortex_.*
    - native_sim

- platforms:
    - qemu_x86
  comment: "filter out qemu_x86"

- architectures:
    - riscv

- simulations:
    - armfvp
```

Test Configuration

A test configuration can be used to customize various aspects of twister and the default enabled options and features. This allows tweaking the filtering capabilities depending on the environment and makes it possible to adapt and improve coverage when targeting different sets of platforms.

The test configuration also adds support for test levels and the ability to assign a specific test to one or more levels. Using command line options of twister it is then possible to select a level and just execute the tests included in this level.

Additionally, the test configuration allows defining level dependencies and additional inclusion of tests into a specific level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels

easier.

To help with testing outside of upstream CI infrastructure, additional options are available in the configuration file, which can be hosted locally. As of now, those options are available:

- Ability to ignore default platforms as defined in board definitions (Those are mostly emulation platforms used to run tests in upstream CI)
- Option to specify your own list of default platforms overriding what upstream defines.
- Ability to override `build_on_all` options used in some test scenarios. This will treat tests or sample as any other just build for default platforms you specify in the configuration file or on the command line.
- Ignore some logic in twister to expand platform coverage in cases where default platforms are not in scope.

Platform Configuration The following options control platform filtering in twister:

- `override_default_platforms`: override default key a platform sets in board configuration and instead use the list of platforms provided in the configuration file as the list of default platforms. This option is set to False by default.
- `increased_platform_scope`: This option is set to True by default, when disabled, twister will not increase platform coverage automatically and will only build and run tests on the specified platforms.
- `default_platforms`: A list of additional default platforms to add. This list can either be used to replace the existing default platforms or can extend it depending on the value of `override_default_platforms`.

And example platforms configuration:

```
platforms:
  override_default_platforms: true
  increased_platform_scope: false
  default_platforms:
    - qemu_x86
```

Test Level Configuration The test configuration allows defining test levels, level dependencies and additional inclusion of tests into a specific test level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels simple.

And example test level configuration:

```
levels:
  - name: my-test-level
    description: >
      my custom test level
    adds:
      - kernel.threads.*
      - kernel.timer.behavior
      - arch.interrupt
      - boards.*
```

Combined configuration To mix the Platform and level configuration, you can take an example as below:

An example platforms plus level configuration:

```
platforms:
  override_default_platforms: true
  default_platforms:
    - frdm_k64f
levels:
  - name: smoke
    description: >
        A plan to be used verifying basic zephyr features.
  - name: unit
    description: >
        A plan to be used verifying unit test.
  - name: integration
    description: >
        A plan to be used verifying integration.
  - name: acceptance
    description: >
        A plan to be used verifying acceptance.
  - name: system
    description: >
        A plan to be used verifying system.
  - name: regression
    description: >
        A plan to be used verifying regression.
```

To run with above test_config.yaml file, only default_platforms with given test level test scenarios will run.

Linux

```
scripts/twister --test-config=<path to>/test_config.yaml
 -T tests --level="smoke"
```

Running in Tests in Random Order

Enable ZTEST framework's `CONFIG_ZTEST_SHUFFLE` config option to run your tests in random order. This can be beneficial for identifying dependencies between test cases. For native_sim platforms, you can provide the seed to the random number generator by providing `-seed=value` as an argument to twister. See *Shuffling Test Sequence* for more details.

Robot Framework Tests

Zephyr supports Robot Framework as one of solutions for automated testing.

Robot files allow you to express interactive test scenarios in human-readable text format and execute them in simulation or against hardware. At this moment Zephyr integration supports running Robot tests in the Renode simulation framework.

To execute a Robot test suite with twister, run the following command:

Linux

```
$ ./scripts/twister --platform hifive1 --test␣
↪samples/subsys/shell/shell_module/sample.shell.shell_module.robot
```

Windows

```
python .\scripts\twister --platform hifive1 --test␣
↪samples/subsys/shell/shell_module/sample.shell.shell_module.robot
```

Writing Robot tests For the list of keywords provided by the Robot Framework itself, refer to the official Robot documentation.

Information on writing and running Robot Framework tests in Renode can be found in the testing section of Renode documentation. It provides a list of the most commonly used keywords together with links to the source code where those are defined.

It's possible to extend the framework by adding new keywords expressed directly in Robot test suite files, as an external Python library or, like Renode does it, dynamically via XML-RPC. For details see the extending Robot Framework section in the official Robot documentation.

Running a single testsuite To run a single testsuite instead of a whole group of test you can run:

```
$ twister -p qemu_riscv32 -s tests/kernel/interrupt/arch.shared_interrupt
```

2.12.3 Twister Status

What is a Twister Status?

Twister Status formulates the current state of

- `Harness`
- `TestCase`
- `TestSuite`
- `TestInstance`

in a comprehensive and easy-to understand way. In practice, most users will be interested in Statuses of Instances and Cases after the conclusion of their Twister runs.

Tip

Nomenclature reminder:

`Harness`

`Harness` is a Python class inside Twister that allows us to capture and analyse output from a program external to Twister. It has been excised from this page for clarity, as it does not appear in final reports.

`TestCase`

`TestCase`, also called Case, is a piece of code that aims to verify some assertion. It is the smallest subdivision of testing in Zephyr.

`TestSuite`

`TestSuite`, also called Suite, is a grouping of Cases. One can modify Twister's behaviour on a per-Suite basis via `testcase.yaml` files. Such grouped Cases should have enough in common for it to make sense to treat them all the same by Twister.

`TestInstance`

`TestInstance`, also called Instance, is a Suite on some platform. Twister typically reports its results for Instances, despite them being called "Suites" there. If a status is marked as applicable for Suites, it is also applicable for Instances. As the distinction between them is not useful in this section, whenever you read "Suite", assume the same for Instances.

More detailed explanation can be found *here*.

Possible Twister Statuses

Table 6: Twister Statuses

In-code	In-text	Description	Suite	Case
FILTER	filtered	A static or runtime filter has eliminated the test from the list of tests to use.	✓	✓
NOTRUN	not run	The test wasn't run because it was not runnable in current configuration. It was, however, built correctly.	✓	✓
BLOCK	blocked	The test was not run because of an error or crash in the test suite.	×	✓
SKIP	skipped	Test was skipped by some other reason than previously delineated.	✓	✓
ERROR	error	The test produced an error in running the test itself.	✓	✓
FAIL	failed	The test produced results different than expected.	✓	✓
PASS	passed	The test produced results as expected.	✓	✓

In-code and **In-text** are the naming contexts of a given status: the former is rather internal for Twister and appears in logs, whereas the latter is used in the JSON reports.

Note

There are two more Statuses that are internal to Twister. `NONE` (A starting status for Cases and Suites) and `STARTED` (Indicating an in-progress Case). Those should not appear in the final Twister report. Appearance of those non-terminal Statuses in one's report files indicates a problem with Twister.

Case and Suite Status combinations

Table 7: Case and Suite Status combinations

Case\Suite	FILTER	ERROR	FAIL	PASS	NOTRUN	SKIP
FILTER	✓	×	×	×	×	×
ERROR	×	✓	×	×	×	×
BLOCK	×	✓	✓	×	×	×
FAIL	×	✓	✓	×	×	×
PASS	×	✓	✓	✓	×	×
NOTRUN	×	×	×	×	✓	×
SKIP	×	✓	✓	✓	×	✓

× indicates that such a combination should not happen in a proper Twister run. In other words, no Suite of a status indicated by the table column should contain any Cases of a status indicated by the table row.

✓ indicates a proper combination.

Detailed explanation, per Suite Status

`FILTER`:
: This status indicates that the whole Suite has been statically filtered out of a given Twister run. Thus, any Case within it should also have such a status.

`ERROR`:
: Suite encountered a problem when running the test. It requires at least one case with `ERROR`

or BLOCK status. As this takes precedence over all other Case statuses, all valid terminal Case statuses can be within such a Suite.

FAIL:
: Suite has at least one Case that did not meet its assertions. This takes precedence over all other Case statuses, given that the conditions for an ERROR status have not been met.

PASS:
: Suite has passed properly. It cannot contain any Cases with BLOCK, ERROR, or FAIL statuses, as those indicate a problem when running the Suite.

NOTRUN:
: Whole suite was not run, but only built. It requires than all Cases within were not run. As runnability is decided on a per-Suite basis, only NOTRUN is applicable for its Cases.

SKIP:
: Whole Suite has been skipped at runtime. All Cases need to have SKIP status as well.

2.12.4 Twister blackbox tests

This guide aims to explain the structure of a test file so the reader will be able to understand existing files and create their own. All developers should fix any tests they break and create new ones when introducing new features, so this knowledge is important for any Twister developer.

Basics

Twister blackbox tests are written in python, using the pytest library. Read up on it *here* . Auxiliary test data follows whichever format it was in originally. Tests and data are wholly contained in the scripts/tests/twister_blackbox directory and prepended with test_.

Blackbox tests should not be aware of the internal twister code. Instead, they should call twister as user would and check the results.

Sample test file

```
#!/usr/bin/env python3
# Copyright (c) 2024 Intel Corporation
#
# SPDX-License-Identifier: Apache-2.0

import importlib
import json
import os
import sys

↪strict=False)
                for val in pair
            ]
        )

        # First, provide the args variable as our Twister command line arguments.
        # Then, catch the exit code in the sys_exit variable.
        with mock.patch.object(sys, "argv", [sys.argv[0]] + args), pytest.raises(
            SystemExit
        ) as sys_exit:
            # Execute the Twister call itself.
            self.loader.exec_module(self.twister_module)

        # Check whether the Twister call succeeded
        assert str(sys_exit.value) == "0"

        # Access to the test file output
        with open(os.path.join(out_path, "testplan.json")) as f:
            j = json.load(f)
        filtered_j = [
```

(continues on next page)

(continued from previous page)

```
            (ts["platform"], ts["name"], tc["identifier"])
            for ts in j["testsuites"]
            for tc in ts["testcases"]
            if "reason" not in tc
        ]

        # Read stdout and stderr to out and err variables respectively
        out, err = capfd.readouterr()
        # Rewrite the captured buffers to stdout and stderr so the user can still␣
↪read them
        sys.stdout.write(out)
        sys.stderr.write(err)

        # Test-relevant checks
        assert expected_tests == len(filtered_j)
```

Comparison with CLI

Test above runs the command

```
twister -i --outdir $OUTDIR -T $TEST_DATA/tests -y --level $LEVEL
--test-config $TEST_DATA/test_config.yaml -p qemu_x86 -p frdm_k64f
```

It presumes a CLI with the `zephyr-env.sh` or `zephyr-env.cmd` already run.

Such a test provides us with all the outputs we typically expect of a Twister run thanks to `importlib`'s `exec_module()`[1] . We can easily set up all flags that we expect from a Twister call via `args` variable[2] . We can check the standard output or stderr in `out` and `err` variables.

Beside the standard outputs, we can also investigate the file outputs, normally placed in `twister-out` directories. Most of the time, we will use the `out_path` fixture in conjunction with `--outdir` flag (L52) to keep test-generated files in temporary directories. Typical files read in blackbox tests are `testplan.json` , `twister.xml` and `twister.log` .

Other functionalities

Decorators

- **`@pytest.mark.usefixtures('clear_log')`**
  - allows us to use `clear_log` fixture from `conftest.py` . The fixture is to become `autouse` in the future. After that, this decorator can be removed.
- **`@pytest.mark.parametrize('level, expected_tests', TESTDATA_X, ids=['smoke', 'acceptance'])`**
  - this is an example of `pytest`'s test parametrization. Read up on it here. TESTDATAs are most often declared as class fields.
- **`@mock.patch.object(TestPlan, 'TESTSUITE_FILENAME', suite_filename_mock)`**
  - this decorator allows us to use only tests defined in the `test_data` and ignore the Zephyr testcases in the `tests` directory. **Note that all "test_data" tests use `test_data.yaml` as a filename, not `testcase.yaml` !** Read up on the `mock` library here.

[1] Take note of the `setup_class()` class function, which allows us to run `twister` python file as if it were called directly (bypassing the `__name__ == '__main__'` check).

[2] We advise you to keep the first section of `args` definition intact in almost all of your tests, as it is used for the common test setup.

Fixtures Blackbox tests use `pytest` 's fixtures, further reading on which is available here.

If you would like to add your own fixtures, consider whether they will be used in just one test file, or in many.

- If in many, create such a fixture in the scripts/tests/twister_blackbox/conftest.py file.
  - scripts/tests/twister_blackbox/conftest.py already contains some fixtures - take a look there for an example.
- If in just one, declare it in that file.
  - Consider using class fields instead - look at TESTDATAs for an example.

How do I...

Call Twister multiple times in one test? Sometimes we want to test something that requires prior Twister use. `--test-only` flag would be a typical example, as it is to be coupled with previous `--build-only` Twister call. How should we approach that?

If we just call the `importlib` 's `exec_module` two times, we will experience log duplication. `twister.log` will duplicate every line (triplicate if we call it three times, etc.) instead of overwriting the log or appending to the end of it.

It is caused by the use of logger module variables in the Twister files. Thus us executing the module again causes the loggers to have multiple handles.

To overcome this, between the calls you ought to use

```
capfd.readouterr()   # To remove output from the buffer
                     # Note that if you want output from all runs after each other,
                     # skip this line.
clear_log_in_test()  # To remove log duplication
```

2.12.5 Integration with pytest test framework

Please mind that integration of twister with pytest is still work in progress. Not every platform type is supported in pytest (yet). If you find any issue with the integration or have an idea for an improvement, please, let us know about it and open a GitHub issue/enhancement.

Introduction

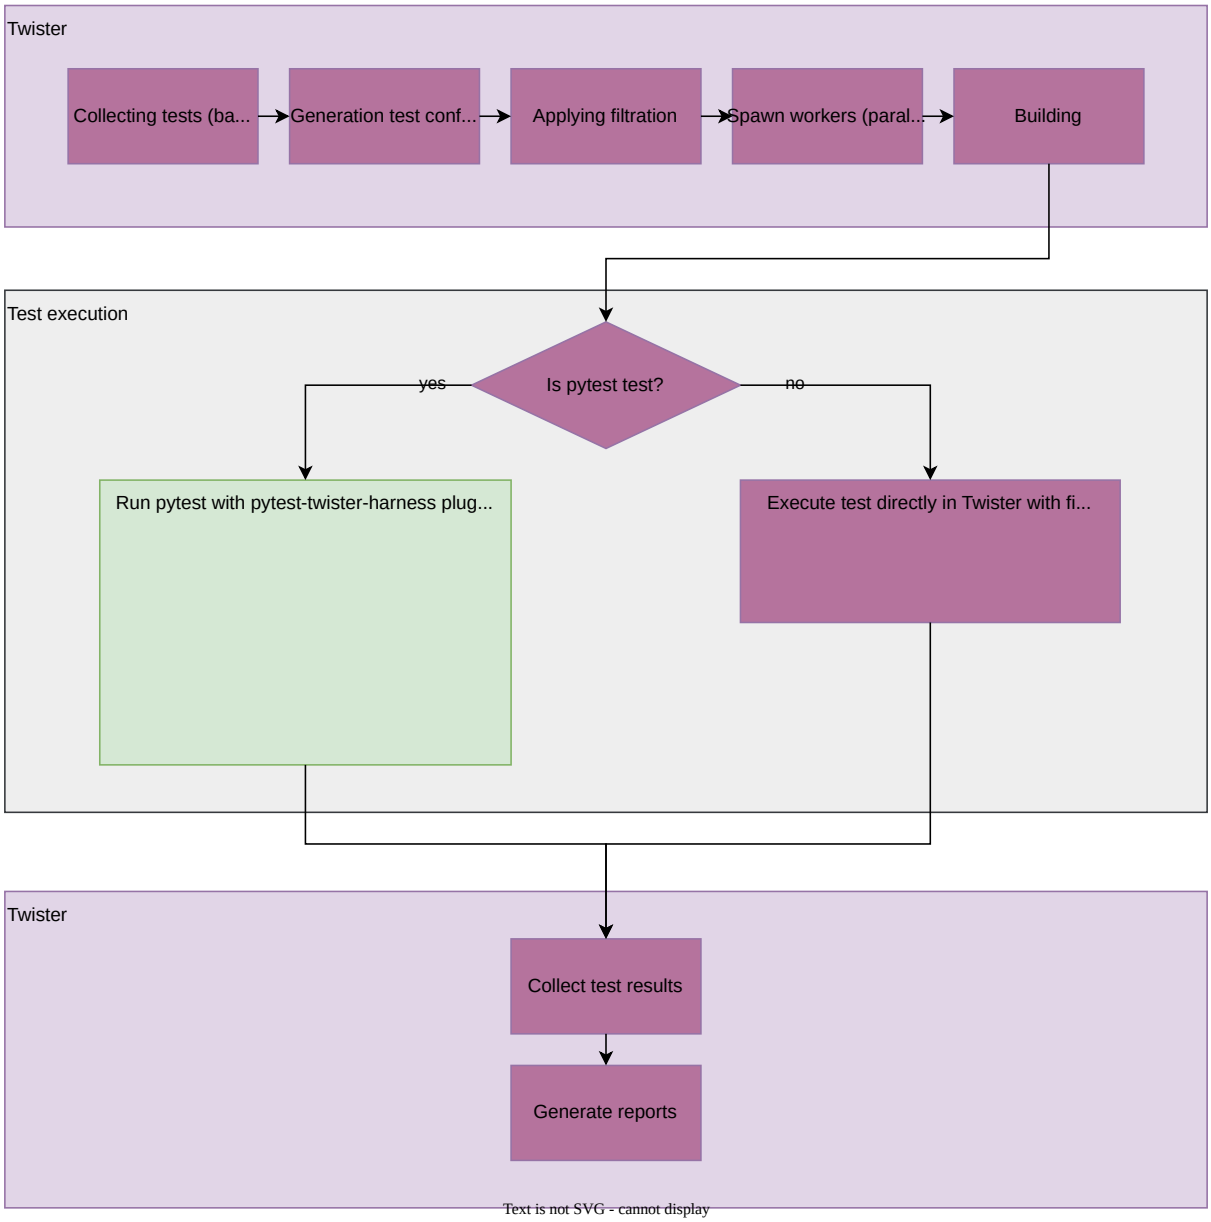
Pytest is a python framework that *"makes it easy to write small, readable tests, and can scale to support complex functional testing for applications and libraries"* (https://docs.pytest.org/en/7.3.x/). Python is known for its free libraries and ease of using it for scripting. In addition, pytest utilizes the concept of plugins and fixtures, increasing its expendability and reusability. A pytest plugin `pytest-twister-harness` was introduced to provide an integration between pytest and twister, allowing Zephyr's community to utilize pytest functionality with keeping twister as the main framework.

Integration with twister

By default, there is nothing to be done to enable pytest support in twister. The plugin is developed as a part of Zephyr's tree. To enable install-less operation, twister first extends `PYTHONPATH` with path to this plugin, and then during pytest call, it appends the command with `-p twister_harness.plugin` argument. If one prefers to use the installed version of the plugin, they must add `--allow-installed-plugin` flag to twister's call.

Pytest-based test suites are discovered the same way as other twister tests, i.e., by a presence of test/sample.yaml. Inside, a keyword `harness` tells twister how to handle a given test. In the case

of `harness: pytest`, most of twister workflow (test suites discovery, parallelization, building and reporting) remains the same as for other harnesses. The change happens during the execution step. The below picture presents a simplified overview of the integration.



If `harness: pytest` is used, twister delegates the test execution to pytest, by calling it as a subprocess. Required parameters (such as build directory, device to be used, etc.) are passed through a YAML configuration file. When pytest is done, twister looks for a pytest report (results.xml) and sets the test result accordingly.

How to create a pytest test

An example folder containing a pytest test, application source code and Twister configuration .yaml file can look like the following:

```
test_foo/
├── pytest/
│   └── test_foo.py
├── src/
```

(continues on next page)

(continued from previous page)

```
|    └── main.c
├── CMakeList.txt
├── prj.conf
└── testcase.yaml
```

An example of a pytest test is given at samples/subsys/testsuite/pytest/shell/pytest/test_shell.py. Using the configuration provided in the `testcase.yaml` file, Twister builds the application from `src` and then, if the .yaml file contains a `harness: pytest` entry, it calls pytest in a separate subprocess. A sample configuration file may look like this:

```
tests:
  some.foo.test:
    harness: pytest
    tags: foo
```

By default, pytest tries to look for tests in a `pytest` directory located next to a directory with binary sources. A keyword `pytest_root` placed under `harness_config` section in .yaml file can be used to point to other files, directories or subtests (more info *here*).

Pytest scans the given locations looking for tests, following its default discovery rules.

Passing extra arguments There are two ways for passing extra arguments to the called pytest subprocess:

1. From .yaml file, using `pytest_args` placed under `harness_config` section - more info *here*.
2. Through Twister command line interface as `--pytest-args` argument. This can be particularly useful when one wants to select a specific testcase from a test suite. For instance, one can use a command:

   ```
   $ ./scripts/twister --platform native_sim -T␣
   ↪samples/subsys/testsuite/pytest/shell \
   -s samples/subsys/testsuite/pytest/shell/sample.pytest.shell \
   --pytest-args='-k test_shell_print_version'
   ```

   The command line arguments will extend those from the .yaml file. If the same argument is present in both places, the one from the command line will take precedence.

Fixtures

dut Give access to a *DeviceAdapter* type object, that represents Device Under Test. This fixture is the core of pytest harness plugin. It is required to launch DUT (initialize logging, flash device, connect serial etc). This fixture yields a device prepared according to the requested type (`native`, `qemu`, `hardware`, etc.). All types of devices share the same API. This allows for writing tests which are device-type-agnostic. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import DeviceAdapter

def test_sample(dut: DeviceAdapter):
    dut.readlines_until(regex='Hello world')
```

shell Provide a *Shell* class object with methods used to interact with shell application. It calls `wait_for_promt` method, to not start scenario until DUT is ready. The shell fixture calls `dut` fixture, hence has access to all its methods. The `shell` fixture adds methods optimized for interactions with a shell. It can be used instead of `dut` for tests. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import Shell

def test_shell(shell: Shell):
   shell.exec_command('help')
```

mcumgr Sample fixture to wrap `mcumgr` command-line tool used to manage remote devices. More information about MCUmgr can be found here *MCUmgr*.

> **Note**
>
> This fixture requires the `mcumgr` available in the system PATH

Only selected functionality of MCUmgr is wrapped by this fixture. For example, here is a test with a fixture `mcumgr`

```
from twister_harness import DeviceAdapter, Shell, McuMgr

def test_upgrade(dut: DeviceAdapter, shell: Shell, mcumgr: McuMgr):
   # free the serial port for mcumgr
   dut.disconnect()
   # upload the signed image
   mcumgr.image_upload('path/to/zephyr.signed.bin')
   # obtain the hash of uploaded image from the device
   second_hash = mcumgr.get_hash_to_test()
   # test a new upgrade image
   mcumgr.image_test(second_hash)
   # reset the device remotely
   mcumgr.reset_device()
   # continue test scenario, check version etc.
```

unlaunched_dut Similar to the `dut` fixture, but it does not initialize the device. It can be used when a finer control over the build process is needed. It becomes responsibility of the test to initialize the device.

```
from twister_harness import DeviceAdapter

def test_sample(unlaunched_dut: DeviceAdapter):
   unlaunched_dut.launch()
   unlaunched_dut.readlines_until(regex='Hello world')
```

Classes

DeviceAdapter

`class` twister_harness.**DeviceAdapter**(*device_config: DeviceConfig*)

This class defines a common interface for all device types (hardware, simulator, QEMU) used in tests to gathering device output and send data to it.

`launch`() → None

Launch the test application on the target device.

This method performs the complete device initialization sequence:

- Close any previously running application (cleanup)
- Generate the execution command if not already set
- Add any extra test arguments to the command

- Start reader threads to capture device output
- Launch the application (flash for hardware, execute for simulators)

The launch process varies by device type:

- Hardware devices: Flash the application and establish serial communication. May connect before or after flashing depending on device configuration.
- QEMU/simulators: Start subprocess and establish FIFO/pipe communication
- Native simulators: Execute binary and connect via process pipes

`close`() → None

Disconnect, close device and close reader threads.

`readline`(*connection_index: int = 0*, ***kwargs*) → str

Read a single line from device output.

Parameters

- `connection_index` – Connection port to read from (0=main UART, 1=second core, etc.)
- `kwargs` – Additional keyword arguments (timeout, print_output)

Returns

Single line of text without trailing newlines

`readlines`(*connection_index: int = 0*, ***kwargs*) → list[str]

Read all available output lines produced by device from internal buffer.

`readlines_until`(*connection_index: int = 0*, ***kwargs*) → list[str]

Read lines from device output until a specific condition is met.

This method provides flexible ways to collect device output: wait for a specific pattern, collect a fixed number of lines, or get all currently available lines.

Parameters

- `connection_index` – Index of the connection/port to read from (default: 0). For hardware devices: 0 = main UART, 1 = second core UART, etc. For QEMU and native: always use 0 (only one connection available)
- `kwargs` – Keyword arguments passed to underlying connection including:
  - regex - Regular expression pattern to search for
  - num_of_lines - Exact number of lines to read
  - timeout - Maximum time in seconds to wait (uses base_timeout if not provided)
  - print_output - Whether to log each line as it's read (default: True)

Returns

List of output lines without trailing newlines

Raises

`AssertionError` – If timeout expires before condition is met

`write`(*data: bytes*, *connection_index: int = 0*) → None

Write data bytes to the target device.

Sends raw bytes to the device through the appropriate communication channel. The underlying transport mechanism varies by device type: Hardware devices write to serial/UART port, QEMU devices write to FIFO queue, and Native simulators write to process stdin pipes.

Parameters

- **data** – Raw bytes to send to the device
- **connection_index** – Index of the connection/port to write to (default: 0)

Shell

class twister_harness.**Shell**(*device:* DeviceAdapter, *prompt: str = 'uart:~$'*, *timeout: float | None = None*)

Helper class that provides methods used to interact with shell application.

exec_command(*command: str*, *timeout: float | None = None*, *print_output: bool = True*) → list[str]

Send shell command to a device and return response. Passed command is extended by double enter sings - first one to execute this command on a device, second one to receive next prompt what is a signal that execution was finished. Method returns printout of the executed command.

wait_for_prompt(*timeout: float | None = None*) → bool

Send every 0.5 second "enter" command to the device until shell prompt statement will occur (return True) or timeout will be exceeded (return False).

get_filtered_output(*command_lines: list[str]*) → list[str]

Filter out prompts and log messages

Take the output of exec_command, which can contain log messages and command prompts, and filter them to obtain only the command output.

Example:

```
>>> # equivalent to `lines = shell.exec_command("kernel version")`
>>> lines = [
>>>     'uart:~$',                    # filter prompts
>>>     'Zephyr version 3.6.0',       # keep this line
>>>     'uart:~$ <dbg> debug message' # filter log messages
>>> ]
>>> filtered_output = shell.get_filtered_output(output)
>>> filtered_output
['Zephyr version 3.6.0']
```

Parameters
command_lines – List of strings i.e. the output of *exec_command*.

Returns
A list of strings containing, excluding prompts and log messages.

Examples of pytest tests in the Zephyr project

- pytest_shell
- MCUmgr tests - tests/boot/with_mcumgr
- LwM2M tests - tests/net/lib/lwm2m/interop
- GDB stub tests - tests/subsys/debug/gdbstub

FAQ

How to flash/run application only once per pytest session?

dut is a fixture responsible for flashing/running application. By default, its scope is set as `function`. This can be changed by adding to .yaml file `pytest_dut_scope` keyword placed under `harness_config` section:

```
harness: pytest
harness_config:
   pytest_dut_scope: session
```

More info can be found *here*.

How to run only one particular test from a python file?

This can be achieved in several ways. In .yaml file it can be added using a `pytest_root` entry placed under `harness_config` with list of tests which should be run:

```
harness: pytest
harness_config:
   pytest_root:
      - "pytest/test_shell.py::test_shell_print_help"
```

Particular tests can be also chosen by pytest `-k` option (more info about pytest keyword filter can be found here). It can be applied by adding `-k` filter in `pytest_args` in .yaml file:

```
harness: pytest
harness_config:
   pytest_args:
      - "-k test_shell_print_help"
```

or by adding it to Twister command overriding parameters from the .yaml file:

```
$ ./scripts/twister ... --pytest-args='-k test_shell_print_help'
```

How to get information about used device type in test?

This can be taken from `dut` fixture (which represents *DeviceAdapter* object):

```
device_type: str = dut.device_config.type
if device_type == 'hardware':
   ...
elif device_type == 'native':
   ...
```

How to rerun locally pytest tests without rebuilding application by Twister?

This can be achieved by running Twister once again with `--test-only` argument added to Twister command. Another way is running Twister with highest verbosity level (`-vv`) and then copy-pasting from logs command dedicated for spawning pytest (log started by `Running pytest command: ...`).

First, run scenario with Twister:

```
$ west twister -vv -ll debug -T samples/subsys/testsuite/pytest/shell \
-s sample.pytest.shell --device-testing -p nrf54l15dk/nrf54l15/cpuapp --
↪device-serial \
/dev/ttyACM1 --west-flash=--erase
```

Twister automatically generates a configuration file `twister_pytest_config.yaml` in the build directory containing all test parameters including device configuration etc.

Then export the required PYTHONPATH environment variable if not already set:

```
$ export PYTHONPATH=$ZEPHYR_BASE/scripts/pylib/pytest-twister-harness/src
```

Finally, run pytest command:

```
$ pytest -s -v -p twister_harness.plugin \
--
↪twister-config=twister-out/.../sample.pytest.shell/twister_pytest_config.yaml␣
↪\
samples/subsys/testsuite/pytest/shell/pytest
```

Is this possible to run pytest tests in parallel?

Basically `pytest-harness-plugin` wasn't written with intention of running pytest tests in parallel. Especially those one dedicated for hardware. There was assumption that parallelization of tests is made by Twister, and it is responsible for managing available sources (jobs and hardwares). If anyone is interested in doing this for some reasons (for example via pytest-xdist plugin) they do so at their own risk.

Limitations

- Not every platform type is supported in the plugin (yet).

2.12.6 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr's gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture

Test coverage reports in embedded devices or QEMU

Overview GCC GCOV is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

Details There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select `CONFIG_HAS_COVERAGE_SUPPORT` in the Kconfig.board file.

To report the coverage for the particular test application set `CONFIG_COVERAGE`.

Steps to generate code coverage reports These steps will produce an HTML coverage report for a single application.

1. Build the code with CONFIG_COVERAGE=y.

```
west build -b mps2/an385 -- -DCONFIG_COVERAGE=y -DCONFIG_COVERAGE_DUMP=y
```

2. Capture the emulator output into a log file. You may need to terminate the emulator with Ctrl-A X for this to complete after the coverage dump has been printed:

```
$ ninja -Cbuild run | tee log.log
```

or

```
$ ninja -Cbuild run | tee log.log
```

3. Generate the gcov .gcda and .gcno files from the log file that was saved:

```
$ python3 scripts/gen_gcov_files.py -i log.log
```

4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke gcovr:

```
$ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"
```

5. Create an output directory for the reports:

```
$ mkdir -p gcov_report
```

6. Run gcovr to get the reports:

```
$ gcovr -r $ZEPHYR_BASE . --html -o gcov_report/coverage.html --html-details -
↪-gcov-executable <gcov_path_in_SDK>
```

Coverage reports using the POSIX architecture

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.

That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set CONFIG_COVERAGE before compiling it. When you run your application, gcov coverage data will be dumped into the respective gcda and gcno files. You may postprocess these with your preferred tools. For example:

```
west build -b native_sim samples/hello_world -- -DCONFIG_COVERAGE=y
```

```
$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
$ lcov --capture --directory ./ --output-file lcov.info -q --rc␣
↪lcov_branch_coverage=1
$ genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --
↪branch-coverage --highlight --legend
```

Note

You need a recent version of lcov (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions.

Alternatively, you can use gcovr (at least version 4.2).

Coverage reports using Twister

Zephyr's *twister script* can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the `--coverage` command line option.

For example, you may invoke:

```
$ twister --coverage -p qemu_x86 -T tests/kernel
```

or:

```
$ twister --coverage -p native_sim -T tests/bluetooth
```

which will produce `twister-out/coverage/index.html` report as well as the coverage data collected by `gcovr` tool in `twister-out/coverage.json`.

Other reports might be chosen with `--coverage-tool` and `--coverage-formats` command line options.

To generate code coverage report including Zephyr sources as well as your application code outside of Zephyr repository (see *Application Types*) call Twister from your project directory with `--coverage-basedir $ZEPHYR_BASE` command line option, for example:

```
$ $ZEPHYR_BASE/scripts/twister --coverage -p native_sim --coverage-basedir
↪$ZEPHYR_BASE -T your_project_dir
```

Note

By default, Twister calls `gcovr` tool which filters source files assuming real paths are everywhere with all symlinks resolved, so when your development environment has directories with symlinks then, to avoid incomplete `gcovr` reports, either your *ZEPHYR_BASE* should contain a real path, or `lcov` tool used instead of `gcovr` with additional Twister command line option `--coverage-tool lcov`.

The process differs for unit tests, which are built with the host toolchain and require a different board:

```
$ twister --coverage -p unit_testing -T tests/unit
```

which produces a report in the same location as non-unit testing.

Using different toolchains Twister looks at the environment variable `ZEPHYR_TOOLCHAIN_VARIANT` to check which gcov tool to use by default. The following are used as the default for the Twister `--gcov-tool` argument default:

Toolchain	`--gcov-tool` value
host	`gcov`
llvm	`llvm-cov gcov`
zephyr	`gcov`

2.12.7 BabbleSim

BabbleSim and Zephyr

In the Zephyr project we use the Babblesim simulator to test some of the Zephyr radio protocols, including the Bluetooth LE stack, 802.15.4, and some of the networking stack.

BabbleSim is a physical layer simulator, which in combination with the Zephyr bsim boards can be used to simulate a network of Bluetooth LE and 15.4 devices. When we build Zephyr targeting

a bsim board we produce a Linux executable, which includes the application, Zephyr OS, and models of the HW.

When there is radio activity, this Linux executable will connect to the BabbleSim Phy simulation to simulate the radio channel.

In the BabbleSim documentation you can find more information on how to get and build the simulator. In the nrf52_bsim, nrf5340bsim, and nrf54l15bsim boards documentation you can find more information about how to build Zephyr targeting these particular boards, and a few examples.

Types of tests

Tests without radio activity: bsim tests with twister The bsim boards can be used without radio activity, and in that case, it is not necessary to connect them to a physical layer simulation. Thanks to this, these target boards can be used just like native_sim with *twister*, to run all standard Zephyr twister tests, but with models of a real SOC HW, and their drivers.

Tests with radio activity When there is radio activity, BabbleSim tests require at the very least a physical layer simulation running, and most, more than 1 simulated device. Due to this, these tests are not build and run with twister, but with a dedicated set of tests scripts.

These tests are kept in the `tests/bsim/` folder. The `compile.sh` and `run_parallel.sh` scripts contained in that folder are used by the CI system to build the needed images and execute these tests in batch.

See sections below for more information about how to build and run them, as well as the conventions they follow.

There are two main sets of tests:

- Self checking embedded application/tests: In which some of the simulated devices applications are built with some checks which decide if the test is passing or failing. These embedded applications tests use the bs_tests system to report the pass or failure, and in many cases to build several tests into the same binary.
- Test using the EDTT tool, in which a EDTT (python) test controls the embedded applications over an RPC mechanism, and decides if the test passes or not. Today these tests include a very significant subset of the BT qualification test suite.

More information about how different tests types relate to BabbleSim and the bsim boards can be found in the bsim boards tests section.

Test coverage and BabbleSim

As the nrf52_bsim and nrf5340bsim, and nrf54l15bsim boards are based on the POSIX architecture, you can easily collect test coverage information.

You can use the script tests/bsim/generate_coverage_report.sh to generate an html coverage report from tests.

Check *the page on coverage generation* for more info.

Building and running the tests

See the nrf52_bsim page for setting up the simulator.

The scripts also expect a few environment variables to be set. For example, from Zephyr's root folder, you can run:

```
# Build all the tests
${ZEPHYR_BASE}/tests/bsim/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Or to build and run only a specific subset, e.g. host advertising tests:

```
# Build the Bluetooth host advertising tests
${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Check the `run_parallel.sh` help for more options and examples on how to use this script to run the tests in batch.

After building the tests' required binaries you can run a test directly using its individual test script.

For example you can build the required binaries for the networking tests with

```
WORK_DIR=${ZEPHYR_BASE}/bsim_out ${ZEPHYR_BASE}/tests/bsim/net/compile.sh
```

and then directly run one of the tests:

```
${ZEPHYR_BASE}/tests/bsim/net/sockets/echo_test/tests_scripts/echo_test_802154.sh
```

Conventions

Test code See the Bluetooth sample test for conventions that apply to test code.

Build scripts The build scripts `compile.sh` simply build all the required test and sample applications for the tests' scripts placed in the subfolders below.

This build scripts use the common compile.source which provide a function (compile) which calls cmake and ninja with the provided application, configuration and overlay files.

To speed up compilation for users interested only in a subset of tests, several compile scripts exist in several subfolders, where the upper ones call into the lower ones.

Note that cmake and ninja are used directly instead of the `west build` wrapper as west is not required, and some Zephyr users do not use or have west, but still use the build and tests scripts.

Test scripts Please follow the existing conventions and do not design one-off bespoke runners (e.g. a python script, or another shell abstraction).

The rationale is that it is easier and faster for the maintainers to perform tree-wide updates for build system or compatibility changes if the tests are run in the same manner, with the same variables, etc..

If you have a good idea for improving your test script, please make a PR changing *all* the test scripts in order to benefit everyone and conserve homogeneity. You can of course discuss it first in an RFC issue or on the babblesim discord channel.

Scripts starting with an underscore (_) are not automatically discovered and run. They can serve as either helper functions for the main script, or can be used for local development utilities, e.g. building and running tests locally, debugging, etc..

Here are the conventions:

- Each test is defined by a shell script with the extension `.sh`, in a subfolder called `test_scripts/`.
- It is recommended to run a single test per script file. It allows for better parallelization of the runs in CI.
- Scripts expect that the binaries they require are already built. They should not compile binaries.
- Scripts will spawn the processes for every simulated device and the physical layer simulation.
- Scripts must return 0 to the invoking shell if the test passes, and not 0 if the test fails.
- Each test must have a unique simulation id, to enable running different tests in parallel.
- Neither the scripts nor the images should modify the workstation filesystem content beyond the `${BSIM_OUT_PATH}/results/<simulation_id>/` or `/tmp/` folders. That is, they should not leave stray files behind.
- Tests that require several consecutive simulations (e.g, if simulating a device pairing, powering off, and powering up after as a new simulation) should use separate simulation ids for each simulation segment, ensuring that the radio activity of each segment can be inspected a posteriori.
- Avoid overly long tests. If the test takes over 20 seconds of runtime, consider if it is possible to split it in several separate tests.
- If the test takes over 5 seconds, set `EXECUTE_TIMEOUT` to a value that is at least 5 times bigger than the measured run-time.
- Do not set `EXECUTE_TIMEOUT` to a value lower than the default.
- Tests should not be overly verbose: less than a hundred lines are expected on the outputs. Do make use of `LOG_DBG()` extensively, but don't enable the `DBG` log level by default.

2.13 Static Code Analysis (SCA)

Support for static code analysis tools in Zephyr is possible through CMake.

The build setting **ZEPHYR_SCA_VARIANT** can be used to specify the SCA tool to use. `ZEPHYR_SCA_VARIANT` is also supported as *environment variable*.

Use `-DZEPHYR_SCA_VARIANT=<tool>`, for example `-DZEPHYR_SCA_VARIANT=sparse` to enable the static analysis tool `sparse`.

2.13.1 SCA Tool infrastructure

Support for an SCA tool is implemented in a `sca.cmake` file. The `sca.cmake` must be placed under *SCA_ROOT*`/cmake/sca/`*tool*`/sca.cmake`. Zephyr itself is always added as an **SCA_ROOT** but the build system offers the possibility to add additional folders to the **SCA_ROOT** setting.

You can provide support for out of tree SCA tools by creating the following structure:

```
<sca_root>/                 # Custom SCA root
└── cmake/
    └── sca/
        └── <tool>/         # Name of SCA tool, this is the value given to␣
```

(continues on next page)

(continued from previous page)

```
↪ZEPHYR_SCA_VARIANT
            └── sca.cmake   # CMake code that configures the tool to be used with␣
↪Zephyr
```

To add `foo` under `/path/to/my_tools/cmake/sca` create the following structure:

```
/path/to/my_tools
          └── cmake/
              └── sca/
                  └── foo/
                      └── sca.cmake
```

To use `foo` as SCA tool you must then specify `-DZEPHYR_SCA_VARIANT=foo`.

Remember to add `/path/to/my_tools` to **SCA_ROOT**.

SCA_TOOL can be set as a regular CMake setting using `-DSCA_ROOT=<sca_root>`, or added by a Zephyr module in its `module.yml` file, see *Zephyr Modules - Build settings*

2.13.2 Native SCA Tool support

The following is a list of SCA tools natively supported by Zephyr build system.

Clang static analyzer support

Clang Static Analyzer is built on top of Clang and LLVM. Strictly speaking, the analyzer is part of Clang, as Clang consists of a set of reusable C++ libraries for building powerful source-level tools. The static analysis engine used by the Clang Static Analyzer is a Clang library, and has the capability to be reused in different contexts and by different clients.

LLVM provides various methods to run the analyzer on a codebase, through either a dedicated set of tools (scan-build and analyze-build), or via command line arguments when running clang ('–analyze').

- 'scan-build' utility comes as the most convenient way for projects using a simple $CC make-file variables, as it will wraps and replace the compiler calls to perform it's analysis.
- 'analyze-build' utility is a sub-tool from 'scan-build', it only relies on a 'compile_commands.json' database to perform the analysis.
- clang option '–analyze' will run the analyzer alongside the build, but objects files are not generated, making any link stage impossible. In our case the first link stage will fail and stop the analysis.

Because of it's complexe build infrastructure, invoking clang analyzer with 'analyze-build' is the most simple way to analyze a Zephyr project.

Clang static analyzer documentation

Installing clang analyzer 'scan-build' and its sub-tool 'analyze-build' come natively with llvm as part of the binaries. Make sure to have the binary directory accessible into your PATH.

'scan-build' is also available as a standalone python package available on pypi.

```
pip install scan-build
```

> **Note**
>
> The analyser requires that the project builds with a LLVM toolchain, and produces a 'compile_commands.json' database.

Run clang static analyzer To run clang static analyzer, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=clang` parameter, alongside the llvm toolchain parameters, e.g.

```
west build -b qemu_x86 samples/userspace/hello_world_user -- -
↪DZEPHYR_TOOLCHAIN_VARIANT=llvm -DLLVM_TOOLCHAIN_PATH=... -
↪DZEPHYR_SCA_VARIANT=clang
```

> **Note**
>
> By default, clang static analyzer produces a html report, but various other outputs can be selected with options (sarif, plist, html)

Configuring clang static analyzer Clang static analyzer can be controlled using specific options. To get an exhaustive list of available options, report to the 'analyze-build' helper and 'scan-build' helper.

```
analyze-build --help
```

Options already activated by default:

- –analyze-headers : Also analyze functions in #included files.

Parameter	Description
CLANG_SCA_OPTS	A semicolon separated list of 'analyze-build' options.

These parameters can be passed on the command line, or be set as environment variables.

```
west build -b stm32h573i_dk samples/hello_world -- -DZEPHYR_TOOLCHAIN_VARIANT=llvm␣
↪-DLLVM_TOOLCHAIN_PATH=... -DZEPHYR_SCA_VARIANT=clang -DCLANG_SCA_OPTS="--
↪sarif;--verbose"
```

CodeChecker support

CodeChecker is a static analysis infrastructure. It executes analysis tools available on the build system, such as Clang-Tidy, Clang Static Analyzer and Cppcheck. Refer to the analyzer's websites for installation instructions.

Installing CodeChecker CodeChecker itself is a python package available on pypi.

```
pip install codechecker
```

Building with CodeChecker To run CodeChecker, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=codechecker` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=codechecker
```

Configuring CodeChecker CodeChecker uses different command steps, each with their respective configuration parameters. The following table lists all these options.

Parameter	Description
CODECHECKER_ANALY	The number of threads to use in analysis. (default: <CPU count>)
CODECHECKER_ANALY	Arguments passed to the `analyze` command directly. (e.g. `--timeout;360`)
CODECHECKER_CLEAN	Perform a cleanup after parsing/storing. This will remove all `plist` files.
CODECHECKER_CONFI	A JSON or YAML file with configuration options passed to all commands.
CODECHECKER_EXPOR	A comma separated list of report types. Allowed types are: `html,json,codeclimate,gerrit,baseline`.
CODECHECKER_NAME	The CodeChecker run metadata name. (default: `zephyr`)
CODECHECKER_PARSE	By default, CodeChecker identified issues will not fail the build, set this option to fail during analysis.
CODECHECKER_PARSE	Arguments passed to the `parse` command directly. (e.g. `--verbose;debug`)
CODECHECKER_PARSE	Skip parsing the analysis, useful if you simply want to store the results.
CODECHECKER_STORE	Run the `store` command after analysis.
CODECHECKER_STORE	Arguments passed to the `store` command directly. Implies `CODECHECKER_STORE`. (e.g. `--url;localhost:8001/Default`)
CODECHECKER_STORE	Pass an identifier `--tag` to the `store` command.
CODECHECKER_TRIM_	Trim the defined path from the analysis results, e.g. `/home/user/zephyrproject`. The value from `west topdir` is added by default.

These parameters can be passed on the command line, or be set as environment variables.

Running twister with CodeChecker When running CodeChecker as part of `twister` some default options are set as following:

Parameter	Value
CODECHECKER_ANALYZE_JOBS	1
CODECHECKER_NAME	<board target>:<testsuite name>
CODECHECKER_STORE_TAG	The value from `git describe` in the application source directory.

To override these values, set an environment variable or pass them as extra arguments.

Coverity

Coverity Scan is a service by which Black Duck provides the results of analysis on open source coding projects to open source code developers that have registered their products with Coverity Scan.

This integration was only tested with scan.coverity.com and the tool distribution available through this service.

Generating Build Data Files To use this integration, coverity tool distribution must be found in your *PATH* environment and *west build* should be called with a `-DZEPHYR_SCA_VARIANT=coverity` parameter, e.g.

```
west build -b qemu_cortex_m3 samples/hello_world -- -DZEPHYR_SCA_VARIANT=coverity
```

Results of the scan will be generated as `build/sca/coverity`.

You can also set `COVERITY_OUTPUT_DIR` as the destination for multiple and incremental scan results.

Result Analysis Follow the instructions on https://scan.coverity.com for uploading results.

Parasoft C/C++test support

Parasoft C/C++test is a software testing and static analysis tool for C and C++. It is a commercial software and you must acquire a commercial license to use it.

Documentation of C/C++test can be found at https://docs.parasoft.com/. Please refer to the documentation for how to use it.

Generating Build Data Files To use C/C++test, `cpptestscan` must be found in your *PATH* environment variable. And *west build* should be called with a `-DZEPHYR_SCA_VARIANT=cpptest` parameter, e.g.

```
west build -b qemu_cortex_m3 zephyr/samples/hello_world -- -
↪DZEPHYR_SCA_VARIANT=cpptest
```

A `.bdf` file will be generated as `build/sca/cpptest/cpptestscan.bdf`.

Generating a report file Please refer to Parasoft C/C++test documentation for more details.

To import and generate a report file, something like the following should work.

```
cpptestcli -data out -localsettings local.conf -bdf␣
↪build/sca/cpptest/cpptestscan.bdf -config "builtin://Recommended Rules" -report␣
↪out/report
```

You might need to set `bdf.import.c.compiler.exec`, `bdf.import.cpp.compiler.exec`, and `bdf.import.linker.exec` to the toolchain *west build* used.

Devicetree diagnostics (`dtdoctor`)

`dtdoctor` is a static analysis tool that helps diagnose Devicetree-related build errors.

It intercepts error messages from the compiler and linker and, when they refer to unresolved Devicetree device symbols (e.g. `__device_dts_ord_*`), provides detailed information about what might be causing the error and how to fix it.

Using dtdoctor To enable `dtdoctor`, build with `-DZEPHYR_SCA_VARIANT=dtdoctor`.

For example:

```
west build -b reel_board samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=dtdoctor
```

ECLAIR support

Bugseng ECLAIR is a certified static analysis tool and platform for software verification. Applications range from coding rule validation, with a particular emphasis on the MISRA and BARR-C coding standards, to the computation of software metrics, to the checking of independence and freedom from interference among software components, to the automatic detection of important classes of software errors.

Prerequisites The ECLAIR tool must be installed and made available in the operating system's PATH variable.

To verify the installation, you can run:

```
eclair -version
```

A valid license or trial license is required to use ECLAIR. To request a trial license, visit this page.

Running ECLAIR To run ECLAIR, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=eclair` parameter.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair
```

Note

This will only invoke the ECLAIR analysis with the predefined ruleset `first_analysis`. If you want to use a different ruleset, you need to provide a configuration file. See the next section for more information.

Configurations The configuration of the ECLAIR SCA environment can either be done via a CMake options file or with adapted options as command line arguments.

To invoke a CMake options file into the ECLAIR call, you can define the `ECLAIR_OPTIONS_FILE` variable, for example:

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair -
↪DECLAIR_OPTIONS_FILE=my_options.cmake
```

The default (if no config file is given) configuration is always `first_analysis`, which is a tiny selection of rules to verify that everything is correctly working.

If the default configuration wants to be overwritten via the command line and not via an options file, that can be achieved by giving the argument `-DOption=ON|OFF`.

For example:

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair -
↪DECLAIR_REPORTS_SARIF=ON
```

Zephyr is a large and complex project, so the configuration sets are split into the Zephyr's guidelines selection (taken from https://docs.zephyrproject.org/latest/contribute/coding_guidelines/index.html) in five sets to make it more digestible to use on a private machine:

- first_analysis (default): a tiny selection of the project's coding guidelines to verify that everything is correctly working.
- STU: Selection of the project's coding guidelines, which can be verified by analyzing the single translation units independently.
- STU_heavy: Selection of complex STU project coding guidelines that require a significant amount of time.
- WP: All whole program project coding guidelines ("system" in MISRA's parlance).
- std_lib: Project coding guidelines about the C Standard Library.

In addition, the zephyr_guidelines ruleset contains all the main rules listed in the Coding Guidelines.

Related CMake options:

- `ECLAIR_RULESET_FIRST_ANALYSIS`
- `ECLAIR_RULESET_STU`
- `ECLAIR_RULESET_STU_HEAVY`
- `ECLAIR_RULESET_WP`
- `ECLAIR_RULESET_STD_LIB`
- `ECLAIR_RULESET_ZEPHYR_GUIDELINES`

User-defined ruleset If you want to use your own defined ruleset instead of the predefined Zephyr coding guidelines rulesets, you can do so by setting `ECLAIR_RULESET_USER=ON`. Create your own ruleset file for ECLAIR with the following naming format: `analysis_<RULESET>.ecl`. After creating the file, define the name of the ruleset for ECLAIR with the CMake variable `ECLAIR_USER_RULESET_NAME`. If the ruleset file is not in the application source directory, you can define the path to the ruleset file with the CMake variable `ECLAIR_USER_RULESET_PATH`. This configuration takes relative paths and absolute paths.

Related CMake options and variables:

- `ECLAIR_RULESET_USER`
- `ECLAIR_USER_RULESET_NAME`
- `ECLAIR_USER_RULESET_PATH`

Generate additional report formats ECLAIR can generate additional report formats (e.g., DOC, ODT, XLSX) and different variants of reports in addition to the default ecd file. Following additional reports and report formats can be generated:

- Metrics in spreadsheet format.
- Findings in spreadsheet format.
- Findings in SARIF format.
- Summary report in plain textual format.
- Summary report in DOC format.
- Summary report in ODT format.
- Summary report in HTML format.
- Detailed reports in txt format.
- Detailed report in DOC format.
- Detailed report in ODT format.
- Detailed report in HTML format.

Related CMake options:

- `ECLAIR_METRICS_TAB`
- `ECLAIR_REPORTS_TAB`
- `ECLAIR_REPORTS_SARIF`
- `ECLAIR_SUMMARY_TXT`
- `ECLAIR_SUMMARY_DOC`
- `ECLAIR_SUMMARY_ODT`
- `ECLAIR_SUMMARY_HTML`
- `ECLAIR_FULL_TXT`
- `ECLAIR_FULL_DOC`
- `ECLAIR_FULL_ODT`
- `ECLAIR_FULL_HTML`

Detail level of full reports The detail level of the txt and doc full reports can also be adapted by a configuration. In this case, the following configurations are available:

- Show all areas
- Show only the first area

Related CMake options:

- ECLAIR_FULL_DOC_ALL_AREAS
- ECLAIR_FULL_DOC_FIRST_AREA
- ECLAIR_FULL_TXT_ALL_AREAS
- ECLAIR_FULL_TXT_FIRST_AREA

GCC static analysis support

Static analysis was introduced in GCC 10 and it is enabled with the option `-fanalyzer`. This option performs a much more expensive and thorough analysis of the code than traditional warnings.

Run GCC static analysis To run GCC static analysis, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=gcc` parameter, e.g.

```
west build -b qemu_x86 samples/userspace/hello_world_user -- -
↪DZEPHYR_SCA_VARIANT=gcc
```

Configuring GCC static analyzer GCC static analyzer can be controlled using specific options.

- Options controlling the analyzer
- Options controlling the diagnostic message formatting

Parameter	Description
GCC_SCA_OPTS	A semicolon separated list of GCC analyzer options.

These parameters can be passed on the command line, or be set as environment variables.

```
west build -b stm32h573i_dk samples/hello_world -- -DZEPHYR_SCA_VARIANT=gcc -
↪DGCC_SCA_OPTS="-fdiagnostics-format=json;-fanalyzer-verbosity=3"
```

Note

GCC static analyzer is under active development, and each new release comes with new options. This page gives an overview of options and fix introduced with each new release of the analyzer.

Latest version of the analyzer Since the Zephyr toolchain may not include the most recent version of the GCC static analyzer, the GCC static analysis can be run with a more recent GNU Arm embedded toolchain to take advantage of the latest analyzer version.

```
west build -b stm32h573i_dk samples/hello_world -- -DZEPHYR_SCA_VARIANT=gcc -
↪DZEPHYR_TOOLCHAIN_VARIANT=gnuarmemb -DGNUARMEMB_TOOLCHAIN_PATH=...
```

IAR C-STAT support

IAR C-STAT is a comprehensive static analysis tool for C/C++ source code. It can find errors and vulnerabilities supporting a number of coding standards such as MISRA C, MISRA C++, CERT C/C++ and CWE.

Installing IAR C-STAT IAR C-STAT comes pre-installed with the IAR Build Tools and with the IAR Embedded Workbench. Refer to your respective product's documentation for details.

Building with IAR C-STAT To run IAR C-STAT, you will need CMake 4.1.0 or later. When building with *west build* append the additional parameter to select IAR C-STAT `-DZEPHYR_SCA_VARIANT=iar_c_stat`, e.g.

```
west build -b stm32f429ii_aca samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=iar_c_stat
```

Configuring IAR C-STAT The IAR C-STAT accepts parameters for customizing the analysis. The following table lists the supported options.

Parameter	Description
CSTAT_RULESE	The pre-defined ruleset to be used. (default: `stdchecks`, accepted values: `all`, `cert`,`misrac2004`,`misrac2012`,`misrac++2008`,`stdchecks`,`security`)
CSTAT_ANALYZI	The number of threads to use in analysis. (default: <CPU count>)
CSTAT_ANALYZI	Arguments passed to the `analyze` command directly. (e.g. `--timeout=900`; `--deterministic`;`--fpe`)
CSTAT_DB	Override the default location of the C-STAT SQLite database. (e.g. `/home/user/cstat.db`)
CSTAT_CLEANUI	Perform a cleanup of the C-STAT SQLite database. (e.g. `true`)

These parameters can be passed on the command line, or be set as environment variables. Below you will find an example of how to enable and combine non-standard rulesets at will:

```
# From the root of the zephyr repository
west build -b stm32f429ii_aca samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=iar_c_stat -DCSTAT_RULESET=misrac2012,cert
```

Polyspace support

Polyspace® is a commercial static code analysis tool from MathWorks, which is certified for use in highest safety contexts. It can check compliance to coding guidelines like MISRA C and CERT C, find CWEs, detect bugs and calculate code complexity metrics. Optionally, it can run a formal proof to verify the absence of run-time errors like array out of bounds access, overflows, race conditions and more, and thus help achieving memory safety.

Installing The Polyspace tools must be installed and made available in the operating system's or container's PATH variable. Specifically, the path `<polyspace_root>/polyspace/bin` must be on the list.

For installation instructions, see here. To use formal verification (proving the *absence* of defects), you additionally need to install this.

A license file must be available in the installation folder. To request a trial license, visit this page.

Running The code analysis can be triggered through the `west` command by appending the option `-DZEPHYR_SCA_VARIANT=polyspace` to the build, for example:

```
west build -b qemu_x86 samples/hello_world -- -DZEPHYR_SCA_VARIANT=polyspace
```

Reviewing results The identified issues are summarized at the end of the build and printed in the console window, along with the path of the folder containing detailed results.

For an efficient review, the folder should be opened in the Polyspace user interface or uploaded to the web interface and reviewed there.

For programmatic access of the results, e.g., in the CI pipeline, the individual issues are also described in a CSV file in the results folder.

Configuration By default, Polyspace scans for typical programming defects on all C and C++ sources. The following options are available to customize the default behavior:

Option	Effect	Example
POLYSPACE_ONLY_API	If set, only user code is analyzed and Zephyr sources are ignored.	-DPOLYSPACE_ONLY_APP=1
POLYSPACE_OPTIONS	Provide additional command line flags, e.g., for selection of coding rules. Separate the options and their values by semicolon. For a list of options, see here.	-DPOLYSPACE_OPTIONS="-misra3; mandatory-required; -checkers;all"
POLYSPACE_OPTIONS_	Command line flags can also be provided in a text file, line by line. Provide the absolute path to the file.	-DPOLYSPACE_OPTIONS_FILE=/workdir/zephyr/myoptions.txt
POLYSPACE_MODE	Switch between bugfinding and proving mode. Default is bugfinding. See here for more details.	-DPOLYSPACE_MODE=prove
POLYSPACE_PROG_NAI	Override the name of the analyzed application. Default is board and application name.	-DPOLYSPACE_PROG_NAME=myapp
POLYSPACE_PROG_VEI	Override the version of the analyzed application. Default is taken from git-describe.	-DPOLYSPACE_PROG_VERSION=v1.0b-28f023

Sparse support

Sparse is a static code analysis tool. Apart from performing common code analysis tasks it also supports an `address_space` attribute, which allows introduction of distinct address spaces in C code with subsequent verification that pointers to different address spaces do not get confused. Additionally it supports a `force` attribute which should be used to cast pointers between different address spaces. At the moment Zephyr introduces a single custom address space `__cache` used to identify pointers from the cached address range on the Xtensa architecture. This helps identify cases where cached and uncached addresses are confused.

Running with sparse To run a sparse verification build *west build* should be called with a `-DZEPHYR_SCA_VARIANT=sparse` parameter, e.g.

```
west build -d hello -b intel_adsp/cavs25 zephyr/samples/hello_world -- -
↪DZEPHYR_SCA_VARIANT=sparse
```

2.14 Toolchains

Guides on how to set up toolchains for Zephyr development.

2.14.1 Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

Supported architectures

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- Microblaze (32-bit)
- MIPS (32-bit and 64-bit)
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- RX
- SPARC (32-bit and 64-bit; SPARC V8, SPARC V9)
- x86 (32-bit and 64-bit)
- Xtensa

Installation bundle and variables

The Zephyr SDK bundle supports all major operating systems (Linux, macOS and Windows) and is delivered as a compressed file. The installation consists of extracting the file and running the included setup script. Additional OS-specific instructions are described in the sections below.

If no toolchain is selected, the build system looks for Zephyr SDK and uses the toolchain from there. You can enforce this by setting the environment variable *ZEPHYR_TOOLCHAIN_VARIANT* to `zephyr`.

If you install the Zephyr SDK outside any of the default locations (listed in the operating system specific instructions below) and you want automatic discovery of the Zephyr SDK, then you must register the Zephyr SDK in the CMake package registry by running the setup script. If you decide not to register the Zephyr SDK in the CMake registry, then the *ZEPHYR_SDK_INSTALL_DIR* can be used to point to the Zephyr SDK installation directory.

You can also set *ZEPHYR_SDK_INSTALL_DIR* to point to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, you can set `ZEPHYR_SDK_INSTALL_DIR` to `/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Zephyr SDK version compatibility

In general, the Zephyr SDK version referenced in this page should be considered the recommended version for the corresponding Zephyr version.

For the full list of compatible Zephyr and Zephyr SDK versions, refer to the Zephyr SDK Version Compatibility Matrix.

Zephyr SDK installation

Note

You can change `0.17.4` to another version in the instructions below if needed; the Zephyr SDK Releases page contains all available SDK releases.

Note

If you want to uninstall the SDK, you may simply remove the directory where you installed it.

Linux

1. Download and verify the Zephyr SDK bundle:

   ```
   cd ~
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.17.4/
   ↪zephyr-sdk-0.17.4_linux-x86_64.tar.xz
   wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
   ↪17.4/sha256.sum | shasum --check --ignore-missing
   ```

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```
   tar xvf zephyr-sdk-0.17.4_linux-x86_64.tar.xz
   ```

   Note

   It is recommended to extract the Zephyr SDK bundle at one of the following locations:

   - `$HOME`
   - `$HOME/.local`
   - `$HOME/.local/opt`
   - `$HOME/bin`
   - `/opt`
   - `/usr/local`

   The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

   ```
   cd zephyr-sdk-0.17.4
   ./setup.sh
   ```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```
sudo cp ~/zephyr-sdk-0.17.4/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
↪contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

macOS

1. Download and verify the Zephyr SDK bundle:

```
cd ~
curl -L -O https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.
↪17.4/zephyr-sdk-0.17.4_macos-x86_64.tar.xz
curl -L https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.17.
↪4/sha256.sum | shasum --check --ignore-missing
```

   If your host architecture is 64-bit ARM (Apple Silicon), replace `x86_64` with `aarch64` in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.17.4_macos-x86_64.tar.xz
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `$HOME`
> - `$HOME/.local`
> - `$HOME/.local/opt`
> - `$HOME/bin`
> - `/opt`
> - `/usr/local`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.17.4
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Windows

1. Open a `cmd.exe` terminal window **as a regular user**
2. Download the Zephyr SDK bundle:

   ```
   cd %HOMEPATH%
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.17.4/
   ↪zephyr-sdk-0.17.4_windows-x86_64.7z
   ```

3. Extract the Zephyr SDK bundle archive:

   ```
   7z x zephyr-sdk-0.17.4_windows-x86_64.7z
   ```

   Note

   It is recommended to extract the Zephyr SDK bundle at one of the following locations:

   - `%HOMEPATH%`
   - `%PROGRAMFILES%`

   The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-<version>`.

4. Run the Zephyr SDK bundle setup script:

   ```
   cd zephyr-sdk-0.17.4
   setup.cmd
   ```

   Note

   You only need to run the setup script once after extracting the Zephyr SDK bundle.

   You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

2.14.2 Arm Compiler 6

1. Download and install a development suite containing the Arm Compiler 6 for your operating system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `armclang`.
   - Set `ARMCLANG_TOOLCHAIN_PATH` to the toolchain installation directory.
3. The Arm Compiler 6 needs the `ARMLMD_LICENSE_FILE` environment variable to point to your license file or server.

For example:

```
# Linux, macOS, license file:
export ARMLMD_LICENSE_FILE=/<path>/license_armds.dat
# Linux, macOS, license server:
export ARMLMD_LICENSE_FILE=8224@myserver
```

```
# Windows, license file:
set ARMLMD_LICENSE_FILE=c:\<path>\license_armds.dat
# Windows, license server:
set ARMLMD_LICENSE_FILE=8224@myserver
```

1. If the Arm Compiler 6 was installed as part of an Arm Development Studio, then you must set the `ARM_PRODUCT_DEF` to point to the product definition file: See also: Product and toolkit configuration. For example if the Arm Development Studio is installed in: `/opt/armds-2020-1` with a Gold license, then set `ARM_PRODUCT_DEF` to point to `/opt/armds-2020-1/gold.elmap`.

   Note

   The Arm Compiler 6 uses `armlink` for linking. This is incompatible with Zephyr's linker script template, which works with GNU ld. Zephyr's Arm Compiler 6 support Zephyr's CMake linker script generator, which supports generating scatter files. Basic scatter file support is in place, but there are still areas covered in ld templates which are not fully supported by the CMake linker script generator.

   Some Zephyr subsystems or modules may also contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `armclang`.

2.14.3 Arm Toolchain for Embedded (ATfE)

Arm Toolchain for Embedded (ATfE) is a C and C++ toolchain from Arm based
on the free and open-source LLVM Compiler Infrastructure and the Picolib C library for baremetal targets.

ATfE is fined-tuned with a particular focus on performance for newer
ARM products (post 2024) like 64-bit Arm Architectures (AArch64), or the M-Profile Vector Extension (MVE, a 32-bit Armv8.1-M extension).

Installation

1. Download and install a Arm toolchain for embedded build for your operating system and extract it on your file system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `llvm`.
   - Set `LLVM_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `LLVM_TOOLCHAIN_PATH` values may be different on your system):

   Ubuntu

   ```
   echo $ZEPHYR_TOOLCHAIN_VARIANT
   llvm
   echo $LLVM_TOOLCHAIN_PATH
   /home/you/Downloads/ATfE
   ```

   macOS

   ```
   echo $ZEPHYR_TOOLCHAIN_VARIANT
   llvm
   echo $LLVM_TOOLCHAIN_PATH
   /home/you/Downloads/ATfE
   ```

   Windows

   ```
   > echo %ZEPHYR_TOOLCHAIN_VARIANT%
   llvm
   ```

(continues on next page)

(continued from previous page)

```
> echo %LLVM_TOOLCHAIN_PATH%
C:\ATfE
```

4. You can also set ZEPHYR_TOOLCHAIN_VARIANT and LLVM_TOOLCHAIN_PATH as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=llvm -DLLVM_TOOLCHAIN_PATH=...
```

Toolchain settings

Because LLVM is widely compatible with GNU tools, When builiding with any LLVM toolchain, you have to specify some settings to let the compiler know what tools to use:

Linker

- Set CONFIG_LLVM_USE_LLD=y to use LLVM linker.
- Set CONFIG_LLVM_USE_LD=y to use the GNU LD linker.

Runtime library

- Set CONFIG_COMPILER_RT_RTLIB=y to use LLVM runtime library.
- Set CONFIG_LIBGCC_RTLIB=y to use LibGCC runtime library.

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=llvm -DLLVM_TOOLCHAIN_PATH=... -
↪DCONFIG_LLVM_USE_LLD=y -DCONFIG_COMPILER_RT_RTLIB=y
```

2.14.4 Cadence Tensilica Xtensa C/C++ Compiler (XCC)

1. Obtain Tensilica Software Development Toolkit targeting the specific SoC on hand. This usually contains two parts:
   - The Xtensa Xplorer which contains the necessary executables and libraries.
   - A SoC-specific add-on to be installed on top of Xtensa Xplorer.
     - This add-on allows the compiler to generate code for the SoC on hand.
2. Install Xtensa Xplorer and then the SoC add-on.
   - Follow the instruction from Cadence on how to install the SDK.
   - Depending on the SDK, there are two set of compilers:
     - GCC-based compiler: `xt-xcc` and its friends.
     - Clang-based compiler: `xt-clang` and its friends.
3. Make sure you have obtained a license to use the SDK, or has access to a remote licensing server.
4. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xcc` or `xt-clang`.
   - Set XTENSA_TOOLCHAIN_PATH to the toolchain installation directory.
   - There are two ways to specify the SoC ID and the SDK version to use. They are mutually exclusive, and cannot be used together.
     1. When building for a single SoC:
        - Set XTENSA_CORE to the SoC ID where application is being targeted.
        - Set TOOLCHAIN_VER to the Xtensa SDK version.

2. When building for multiple SoCs, for each SoC and board combination:
   - Set `XTENSA_CORE_{normalized_board_target}` to the SoC ID where application is being targeted.
   - Set `TOOLCHAIN_VAR_{normalized_board_target}` to the Xtensa SDK version.

5. For example, assuming the SDK is installed in `/opt/xtensa`, and using the SDK for application development on `intel_adsp/ace15_mtpm`, setup the environment using the two above mentioned ways:
   1. Single SoC:

```
# Linux
export ZEPHYR_TOOLCHAIN_VARIANT=xt-clang
export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
export XTENSA_CORE=ace10_LX7HiFi4_2022_10
export TOOLCHAIN_VER=RI-2022.10-linux
```

   2. Multiple SoCs:

```
# Linux
export ZEPHYR_TOOLCHAIN_VARIANT=xt-clang
export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
export TOOLCHAIN_VER_intel_adsp_ace15_mtpm=RI-2022.10-linux
export XTENSA_CORE_intel_adsp_ace15_mtpm=ace10_LX7HiFi4_2022_10
```

6. To use Clang-based compiler:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xt-clang`.
   - Note that the Clang-based compiler may contain an old LLVM bug which results in the following error:

```
/tmp/file.s: Assembler messages:
/tmp/file.s:20: Error: file number 1 already allocated
clang-3.9: error: Xtensa-as command failed with exit code 1
```

     If this happens, set `XCC_NO_G_FLAG` to `1`.
     - For example:

```
# Linux
export XCC_NO_G_FLAG=1
```

2.14.5 DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have ARC MWDT installed on your host.
2. You need to have *Zephyr SDK* installed on your host.

> **Note**
>
> A Zephyr SDK is used as a source of tools like device tree compiler (DTC), QEMU, etc... Even though ARC MWDT toolchain is used for Zephyr RTOS build, still the GNU preprocessor & GNU objcopy might be used for some steps like device tree preprocessing and `.bin` file generation. We used Zephyr SDK as a source of these ARC GNU tools as well. To setup ARC GNU toolchain please use SDK Bundle (Full or Minimal) instead of manual installation of separate tarballs. It installs and registers toolchain and host tools in the system, that allows you to avoid toolchain related issues while building Zephyr.

3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `arcmwdt`.
   - Set `ARCMWDT_TOOLCHAIN_PATH` to the toolchain installation directory. MWDT installation provides `METAWARE_ROOT` so simply set `ARCMWDT_TOOLCHAIN_PATH` to `$METAWARE_ROOT/../` (Linux) or `%METAWARE_ROOT%\..\` (Windows).

> **Tip**
>
> If you have only one ARC MWDT toolchain version installed on your machine you may skip setting `ARCMWDT_TOOLCHAIN_PATH` - it would be detected automatically.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `ARCMWDT_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
arcmwdt
$ echo $ARCMWDT_TOOLCHAIN_PATH
/home/you/ARC/MWDT_2023.03/

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
arcmwdt
> echo %ARCMWDT_TOOLCHAIN_PATH%
C:\ARC\MWDT_2023.03\
```

2.14.6 GNU Arm Embedded

1. Download and install a GNU Arm Embedded build for your operating system and extract it on your file system.

> **Note**
>
> On Windows, we'll assume for this guide that you install into the directory `C:\gnu_arm_embedded`. You can also choose the default installation path used by the ARM GCC installer, in which case you will need to adjust the path accordingly in the guide below.

> **Warning**
>
> On macOS Catalina or later you might need to *change a security policy* for the toolchain to be able to run from the terminal.

2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `GNUARMEMB_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
gnuarmemb
$ echo $GNUARMEMB_TOOLCHAIN_PATH
/home/you/Downloads/gnu_arm_embedded

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
gnuarmemb
> echo %GNUARMEMB_TOOLCHAIN_PATH%
C:\gnu_arm_embedded
```

Warning

On macOS, if you are having trouble with the suggested procedure, there is an unofficial package on brew that might help you. Run `brew install gcc-arm-embedded` and configure the variables

- Set *ZEPHYR_TOOLCHAIN_VARIANT* to `gnuarmemb`.
- Set `GNUARMEMB_TOOLCHAIN_PATH` to the brew installation directory (something like `/usr/local`)

2.14.7 IAR Arm Toolchain

1. Download and install a release v9.70 or newer of IAR Arm Toolchain on your host (IAR Embedded Workbench or IAR Build Tools, perpetual or subscription licensing)
2. Make sure you have *Zephyr SDK* installed on your host.
3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `iar`.
   - Set `IAR_TOOLCHAIN_PATH` to the toolchain installation directory.
4. The cloud licensed variant of the IAR Toolchain needs the `IAR_LMS_BEARER_TOKEN` environment variable to be set to a valid `license bearer token` (subscription licensing).

For example:

```
# Linux (default installation path):
export IAR_TOOLCHAIN_PATH=/opt/iar/cxarm-<version>/arm
export ZEPHYR_TOOLCHAIN_VARIANT=iar
export IAR_LMS_BEARER_TOKEN="<BEARER-TOKEN>"
```

```
# Windows:
set IAR_TOOLCHAIN_PATH=c:\<path>\cxarm-<version>\arm
set ZEPHYR_TOOLCHAIN_VARIANT=iar
set IAR_LMS_BEARER_TOKEN="<BEARER-TOKEN>"
```

Note

Known limitations:

- The IAR Toolchain uses `ilink` for linking and depends on Zephyr's CMAKE_LINKER_GENERATOR. `ilink` is incompatible with Zephyr's linker script template, which works with GNU ld.

- The GNU Assembler distributed with the Zephyr SDK is used for `.S-files`.
- C library support for `Minimal libc` only. C++ is not supported.
- Some Zephyr subsystems or modules may contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `iar`.
- TrustedFirmware is not supported

2.14.8 Intel oneAPI Toolkit

1. Download Intel oneAPI Base Toolkit
2. Assuming the toolkit is installed in `/opt/intel/oneApi`, set environment using:

   ```
   # Linux, macOS:
   export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
   source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh

   # Windows:
   > set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
   ```

   To setup the complete oneApi environment, use:

   ```
   source  /opt/intel/oneapi/setvars.sh
   ```

   The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.
3. Set *ZEPHYR_TOOLCHAIN_VARIANT* to `oneApi`.

2.14.9 Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to reuse the native development tools provided by your operating system.

To use your host gcc, set the *ZEPHYR_TOOLCHAIN_VARIANT environment variable* to `host`. To use clang, set *ZEPHYR_TOOLCHAIN_VARIANT* to `llvm`.

2.14.10 Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system's mechanism of using a `CROSS_COMPILE` environment variable to set up a GNU-based cross toolchain.

Examples of such "other cross compilers" are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in *Toolchains*, the Zephyr build system may not have been tested with them, and doesn't officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. Install a cross compiler suitable for your host and target systems.

   For example, you might install the `gcc-arm-none-eabi` package on Debian-based Linux systems, or `arm-none-eabi-newlib` on Fedora or Red Hat:

   ```
   # On Debian or Ubuntu
   sudo apt-get install gcc-arm-none-eabi
   # On Fedora or Red Hat
   sudo dnf install arm-none-eabi-newlib
   ```

2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `cross-compile`.
   - Set `CROSS_COMPILE` to the common path prefix which your toolchain's binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `CROSS_COMPILE` value may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
cross-compile
$ echo $CROSS_COMPILE
/usr/bin/arm-none-eabi-
```

   You can also set `CROSS_COMPILE` as a CMake variable.

When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The `CROSS_COMPILE` variable is set to the directory concatenated with the file name prefix. In the Debian example above, the `gcc-arm-none-eabi` package installs binaries such as `arm-none-eabi-gcc` and `arm-none-eabi-ld` in directory `/usr/bin/`, so the common prefix is `/usr/bin/arm-none-eabi-` (including the trailing dash, `-`). If your toolchain is installed in `/opt/mytoolchain/bin` with binary names based on target triplet `myarch-none-elf`, `CROSS_COMPILE` would be set to `/opt/mytoolchain/bin/myarch-none-elf-`.

2.14.11 Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, *set these environment variables*:

- Set *ZEPHYR_TOOLCHAIN_VARIANT* to your toolchain's name
- Set `TOOLCHAIN_ROOT` to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the `TOOLCHAIN_ROOT` directory:

- `cmake/toolchain/<toolchain name>/generic.cmake`: configures the toolchain for "generic" use, which mostly means running the C preprocessor on the generated *Devicetree* file.
- `cmake/toolchain/<toolchain name>/target.cmake`: configures the toolchain for "target" use, i.e. building Zephyr and your application's source code.

Here <toolchain name> is the same as the name provided in *ZEPHYR_TOOLCHAIN_VARIANT* See the zephyr files cmake/modules/FindHostTools.cmake and cmake/modules/FindTargetTools.cmake for more details on what your `generic.cmake` and `target.cmake` files should contain.

You can also set `ZEPHYR_TOOLCHAIN_VARIANT` and `TOOLCHAIN_ROOT` as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, `-C <initial-cache>` cmake option may useful. If you save your **ZEPHYR_TOOLCHAIN_VARIANT**, **TOOLCHAIN_ROOT**, and other settings in a file named `my-toolchain.cmake`, you can then invoke cmake as `cmake -C my-toolchain.cmake ...` to save typing.

Zephyr includes `include/zephyr/toolchain.h` which again includes a toolchain specific header based on the compiler identifier, such as `__llvm__` or `__GNUC__`. Some custom compilers identify themselves as the compiler on which they are based, for example `llvm` which then gets the `toolchain/llvm.h` included. This included file may though not be right for the custom

toolchain. In order to solve this, and thus to get the `include/other.h` included instead, add the set(TOOLCHAIN_USE_CUSTOM 1) cmake line to the generic.cmake and/or target.cmake files located under `<TOOLCHAIN_ROOT>/cmake/toolchain/<toolchain name>/`.

When **TOOLCHAIN_USE_CUSTOM** is set, the `other.h` must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the `other.h` header file, would be a directory under the directory specified in `TOOLCHAIN_ROOT` as `include/zephyr/toolchain`. To get the toolchain header included in zephyr's build, the **USERINCLUDE** can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

2.15 Tools and IDEs

2.15.1 CLion

Note

This guide describes how to set up, build, and debug Zephyr's sample application in CLion, using the IDE's CMake integration. This approach is no longer optimal.

CLion now features native Zephyr West integration which provides an easier and more intuitive way to open, build, and run/debug Zephyr projects. This guide will be updated soon, but is still valid if you prefer to use CMake.

CLion is a cross-platform C/C++ IDE that supports multi-threaded RTOS debugging.

This guide describes the process of setting up, building, and debugging Zephyr's multi-thread-blinky sample in CLion.

The instructions have been tested on Windows. In terms of the CLion workflow, the steps would be the same for macOS and Linux, but make sure to select the correct environment file and to adjust the paths.

Get CLion

Download CLion and install it.

Initialize a new workspace

This guide gives details on how to build and debug the multi-thread-blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in CLion

1. In CLion, click *Open* on the Welcome screen or select *File* ▸ *Open* from the main menu.
2. Navigate to your Zephyr workspace (i.e.the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions), then select `zephyr/samples/basic/threads` or another sample project folder.

   Click *OK*.
3. If prompted, click *Trust Project*.

   See the Project security section in CLion web help for more information on project security.

Configure the toolchain and CMake profile

CLion will open the *Open Project Wizard* with the CMake profile settings. If that does not happen, go to *Settings* ▸ *Build, Execution, Deployment* ▸ *CMake*.

1. Click *Manage Toolchains* next to the *Toolchain* field. This will open the *Toolchain* settings dialog.
2. We recommend that you use the *Bundled MinGW* toolchain with default settings on Windows, or the *System* (default) toolchain on Unix machines.
3. Click *Add environment* ▸ *From file* and select `..\.venv\Scripts\activate.bat`.

   Click *Apply* to save the changes.

4. Back in the CMake profile settings dialog, specify your board in the *CMake options* field. For example:

   ```
   -DBOARD=nrf52840dk/nrf52840
   ```

5. Click *Apply* to save the changes.

   CMake load should finish successfully.

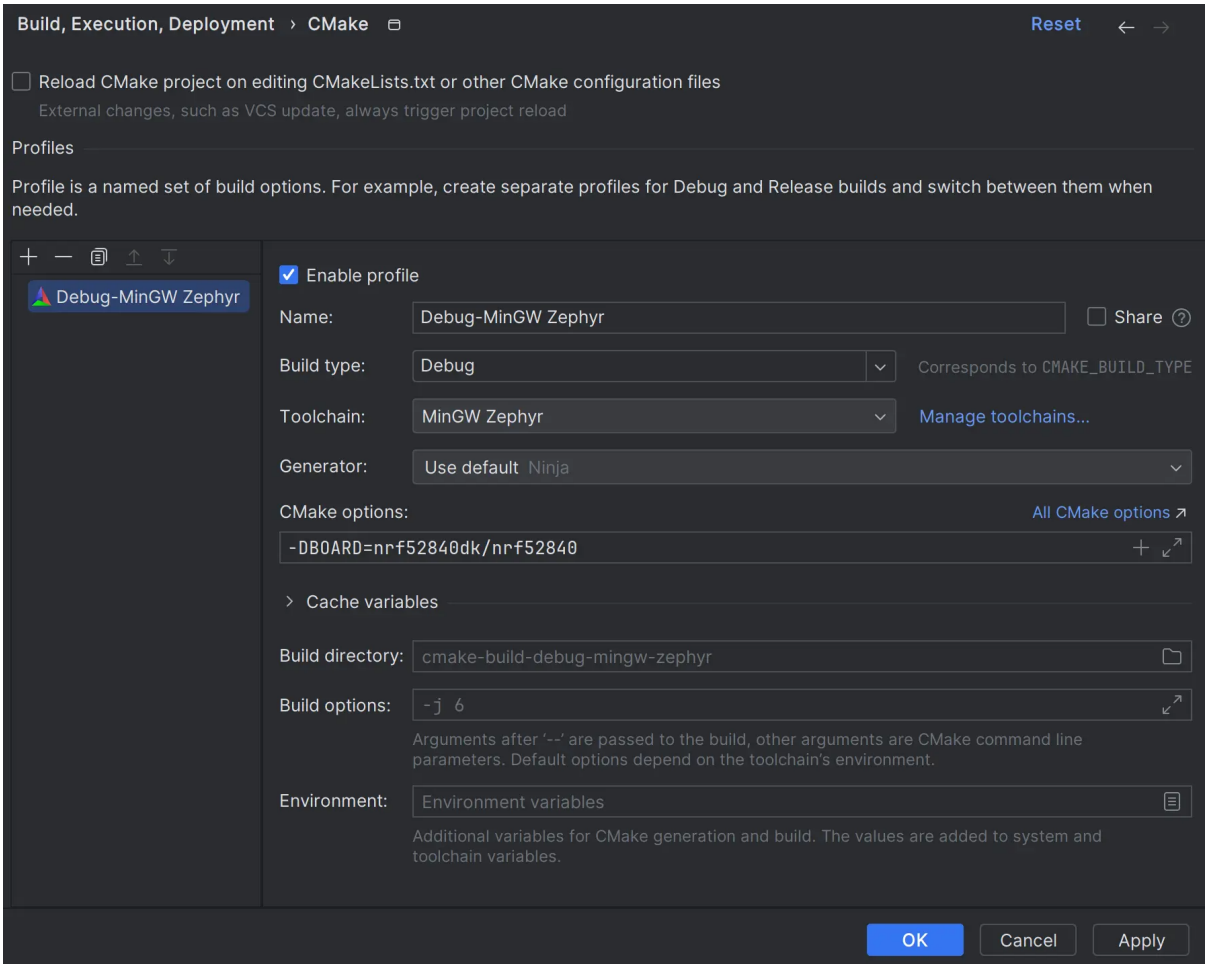
Configure Zephyr parameters for debug

1. In the configuration switcher on the top right, select *guiconfig* and click the hammer icon.
2. Use the GUI application to set the following flags:

   ```
   DEBUG_THREAD_INFO
   THREAD_RUNTIME_STATS
   DEBUG_OPTIMIZATIONS
   ```

Build the project

In the configuration switcher, select **zephyr_final** and click the hammer icon.



Build, Execution, Deployment › CMake
Reset
Reload CMake project on editing CMakeLists.txt or other CMake configuration files
External changes, such as VCS update, always trigger project reload
Profiles
Profile is a named set of build options. For example, create separate profiles for Debug and Release builds and switch between them when needed.
Debug-MinGW Zephyr
Enable profile
Name:
Debug-MinGW Zephyr
Share
Build type:
Debug
Corresponds to CMAKE_BUILD_TYPE
Toolchain:
MinGW Zephyr
Manage toolchains...
Generator:
Use default Ninja
CMake options:
All CMake options
-DBOARD=nrf52840dk/nrf52840
Cache variables
Build directory:
cmake-build-debug-mingw-zephyr
Build options:
-j 6
Arguments after '--' are passed to the build, other arguments are CMake command line parameters. Default options depend on the toolchain's environment.
Environment:
Environment variables
Additional variables for CMake generation and build. The values are added to system and toolchain variables.
OK
Cancel
Apply

Note that other CMake targets like `puncover` or `hardenconfig` can also be called at this point.

Enable RTOS integration

1. Go to *Settings* ▸ *Build, Execution, Deployment* ▸ *Embedded Development* ▸ *RTOS Integration*.
2. Set the *Enable RTOS Integration* checkbox.

   This option enables Zephyr tasks view during debugging. See Multi-threaded RTOS debug in CLion web help for more information.

   You can leave the option set to *Auto*. CLion will detect Zephyr automatically.

Create an Embedded GDB Server configuration

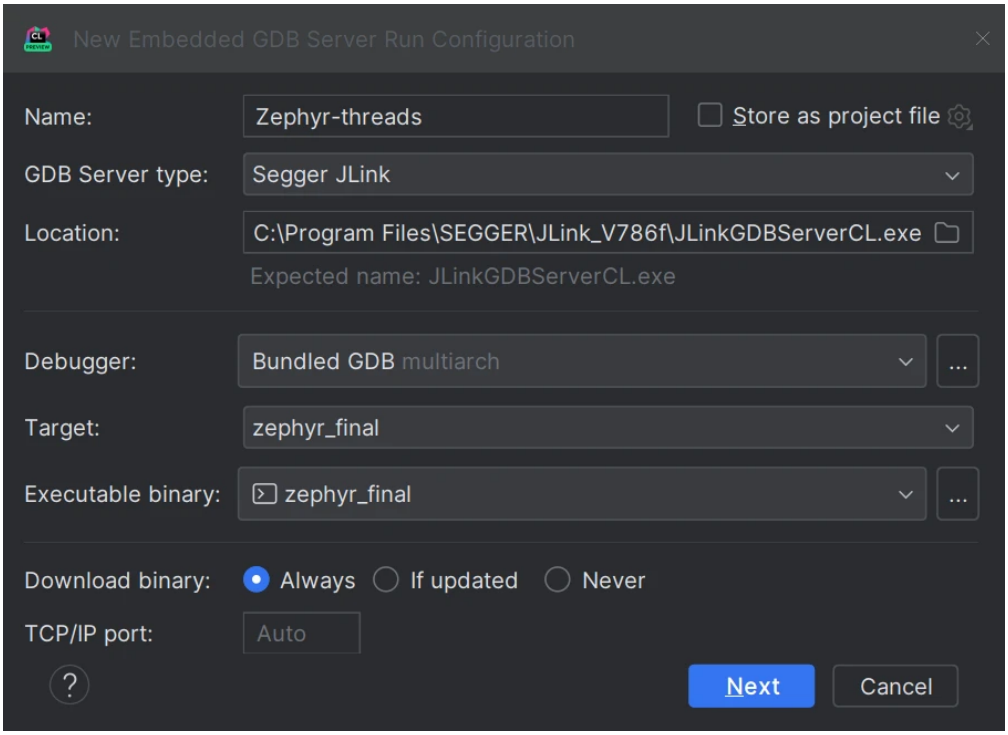
In order to debug a Zephyr application in CLion, you need to create a run/debug configuration out of the Embedded GDB Server template.

Instructions below show the case of a Nordic Semiconductor board and a Segger J-Link debug probe. If your setup is different, make sure to adjust the configuration settings accordingly.

1. Select *Run* ▸ *New Embedded Configuration* from the main menu.
2. Configure the settings:

Option	Value
Nam (optiona	Zephyr-threads
GDB Serv Type	Segger JLink
Location	The path to `JLinkGDBServerCL.exe` on Windows or the `JLinkGDBServer` binary on macOS/Linux.
Debugger	Bundled GDB **Note** For non-ARM and non-x86 architectures, use a GDB executable from Zephyr SDK. Make sure to pick a version with Python support (for example, **riscv64-zephyr-elf-gdb-py**) and check that Python is present in the system `PATH`.
Target	zephyr-final
Executa binary	zephyr-final
Dow load bi- nary	Always
TCP/ port	Auto

3. Click *Next* to set the Segger J-Link parameters.



New Embedded GDB Server Run Configuration
Name:
Zephyr-threads
Store as project file
GDB Server type:
Segger JLink
Location:
C:\Program Files\SEGGER\JLink_V786f\JLinkGDBServerCL.exe

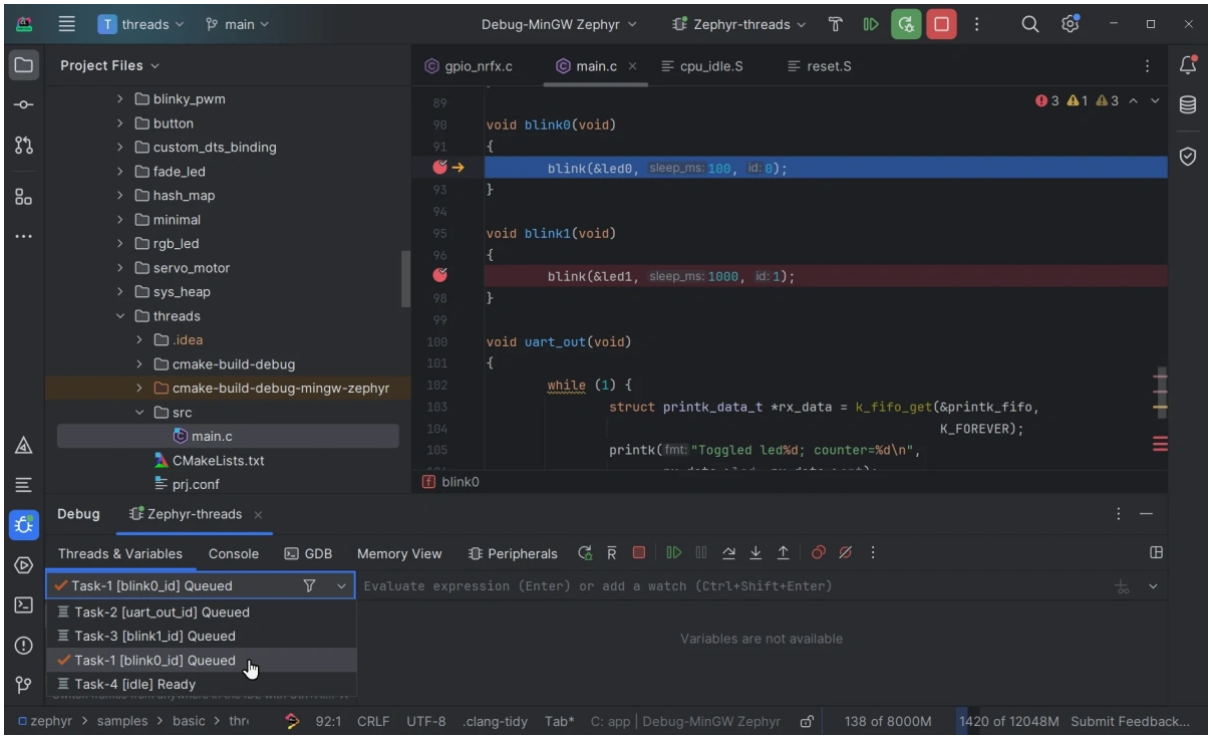
Nuclei System
Previous
Create
Cancel

4. Click *Create* when ready.

Start debugging

1. Place breakpoints by clicking in the left gutter next to the code lines.
2. Make sure that **Zephyr-threads** is selected in the configuration switcher and click the bug icon or press `Ctrl+D`.
3. When a breakpoint is hit, CLion opens the Debug tool window.

   Zephyr tasks are listed in the *Threads & Variables* pane. You can switch between them and inspect the variables for each task.



Refer to CLion web help for detailed description of the IDE debug capabilities.

2.15.2 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

> **Note**
>
> Linux and macOS development environments are supported, but not Windows.

Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g. :

- Debian
- Fedora
- Ubuntu
- OpenSUSE
- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at https://coccinelle.lip6.fr/

Or from Github at:

https://github.com/coccinelle/coccinelle

Once you have it, run the following commands:

```
./autogen
./configure
make
```

as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

https://github.com/coccinelle/coccinelle/blob/master/install.txt

Supplemental documentation

For Semantic Patch Language(SmPL) grammar documentation refer to:

https://coccinelle.gitlabpages.inria.fr/website/documentation.html

Using Coccinelle on Zephyr

`coccicheck` checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: `patch`, `report`, `context`, and `org`. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- `patch` proposes a fix, when possible.
- `report` generates a list in the following format: file:line:column-column: message
- `context` highlights lines of interest and their context in a diff-like style.Lines of interest are indicated with `-`.
- `org` generates a report in the Org mode format of Emacs.

Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is `report`.

Two other modes provide some common combinations of these modes.

- `chain` tries the previous modes in the order above until one succeeds.
- `rep+ctxt` runs successively the report mode and the context mode. It should be used with the C option (described later) which checks the code on a file basis.

Examples

To make a report for every semantic patch, run the following command:

```
./scripts/coccicheck --mode=report
```

To produce patches, run:

```
./scripts/coccicheck --mode=patch
```

The `coccicheck` target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

To enable verbose messages set `--verbose=1` option, for example:

```
./scripts/coccicheck --mode=report --verbose=1
```

Coccinelle parallelization

By default, `coccicheck` tries to run as parallel as possible. To change the parallelism, set the `--jobs=<number>` option. For example, to run across 4 CPUs:

```
./scripts/coccicheck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled `coccicheck` will enable dynamic load balancing by using `--chunksize 1` argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the `coccicheck` command captures this return value.

Using Coccinelle with a single semantic patch

The option `--cocci` can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccicheck --mode=report --cocci=<example.cocci>
```

or:

```
./scripts/coccicheck --mode=report --cocci=./path/to/<example.cocci>
```

Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check `drivers/usb/` one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The `report` mode is the default. You can select another one with the `--mode=<mode>` option explained above.

Debugging Coccinelle SmPL patches

Using `coccicheck` is best as it provides in the spatch command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for stderr to be redirected to stderr, by default stderr is redirected to /dev/null, if you'd like to capture stderr you can specify the `--debug=file.err` option to `coccicheck`. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
cat cocci.err
```

Debugging support is only supported when using Coccinelle >= 1.0.2.

Additional Flags

Additional flags can be passed to spatch through the SPFLAGS variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle >= 1.0.6. When no ID file is specified coccinelle assumes your ID database file is in the file .id-utils.index on the top level of the kernel, coccinelle carries a script scripts/idutils_index.sh which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn't recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the `---macro-file-builtins <headerfile.h>` flag.

The `<headerfile.h>` should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.

For example:

`Z_SYSCALL_HANDLER` is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example `mymacros.h`.

```
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file `mymacros.h` during transformation:

```
./scripts/coccicheck --sp-flag="---macro-file-builtins mymacros.h"
```

See `spatch --help` to learn more about spatch options.

Note that the `--use-glimpse` and `--use-idutils` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```
// Options: --no-includes --include-headers
```

Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have `report` mode.
- The first few lines should state the purpose of the script using `///` comments . Usually, this message would be used as the commit log when proposing a patch based on the script.

Example

```
/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element
```

- A more detailed information about the script with exceptional cases or false positives (if any) can be listed using `//#` comments.

Example

```
//# This makes an effort to find cases where ARRAY_SIZE can be used such as
//# where there is a division of sizeof the array by the sizeof its first
//# element or by any indexed element or the element type. It replaces the
//# division of the two sizeofs by ARRAY_SIZE.
```

- Confidence: It is a property defined to specify the accuracy level of the script. It can be either `High`, `Moderate` or `Low` depending upon the number of false positives observed.

Example

```
// Confidence: High
```

- Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.

Example

```
virtual context

@depends on context@

|
```

(continues on next page)

(continued from previous page)

```
* (sizeof(E)/sizeof(E[...]))
|
* (sizeof(E)/sizeof(T))
)
```

Detailed description of the `report` mode

`report` generates a list in the following format:

```
file:line:column-column: message
```

Example Running:

```
./scripts/coccicheck --mode=report --cocci=scripts/coccinelle/array_size.cocci
```

will execute the following part of the SmPL script:

```

ext/hal/nxp/mcux/drivers/imx/fsl_dcp.c:944:45-46: WARNING: Use ARRAY_SIZE
```

Detailed description of the `patch` mode

When the `patch` mode is available, it proposes a fix for each problem identified.

Example Running:

```
./scripts/coccicheck --mode=patch --cocci=scripts/coccinelle/misc/array_size.cocci
```

will execute the following part of the SmPL script:

```
<smpl>

@depends on patch@

2.15.3 STM32CubeIDE

STM32CubeIDE is an Eclipse-based integrated development environment from STMicroelectronics designed for the STM32 series of MCUs and MPUs.

This guide describes the process of setting up, building, and debugging Zephyr applications using the IDE.

A project must have already been created with Zephyr and west.

These directions have been validated to work with version 1.16.0 of the IDE on Linux.

Project Setup

1. Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.
2. Run STM32CubeIDE from your Zephyr environment. Example:

   ```
   $ /opt/st/stm32cubeide_1.16.0/stm32cubeide
   ```

3. Open your already existing project by going to *File* ▸ *New* ▸ *STM32 CMake Project*:
4. Select *Project with existing CMake sources*, then click *Next*.
5. Select *Next* and browse to the location of your sources. The folder that is opened should have the `CMakeLists.txt` and `prj.conf` files.
6. Select *Next* and select the appropriate MCU. Press *Finish* and your project should now be available. However, more actions must still be done in order to configure it properly.
7. Right-click on the newly created project in the workspace, and select *Properties*.
8. Go to the *C/C++ Build* page and set the Generator to `Ninja`. In *Other Options*, specify the target `BOARD` in CMake argument format. If an out-of-tree board is targeted, the `BOARD_ROOT` option must also be set. The resulting settings page should look similar to this:

   These options may or may not be needed depending on if you have an out-of-tree project or not.

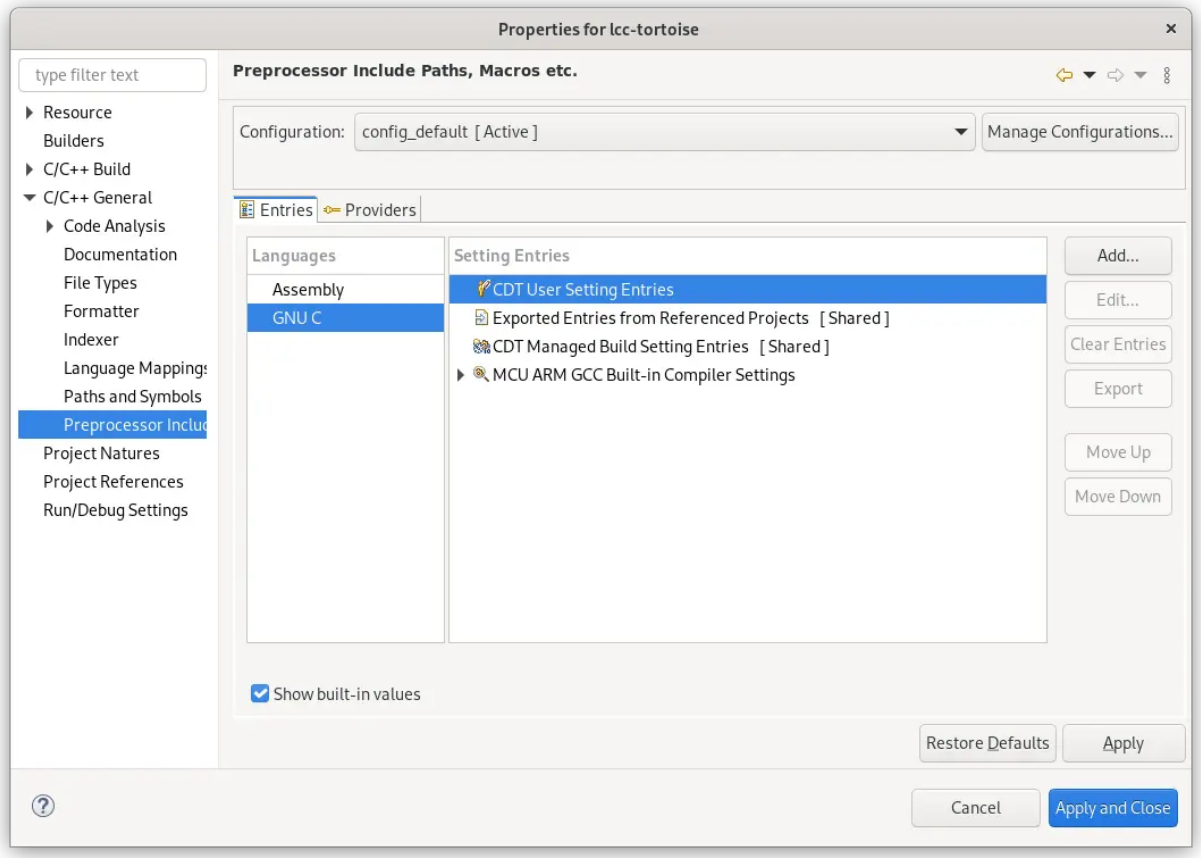
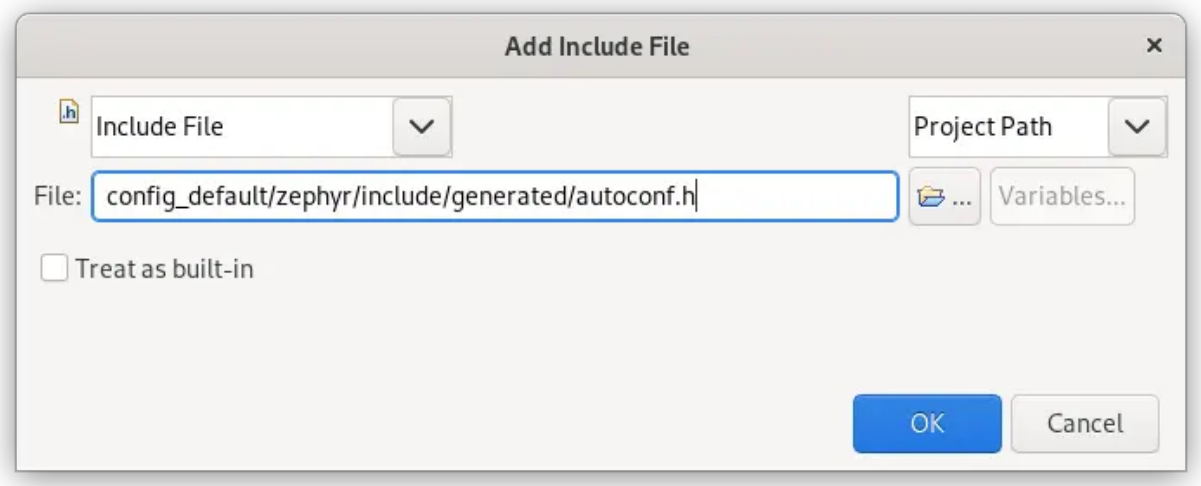
Apply and Close

9. Go to the *C/C++ General ▸ Preprocessor Include* page. Select the *GNU C* language, and click on the *CDT User Settings Entries* option.

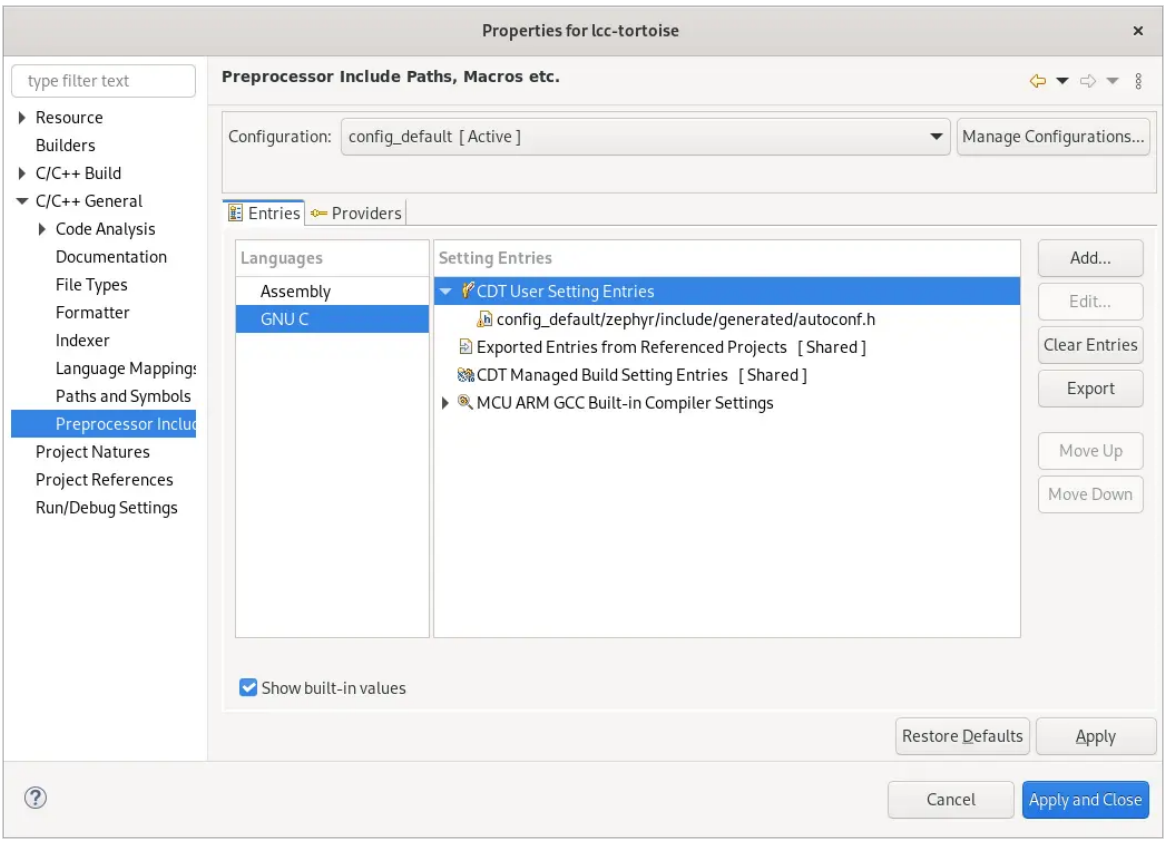


Click *Add* to add an *Include File* that points to Zephyr's `autoconf.h`, which is located in `<build dir>/zephyr/include/generated/autoconf.h`. This will ensure that STM32CubeIDE picks up Zephyr configuration options. The following dialog will be shown. Fill it in as follows:



Once the include file has been added, your properties page should look similar to the following:

10. Click *Apply and Close*
11. You may now build the project using the *Build* button on the toolbar. The project can be run using the *Run* button, as well as debugged using the *Debug* button.



Debugging only

If you only want to use STM32CubeIDE to debug your project you can proceed as follows:

1. First, make sure to compile your project and have the `zephyr.elf` available.
2. Run STM32CubeIDE and import your project by going to *File* ▸ *Import...*:
3. Select *C/C++* ▸ *STM32 Cortex-M Executable*, then click *Next*:
4. Click on *Browse* to browse to your build folder and select your `zephyr.elf`.
5. Click on *Select* to select your MCU. If relevant, choose also your CPU and/or core.
6. Click on *Finish*.
7. The project can now be debugged using the *Debug* button.

Troubleshooting

When configuring your project you see an error that looks similar to:

```
Error message: Traceback (most recent call last):

  File "/path/to/zephyr/scripts/list_boards.py", line 11, in <module>
    import pykwalify.core

ModuleNotFoundError: No module named 'pykwalify'
```

This means that you did not start the IDE in a Zephyr environment. You must delete the `config_default` build directory and start STM32CubeIDE again, making sure that you can run `west` in the shell that you start STM32CubeIDE from.

2.15.4 Visual Studio Code

Visual Studio Code (VS Code for short) is a popular cross-platform IDE that supports C projects and has a rich set of extensions.

This guide describes the process of setting up VS Code for Zephyr's blinky sample in VS Code.

The instructions have been tested on Linux, but the steps should be the same for macOS and Windows, just make sure to adjust the paths if needed.

Get VS Code

Download VS Code and install it.

Install the required extensions through the *Extensions* marketplace in the left panel. Search for the C/C++ Extension Pack and install it.

Initialize a new workspace

This guide gives details on how to configure the blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in VS Code

1. In VS Code, select *File* ▸ *Open Folder* from the main menu.
2. Navigate to your Zephyr workspace and select it (i.e. the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions).

3. If prompted, enable workspace trust.

Generate compile commands

In order to support code navigation and linting capabilities, you must compile your project once to generate the `compile_commands.json` file that will provide the C/C++ extension with the required information (ex. include paths). You may do it from VS Code embedded terminal; select *Terminal* ▸ *New Terminal* from the top menu or the command palette (`Ctrl+Shift+P`), then type:

```
$ cd zephyr
$ west build -p always -b native_sim/native/64
```

Configure the C/C++ extension

You'll now need to point to the generated `compile_commands.json` file to enable linting and code navigation in VS Code.

1. Go to the *File* ▸ *Preferences* ▸ *Settings* in the VS Code top menu.
2. Search for the parameter *C_Cpp* > *Default: Compile Commands* and set its value to: `zephyr/build/compile_commands.json`.

   Linting errors in the code should now be resolved, and you should be able to navigate through the code.

Additional resources

There are many other extensions that can be useful when working with Zephyr and VS Code. While this guide does not cover them yet, you may refer to their documentation to set them up:

Contribution tooling

- Checkpatch Extension
- EditorConfig Extension

Documentation languages extensions

- reStructuredText Extension Pack

IDE extensions

- CMake Extension documentation
- nRF Kconfig Extension
- nRF DeviceTree Extension
- GNU Linker Map files Extension

Additional guides

- How to Develop Zephyr Apps with a Modern, Visual IDE

> **Note**
>
> Please be aware that these extensions might not all have the same level of quality and maintenance.

2.15.5 Workbench for Zephyr

Workbench for Zephyr is a Visual Studio Code (VS Code) extension that adds Zephyr development support, including **SDK management**, **project creation wizard**, **build/flash**, and **debugging**.

Check the Getting started tutorial for a walkthrough.

Key features

- Install native Host Tools (Python, CMake, ...)
- Install and assign toolchains (Zephyr SDK, IAR, ...)
- Import West workspaces
- Create and import Zephyr applications
- Build and flash applications
- Debug applications
- Install runners automatically
- Perform memory and static analysis

Compatibility

- Windows 10-11
- Linux (x86_64)
  - Ubuntu
  - Debian
  - Fedora
  - Other distributions may also work (not tested)
- macOS

Getting started

1. Install the extension

   Install Workbench for Zephyr from the VS Code Marketplace.

2. Open the Workbench for Zephyr extension

   In the Activity Bar, click the *Workbench for Zephyr* icon.

3. Install Host Tools

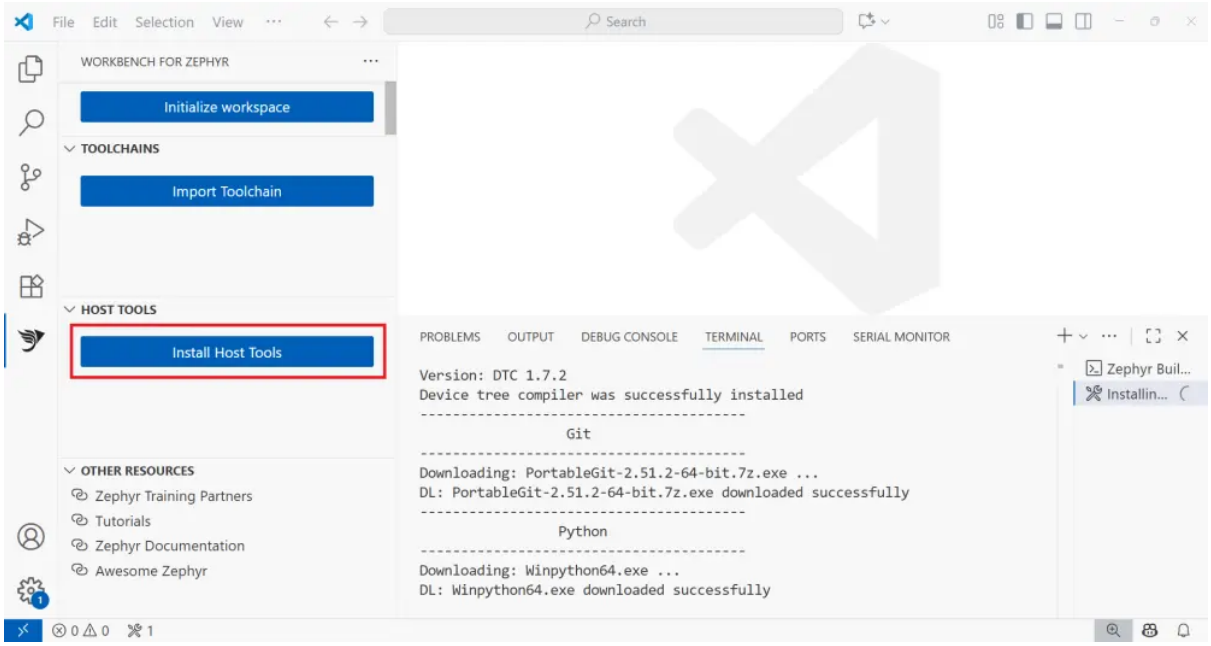
   Click *Install Host Tools* to download and install the native tools (typically into `${HOME}/.zinstaller`).

   > **Note**
   >
   > Some host tools may require administrator privileges. On Windows, this is required when installing 7z. On Linux, this is required when installing tools using the package manager, for example when running `apt install`.

4. Import a toolchain

   Click *Import Toolchain*, choose a toolchain, and select the destination folder.

   A toolchain provides the compiler and debugger required to build and debug Zephyr applications. The Zephyr SDK is the recommended option and can be installed as either the full



package or a minimal target-specific version. Workbench also supports other toolchains, such as IAR.

5. Initialize / Import a West workspace

   Click *Initialize workspace* and fill the workspace information.

   Workbench will create the workspace and parse the west manifest to configure projects.

6. Create a new application

   On Workbench for Zephyr, new projects are based on samples from Zephyr sources.

   - Click *Create New Application*.
   - Select the *West Workspace* to attach to.
   - Select the *Zephyr SDK* to use.
   - Select the target *Board* (for example, `ST STM32F4 Discovery`).
   - Select the *Sample* project to base on (for example, `hello_world`).
   - Enter the project name.
   - Enter the project location.

7. Build the application

   Click *Build* in the status bar, or select the application folder to build. Build output is shown in the integrated terminal.

8. Configure and run a debug session

   Use *Debug Manager* to generate/update a debug configuration (`.vscode/launch.json`):

   - Generated ELF (Program Path)
   - SVD file (optional)
   - GDB/port/address (if needed)
   - Debug server/runner (OpenOCD, J-Link, LinkServer, pyOCD, ...)

   Then start debugging normally via *Run and Debug*

Chapter 3

Kernel

3.1 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel's features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

3.1.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

Threads

Note

There is also limited support for using *Operation without Threads*.

- *Lifecycle*
  - *Thread Creation*
  - *Thread Termination*
  - *Thread Aborting*
  - *Thread Suspension*
- *Thread States*

- *Thread Stack objects*
  - *Kernel-only Stacks*
  - *Thread stacks*
- *Thread Priorities*
  - *Meta-IRQ Priorities*
- *Thread Options*
- *Thread Custom Data*
- *Implementation*
  - *Spawning a Thread*
  - *Dropping Permissions*
  - *Terminating a Thread*
- *Runtime Statistics*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A *thread* is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a *thread id* that is assigned when the thread is spawned.

A thread has the following key properties:

- A **stack area**, which is a region of memory used for the thread's stack. The **size** of the stack area can be tailored to conform to the actual needs of the thread's processing. Special macros exist to create and work with stack memory regions.
- A **thread control block** for private kernel bookkeeping of the thread's metadata. This is an instance of type `k_thread`.
- An **entry point function**, which is invoked when the thread is started. Up to 3 **argument values** can be passed to this function.
- A **scheduling priority**, which instructs the kernel's scheduler how to allocate CPU time to the thread. (See *Scheduling*.)
- A set of **thread options**, which allow the thread to receive special treatment by the kernel under specific circumstances. (See *Thread Options*.)
- A **start delay**, which specifies how long the kernel should wait before starting the thread.
- An **execution mode**, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the `CONFIG_USERSPACE` option. See *User Mode*.

Lifecycle

Thread Creation A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread's stack is typically left uninitialized.

Specifying a start delay of `K_NO_WAIT` instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

Thread Termination Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as **termination**.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does *not* reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the `k_thread_join()` API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a `k_thread_abort()` call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be reused for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread's own logic signals completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use `k_thread_join()` or `k_thread_abort()` to synchronize on thread termination state and not rely on signaling from within application logic.

Thread Aborting A thread may asynchronously end its execution by **aborting**. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer.

A thread can also be aborted by another thread (or by itself) by calling `k_thread_abort()`. However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it.

As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

Note

The kernel does not currently make any claims regarding an application's ability to respawn a thread that aborts.

Thread Suspension A thread can be prevented from executing for an indefinite period of time if it becomes **suspended**. The function `k_thread_suspend()` can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect.

Once suspended, a thread cannot be scheduled until another thread calls `k_thread_resume()` to remove the suspension.

Note

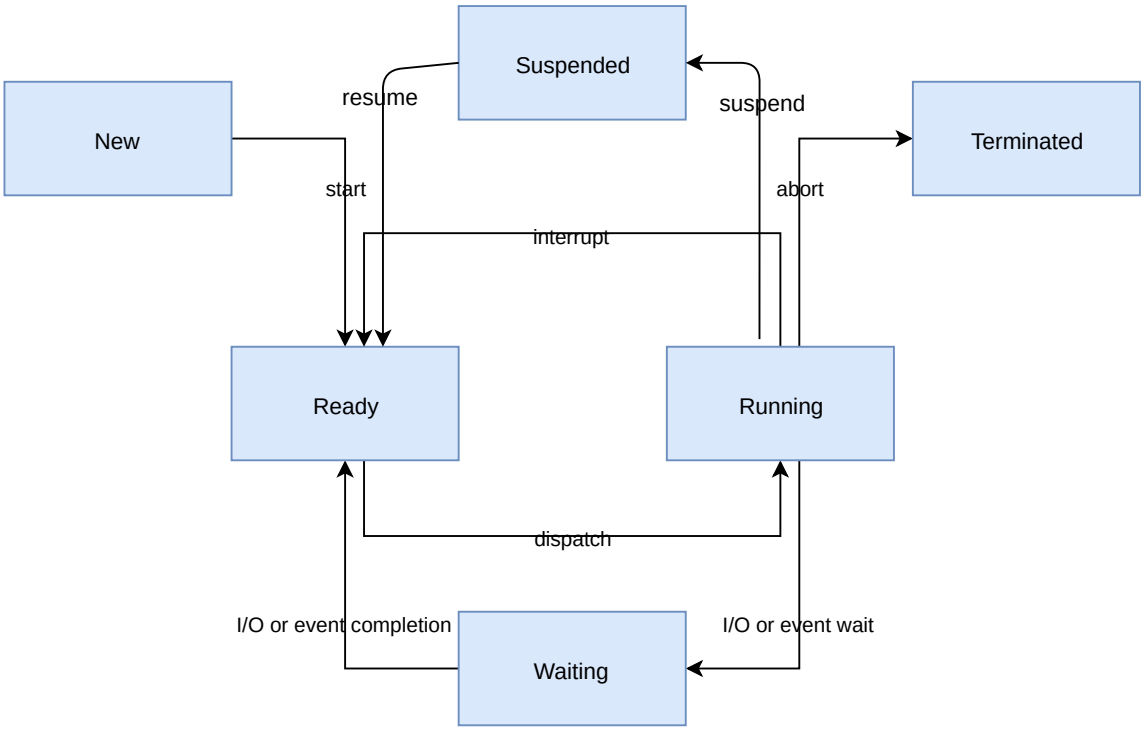
A thread can prevent itself from executing for a specified period of time using `k_sleep()`. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

Thread States A thread that has no factors that prevent its execution is deemed to be **ready**, and is eligible to be selected as the current thread.

A thread that has one or more factors that prevent its execution is deemed to be **unready**, and cannot be selected as the current thread.

The following factors make a thread unready:

- The thread has not been started.
- The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
- The thread is waiting for a timeout to occur.
- The thread has been suspended.
- The thread has terminated or aborted.



Note

Although the diagram above may appear to suggest that both **Ready** and **Running** are distinct thread states, that is not the correct interpretation. **Ready** is a thread state, and **Running** is a schedule state that only applies to **Ready** threads.

Thread Stack objects Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

- There may need to be additional memory reserved for memory management structures

- If guard-based stack overflow detection is enabled, a small write-protected memory management region must immediately precede the stack buffer to catch overflows.
- If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
- If userspace is enabled, the thread's stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can't simply pass an arbitrary character buffer to `k_thread_create()`. Special macros exist to instantiate stacks statically, prefixed with `K_KERNEL_STACK` and `K_THREAD_STACK`.

Additionally, stacks may be instantiated dynamically using `k_thread_stack_alloc()` and subsequently freed with `k_thread_stack_free()`.

Kernel-only Stacks If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the `K_KERNEL_STACK` macros.

These stacks save memory because an MPU region will never need to be programmed to cover the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with `K_THREAD_STACK` macros. This may use more memory but the stack object is suitable for hosting user threads.

If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

Thread Priorities A thread's priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 *higher* priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread's priority.

- A *cooperative thread* has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A *preemptible thread* has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

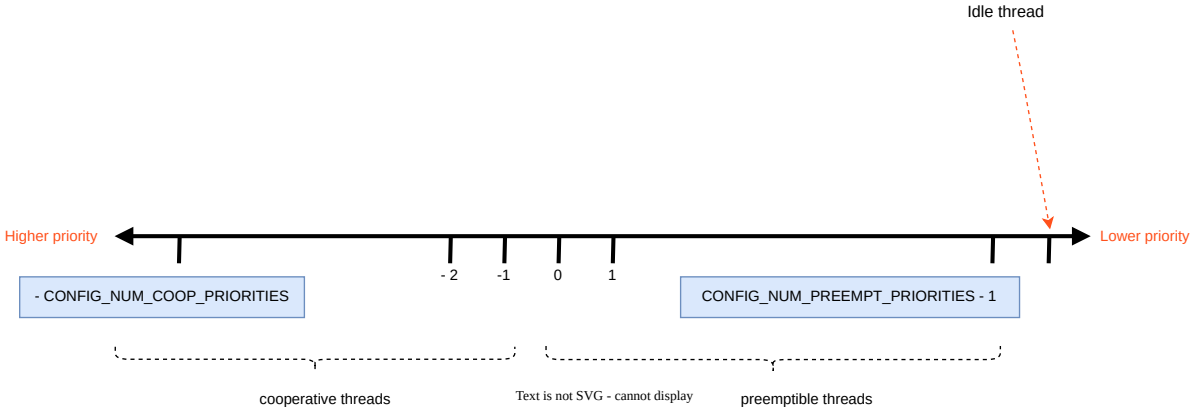
A thread's initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

Note

The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application's request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options `CONFIG_NUM_COOP_PRIORITIES` and `CONFIG_NUM_PREEMPT_PRIORITIES` specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: (`-CONFIG_NUM_COOP_PRIORITIES`) to -1
- preemptive threads: 0 to (`CONFIG_NUM_PREEMPT_PRIORITIES` - 1)



For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges -5 to -1 and 0 to 9, respectively.

Meta-IRQ Priorities When enabled (see `CONFIG_NUM_METAIRQ_PRIORITIES`), there is a special subclass of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

Note

When a cooperative (or schedule-locked) thread that was preempted by a meta-IRQ thread resumes its execution after the meta-IRQ thread completes, it will be on the same CPU–assuming it was neither suspended nor aborted. This helps ensure that these threads are not unexpectedly shuffled to another CPU while in the midst of querying the properties associated with their own CPU.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling k_sem_give(), etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like "pended IRQ" when done from true interrupt context. The intent is that this feature will be used to implement interrupt "bottom half" processing and/or "tasklet" features in driver subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won't schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

Thread Options The kernel supports a small set of *thread options* that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the | character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

`K_ESSENTIAL`
: This option tags the thread as an *essential thread*. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.

  By default, the thread is not considered to be an essential thread.

`K_SSE_REGS`
: This x86-specific option indicate that the thread uses the CPU's SSE registers. Also see `K_FP_REGS`.

  By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

`K_FP_REGS`
: This option indicate that the thread uses the CPU's floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see *Floating Point Services*.)

  By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

`K_USER`
: If `CONFIG_USERSPACE` is enabled, this thread will be created in user mode and will have reduced privileges. See *User Mode*. Otherwise this flag does nothing.

`K_INHERIT_PERMS`
: If `CONFIG_USERSPACE` is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See *User Mode*.

Thread Custom Data Every thread has a 32-bit *custom data* area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

> **Note**
>
> Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option `CONFIG_THREAD_CUSTOM_DATA` can be used to enable support.

The `k_thread_custom_data_set()` and `k_thread_custom_data_get()` functions are used to write and read a thread's custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.

Note

Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

Implementation

Spawning a Thread A thread is spawned by defining its stack area and its thread control block, and then calling `k_thread_create()`.

The stack area may be statically allocated using `K_THREAD_STACK_DEFINE` or `K_KERNEL_STACK_DEFINE` to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to `K_THREAD_STACK` or `K_KERNEL_STACK` family of stack instantiation macros.
- For a stack object defined with the `K_THREAD_STACK` family of macros, the return value of `K_THREAD_STACK_SIZEOF()` for that' object.
- For a stack object defined with the `K_KERNEL_STACK` family of macros, the return value of `K_KERNEL_STACK_SIZEOF()` for that object.

Alternatively, the stack area may be dynamically allocated using `k_thread_stack_alloc()` and freed using `k_thread_stack_free()`.

The thread spawning function returns its thread id, which can be used to reference the thread.

The following code spawns a thread that starts immediately.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;

k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area,
```

(continues on next page)

(continued from previous page)

```
                                K_THREAD_STACK_SIZEOF(my_stack_area),
                                my_entry_point,
                                NULL, NULL, NULL,
                                MY_PRIORITY, 0, K_NO_WAIT);
```

Alternatively, a thread can be declared at compile time by calling K_THREAD_DEFINE. Observe that the macro defines the stack area, control block, and thread id variables automatically.

The following code has the same effect as the code segment above.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_DEFINE(my_tid, MY_STACK_SIZE,
                my_entry_point, NULL, NULL, NULL,
                MY_PRIORITY, 0, 0);
```

Note

The delay parameter to k_thread_create() is a k_timeout_t value, so K_NO_WAIT means to start the thread immediately. The corresponding parameter to K_THREAD_DEFINE is a duration in integral milliseconds, so the equivalent argument is 0.

The following code dynamically allocates a thread stack, waits until the thread has joined, and then frees the dynamically allocated thread stack.

```
extern void my_entry_point(void *, void *, void *);

k_tid_t my_tid;
void *my_stack_area;

my_stack_area = k_thread_stack_alloc(CONFIG_DYNAMIC_THREAD_STACK_SIZE);
my_tid = k_thread_create(&my_thread_data, my_stack_area,
                         CONFIG_DYNAMIC_THREAD_STACK_SIZE,
                         my_entry_point,
                         NULL, NULL, NULL,
                         MY_PRIORITY, 0, K_NO_WAIT);
k_thread_join(my_tid, K_FOREVER);
k_thread_stack_free(my_stack_area);
```

User Mode Constraints This section only applies if CONFIG_USERSPACE is enabled, and a user thread tries to create a new thread. The k_thread_create() API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The K_USER option must be used, as user threads can only create other user threads.

- The K_ESSENTIAL option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

Dropping Permissions If CONFIG_USERSPACE is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the k_thread_user_mode_enter() API. This is a one-way operation which will reset and zero the thread's stack memory. The thread will be marked as non-essential.

Terminating a Thread A thread terminates itself by returning from its entry point function.

The following code illustrates the ways a thread can terminate.

```
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ...
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }

    /* thread terminates at end of entry point function */
}
```

If CONFIG_USERSPACE is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be reused.

Runtime Statistics Thread runtime statistics can be gathered and retrieved if CONFIG_THREAD_RUNTIME_STATS is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS.

Here is an example:

```
k_thread_runtime_stats_t rt_stats_thread;

k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);

printk("Cycles: %llu\n", rt_stats_thread.execution_cycles);
```

Suggested Uses Use threads to handle processing that cannot be handled in an ISR.

Use separate threads to handle logically distinct processing operations that can execute in parallel.

Configuration Options Related configuration options:

- CONFIG_MAIN_THREAD_PRIORITY
- CONFIG_MAIN_STACK_SIZE
- CONFIG_IDLE_STACK_SIZE
- CONFIG_THREAD_CUSTOM_DATA

- CONFIG_NUM_COOP_PRIORITIES
- CONFIG_NUM_PREEMPT_PRIORITIES
- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
- CONFIG_TIMESLICE_PRIORITY
- CONFIG_USERSPACE

Thread Stack APIs

Scheduling

The kernel's priority-based scheduler allows an application's threads to share the CPU.

Concepts The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the **current thread**.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread, meaning when the scheduler switches the CPU's execution from one thread to another. These points are called **reschedule points**. Some potential reschedule points are:

- transition of a thread from running state to a suspended or waiting state, for example by `k_sem_take()` or `k_sleep()`.
- transition of a thread to the *ready state*, for example by `k_sem_give()` or `k_thread_start()`
- return to thread context after processing an interrupt
- when a running thread invokes `k_yield()`

A thread **sleeps** when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.

Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread's CPU register values. These register values get restored when the thread later resumes execution.

Scheduling Algorithm The kernel's scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread's relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (CONFIG_SCHED_DEADLINE) and a choice of threads

have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine `k_thread_deadline_set()` is used to set a thread's deadline.

Note

Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

- Simple linked-list ready queue (`CONFIG_SCHED_SIMPLE`)

  The scheduler ready queue will be implemented as a simple unordered list, with very fast constant time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

- Red/black tree ready queue (`CONFIG_SCHED_SCALABLE`)

  The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not otherwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.

  Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won't need this ready queue implementation.

- Traditional multi-queue ready queue (`CONFIG_SCHED_MULTIQ`)

  When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority.

  This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.

  It incurs only a tiny code size overhead vs. the "dumb" scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.

  Typical applications with small numbers of runnable threads probably want the simple scheduler.

The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend data structure choices as the scheduler, and can use the same options.

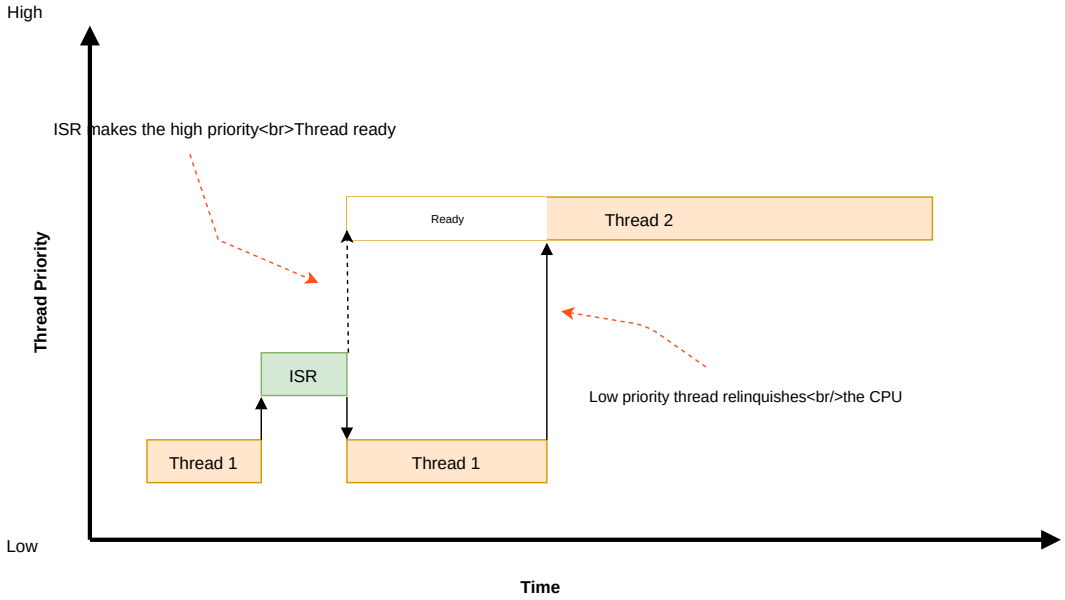
- Scalable wait_q implementation (`CONFIG_WAITQ_SCALABLE`)

  When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect to have many threads waiting on individual primitives. There is a ~2kb code size increase over `CONFIG_WAITQ_SIMPLE` (which may be shared with `CONFIG_SCHED_SCALABLE`) if the red/black tree is not used elsewhere in the application, and pend/unpend operations on "small" queues will be somewhat slower (though this is not generally a performance path).

- Simple linked-list wait_q (`CONFIG_WAITQ_SIMPLE`)

When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect to have only a few threads blocked on any single IPC primitive.

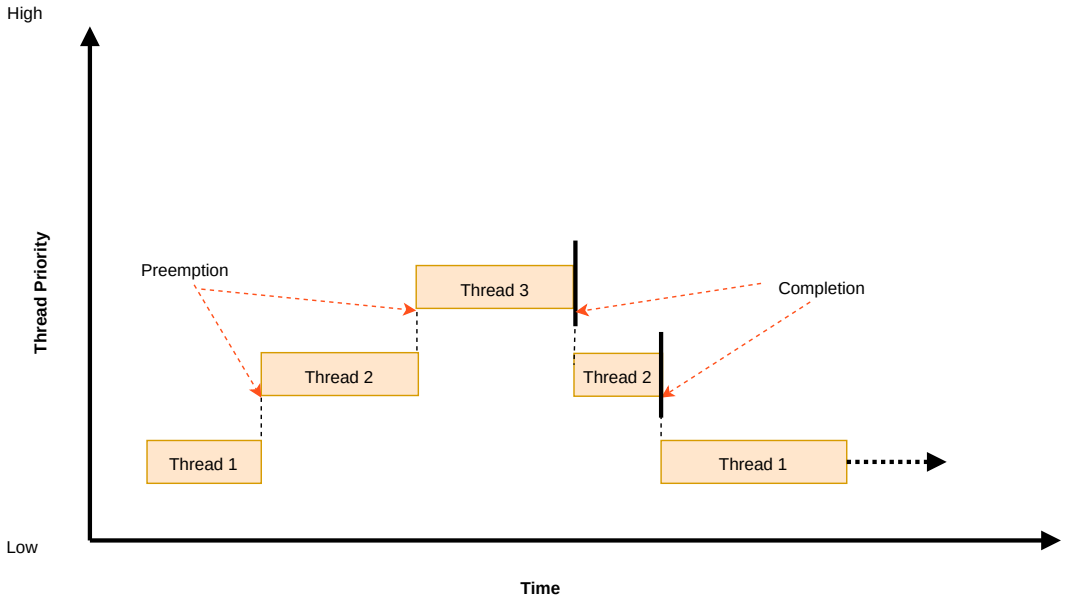
Cooperative Time Slicing Once a cooperative thread becomes the current thread, it remains the current thread until it performs an action that makes it unready. Consequently, if a cooperative thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of higher priority and equal priority.



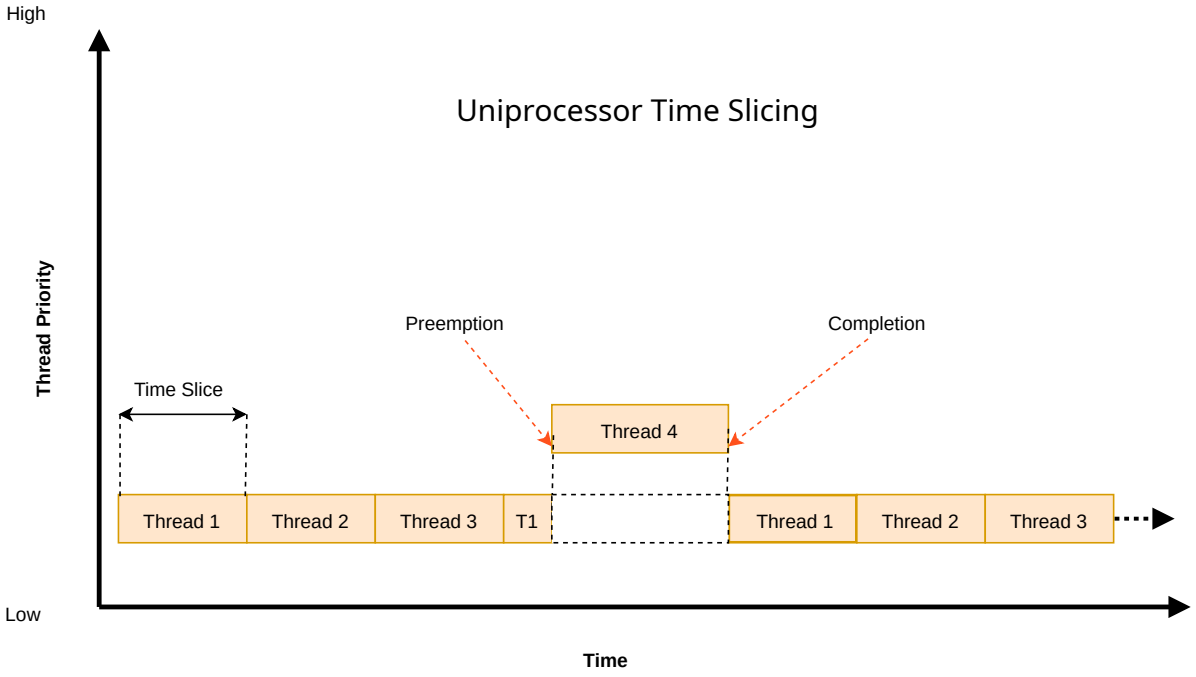
To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time to permit other threads to execute. A thread can relinquish the CPU in two ways:

- Calling `k_yield()` puts the thread at the back of the scheduler's prioritized list of ready threads, and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the yielding thread are then allowed to execute before the yielding thread is rescheduled. If no such ready threads exist, the scheduler immediately reschedules the yielding thread without context switching.
- Calling `k_sleep()` makes the thread unready for a specified time period. Ready threads of *all* priorities are then allowed to execute; however, there is no guarantee that threads whose priority is lower than that of the sleeping thread will actually be scheduled before the sleeping thread becomes ready once again.

Preemptive Time Slicing Once a preemptive thread becomes the current thread, it remains the current thread until a higher priority thread becomes ready, or until the thread performs an action that makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of equal priority.



To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler's time slicing capability can be used to allow other threads of the same priority to execute.



Note

For SMP, the behavior would be similar to the above UP image, except that Thread 1 would not immediately follow Thread 4. Instead it would be Thread 2, Thread 3, Thread 1, ...

The scheduler divides time on each CPU into a series of **time slices**, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running. Scheduling a new thread causes the time slice timer to be reset.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no

other threads of equal priority are ready, then the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

Note

The kernel's time slicing algorithm does *not* ensure that a set of equal-priority threads receive an equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm *does* ensure that a thread never executes for longer than a single time slice without being required to yield.

Scheduler Locking A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling `k_sched_lock()`. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call `k_sched_unlock()` to restore its normal, preemptible status.

If a thread calls `k_sched_lock()` and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

Note

Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.

Thread Sleeping A thread can call `k_sleep()` to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using `k_wakeup()`. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred *without* requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

Busy Waiting A thread can call `k_busy_wait()` to perform a `busy wait` that delays its processing for a specified time period *without* relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

Suggested Uses Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutually exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

Configuration Options

- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
- CONFIG_TIMESLICE_PRIORITY

CPU Idling

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.

- *Concepts*
- *Implementation*
  - *Making the CPU idle*
  - *Making the CPU idle in an atomic fashion*
- *Suggested Uses*
- *API Reference*

Concepts Making the CPU idle causes the kernel to pause all operations until an event, normally an interrupt, wakes up the CPU. In a regular system, the idle thread is responsible for this. However, in some constrained systems, it is possible that another thread takes this duty.

Implementation

Making the CPU idle Making the CPU idle is simple: call the k_cpu_idle() API. The CPU will stop executing instructions until an event occurs. Most likely, the function will be called within a loop. Note that in certain architectures, upon return, k_cpu_idle() unconditionally unmasks interrupts.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    /* wait for semaphore from ISR, then do related work */

    for (;;) {

        /* wait for ISR to trigger work to perform */
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            /* ... do processing */

        }
```

(continues on next page)

(continued from previous page)

```
        /* put CPU to sleep to save power */
        k_cpu_idle();
    }
}
```

Making the CPU idle in an atomic fashion It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, k_cpu_atomic_idle() should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until *another* interrupt occurs, which might be *never*, thus hanging the system completely. To prevent this, k_cpu_atomic_idle() should have been used, like in this example.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    for (;;) {

        unsigned int key = irq_lock();

        /*
         * Wait for semaphore from ISR; if acquired, do related work, then
         * go to next loop iteration (the semaphore might have been given
         * again); else, make the CPU idle.
         */

        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            irq_unlock(key);

            /* ... do processing */

        } else {
            /* put CPU to sleep to save power */
            k_cpu_atomic_idle(key);
        }
    }
}
```

Suggested Uses Use k_cpu_atomic_idle() when a thread has to do some real work in addition to idling the CPU to wait for an event. See example above.

Use k_cpu_idle() only when a thread is only responsible for idling the CPU, i.e. not doing any real work, like in this example below.

```
int main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;) {
        k_cpu_idle();
    }
}
```

Note

Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes care of power management, including CPU idling.

CPU Idling APIs

System Threads

- *Implementation*
  - *Writing a main() function*
- *Suggested Uses*

A *system thread* is a thread that the kernel spawns automatically during system initialization.

The kernel spawns the following system threads:

Main thread
: This thread performs kernel initialization, then calls the application's `main()` function (if one is defined).

  By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the kernel is not configured to support preemptible threads, the main thread uses the lowest configured cooperative thread priority (i.e. -1).

  The main thread is an essential thread while it is performing kernel initialization or executing the application's `main()` function; this means a fatal system error is raised if the thread aborts. If `main()` is not defined, or if it executes and then does a normal return, the main thread terminates normally and no error is raised.

Idle thread
: This thread executes when there is no other work for the system to do. If possible, the idle thread activates the board's power management support to save power; otherwise, the idle thread simply performs a "do nothing" loop. The idle thread remains in existence as long as the system is running and never terminates.

  The idle thread always uses the lowest configured thread priority.

  The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See *Workqueue Threads*.)

Implementation

Writing a main() function An application-supplied `main()` function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function, unless `CONFIG_BOOTARGS` is selected. In such case the kernel passes arguments to it and `main(int, char **)` can be used.

The following code outlines a trivial `main(void)` function. The function used by a real application can be as complex as needed.

```
int main(void)
{
    /* initialize a semaphore */
    ...

    /* register an ISR that gives the semaphore */
    ...

    /* monitor the semaphore forever */
    while (1) {
        /* wait for the semaphore to be given by the ISR */
        ...
        /* do whatever processing is now needed */
        ...
    }
}
```

Suggested Uses Use the main thread to perform thread-based processing in an application that only requires a single thread, rather than defining an additional application-specific thread.

Workqueue Threads

- *Work Item Lifecycle*
- *Delayable Work*
- *Triggered Work*
- *System Workqueue*
- *How to Use Workqueues*
- *Workqueue Best Practices*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

A *workqueue* is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A **queue** of work items that have been added, but not yet processed.
- A **thread** that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

Note

The behavior described here is changed from the Zephyr workqueue implementation used prior to release 2.6. Among the changes are:

- Precise tracking of the status of cancelled work items, so that the caller need not be concerned that an item may be processing when the cancellation returns. Checking of return values on cancellation is still required.
- Direct submission of delayable work items to the queue with `K_NO_WAIT` rather than always going through the timeout API, which could introduce delays.
- The ability to wait until a work item has completed or a queue has been drained.
- Finer control of behavior when scheduling a delayable work item, specifically allowing a previous deadline to remain unchanged when a work item is scheduled again.
- Safe handling of work item resubmission when the item is being processed on another workqueue.

Using the return values of `k_work_busy_get()` or `k_work_is_pending()`, or measurements of remaining time until delayable work is scheduled, should be avoided to prevent race conditions of the type observed with the previous implementation. See also *Workqueue Best Practices*.

Work Item Lifecycle Any number of **work items** can be defined. Each work item is referenced by its memory address.

A work item is assigned a **handler function**, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be **queued** (`K_WORK_QUEUED`) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be **scheduled** (`K_WORK_DELAYED`) to a workqueue; see *Delayable Work*.

A work item will be **running** (`K_WORK_RUNNING`) when it is running on a work queue, and may also be **canceling** (`K_WORK_CANCELING`) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:

- running on a queue;

- marked canceling (because a thread used `k_work_cancel_sync()` to wait until the work item completed);
- queued to run again on the same queue;
- scheduled to be submitted to a (possibly different) queue

all simultaneously. A work item that is in any of these states is **pending** (`k_work_is_pending()`) or **busy** (`k_work_busy_get()`).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with `CONTAINER_OF`, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

Important

A pending work item *must not* be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

Delayable Work An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by **scheduling** a **delayable work item** to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.

A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from `k_work_delayable`. To get access to an object that contains the delayable work object use this idiom:

```
static void work_handler(struct k_work *work)
{
        struct k_work_delayable *dwork = k_work_delayable_from_work(work);
        struct work_context *ctx = CONTAINER_OF(dwork, struct work_context,
                                                timed_work);
        ...
```

Triggered Work The `k_work_poll_submit()` interface schedules a triggered work item in response to a **poll event** (see *Polling API*), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to `k_poll()`, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object's changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

Important

The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.

An ISR or a thread may **cancel** a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

System Workqueue The kernel defines a workqueue known as the *system workqueue*, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

Important

Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

How to Use Workqueues

Defining and Controlling a Workqueue A workqueue is defined using a variable of type `k_work_q`. The workqueue is initialized by defining the stack area used by its thread, initializing the `k_work_q`, either zeroing its memory or calling `k_work_queue_init()`, and then calling `k_work_queue_start()`. The stack area must be defined using `K_THREAD_STACK_DEFINE` to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

```
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
```

(continues on next page)

(continued from previous page)

```
struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area,
                   K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY,
                   NULL);
```

In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see `k_work_queue_start()` for details.

The following API can be used to interact with a workqueue:

- `k_work_queue_drain()` can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is "plugged". Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.
- `k_work_queue_unplug()` removes any previous block on submission to the queue due to a previous drain operation.

Submitting a Work Item A work item is defined using a variable of type `k_work`. It must be initialized by calling `k_work_init()`, unless it is defined using `K_WORK_DEFINE` in which case initialization is performed at compile-time.

An initialized work item can be submitted to the system workqueue by calling `k_work_submit()`, or to a specified workqueue by calling `k_work_submit_to_queue()`.

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg)
{
    ...
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}

void print_error(struct k_work *item)
{
    struct device_info *the_device =
        CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}

/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");
```

(continues on next page)

(continued from previous page)

```
/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...
```

The following API can be used to check the status of or synchronize with the work item:

- `k_work_busy_get()` returns a snapshot of flags indicating work item state. A zero value indicates the work is not scheduled, submitted, being executed, or otherwise still being referenced by the workqueue infrastructure.
- `k_work_is_pending()` is a helper that indicates `true` if and only if the work is scheduled, queued, or running.
- `k_work_flush()` may be invoked from threads to block until the work item has completed. It returns immediately if the work is not pending.
- `k_work_cancel()` attempts to prevent the work item from being executed. This may or may not be successful. This is safe to invoke from ISRs.
- `k_work_cancel_sync()` may be invoked from threads to block until the work completes; it will return immediately if the cancellation was successful or not necessary (the work wasn't submitted or running). This can be used after `k_work_cancel()` is invoked (from an ISR)' to confirm completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item A delayable work item is defined using a variable of type `k_work_delayable`. It must be initialized by calling `k_work_init_delayable()`.

For delayed work there are two common use cases, depending on whether a deadline should be extended if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from a UART associated with a keyboard. There are two APIs that submit work after a delay:

- `k_work_schedule()` (or `k_work_schedule_for_queue()`) schedules work to be executed at a specific time or after a delay. Further attempts to schedule the same item with this API before the delay completes will not change the time at which the item will be submitted to its queue. Use this if the policy is to keep collecting data until a specified delay since the **first** unprocessed data was received;
- `k_work_reschedule()` (or `k_work_reschedule_for_queue()`) unconditionally sets the deadline for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the **last** unprocessed data was received.

If the work item is not scheduled both APIs behave the same. If `K_NO_WAIT` is specified as the delay the behavior is as if the item was immediately submitted directly to the target queue, without waiting for a minimal timeout (unless `k_work_schedule()` is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.

The helper function `k_work_delayable_from_work()` can be used to get a pointer to the containing `k_work_delayable` from a pointer to `k_work` that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- `k_work_delayable_busy_get()` is the analog to `k_work_busy_get()` for delayable work.
- `k_work_delayable_is_pending()` is the analog to `k_work_is_pending()` for delayable work.
- `k_work_flush_delayable()` is the analog to `k_work_flush()` for delayable work.

- k_work_cancel_delayable() is the analog to k_work_cancel() for delayable work; similarly with k_work_cancel_delayable_sync().

Synchronizing with Work Items While the state of both regular and delayable work items can be determined from any context using k_work_busy_get() and k_work_delayable_busy_get() some use cases require synchronizing with work items after they've been submitted. k_work_flush(), k_work_cancel_sync(), and k_work_cancel_delayable_sync() can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a k_work_sync object that has no application-inspectable components but is needed to provide the synchronization objects. These objects should not be allocated on a stack if the code is expected to work on architectures with CONFIG_KERNEL_COHERENCE.

Workqueue Best Practices

Avoid Race Conditions Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a k_queue by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags *Atomic Services* may be sufficient. In other cases spin locks (k_spinlock) or thread-aware locks (k_sem, k_mutex , ...) may be used to ensure data races don't occur.

If the selected lock mechanism can *sleep* then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:

```
static void work_handler(struct work *work)
{
        struct work_context *parent = CONTAINER_OF(work, struct work_context,
                                                   work_item);

        if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
                /* NB: Submit will fail if the work item is being cancelled. */
                (void)k_work_submit(work);
                return;
        }

        /* do stuff under lock */
        k_mutex_unlock(&parent->lock);
        /* do stuff without lock */
}
```

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission may starve the thread that would release the lock, causing the application to fail. Where the idiom above is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero delay to allow the thread holding the lock to make progress.

Note that submitting from the work handler can fail if the work item had been cancelled. Generally this is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don't need to hold an external lock just to submit or schedule them. Even if you use external state protected by such a lock to prevent further resubmission, it's safe to do the resubmit as long as you're sure that eventually the item will take its lock and check that state to determine whether it should do anything. Where a delayable

work item is being rescheduled in its handler due to inability to take the lock some other self-locking state, such as an atomic flag set by the application/driver when the cancel is initiated, would be required to detect the cancellation and avoid the cancelled work item being submitted again after the deadline.

Check Return Values All work API functions return status of the underlying operation, and in many cases it is important to verify that the intended result was obtained.

- Submitting a work item (`k_work_submit_to_queue()`) can fail if the work is being cancelled or the queue is not accepting new items. If this happens the work will not be executed, which could cause a subsystem that is animated by work handler activity to become non-responsive.
- Asynchronous cancellation (`k_work_cancel()` or `k_work_cancel_delayable()`) can complete while the work item is still being run by a handler. Proceeding to manipulate state shared with the work handler will result in data races that can cause failures.

Many race conditions have been present in Zephyr code because the results of an operation were not checked.

There may be good reason to believe that a return value indicating that the operation did not complete as expected is not a problem. In those cases the code should clearly document this, by (1) casting the return value to `void` to indicate that the result is intentionally ignored, and (2) documenting what happens in the unexpected case. For example:

```
/* If this fails, the work handler will check pub->active and
 * exit without transmitting.
 */
(void)k_work_cancel_delayable(&pub->timer);
```

However in such a case the following code must still avoid data races, as it cannot guarantee that the work thread is not accessing work-related state.

Don't Optimize Prematurely The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item's state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don't attempt to "optimize" by checking whether the work item is already submitted by inspecting snapshot state with `k_work_is_pending()` or `k_work_busy_get()`, or checking for a non-zero delay from `k_work_delayable_remaining_get()`. Those checks are fragile: a "busy" indication can be obsolete by the time the test is returned, and a "not-busy" indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use `k_work_is_pending()` is as a check to avoid invoking `k_work_flush()` or `k_work_cancel_sync()`, if you are *certain* that nothing else might submit the work while you're checking (generally because you're holding a lock that prevents access to state used for submission).

Suggested Uses Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system's ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

Configuration Options Related configuration options:

- CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE
- CONFIG_SYSTEM_WORKQUEUE_PRIORITY
- CONFIG_SYSTEM_WORKQUEUE_NO_YIELD

API Reference
Work Queue APIs

Operation without Threads

Thread support is not necessary in some applications:

- Bootloaders
- Simple event-driven applications
- Examples intended to demonstrate core functionality

Thread support can be disabled by setting CONFIG_MULTITHREADING to n. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

What Can be Expected to Work These core capabilities shall function correctly when CONFIG_MULTITHREADING is disabled:

- The *build system*
- The ability to boot the application to main()
- *Interrupt management*
- The system clock including k_uptime_get()
- Timers, i.e. k_timer()
- Non-sleeping delays e.g. k_busy_wait().
- Sleeping k_cpu_idle().
- Pre main() drivers and subsystems initialization e.g. SYS_INIT.
- *Memory Management*
- Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example CONFIG_SYS_CLOCK_EXISTS cannot be set to n.

What Cannot be Expected to Work Functionality that will not work when CONFIG_MULTITHREADING is disabled includes majority of the kernel API:

- *Threads*
- *Scheduling*
- *Workqueue Threads*
- *Polling API*
- *Semaphores*
- *Mutexes*
- *Condition Variables*
- *Data Passing*

Subsystem Behavior Without Thread Support The sections below list driver and functional subsystems that are expected to work to some degree when `CONFIG_MULTITHREADING` is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

Flash The *Flash* is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

List/table of supported drivers to go here

GPIO The *General-Purpose Input/Output (GPIO)* is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

List/table of supported drivers to go here

UART A subset of the *Universal Asynchronous Receiver-Transmitter (UART)* is expected to work for all SoC UART peripheral drivers.

- Applications that select `CONFIG_UART_INTERRUPT_DRIVEN` may work, depending on driver implementation.
- Applications that select `CONFIG_UART_ASYNC_API` may work, depending on driver implementation.
- Applications that do not select either `CONFIG_UART_ASYNC_API` or `CONFIG_UART_INTERRUPT_DRIVEN` are expected to work.

List/table of supported drivers to go here, including which API options are supported

Interrupts

An *interrupt service routine* (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low overhead. Thread execution resumes only once all ISR work has been completed.

  - *Implementation Details*

- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of ISRs can be defined (limited only by available RAM), subject to the constraints imposed by underlying hardware.

An ISR has the following key properties:

- An **interrupt request (IRQ) signal** that triggers the ISR.
- A **priority level** associated with the IRQ.
- An **interrupt service routine** that is invoked to handle the interrupt.
- An **argument value** that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR's function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports **interrupt nesting**. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR executes in the kernel's **interrupt context**. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

Important

Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the `k_is_in_isr()` API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.

Multi-level Interrupt Handling A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.

If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be enabled, and `CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number, providing support for up to four interrupt levels using this arch, as illustrated and explained below:

```
        9             2   0
  _ _ _ _ _ _ _ _ _ _ _ _ _        (LEVEL 1)
```

(continues on next page)

(continued from previous page)

```
  5       |         A   |
- - - - - - -         - - - - - - - -   (LEVEL 2)
  |   C                       B
- - - - - - -                         (LEVEL 3)
        D
```

There are three interrupt levels shown here.

- '-' means interrupt line and is numbered from 0 (right most).
- LEVEL 1 has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one device 'A' on line 4.
- One of the LEVEL 2 controllers has interrupt line 5 connected to a LEVEL 3 nested controller and one device 'C' on line 3.
- The other LEVEL 2 controller has no nested controllers but has one device 'B' on line 2.
- The LEVEL 3 controller has one device 'D' on line 2.

Here's how unique interrupt numbers are generated for each hardware interrupt. Let's consider four interrupts shown above as A, B, C, and D:

```
A -> 0x00000004
B -> 0x00000302
C -> 0x00000409
D -> 0x00030609
```

Note

The bit positions for LEVEL 2 and onward are offset by 1, as 0 means that interrupt number is not present for that level. For our example, the LEVEL 3 controller has device D on line 2, connected to the LEVEL 2 controller's line 5, that is connected to the LEVEL 1 controller's line 9 (2 -> 5 -> 9). Because of the encoding offset for LEVEL 2 and onward, device D is given the number 0x00030609.

Preventing Interruptions In certain situations it may be necessary for the current thread to prevent ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be applied even when it is already in effect, so routines can use it without having to know if it is already in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts can be once again processed by the kernel while the thread is running.

Important

The IRQ lock is thread-specific. If thread A locks out interrupts then performs an operation that puts itself to sleep (e.g. sleeping for N milliseconds), the thread's IRQ lock no longer applies once thread A is swapped out and the next ready thread B starts to run.

This means that interrupts can be processed while thread B is running unless thread B has also locked out interrupts using its own IRQ lock. (Whether interrupts can be processed while the kernel is switching between two threads that are using the IRQ lock is architecture-specific.)

When thread A eventually becomes the current thread once again, the kernel re-establishes thread A's IRQ lock. This ensures thread A won't be interrupted until it has explicitly unlocked its IRQ lock.

If thread A does not sleep but does make a higher-priority thread B ready, the IRQ lock will inhibit any preemption that would otherwise occur. Thread B will not run until the next *reschedule point* reached after releasing the IRQ lock.

Alternatively, a thread may temporarily **disable** a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently **enabled** to permit the ISR to execute.

Important

Disabling an IRQ prevents *all* threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

Zero Latency Interrupts Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.

The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as *zero-latency interrupts*. The support for zero-latency interrupts requires `CONFIG_ZERO_LATENCY_IRQS` to be enabled. Any interrupts configured as zero-latency must also be declared as *direct ISRs* (and must not use the `ISR_DIRECT_PM` in them), since regular ISRs interact with the kernel. In addition to that, the flag `IRQ_ZERO_LATENCY` must be passed to the `IRQ_DIRECT_CONNECT` macro to configure the particular interrupt with zero latency. Declaring a zero-latency interrupt ISR to be both direct and dynamic is possible on some architectures, see *Defining a 'direct' ISR*.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to interoperate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e. an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g. kernel panic).

Important

Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

Tip

To mitigate flash access latency, consider relocating ISRs and all related symbols to RAM.

Offloading ISR Work An ISR should execute quickly to ensure predictable system operation. If time consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel's ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.
- An ISR can instruct the system workqueue thread to execute a work item. (See *Workqueue Threads*.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the offload, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the offload is scheduled.

Sharing interrupt lines In the case of some hardware platforms, the same interrupt lines may be used by different IPs. For example, interrupt 17 may be used by a DMA controller to signal that a data transfer has been completed or by a DAI controller to signal that the transfer FIFO has reached its watermark. To make this work, one would have to either employ some special logic or find a workaround (for example, using the shared_irq interrupt controller), which doesn't scale very well.

To solve this problem, one may use shared interrupts, which can be enabled using `CONFIG_SHARED_INTERRUPTS`. Whenever an attempt to register a second ISR/argument pair on the same interrupt line is made (using `IRQ_CONNECT` or `irq_connect_dynamic()`), the interrupt line will become shared, meaning the two ISR/argument pairs (previous one and the one that has just been registered) will be invoked each time the interrupt is triggered. The entities that make use of an interrupt line in the shared interrupt context are known as clients. The maximum number of allowed clients for an interrupt is controlled by `CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS`.

Interrupt sharing is transparent to the user. As such, the user may register interrupts using `IRQ_CONNECT` and `irq_connect_dynamic()` as they normally would. The interrupt sharing is taken care of behind the scenes.

Enabling the shared interrupt support and dynamic interrupt support will allow users to dynamically disconnect ISRs using `irq_disconnect_dynamic()`. After an ISR is disconnected, whenever the interrupt line for which it was register gets triggered, the ISR will no longer get invoked.

Please note that enabling `CONFIG_SHARED_INTERRUPTS` will result in a non-negligible increase in the binary size. Use with caution.

Implementation

Defining a regular ISR An ISR is defined at runtime by calling `IRQ_CONNECT`. It must then be enabled by calling `irq_enable()`.

> **Important**
>
> IRQ_CONNECT() is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG  DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0       /* IRQ flags */

void my_isr(void *arg)
{
    ... /* ISR code */
}

void my_isr_installer(void)
```

(continues on next page)

(continued from previous page)

```
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Since the `IRQ_CONNECT` macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with `irq_connect_dynamic()`. It is used in exactly the same way as `IRQ_CONNECT`:

```
void my_isr_installer(void)
{
   ...
   irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG,
                       MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Dynamic interrupts require the `CONFIG_DYNAMIC_INTERRUPTS` option to be enabled. Removing or re-configuring a dynamic interrupt is currently unsupported.

Defining a 'direct' ISR Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision
- *Zero Latency Interrupts* must always be declared as direct ISRs, since regular ISRs interact with the kernel

Zephyr supports so-called 'direct' interrupts, which are installed via `IRQ_DIRECT_CONNECT` and whose handlers are declared using `ISR_DIRECT_DECLARE`. These direct interrupts have some special implementation requirements and a reduced feature set; see the definitions of `IRQ_DIRECT_CONNECT` and `ISR_DIRECT_DECLARE` for details.

The following code demonstrates a direct ISR:

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
#define MY_IRQ_FLAGS 0       /* IRQ flags */

ISR_DIRECT_DECLARE(my_isr)
{
   do_stuff();
   /* PM done after servicing interrupt for best latency. This cannot be
   used for zero-latency IRQs because it accesses kernel data. */
   ISR_DIRECT_PM();
   /* Ask the kernel to check if scheduling decision should be made. If the
   ISR is for a zero-latency IRQ then the return value must always be 0. */
   return 1;
```

(continues on next page)

(continued from previous page)

```
}

void my_isr_installer(void)
{
   ...
   IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. The feature is currently implemented in the Arm Cortex-M architecture variant via the macro `ARM_IRQ_DIRECT_DYNAMIC_CONNECT`, which can be used to declare a direct and dynamic interrupt.

RAM-based ISR Execution For ultra-low latency, ISRs and vector tables can be relocated to RAM to eliminate flash access delays. That can be achieved by enabling the `CONFIG_SRAM_VECTOR_TABLE` and `CONFIG_SRAM_SW_ISR_TABLE` options which will result in vector tables being placed in RAM. Then, Zephyr *Code and Data Relocation* can be used to relocate the ISR code and all the related symbols to RAM as well.

Sharing an interrupt line The following code defines two ISRs using the same interrupt number.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */

void my_first_isr(void *arg)
{
   ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
   ... /* even more magic happens here */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   ...
}
```

The same restrictions regarding `IRQ_CONNECT` described in *Defining a regular ISR* are applicable here. If `CONFIG_SHARED_INTERRUPTS` is disabled, the above code will generate a build error. Otherwise, the above code will result in the two ISRs being invoked each time interrupt 24 is triggered.

If CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS is set to a value lower than 2 (current number of clients), a build error will be generated.

If dynamic interrupts are enabled, irq_connect_dynamic() will allow sharing interrupts during runtime. Exceeding the configured maximum number of allowed clients will result in a failed assertion.

Dynamically disconnecting an ISR The following code defines two ISRs using the same interrupt number. The second ISR is disconnected during runtime.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */

void my_first_isr(void *arg)
{
   ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
   ... /* even more magic happens here */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   ...
}

void my_isr_uninstaller(void)
{
   ...
   irq_disconnect_dynamic(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr,␣
↪MY_FST_ISR_ARG, MY_IRQ_FLAGS);
   ...
}
```

The irq_disconnect_dynamic() call will result in interrupt 24 becoming unshared, meaning the system will act as if the first IRQ_CONNECT call never happened. This behaviour is only allowed if CONFIG_DYNAMIC_INTERRUPTS is enabled, otherwise a linker error will be generated.

Implementation Details Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the *x86 Details* section below.

The invocation of IRQ_CONNECT will declare an instance of struct _isr_list which is placed in a special .intList section. This section is placed in compiled code on precompilation stages only. It is meant to be used by Zephyr script to generate interrupt tables and is removed from the final build. The script implements different parsers to process the data from .intList section and produce the required output.

The default parser generates C arrays filled with arguments and interrupt handlers in a form of addresses directly taken from .intList section entries. It works with all the architectures and compilers (with the exception mentioned above). The limitation of this parser is the fact that after the arrays are generated it is expected for the code not to relocate. Any relocation on this stage may lead to the situation where the entry in the interrupt array is no longer pointing to the function that was expected. It means that this parser, being more compatible is limiting us from using Link Time Optimization.

The local isr declaration parser uses different approach to construct the same arrays at binary level. All the entries to the arrays are declared and defined locally, directly in the file where `IRQ_CONNECT` is used. They are placed in a section with the unique, synthesized name. The name of the section is then placed in .intList section and it is used to create linker script to properly place the created entry in the right place in the memory. This parser is now limited to the supported architectures and toolchains but in reward it keeps the information about object relations for linker thus allowing the Link Time Optimization.

Implementation using C arrays This is the default configuration available for all Zephyr supported architectures.

Any invocation of `IRQ_CONNECT` will declare an instance of struct _isr_list which is placed in a special .intList section:

```
struct _isr_list {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** ISR to call */
    void *func;
    /** Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces `${ZEPHYR_PREBUILT_EXECUTABLE}.elf` which contains all the entries in the .intList section preceded by a header:

```
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isrs;
    uint32_t num_vectors;
    struct _isr_list isrs[];  <- of size num_isrs
};
```

This data consisting of the header and instances of struct _isr_list inside `${ZEPHYR_PREBUILT_EXECUTABLE}.elf` is then used by the gen_isr_tables.py script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.

The priority level of any interrupt is not encoded in these tables, instead `IRQ_CONNECT` also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

Vector Table A vector table is generated when `CONFIG_GEN_IRQ_VECTOR_TABLE` is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element n corresponds to the IRQ handler for IRQ line n, and the function pointers are:

1. For 'direct' interrupts declared with IRQ_DIRECT_CONNECT, the handler function will be placed here.
2. For regular interrupts declared with IRQ_CONNECT, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.
3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures have a common entry point for all interrupts and do not support a vector table, in which case the CONFIG_GEN_IRQ_VECTOR_TABLE option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case CONFIG_GEN_IRQ_START_VECTOR needs to be set to properly offset the indices in the table.

SW ISR Table This is an array of struct _isr_table_entry:

```
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

Shared SW ISR Table This is an array of struct z_shared_isr_table_entry:

```
struct z_shared_isr_table_entry {
    struct _isr_table_entry clients[CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS];
    size_t client_num;
};
```

This table keeps track of the registered clients for each of the interrupt lines. Whenever an interrupt line becomes shared, z_shared_isr() will replace the currently registered ISR in _sw_isr_table. This special ISR will iterate through the list of registered clients and invoke the ISRs.

Implementation using linker script This way of prepare and parse .isrList section to implement interrupt vectors arrays is called local isr declaration. The name comes from the fact that all the entries to the arrays that would create interrupt vectors are created locally in place of invocation of IRQ_CONNECT macro. Then automatically generated linker scripts are used to place it in the right place in the memory.

This option requires enabling by the choose of CONFIG_ISR_TABLES_LOCAL_DECLARATION. If this configuration is supported by the used architecture and toolchaing the CONFIG_ISR_TABLES_LOCAL_DECLARATION_SUPPORTED is set. See details of this option for the information about currently supported configurations.

Any invocation of IRQ_CONNECT or IRQ_DIRECT_CONNECT will declare an instance of struct _isr_list_sname which is placed in a special .intList section:

```
struct _isr_list_sname {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** The section name */
```

(continues on next page)

(continued from previous page)

```
    const char sname[];
};
```

Note that the section name is placed in flexible array member. It means that the size of the initialized structure will vary depending on the structure name length. The whole entry is used by the script during the build of the application and has all the information needed for proper interrupt placement.

Beside of the _isr_list_sname the `IRQ_CONNECT` macro generates an entry that would be the part of the interrupt array:

```
struct _isr_table_entry {
    const void *arg;
    void (*isr)(const void *);
};
```

This array is placed in a section with the name saved in _isr_list_sname structure.

The values created by `IRQ_DIRECT_CONNECT` macro depends on the architecture. It can be changed to variable that points to a interrupt handler:

```
static uintptr_t <unique name> = ((uintptr_t)func);
```

Or to actually naked function that implements a jump to the interrupt handler:

```
static void <unique name>(void)
{
    __asm(ARCH_IRQ_VECTOR_JUMP_CODE(func));
}
```

Similar like for `IRQ_CONNECT`, the created variable or function is placed in a section, saved in _isr_list_sname section.

Files generated by the script The interrupt tables generator script creates 3 files: `isr_tables.c`, `isr_tables_swi.ld`, and `isr_tables_vt.ld`.

The `isr_tables.c` will contain all the structures for interrupts, direct interrupts and shared interrupts (if enabled). This file implements only all the structures that are not implemented by the application, leaving a comment where the interrupt not implemented here can be found.

Then two linker files are used. The `isr_tables_vt.ld` file is included in place where the interrupt vectors are required to be placed in the selected architecture. The `isr_tables_swi.ld` file describes the placement of the software interrupt table elements. The separated file is required as it might be placed in writable or nonwritable section, depending on the current configuration.

x86 Details The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the *arch/x86/gen_idt.py* tool uses the .intList section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the *arch/x86/gen_idt.py* tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the `IRQ_CONNECT` call creates a small assembly language function which calls the common

interrupt code in `_interrupt_enter()` with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with `IRQ_DIRECT_CONNECT` the parameterless ISR is placed directly in the IDT.

On systems where the position in the vector table corresponds to the interrupt's priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. *arch/x86/gen_idt.py* additionally creates an _irq_to_interrupt_vector array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by `IRQ_CONNECT` to program the IRQ-to-vector association in the interrupt controller.

For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the `CONFIG_X86_DYNAMIC_IRQ_STUBS` option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

Going Beyond the Default Supported Number of Interrupts When generating interrupts in the multi-level configuration, 8-bits per level is the default mask used when determining which level a given interrupt code belongs to. This can become a problem when dealing with CPUs that support more than 255 interrupts per single aggregator. In this case it may be desirable to override these defaults and use a custom number of bits per level. Regardless of how many bits used for each level, the sum of the total bits used between all levels must sum to be less than or equal to 32-bits, fitting into a single 32-bit integer. To modify the bit total per level, override the default 8 in `Kconfig.multilevel` by setting `CONFIG_1ST_LEVEL_INTERRUPT_BITS` for the first level, `CONFIG_2ND_LEVEL_INTERRUPT_BITS` for the second level and `CONFIG_3RD_LEVEL_INTERRUPT_BITS` for the third level. These masks control the length of the bit masks and shift to apply when generating interrupt values, when checking the interrupts level and converting interrupts to a different level. The logic controlling this can be found in `irq_multilevel.h`

Suggested Uses Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

> **Note**
>
> Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See *Offloading ISR Work* for a description of various techniques that can be used in an application.

Configuration Options Related configuration options:

- `CONFIG_ISR_STACK_SIZE`

Additional architecture-specific and device-specific configuration options also exist.

API Reference
Interrupt Service Routine APIs

Polling API

The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.

- *Concepts*
- *Implementation*
  - *Using k_poll()*

  - *Using k_poll_signal_raise()*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The polling API's main function is `k_poll()`, which is very similar in concept to the POSIX `poll()` function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a kernel message queue contains data ready to be retrieved
- a kernel pipe contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of **poll events**, one for each condition.

All events in the array must be initialized before the array can be polled on.

Each event must specify which **type** of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what **kernel object** it wants the condition to be satisfied.

Each event must specify which **mode** of operation is used when the condition is satisfied.

Each event can optionally specify a **tag** to group multiple events together, to the user's discretion.

Apart from the kernel objects, there is also a **poll signal** pseudo-object type that be directly signaled.

The `k_poll()` function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when `k_poll()` returns, if they were fulfilled before `k_poll()` was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figure out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when `k_poll()` returns and the poll event states that the semaphore is available, the caller of `k_poll()` must then invoke `k_sem_take()` to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when `k_sem_take()` is called.

Implementation

Using k_poll() The main API is `k_poll()`, which operates on an array of poll events of type `k_poll_event`. Each entry in the array represents one event a call to `k_poll()` will wait for its condition to be fulfilled.

Poll events can be initialized using either the runtime initializers `K_POLL_EVENT_INITIALIZER()` or `k_poll_event_init()`, or the static initializer `K_POLL_EVENT_STATIC_INITIALIZER()`. An object that matches the **type** specified must be passed to the initializers. The **mode** *must* be set to `K_POLL_MODE_NOTIFY_ONLY`. The state *must* be set to `K_POLL_STATE_NOT_READY` (the initializers

take care of this). The user **tag** is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the `k_poll_event` data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to `K_POLL_TYPE_IGNORE`.

```
struct k_poll_event events[4] = {
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_SEM_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_fifo, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_msgq, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_pipe, 0),
};
```

or at runtime

```
struct k_poll_event events[4];
void some_init(void)
{
    k_poll_event_init(&events[0],
                      K_POLL_TYPE_SEM_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_sem);

    k_poll_event_init(&events[1],
                      K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_fifo);

    k_poll_event_init(&events[2],
                      K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_msgq);

    k_poll_event_init(&events[3],
                      K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_pipe);

    // tags are left uninitialized if unused
}
```

After the events are initialized, the array can be passed to `k_poll()`. A timeout can be specified to wait only for a specified amount of time, or the special values `K_NO_WAIT` and `K_FOREVER` to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, `k_poll()` returns 0. If it times out, it returns -`EAGAIN`.

```
// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available

void do_stuff(void)
{
    rc = k_poll(events, ARRAY_SIZE(events), K_MSEC(1000));
    if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        } else if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        } else if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            bytes_read = k_pipe_read(events[3].pipe, buf, bytes_to_read,␣
↪K_NO_WAIT);
            // handle data
        }
    } else {
        // handle timeout
    }
}
```

When `k_poll()` is called in a loop, the events state must be reset to `K_POLL_STATE_NOT_READY` by the user.

```
void do_stuff(void)
{
    for(;;) {
        rc = k_poll(events, ARRAY_SIZE(events), K_FOREVER);
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        }
        if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
        if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        }
        if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            bytes_read = k_pipe_read(events[3].pipe, buf, bytes_to_read,␣
↪K_NO_WAIT);
            // handle data
        }
        events[0].state = K_POLL_STATE_NOT_READY;
        events[1].state = K_POLL_STATE_NOT_READY;
        events[2].state = K_POLL_STATE_NOT_READY;
        events[3].state = K_POLL_STATE_NOT_READY;
    }
}
```

Using k_poll_signal_raise() One of the types of events is `K_POLL_TYPE_SIGNAL`: this is a "direct" signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can

wait for.

A poll signal is a separate object of type `k_poll_signal` that must be attached to a k_poll_event, similar to a semaphore or FIFO. It must first be initialized either via `K_POLL_SIGNAL_INITIALIZER()` or `k_poll_signal_init()`.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);
}
```

It is signaled via the `k_poll_signal_raise()` function. This function takes a user **result** parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

```
struct k_poll_signal signal;

// thread A
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                                 K_POLL_MODE_NOTIFY_ONLY,
                                 &signal),
    };

    k_poll(events, 1, K_FOREVER);

    int signaled, result;

    k_poll_signal_check(&signal, &signaled, &result);

    if (signaled && (result == 0x1337)) {
        // A-OK!
    } else {
        // weird error
    }
}

// thread B
void signal_do_stuff(void)
{
    k_poll_signal_raise(&signal, 0x1337);
}
```

If the signal is to be polled in a loop, *both* its event state must be reset to `K_POLL_STATE_NOT_READY` *and* its `result` must be reset using `k_poll_signal_reset()` on each iteration if it has been signaled.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
```

(continues on next page)

(continued from previous page)

```
                                K_POLL_MODE_NOTIFY_ONLY,
                                &signal),
    };

    for (;;) {
        k_poll(events, 1, K_FOREVER);

        int signaled, result;

        k_poll_signal_check(&signal, &signaled, &result);

        if (signaled && (result == 0x1337)) {
            // A-OK!
        } else {
            // weird error
        }

        k_poll_signal_reset(&signal);
        events[0].state = K_POLL_STATE_NOT_READY;
    }
}
```

Note that poll signals are not internally synchronized. A `k_poll()` call that is passed a signal will return after any code in the system calls `k_poll_signal_raise()`. But if the signal is being externally managed and reset via `k_poll_signal_init()`, it is possible that by the time the application checks, the event state may no longer be equal to `K_POLL_STATE_SIGNALED`, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the `k_poll()` loop, or else to use some other event type which tracks event counts: semaphores and FIFOs are more error-proof in this sense because they can't "miss" events, architecturally.

Suggested Uses Use `k_poll()` to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

Note

Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main "server" or "dispatcher" for multiple objects and is the only one trying to acquire these objects.

Semaphores

A *semaphore* is a kernel object that implements a traditional counting semaphore.

- *Concepts*
- *Implementation*
  - *Defining a Semaphore*
  - *Giving a Semaphore*
  - *Taking a Semaphore*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *User Mode Semaphore API Reference*

Concepts Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address.

A semaphore has the following key properties:

- A **count** that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.
- A **limit** that indicates the maximum value the semaphore's count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be **given** by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be **taken** by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable a thread may choose to wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

Note

You may initialize a "full" semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

Note

The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

Implementation

Defining a Semaphore A semaphore is defined using a variable of type `k_sem`. It must then be initialized by calling `k_sem_init()`.

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```
struct k_sem my_sem;

k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling K_SEM_DEFINE.

The following code has the same effect as the code segment above.

```
K_SEM_DEFINE(my_sem, 0, 1);
```

Giving a Semaphore A semaphore is given by calling k_sem_give().

The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.

```
void input_data_interrupt_handler(void *arg)
{
    /* notify thread that data is available */
    k_sem_give(&my_sem);

    ...
}
```

Taking a Semaphore A semaphore is taken by calling k_sem_take().

The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

```
void consumer_thread(void)
{
    ...

    if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
        printk("Input data not available!");
    } else {
        /* fetch available data */
        ...
    }
    ...
}
```

Suggested Uses Use a semaphore to control access to a set of resources by multiple threads.

Use a semaphore to synchronize processing between a producing and consuming threads or ISRs.

Mutexes

A *mutex* is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- *Concepts*
  - *Reentrant Locking*
  - *Priority Inheritance*
- *Implementation*
  - *Defining a Mutex*
  - *Locking a Mutex*
  - *Unlocking a Mutex*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *Futex API Reference*
- *User Mode Mutex API Reference*

Concepts Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A **lock count** that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.
- An **owning thread** that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by **locking** the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must **unlock** the mutex to allow other threads to use the resource.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

> **Note**
>
> Mutex objects are *not* designed for use by ISRs.

Reentrant Locking A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.

A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.

Priority Inheritance The thread that has locked a mutex is eligible for *priority inheritance*. This means the kernel will *temporarily* elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

> **Note**
>
> The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of -128 permits unlimited. Setting this to a priority level that is at or lower than the priority of the idle thread disables it.

The owning thread's base priority is saved in the mutex when it obtains the lock. Each time a higher priority thread waits on a mutex, the kernel adjusts the owning thread's priority. When the owning thread releases the lock (or if the high priority waiting thread times out), the kernel restores the thread's base priority from the value saved in the mutex.

This works well for priority inheritance as long as only one locked mutex is involved. However, if multiple mutexes are involved, sub-optimal behavior will be observed if the mutexes are not unlocked in the reverse order to which the owning thread's priority was previously raised. Consequently it is recommended that a thread lock only a single mutex at a time when multiple mutexes are shared between threads of different priorities.

Implementation

Defining a Mutex A mutex is defined using a variable of type `k_mutex`. It must then be initialized by calling `k_mutex_init()`.

The following code defines and initializes a mutex.

```
struct k_mutex my_mutex;

k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling `K_MUTEX_DEFINE`.

The following code has the same effect as the code segment above.

```
K_MUTEX_DEFINE(my_mutex);
```

Locking a Mutex A mutex is locked by calling `k_mutex_lock()`.

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
    /* mutex successfully locked */
} else {
    printf("Cannot lock XYZ display\n");
}
```

Unlocking a Mutex A mutex is unlocked by calling `k_mutex_unlock()`.

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.

```
k_mutex_unlock(&my_mutex);
```

Suggested Uses Use a mutex to provide exclusive access to a resource, such as a physical device.

- Dining PhilosophersImplement a solution to the Dining Philosophers problem using Zephyr kernel services.

Futex API Reference k_futex is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. k_futex are tracked as kernel objects and can live in user memory so that any access bypasses the kernel object permission management mechanism.

FUTEX APIs

User Mode Mutex API Reference sys_mutex behaves almost exactly like k_mutex, with the added advantage that a sys_mutex instance can reside in user memory. When user mode isn't enabled, sys_mutex behaves like k_mutex.

User mode mutex APIs

Condition Variables

A *condition variable* is a synchronization primitive that enables threads to wait until a particular condition occurs.

- *Concepts*
- *Implementation*
  - *Defining a Condition Variable*
  - *Waiting on a Condition Variable*
  - *Signaling a Condition Variable*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function `k_condvar_wait()` performs atomically the following steps;

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using `k_condvar_signal()` or `k_condvar_broadcast()` then it:

1. Re-acquires the mutex previously released.
2. Returns from `k_condvar_wait()`.

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable A condition variable is defined using a variable of type `k_condvar`. It must then be initialized by calling `k_condvar_init()`.

The following code defines a condition variable:

```
struct k_condvar my_condvar;

k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling `K_CONDVAR_DEFINE`.

The following code has the same effect as the code segment above.

```
K_CONDVAR_DEFINE(my_condvar);
```

Waiting on a Condition Variable A thread can wait on a condition by calling `k_condvar_wait()`.

The following code waits on the condition variable.

```
K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

int main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /* block this thread until another thread signals cond. While
     * blocked, the mutex is released, then re-acquired before this
     * thread is woken up and the call returns.
     */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}
```

Signaling a Condition Variable A condition variable is signaled on by calling `k_condvar_signal()` for one thread or by calling `k_condvar_broadcast()` for multiple threads.

The following code builds on the example above.

```
void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /*
     * Do some work and fulfill the condition
     */
    ...
    ...
    k_condvar_signal(&condvar);
    k_mutex_unlock(&mutex);
}
```

Suggested Uses Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options Related configuration options:

- None.

Events

An *event object* is a kernel object that implements traditional events.

- *Concepts*
- *Implementation*
  - *Defining an Event Object*
  - *Setting Events*
  - *Posting Events*
  - *Waiting for Events (without removal)*
  - *Waiting for Events (with removal)*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of event objects can be defined (limited only by available RAM). Each event object is referenced by its memory address. One or more threads may wait on an event object until the desired set of events has been delivered to the event object. When new events are delivered to the event object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

- A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be **delivered** by a thread or an ISR. When delivering events, the events may either overwrite the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events, this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting. Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting on the event object. All threads whose match conditions have been met are made active at the same time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for any of them. Furthermore, threads making a wait request have the option of resetting the current set of events tracked by the event object prior to waiting. Care must be taken with this option when multiple threads wait on the same event object.

Note

The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait for the events.

Implementation

Defining an Event Object An event object is defined using a variable of type `k_event`. It must then be initialized by calling `k_event_init()`.

The following code defines an event object.

```
struct k_event my_event;

k_event_init(&my_event);
```

Alternatively, an event object can be defined and initialized at compile time by calling K_EVENT_DEFINE.

The following code has the same effect as the code segment above.

```
K_EVENT_DEFINE(my_event);
```

Setting Events Events in an event object are set by calling k_event_set().

The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */

    k_event_set(&my_event, 0x001);

    ...
}
```

Posting Events Events are posted to an event object by calling k_event_post().

The following code builds on the example above, and posts a set of events to the event object.

```
void input_available_interrupt_handler(void *arg)
{
    ...

    /* notify threads that more data is available */

    k_event_post(&my_event, 0x120);

    ...
}
```

Waiting for Events (without removal) Threads wait for events by calling k_event_wait().

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events before continuing.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

Waiting for Events (with removal) Threads wait for events (with atomic removal upon receipt) by calling `k_event_wait_safe()`.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

If events are received on time, then they will not be present in the event object until the next time that the events are set or posted.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_safe(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events (with atomic removal upon receipt) before continuing using `k_event_wait_all_safe()`.

If all events are received on time, then they will not be present in the event object until the next time that the events are set or posted.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_all_safe(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

Suggested Uses Use events to indicate that a set of conditions have occurred.

Use events to pass small amounts of data to multiple threads at once.

Configuration Options Related configuration options:

- CONFIG_EVENTS

API Reference
Event APIs

Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is "symmetric" in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the CONFIG_SMP kconfig variable. This must be set to "y" to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it's supported. When enabled, the number of physical CPUs available is visible at build time as CONFIG_MP_MAX_NUM_CPUS. Likewise, the default for this will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).

Synchronization At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the irq_lock()/irq_unlock() primitives to implement fine grained critical sections using interrupt masking. These APIs continue to work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

Spinlocks SMP systems provide a more constrained k_spin_lock() primitive that not only masks interrupts locally, as done by irq_lock(), but also atomically validates that a shared lock variable has been modified before returning to the caller, "spinning" on the check if needed to wait for the other CPU to exit the lock. The default Zephyr implementation of k_spin_lock() and k_spin_unlock() is built on top of the pre-existing atomic_ layer (itself usually implemented using compiler intrinsics), though facilities exist for architectures to define their own for performance reasons.

One important difference between IRQ locks and spinlocks is that the earlier API was naturally recursive: the lock was global, so it was legal to acquire a nested lock inside of a critical section. Spinlocks are separable: you can have many locks for separate subsystems or data structures, preventing CPUs from contending on a single global resource. But that means that spinlocks must not be used recursively. Code that holds a specific lock must not try to re-acquire it or it will deadlock (it is perfectly legal to nest **distinct** spinlocks, however). A validation layer is available to detect and report bugs like this.

When used on a uniprocessor system, the data component of the spinlock (the atomic lock variable) is unnecessary and elided. Except for the recursive semantics above, spinlocks in single-CPU contexts produce identical code to legacy IRQ locks. In fact the entirety of the Zephyr core kernel has now been ported to use spinlocks exclusively.

Legacy irq_lock() emulation For the benefit of applications written to the uniprocessor locking API, `irq_lock()` and `irq_unlock()` continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using `irq_lock()` are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

CPU Mask It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the `CONFIG_SCHED_CPU_MASK` kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling `k_thread_cpu_mask_disable()` with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise `k_thread_cpu_mask_enable()` will re-enable execution. There are also `k_thread_cpu_mask_clear()` and `k_thread_cpu_mask_enable_all()` APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an `-EINVAL` will be returned.

Note that when this feature is enabled, the scheduler algorithm involved in doing the per-CPU mask test requires that the list be traversed in full. The kernel does not keep a per-CPU run queue. That means that the performance benefits from the `CONFIG_SCHED_SCALABLE` and `CONFIG_SCHED_MULTIQ` scheduler backends cannot be realized. CPU mask processing is available only when `CONFIG_SCHED_SIMPLE` is the selected backend. This requirement is enforced in the configuration layer.

SMP Boot Process A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application `main()` function, the kernel calls `z_smp_init()` to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using `arch_cpu_start()` for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU's interrupt stack), the address of a local `smp_init_top()` callback function to run on that CPU, and a pointer to a "start flag" address which will be used as an atomic signal.

The local SMP initialization (`smp_init_top()`) on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling `smp_timer_init()` to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic "start flag" to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls `z_swap()` to transfer control to the appropriate runnable thread via the standard scheduler API.

Interprocessor Interrupts When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.

One example is the Zephyr `k_thread_abort()` API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

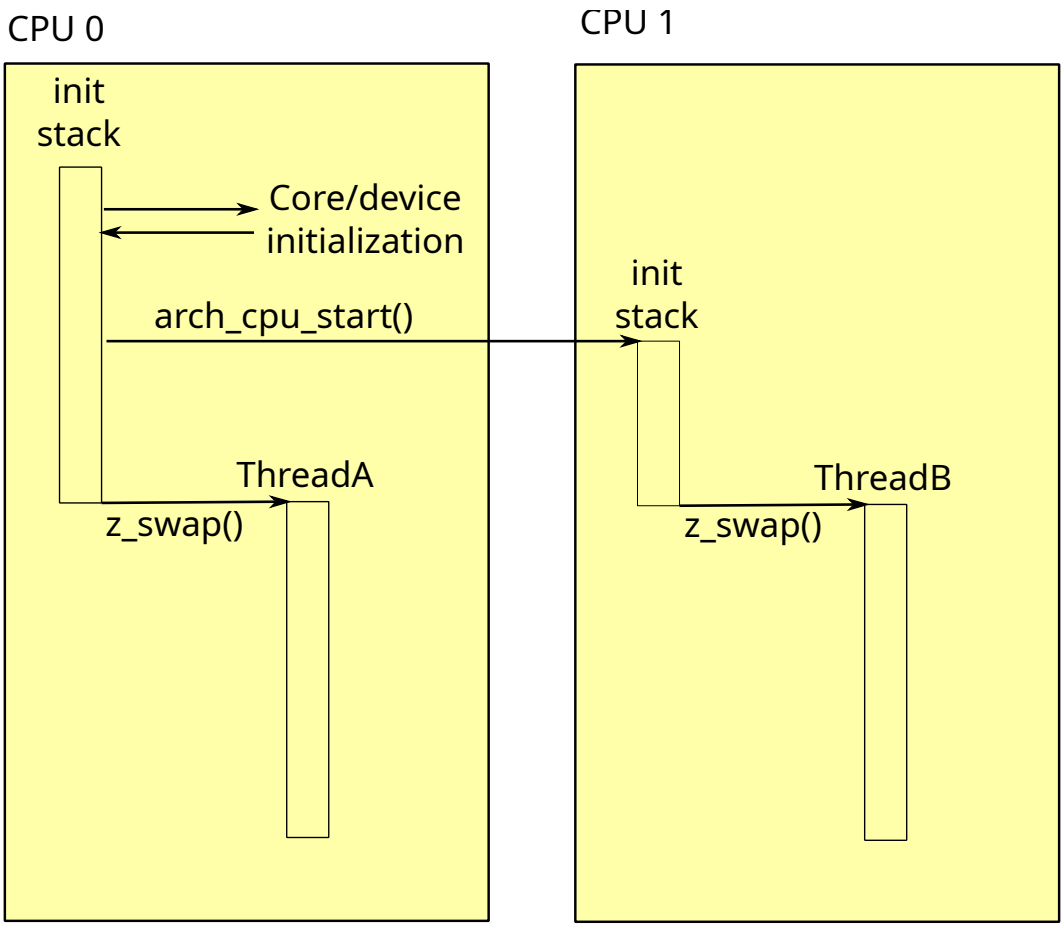

Fig. 1: Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.

Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to "wake up" to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides at least a `arch_sched_broadcast_ipi()` call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior). If the architecture supports directed IPIs (see `CONFIG_ARCH_HAS_DIRECTED_IPIS`), then the architecture also provides a `arch_sched_directed_ipi()` call, which when invoked will flag an interrupt on the specified CPUs. When an interrupt is flagged on the CPUs, the `z_sched_ipi()` function implemented in the scheduler will get invoked on those CPUs. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, `k_thread_abort()` becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler), we broadcast an IPI and spin, waiting for the thread to either become "DEAD" or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the "aborted" check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will **not** enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

IPI Cascades The kernel can not control the order in which IPIs are processed by the CPUs in the system. In general, this is not an issue and a single set of IPIs is sufficient to trigger a reschedule on the N CPUs that results with them scheduling the highest N priority ready threads to execute. When CPU masking is used, there may be more than one valid set of threads (not to be confused with an optimal set of threads) that can be scheduled on the N CPUs and a single set of IPIs may be insufficient to result in any of these valid sets.

Note

When CPU masking is not in play, the optimal set of threads is the same as the valid set of threads. However when CPU masking is in play, there may be more than one valid set–one of which may be optimal.

To better illustrate the distinction, consider a 2-CPU system with ready threads T1 and T2 at priorities 1 and 2 respectively. Let T2 be pinned to CPU0 and T1 not be pinned. If CPU0 is executing T2 and CPU1 executing T1, then this set is is both valid and optimal. However, if CPU0 is executing T1 and CPU1 is idling, then this too would be valid though not optimal.

In those cases where a single set of IPIs is not sufficient to generate a valid set, the resulting set of executing threads are expected to be close to a valid set, and subsequent IPIs can generally be expected to correct the situation soon. However, for cases where neither the approximation nor the delay are acceptable, enabling `CONFIG_SCHED_IPI_CASCADE` will allow the kernel to generate cascading IPIs until the kernel has selected a valid set of ready threads for the CPUs.

There are three types of costs/penalties associated with the IPI cascades–and for these reasons they are disabled by default. The first is a cost incurred by the CPU producing the IPI when a new thread preempts the old thread as checks must be done to compare the old thread against the threads executing on the other CPUs. The second is a cost incurred by the CPUs receiving the IPIs as they must be processed. The third is the apparent sputtering of a thread as it "winks in" and then "winks out" due to cascades stemming from the aforementioned first cost.

IPI Work Items The kernel allows developers to execute functions on other CPUs at ISR level using one or more IPI work items. After IPI work items have been added to the specified CPUs' work queues using `k_ipi_work_add()`, the targeted CPUs will process them after receiving an IPI. Signaling an IPI is done by calling `k_ipi_work_signal()`. Waiting for an IPI work item to be completed by the targeted CPUs is done by calling `k_ipi_work_wait()`. Only a single waiter is permitted at a time.

> **Note**
>
> IPI work items will only be added to the IPI work queues of other CPUs. If adding IPI work items at thread level, the developer must ensure that the current thread does not change CPUs until after signaling the IPIs.

Sample Use The following code outlines how to use IPI work items to update status information across a set of CPUs as a result of one CPU handling an ISR.

```
struct k_ipi_work my_work;

void remote_cpu_action(struct k_ipi_work *arg)
{
    ...
}

void my_isr(void)
{
    /*
     * Wait for previous use of <my_work> to complete.
     * It assumes that <my_work> was initialized elsewhere.
     */

    uint32_t cpu_mask = <bitmask identifying CPUs to update>;

    while (k_ipi_work_wait(&my_work, K_NO_WAIT) == -EAGAIN) {
    }

    /* Add and signal the new work */

    k_ipi_work_add(&my_work, cpu_mask, remote_cpu_action);

    k_ipi_signal();
}
```

SMP Kernel Internals In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

Per-CPU data Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the `_current` thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct `_cpu` instance within the `_kernel` struct, which has a `cpus[]` array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of `cpus[0]` using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that `arch_curr_cpu()` will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global "idle thread" at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for "_is_idle()" in the scheduler, which is a hot path performance environment, more complicated than simply testing the thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.

Switch-based context switching The traditional Zephyr context switch primitive has been `z_swap()`. Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified and cached the resulting "next thread" pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP "switch to" decision needs to be made synchronously with the swap call, and as we don't want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: `arch_switch()` is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out. The kernel then implements a portable `z_swap()` implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn't need to understand it.

Similarly, on interrupt exit, switch-based architectures are expected to call `z_get_next_switch_handle()` to retrieve the next thread to run from the scheduler. The argument to `z_get_next_switch_handle()` is either the interrupted thread's "handle" reflecting the same opaque type used by `arch_switch()`, or NULL if that thread cannot be released to the scheduler just yet. The choice between a handle value or NULL depends on the way CPU interrupt mode is implemented.

Architectures with a large CPU register file would typically preserve only the caller-saved registers on the current thread's stack when interrupted in order to minimize interrupt latency, and preserve the callee-saved registers only when `arch_switch()` is called to minimize context switching latency. Such architectures must use NULL as the argument to `z_get_next_switch_handle()` to determine if there is a new thread to schedule, and follow through with their own `arch_switch()` or derivative if so, or directly leave interrupt mode otherwise. In the former case it is up to that switch code to store the handle resulting from the thread that is being switched out in that thread's "switch_handle" field after its context has fully been saved.

Architectures whose entry in interrupt mode already preserves the entire thread state may pass that thread's handle directly to `z_get_next_switch_handle()` and be done in one step.

Note that while SMP requires `CONFIG_USE_SWITCH`, the reverse is not true. A uniprocessor architecture built with `CONFIG_SMP` set to No might still decide to implement its context switching using `arch_switch()`.

Thread Queue Ordering When a thread is preempted by another thread of higher priority in an SMP system, it is moved to the back of the queue for its priority level. In contrast, on UP systems, a preempted thread does not move to the back of its priority queue; it simply waits to regain the CPU, preserving its original ordering relative to other threads of the same priority.

Spinlock APIs

3.1.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs.

The following table summarizes their high-level features.

Object	Bidirectional?	Data structure	Data item size	Data Alignment	ISRs can receive?	ISRs can send?	Overrun handling
FIFO	No	Queue	Arbitrary[1]	4 B[2]	Yes[3]	Yes	N/A
LIFO	No	Queue	Arbitrary[1]	4 B[2]	Yes[3]	Yes	N/A
Stack	No	Array	Word	Word	Yes[3]	Yes	Undefined behavior
Message queue	No	Ring buffer	Arbitrary[6]	Power of two	Yes[3]	Yes	Pend thread or return -errno
Mailbox	Yes	Queue	Arbitrary[1]	Arbitrary	No	No	N/A
Pipe	No	Ring buffer[4]	Arbitrary	Arbitrary	Yes[5]	Yes[5]	Pend thread or return -errno

Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both *k_fifo* and *k_lifo*. For more information on usage see *k_fifo*.

Configuration Options Related configuration options:

- None

API Reference
Queue APIs

[1] Callers allocate space for queue overhead in the data elements themselves.
[2] Objects added with `k_fifo_alloc_put()` and `k_lifo_alloc_put()` do not have alignment constraints, but use temporary memory from the calling thread's resource pool.
[3] ISRs can receive only when passing K_NO_WAIT as the timeout argument.
[6] Data item size must be a multiple of the data alignment.
[4] Optional.
[5] ISRs can send and/or receive only when passing K_NO_WAIT as the timeout argument.

FIFOs

A *FIFO* is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- *Concepts*
- *Implementation*
  - *Defining a FIFO*
  - *Writing to a FIFO*
  - *Reading from a FIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_fifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

FIFO data items are restricted to single active instance across all FIFO data queues. Any attempt to re-add a FIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, **multiple data items** can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets

of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

Implementation

Defining a FIFO A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling `k_fifo_init()`.

The following code defines and initializes an empty FIFO.

```
struct k_fifo my_fifo;

k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling `K_FIFO_DEFINE`.

The following code has the same effect as the code segment above.

```
K_FIFO_DEFINE(my_fifo);
```

Writing to a FIFO A data item is added to a FIFO by calling `k_fifo_put()`.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *fifo_reserved;   /* 1st word reserved for use by FIFO */
    ...
};

struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_fifo_put(&my_fifo, &tx_data);

        ...
    }
}
```

Additionally, a singly-linked list of data items can be added to a FIFO by calling `k_fifo_put_list()` or `k_fifo_put_slist()`.

Finally, a data item can be added to a FIFO with `k_fifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a FIFO A data item is removed from a FIFO by calling `k_fifo_get()`.

The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}
```

Suggested Uses Use a FIFO to asynchronously transfer data items of arbitrary size in a "first in, first out" manner.

LIFOs

A *LIFO* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- *Concepts*
- *Implementation*
  - *Defining a LIFO*
  - *Writing to a LIFO*
  - *Reading from a LIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

LIFO data items are restricted to single active instance across all LIFO data queues. Any attempt to re-add a LIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a LIFO by a thread. If the LIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

Implementation

Defining a LIFO A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling `k_lifo_init()`.

The following defines and initializes an empty LIFO.

```
struct k_lifo my_lifo;

k_lifo_init(&my_lifo);
```

Alternatively, an empty LIFO can be defined and initialized at compile time by calling `K_LIFO_DEFINE`.

The following code has the same effect as the code segment above.

```
K_LIFO_DEFINE(my_lifo);
```

Writing to a LIFO A data item is added to a LIFO by calling `k_lifo_put()`.

The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *LIFO_reserved;   /* 1st word reserved for use by LIFO */
    ...
};
```

(continues on next page)

(continued from previous page)

```
struct data_item_t tx data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_lifo_put(&my_lifo, &tx_data);

        ...
    }
}
```

A data item can be added to a LIFO with `k_lifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a LIFO A data item is removed from a LIFO by calling `k_lifo_get()`.

The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_lifo_get(&my_lifo, K_FOREVER);

        /* process LIFO data item */
        ...
    }
}
```

Suggested Uses Use a LIFO to asynchronously transfer data items of arbitrary size in a "last in, first out" manner.

Stacks

A *stack* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

- *Concepts*
- *Implementation*
  - *Defining a Stack*
  - *Pushing to a Stack*
  - *Popping from a Stack*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

- A **queue** of integer data values that have been added but not yet removed. The queue is implemented using an array of stack_data_t values and must be aligned on a native word boundary. The stack_data_t type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.
- A **maximum quantity** of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be **added** to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO's queue.

Note

If `CONFIG_NO_RUNTIME_CHECKS` is enabled, the kernel will *not* detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.

A data value may be **removed** from a stack by a thread. If the stack's queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

Implementation

Defining a Stack A stack is defined using a variable of type `k_stack`. It must then be initialized by calling `k_stack_init()` or `k_stack_alloc_init()`. In the latter case, a buffer is not provided and it is instead allocated from the calling thread's resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```
#define MAX_ITEMS 10

stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;

k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling K_STACK_DEFINE.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

Pushing to a Stack A data item is added to a stack by calling k_stack_push().

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
    };
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

Popping from a Stack A data item is taken from a stack by calling k_stack_pop().

The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.

```
struct my_buffer_type *new_buffer;

k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...
```

Suggested Uses Use a stack to store and retrieve integer data values in a "last in, first out" manner, when the maximum number of stored items is known.

Message Queues

A *message queue* is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

- *Concepts*
- *Implementation*
  - *Defining a Message Queue*
  - *Writing to a Message Queue*
  - *Reading from a Message Queue*
  - *Peeking into a Message Queue*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

- A **ring buffer** of data items that have been sent but not yet received.
- A **data item size**, measured in bytes.
- A **maximum quantity** of data items that can be queued in the ring buffer.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be **sent** to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue's ring buffer, if space is available. In either case, the size of the data area being sent *must* equal the message queue's data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be **received** from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.

A thread can also **peek** at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

Note

The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.

Note

Alignment of the message queue's ring buffer is not necessary. The underlying implementation uses `memcpy()` (which is alignment-agnostic) and does not expose any internal pointers.

Implementation

Defining a Message Queue A message queue is defined using a variable of type `k_msgq`. It must then be initialized by calling `k_msgq_init()`.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};

char my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;

k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling `K_MSGQ_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 1);
```

Writing to a Message Queue A data item is added to a message queue by calling `k_msgq_put()`.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved. Note that this api will trigger reschedule.

```
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        data = ...

        /* send data to consumers */
        while (k_msgq_put(&my_msgq, &data, K_NO_WAIT) != 0) {
            /* message queue is full: purge old data & try again */
            k_msgq_purge(&my_msgq);
        }

        /* data item was successfully added to message queue */
    }
}
```

Reading from a Message Queue A data item is taken from a message queue by calling `k_msgq_get()`.

The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of `k_msgq_get()` should be tested as `-ENOMSG` can be returned due to `k_msgq_purge()`.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);

        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue A data item is read from a message queue by calling `k_msgq_peek()`.

The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);

        /* process data item */
        ...
    }
}
```

Suggested Uses Use a message queue to transfer small data items between threads in an asynchronous manner.

Note

A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read a data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.

A synchronous transfer can be achieved by using the kernel's mailbox object type.

Mailboxes

A *mailbox* is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- *Concepts*
  - *Message Format*
  - *Message Lifecycle*
  - *Thread Compatibility*
  - *Message Flow Control*
- *Implementation*
  - *Defining a Mailbox*
  - *Message Descriptors*
  - *Sending a Message*
  - *Receiving a Message*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A **send queue** of messages that have been sent but not yet received.
- A **receive queue** of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the **sending thread**, while a thread that receives the message is known as the **receiving thread**. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.

Message Format A **message descriptor** is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and

receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of **message data**. The size and format of the message data is application-defined, and can vary from one message to the next.

A **message buffer** is an area of memory provided by the thread that sends or receives the message data. An array or structure variable can often be used for this purpose.

A message that has neither form of message data is called an **empty message**.

> **Note**
>
> A message whose message buffer exists, but contains zero bytes of actual data, is *not* an empty message.

Message Lifecycle The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

Thread Compatibility A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying `K_ANY`. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying `K_ANY`. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be **compatible**.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).

Message Flow Control Mailbox messages can be exchanged **synchronously** or **asynchronously**. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) *before* the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

Implementation

Defining a Mailbox A mailbox is defined using a variable of type `k_mbox`. It must then be initialized by calling `k_mbox_init()`.

The following code defines and initializes an empty mailbox.

```
struct k_mbox my_mailbox;

k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling K_MBOX_DEFINE.

The following code has the same effect as the code segment above.

```
K_MBOX_DEFINE(my_mailbox);
```

Message Descriptors A message descriptor is a structure of type k_mbox_msg. Only the fields listed below should be used; any other fields are for internal mailbox use only.

info
: A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

size
: The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

tx_data
: A pointer to the sending thread's message buffer. Set it to NULL when sending an empty message. Leave this field uninitialized when receiving a message.

tx_target_thread
: The address of the desired receiving thread. Set it to K_ANY to allow any thread to receive the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

rx_source_thread
: The address of the desired sending thread. Set it to K_ANY to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.

Sending a Message A thread sends a message by first creating its message data, if any.

Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section.

Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue.

Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first.

For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

Note

A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is *no* limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

Note

A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

Sending an Empty Message This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message "info" field is large enough to carry the information being exchanged, so the data portion of the message isn't used.

```
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {

        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();

        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);
    }
}
```

Sending Data Using a Message Buffer This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void producer_thread(void)
{
```

(continues on next page)

(continued from previous page)

```
    char buffer[100];
    int buffer_bytes_used;

    struct k_mbox_msg send_msg;

    while (1) {

        /* generate data to send */
        ...
        buffer_bytes_used = ... ;
        memcpy(buffer, source, buffer_bytes_used);

        /* prepare to send message */
        send_msg.info = buffer_bytes_used;
        send_msg.size = buffer_bytes_used;
        send_msg.tx_data = buffer;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

        /* info, size, and tx_target_thread fields have been updated */

        /* verify that message data was fully received */
        if (send_msg.size < buffer_bytes_used) {
            printf("some message data dropped during transfer!");
            printf("receiver only had room for %d bytes", send_msg.info);
        }
    }
}
```

Receiving a Message A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads are sorted according to their priority; threads of equal priority are sorted so that the one that started waiting first can receive a message first.

Note

Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the thread compatibility constraints specified by the message descriptors. For example, if thread A waits to receive a message only from thread X and then thread B waits to receive a message from thread Y, an incoming message from thread Y to any thread will be given to thread B and thread A will continue to wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where the data ends up. The thread may choose to take all of the data in the message, to take only the initial part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into a message buffer of its choice.

The following sections outline various approaches a receiving thread may use when retrieving message data.

Retrieving Data at Receive Time The most straightforward way for a thread to retrieve message data is to specify a message buffer when the message is received. The thread indicates both the location of the message buffer (which must not be NULL) and its size.

The mailbox copies the message's data to the message buffer as part of the receive operation. If the message buffer is not big enough to contain all of the message's data, any uncopied data is lost. If the message is not big enough to fill all of the buffer with data, the unused portion of the message buffer is left unchanged. In all cases the mailbox updates the receiving thread's message descriptor to indicate how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a message is known in advance.

The following code uses a mailbox to process variable-sized requests from any producing thread, using the immediate data retrieval technique. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];

    int i;
    int total;

    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!");
            printf("sender tried to send %d bytes", recv_msg.info);
        }

        /* compute sum of all message bytes (from 0 to 100 of them) */
        total = 0;
        for (i = 0; i < recv_msg.size; i++) {
            total += buffer[i];
        }
    }
}
```

Retrieving Data Later Using a Message Buffer A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of NULL and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the

mailbox still updates the receiving thread's message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender's message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.
- If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call `k_mbox_data_get()` and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.
- If the message descriptor size is non-zero and the receiving thread does *not* want to retrieve the data, the thread must call `k_mbox_data_get()` and specify a message buffer of `NULL`. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

The following code uses a mailbox's deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message "info" field supplied by the sender is used to classify the message.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);

            /* process data in "buffer" */
            ...
        } else {
            /* ignore message data and delete the message */
            k_mbox_data_get(&recv_msg, NULL);
        }
    }
}
```

Suggested Uses Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

Concepts Any number of pipes can be defined, limited only by available RAM. Each pipe is referenced by its memory address.

A pipe has the following key property:

- A **size** that indicates the capacity of the pipe's ring buffer. Note that a size of zero defines a pipe with no ring buffer.

A pipe must be initialized before it can be used. When initialized, the pipe is empty.

Threads interact with the pipe as follows:

- **Writing**: Data is synchronously written, either in whole or in part, to a pipe by a thread. Accepted data is either copied directly to the waiting reader(s) or to the pipe's ring buffer. If the ring buffer is full or simply absent, the operation blocks until sufficient space becomes available or the specified timeout expires.
- **Reading**: Data is synchronously read, either in whole or in part, from a pipe by a thread. Accepted data is either copied from the pipe's ring buffer or directly from the waiting sender(s). If the ring buffer is empty or simply absent, the operation blocks until data becomes available or the specified timeout expires.
- **Resetting**: A thread can reset a pipe, which resets its internal state and ends all pending read and write operations with an error code.

Pipes are well-suited for scenarios like producer-consumer patterns or streaming data between threads.

Implementation A pipe is defined using a variable of type `k_pipe` and a byte buffer. The pipe must then be initialized by calling `k_pipe_init()`.

The following code defines and initializes an empty pipe with a ring buffer capable of holding 100 bytes, aligned to a 4-byte boundary:

```
uint8_t __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time using the K_PIPE_DEFINE macro, which defines both the pipe and its ring buffer:

```
K_PIPE_DEFINE(my_pipe, 100, 4);
```

This has the same effect as the code above.

When no ring buffer is used, the buffer pointer argument should be NULL and the size argument should be 0.

Writing to a Pipe Data is added to a pipe by calling k_pipe_write().

The following example demonstrates using a pipe to send data from a producer thread to one or more consumer threads. If the pipe's ring buffer fills up, the producer thread waits for a specified amount of time.

```
struct message_header {
    size_t num_data_bytes; /* Example field */
    ...
};

void producer_thread(void)
{
    int rc;
    uint8_t *data;
    size_t total_size;
    size_t bytes_written;

    while (1) {
        /* Craft message to send in the pipe */
        make_message(data, &total_size);
        bytes_written = 0;

        /* Write data to the pipe, handling partial writes */
        while (bytes_written < total_size) {
            rc = k_pipe_write(&my_pipe, &data[bytes_written], total_size -␣
↪bytes_written, K_NO_WAIT);

            if (rc < 0) {
                /* Error occurred */
                ...
                break;
            } else {
                /* Partial or full write succeeded; adjust for next iteration */
                bytes_written += rc;
            }
        }

        /* Reset bytes_written for the next message */
        bytes_written = 0;
        ...
    }
}
```

Reading from a Pipe Data is retrieved from the pipe by calling k_pipe_read().

The following example builds on the producer thread example above. It shows a consumer thread that processes data generated by the producer.

```
struct message_header {
    size_t num_data_bytes; /* Example field */
    ...
};

void consumer_thread(void)
{
    int rc;
    uint8_t buffer[128];
    size_t bytes_read = 0;
    struct message_header *header = (struct message_header *)buffer;

    while (1) {
        /* Step 1: Read the message header */
        bytes_read = 0;
   read_header:
        while (bytes_read < sizeof(*header)) {
            rc = k_pipe_read(&my_pipe, &buffer[bytes_read], sizeof(*header) -␣
↪bytes_read, &bytes_read, K_NO_WAIT);

            if (rc < 0) {
                /* Error occurred */
                ...
                goto read_header;
            }

            /* Adjust for partial reads */
            bytes_read += rc;
        }

        /* Step 2: Read the message body */
        bytes_read = 0;
        while (bytes_read < header->num_data_bytes) {
            rc = k_pipe_read(&my_pipe, &buffer[sizeof(*header) + bytes_read],␣
↪header->num_data_bytes - bytes_read, K_NO_WAIT);

            if (rc < 0) {
                /* Error occurred */
                ...
                goto read_header;
            }

            /* Adjust for partial reads */
            bytes_read += rc;
        }
        /* Successfully received the complete message */
    }
}
```

Resetting a Pipe The pipe can be reset by calling `k_pipe_reset()`. Resetting a pipe resets its internal state and ends all pending operations with an error code.

The following example demonstrates resetting a pipe in response to a critical error:

```
void monitor_thread(void)
{
    while (1) {
```

(continues on next page)

(continued from previous page)

```
        ...
        /* Critical error detected: reset the entire pipe to reset it. */
        k_pipe_reset(&my_pipe);
        ...
    }
}
```

Suggested Uses Pipes are useful for sending streams of data between threads. Typical applications include:

- Implementing producer-consumer patterns.
- Streaming logs or packets between threads.
- Handling variable-length message passing in real-time systems.

Pipe APIs

3.1.3 Memory Management

See *Memory Management*.

3.1.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.

Time Units Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a "cycle" count via the `k_cycle_get_32()` and `k_cycle_get_64()` APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is available from `sys_clock_hw_cycles_per_sec()`. On most platforms this is a runtime constant that evaluates to `CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC` and is fixed for the lifetime of the system. On platforms where the system timer frequency is not fixed, `sys_clock_hw_cycles_per_sec()` returns a runtime value and application code must not assume a single immutable frequency.

Runtime System Timer Frequency Some platforms need the system timer frequency to be available at runtime, either because the timer driver discovers the clock rate from hardware or because the timer clock rate can change after boot.

Platforms that can change the active system timer frequency at runtime must enable `CONFIG_SYSTEM_CLOCK_HW_CYCLES_PER_SEC_RUNTIME_UPDATE` and:

- Call `z_sys_clock_hw_cycles_per_sec_update()` after applying the clock change.

- If the system timer driver caches derived constants (e.g. cycles-per-tick) or needs to reprogram hardware when the clock changes, provide a timer-driver override of `z_sys_clock_hw_cycles_per_sec_update()`.

The default implementation of `z_sys_clock_hw_cycles_per_sec_update()` only updates the stored frequency value.

> **Note**
>
> `CONFIG_SYSTEM_CLOCK_HW_CYCLES_PER_SEC_RUNTIME_UPDATE` tracks the system timer frequency as a single **global** value. It is not compatible with per-CPU frequency scaling configurations where different CPUs could observe different system timer frequencies.
>
> When enabled, `sys_clock_hw_cycles_per_sec()` and time unit conversions follow the current runtime value.

For asynchronous timekeeping, the kernel defines a "ticks" concept. A "tick" is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via `CONFIG_SYS_CLOCK_TICKS_PER_SEC`. Defaults on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of "ms" (milliseconds), "us" (microseconds), "tick", or "cyc" can be converted to any other. Control of rounding is provided, and each conversion is available in "floor" (round down to nearest output unit), "ceil" (round up) and "near" (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: `k_ms_to_ticks_ceil32()` will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and `k_cyc_to_us_floor64()` will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime The kernel tracks a system uptime count on behalf of the application. This is available at all times via `k_uptime_get()`, which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with `k_uptime_ticks()`.

`k_uptime_delta()` can be used to get the time elapsed between a reference and the current time. The referenced time will be updated to the current uptime, to easily calculate the next elapsed time.

Timeouts The Zephyr kernel provides many APIs with a "timeout" parameter. Conceptually, this indicates the time at which an event will occur. For example:

- Kernel blocking operations like `k_sem_take()` or `k_queue_get()` may provide a timeout after which the routine will return with an error code if no data is available.
- Kernel `k_timer` objects must specify delays for their duration and period.
- The kernel `k_work_delayable` API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a k_timeout_t value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, K_MSEC, defines a time in milliseconds after the current time.

What is meant by "current time" for relative timeouts depends on the context:

- When scheduling a relative timeout from within a timeout callback (e.g. from within the expiry function passed to k_timer_init() or the work handler passed to k_work_init_delayable()), "current time" is the exact time at which the currently firing timeout was originally scheduled even if the "real time" will already have advanced. This is to ensure that timers scheduled from within another timer's callback will always be calculated with a precise offset to the firing timer. It is thereby possible to fire at regular intervals without introducing systematic clock drift over time.
- When scheduling a timeout from application context, "current time" means the value returned by k_uptime_ticks() at the time at which the kernel receives the timeout value.

Other options for timeout initialization follow the unit conventions described above: K_NSEC(), K_USEC, K_TICKS and K_CYC() specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of k_timeout_t values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.

Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with K_TIMEOUT_ABS_MS indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

Timing Internals

Timeout Queue All Zephyr k_timeout_t events specified using the API above are managed in a single, global queue of events. Each event is stored in a double-linked list, with an attendant delta count in ticks from the previous event. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a _timeout tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a wait_q struct, or a k_tid_t thread struct).

Note that all variant units passed via a k_timeout_t are converted to ticks once on insertion into the list. There no multiple-conversion steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

Note that the list structure means that the CPU work involved in managing large numbers of timeouts is quadratic in the number of active timeouts. The API design of the timeout queue was intended to permit a more scalable backend data structure, but no such implementation exists currently.

Timer Drivers Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

- The driver is expected to be able to "announce" new ticks to the kernel via the sys_clock_announce() call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not "halfway through" a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.
- The driver is expected to provide a sys_clock_set_timeout() call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though

they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets "reset" incorrectly and causes clock skew.

- The driver is expected to provide a `sys_clock_elapsed()` call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to `sys_clock_announce()`, which the kernel needs to test newly arriving timeouts for expiration.

Note that a natural implementation of this API results in a "tickless" kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, "ticked" or "dumb" counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling `sys_clock_announce()` with an argument of one each time.
- The driver can ignore calls to `sys_clock_set_timeout()`, as every tick will be announced regardless of timeout status.
- The driver can return zero for every call to `sys_clock_elapsed()` as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

SMP Details In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:

- Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.
- The `sys_clock_announce()` call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire near simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not "skip" the announce call because of timeslicing requirements (see below).
- Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.
- The next timeout value passed back to the driver via `sys_clock_set_timeout()` is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to `sys_clock_announce()`. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

Time Slicing An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to `sys_clock_set_timeout()` may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

Subsystems that keep millisecond APIs In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using `K_MSEC()` at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is `K_FOREVER`. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent "forever". `K_NO_WAIT` has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.

Subsystems using `k_timeout_t` Ideally, code that takes a "timeout" parameter specifying a time to wait should be using the kernel native abstraction where possible. But `k_timeout_t` is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for `K_FOREVER` can simply use the `K_TIMEOUT_EQ()` macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:

```
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();

        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);

        /* Subtract elapsed time */
        timeout_in_ms -= (k_uptime_get_32() - start);
    }
}
```

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides the internal `sys_timepoint_calc()` and `sys_timepoint_timeout()` routines that converts an arbitrary timeout to and from a timepoint value based on an uptime tick at which it will expire. So such a loop might look like:

```
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout)
{
    /* Compute the end time from the timeout */
    k_timepoint_t end = sys_timepoint_calc(timeout);

    do {
        if (is_event_complete(obj)) {
            return;
        }

        /* Update timeout with remaining time */
```

(continues on next page)

(continued from previous page)

```
        timeout = sys_timepoint_timeout(end);

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout);
    } while (!K_TIMEOUT_EQ(timeout, K_NO_WAIT));
}
```

Note that `sys_timepoint_calc()` accepts special values `K_FOREVER` and `K_NO_WAIT`, and works identically for absolute timeouts as well as conventional ones. Conversely, `sys_timepoint_timeout()` may return `K_FOREVER` or `K_NO_WAIT` if those were used to create the timepoint, the later also being returned if the timepoint is now in the past. For simple cases, `sys_timepoint_expired()` can be used as well.

But some care is still required for subsystems that use those. Note that delta timeouts need to be interpreted relative to a "current time", and obviously that time is the time of the call to `sys_timepoint_calc()`. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation in user code. It should not be used on a "stored" timeout value, and should never be called iteratively in a loop.

API Reference

System Clock APIs

Timers

A *timer* is a kernel object that measures the passage of time using the kernel's system clock. When a timer's specified time limit is reached it can perform an application-defined action, or it can simply record the expiration and wait for the application to read its status.

- *Concepts*
- *Implementation*
  - *Defining a Timer*
  - *Using a Timer Expiry Function*
  - *Reading Timer Status*
  - *Using Timer Status Synchronization*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A **duration** specifying the time interval before the timer expires for the first time. This is a `k_timeout_t` value that may be initialized via different units.
- A **period** specifying the time interval between all timer expirations after the first one, also a `k_timeout_t`. It must be non-negative. A period of `K_NO_WAIT` (i.e. zero) or `K_FOREVER` means that the timer is a one-shot timer that stops after a single expiration. (For example

then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200 ms and then every 75 ms after that.)

- An **expiry function** that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a `NULL` function can be specified.
- A **stop function** that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a `NULL` function can be specified.
- A **status** value that indicates how many times the timer has expired since the status value was last read.

A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the **stopped** state.

A timer is **started** by specifying a duration and a period. The timer's status is reset to zero, and then the timer enters the **running** state and begins counting down towards expiry.

Note

The timer's duration is a **minimum** delay relative to the time the timer was started. The timer's period is a **minimum** delay relative to the last time the timer "should" have expired. This means that a periodic timer will not drift relative to the system timer, and that its periodic delay can be shorter or longer than the specified period.

To ensure a minimum delay until the timer expires, restart the timer from within the **expiry function** or after the timer expired.

The variability of the delays stem from system variables like interrupt handling delays and execution time of preceding timer handlers.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise, the timer restarts with a new duration equal to the delta between the time the timer "should" have expired and its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by **synchronizing** with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

Note

Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should syn-

chronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

Implementation

Defining a Timer A timer is defined using a variable of type `k_timer`. It must then be initialized by calling `k_timer_init()`.

The following code defines and initializes a timer.

```
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);

k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling `K_TIMER_DEFINE`.

The following code has the same effect as the code segment above.

```
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```

Using a Timer Expiry Function The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at the interrupt level, the timer's expiry function submits a work item to the *system workqueue*, whose thread performs the work.

```
void my_work_handler(struct k_work *work)
{
    /* do the processing that needs to be done periodically */
    ...
}

K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy)
{
    k_work_submit(&my_work);
}

K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);

...

/* start a periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

Reading Timer Status The following code reads a timer's status directly to determine if the timer has expired or not.

```
K_TIMER_DEFINE(my_status_timer, NULL, NULL);

...

/* start a one-shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);
```

(continues on next page)

(continued from previous page)

```
/* do work */
...

/* check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
    /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
    /* timer was stopped (by someone else) before expiring */
} else {
    /* timer is still running */
}
```

Using Timer Status Synchronization The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```
K_TIMER_DEFINE(my_sync_timer, NULL, NULL);

...

/* do first protocol operation */
...

/* start a one-shot timer that expires after 500 ms */
k_timer_start(&my_sync_timer, K_MSEC(500), K_NO_WAIT);

/* do other work */
...

/* ensure timer has expired (waiting for expiry, if necessary) */
k_timer_status_sync(&my_sync_timer);

/* do second protocol operation */
...
```

Note

If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

Suggested Uses Use a timer to initiate an asynchronous operation after a specified amount of time.

Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler `k_sleep()` and `k_usleep()` calls.

Use a timer to perform other work while carrying out operations involving time limits.

Note

If a thread needs to measure the time required to perform an operation it can read the *system clock or the hardware clock* directly, rather than using a timer.

These pages cover other kernel services.

Atomic Services

An *atomic variable* is one that can be read and modified by threads and ISRs in an uninterruptible manner. It is a 32-bit variable on 32-bit machines and a 64-bit variable on 64-bit machines.

- *Concepts*
- *Implementation*
  - *Defining an Atomic Variable*
  - *Manipulating an Atomic Variable*
  - *Manipulating an Array of Atomic Variables*
  - *Memory Ordering*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of atomic variables can be defined (limited only by available RAM).

Using the kernel's atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

Implementation

Defining an Atomic Variable An atomic variable is defined using a variable of type `atomic_t`.

By default an atomic variable is initialized to zero. However, it can be given a different value using `ATOMIC_INIT`:

```
atomic_t flags = ATOMIC_INIT(0xFF);
```

Manipulating an Atomic Variable An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.

```
atomic_t call_count;

int call_counting_routine(void)
{
    /* increment invocation counter */
    atomic_inc(&call_count);

    /* do rest of routine's processing */
    ...
}
```

Manipulating an Array of Atomic Variables An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using ATOMIC_DEFINE.

A single bit in array of atomic variables can be manipulated using the APIs listed at the end of this section that end with _bit().

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

```
#define NUM_FLAG_BITS 200

ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}
```

Memory Ordering For consistency and correctness, all Zephyr atomic APIs are expected to include a full memory barrier (in the sense of e.g. "serializing" instructions on x86, "DMB" on ARM, or a "sequentially consistent" operation as defined by the C++ memory model) where needed by hardware to guarantee a reliable picture across contexts. Any architecture-specific implementations are responsible for ensuring this behavior.

Suggested Uses Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

> **Note**
>
> Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

Configuration Options Related configuration options:

Atomic Services APIs

Floating Point Services

The kernel allows threads to use floating point registers on board configurations that support these registers.

Note

Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific.

The kernel does not support the use of floating point registers by ISRs.

- *Concepts*
  - *No FP registers mode*
  - *Unshared FP registers mode*
  - *Shared FP registers mode*
- *Implementation*
  - *Performing Floating Point Arithmetic*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.

No FP registers mode This mode is used when the application has no threads that use floating point registers. It is the kernel's default floating point services mode.

If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

Unshared FP registers mode This mode is used when the application has only a single thread that uses floating point registers.

On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization in skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

Note

The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

Shared FP registers mode This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.

Note

The Shared FP registers mode is the default Floating Point Services mode in ARM Cortex-M.

ARM Cortex-M architecture (with the Floating Point Extension) On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats *all* threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below.

- A statically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `k_thread_create()`.

Pretagging a thread with the `K_FP_REGS` option instructs the MPU-based stack protection mechanism to properly configure the size of the thread's guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.

During thread context switching the ARM kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.

Lazy Stacking is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with `K_FP_REGS`

- Lazy stacking is activated dynamically on threads that are not pretagged with `K_FP_REGS`, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

Note

The Shared FP registers mode is the default Floating Point Services mode on ARM64. The compiler is free to optimize code using FP/SIMD registers, and library functions such as memcpy are known to make use of them.

ARM64 architecture On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

ARCv2 architecture On the ARCv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques.

- A statically-created ARC thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARC thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

If an ARC thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

RISC-V architecture On the RISC-V architecture the kernel treats each thread as an FPU user on a case-by-case basis with the FPU access allocated on demand. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the FPU registers are *not* saved when switching from an FPU user to a non-user thread (or an FPU user that doesn't touch the FPU during its scheduling slot), and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the

thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

As an optimization, the FPU context is preemptively restored upon scheduling back an "active FPU user" thread that had its FPU context saved away due to FPU usage by another thread. Active FPU users are so designated when they make the FPU state "dirty" during their most recent scheduling slot before being scheduled out. So if a thread doesn't modify the FPU state within its scheduling slot and another thread claims the FPU for itself afterwards then that first thread will be subjected to the on-demand regime and won't have its FPU context restored until it attempts to access it again. But if that thread does modify the FPU before being scheduled out then it is likely to continue using it when scheduled back in and preemptively restoring its FPU context saves on the exception trap overhead that would occur otherwise.

Each thread object becomes 136 bytes (single-precision floating point hardware) or 264 bytes (double-precision floating point hardware) larger when Shared FP registers mode is enabled.

SPARC architecture On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

During thread context switch at exit from interrupt handler, the SPARC kernel saves *all* floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread's stack. Floating point registers are restored when a thread context is restored iff they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy. The FPU is always disabled when an ISR is called (independent of `CONFIG_FPU_SHARING`).

Floating point disabling with `k_float_disable()` is not implemented.

When `CONFIG_FPU_SHARING` is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if `CONFIG_FPU_SHARING` is not used.

x86 architecture On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

Thread type	FP register use	Extra stack space required
cooperative	any	0 bytes
preemptive	none	0 bytes
preemptive	FPU	108 bytes
preemptive	SSE	464 bytes

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

- A statically-created x86 thread can be pretagged by passing the K_FP_REGS or K_SSE_REGS option to K_THREAD_DEFINE.
- A dynamically-created x86 thread can be pretagged by passing the K_FP_REGS or K_SSE_REGS option to k_thread_create().
- An already-created x86 thread can pretag itself once it has started by passing the K_FP_REGS or K_SSE_REGS option to k_float_enable().

If an x86 thread uses the floating point registers infrequently it can call k_float_disable() to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling k_float_enable().

Implementation

Performing Floating Point Arithmetic No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

```
int average(int *values, int num_values)
{
    double sum;
    int i;

    sum = 0.0;

    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
    }

    return (int)((sum / num_values) + 0.5);
}
```

Suggested Uses Use the kernel floating point services when an application needs to perform floating point operations.

Configuration Options To configure unshared FP registers mode, enable the CONFIG_FPU configuration option and leave the CONFIG_FPU_SHARING configuration option disabled.

To configure shared FP registers mode, enable both the CONFIG_FPU configuration option and the CONFIG_FPU_SHARING configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the CONFIG_X86_SSE configuration option to enable support for SSEx instructions.

Fatal Errors

Software Errors Triggered in Source Code Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Runtime Assertions Zephyr provides some macros to perform runtime assertions which may be conditionally compiled. Their definitions may be found in include/zephyr/sys/__assert.h.

Assertions are enabled by setting the `__ASSERT_ON` preprocessor symbol to a non-zero value. There are two ways to do this:

- Use the `CONFIG_ASSERT` and `CONFIG_ASSERT_LEVEL` kconfig options.
- Add `-D__ASSERT_ON=<level>` to the project's CFLAGS, either on the build command line or in a CMakeLists.txt.

The `__ASSERT_ON` method takes precedence over the kconfig option if both are used.

Specifying an assertion level of 1 causes the compiler to issue warnings that the kernel contains debug-type `__ASSERT()` statements; this reminder is issued since assertion code is not normally present in a final product. Specifying assertion level 2 suppresses these warnings.

Assertions are enabled by default when running Zephyr test cases, as configured by the `CONFIG_TEST` option.

The policy for what to do when encountering a failed assertion is controlled by the implementation of `assert_post_action()`. Zephyr provides a default implementation with weak linkage which invokes a kernel oops if the thread that failed the assertion was running in user mode, and a kernel panic otherwise.

__ASSERT() The `__ASSERT()` macro can be used inside kernel and application code to perform optional runtime checks which will induce a fatal error if the check does not pass. The macro takes a string message which will be printed to provide context to the assertion. In addition, the kernel will print a text representation of the expression code that was evaluated, and the file and line number where the assertion can be found.

For example:

```
__ASSERT(foo == 0xF0CACC1A, "Invalid value of foo, got 0x%x", foo);
```

If at runtime `foo` had some unexpected value, the error produced may look like the following:

```
ASSERTION FAIL [foo == 0xF0CACC1A] @ ZEPHYR_BASE/tests/kernel/fatal/src/main.c:367
        Invalid value of foo, got 0xdeadbeef
[00:00:00.000,000] <err> os: r0/a1:  0x00000004  r1/a2:  0x0000016f  r2/a3: ␣
↪0x00000000
[00:00:00.000,000] <err> os: r3/a4:  0x00000000 r12/ip:  0x00000000 r14/lr: ␣
↪0x00000a6d
[00:00:00.000,000] <err> os:  xpsr:  0x61000000
[00:00:00.000,000] <err> os: Faulting instruction address (r15/pc): 0x00009fe4
[00:00:00.000,000] <err> os: >>> ZEPHYR FATAL ERROR 4: Kernel panic
[00:00:00.000,000] <err> os: Current thread: 0x20000414 (main)
[00:00:00.000,000] <err> os: Halting system
```

__ASSERT_EVAL() The `__ASSERT_EVAL()` macro can also be used inside kernel and application code, with special semantics for the evaluation of its arguments.

It makes use of the `__ASSERT()` macro, but has some extra flexibility. It allows the developer to specify different actions depending whether the `__ASSERT()` macro is enabled or not. This can be particularly useful to prevent the compiler from generating comments (errors, warnings or remarks) about variables that are only used with `__ASSERT()` being assigned a value, but otherwise unused when the `__ASSERT()` macro is disabled.

Consider the following example:

```
int x;
x = foo();
__ASSERT(x != 0, "foo() returned zero!");
```

If `__ASSERT()` is disabled, then 'x' is assigned a value, but never used. This type of situation can be resolved using the __ASSERT_EVAL() macro.

```
__ASSERT_EVAL ((void) foo(),
               int x = foo(),
               x != 0,
               "foo() returned zero!");
```

The first parameter tells `__ASSERT_EVAL()` what to do if `__ASSERT()` is disabled. The second parameter tells `__ASSERT_EVAL()` what to do if `__ASSERT()` is enabled. The third and fourth parameters are the parameters it passes to `__ASSERT()`.

__ASSERT_NO_MSG() The `__ASSERT_NO_MSG()` macro can be used to perform an assertion that reports the failed test and its location, but lacks additional debugging information provided to assist the user in diagnosing the problem; its use is discouraged.

Custom Header In some cases, asserts need to be redirected at the macro level. For these cases, `CONFIG_ASSERT_CUSTOM_HEADER` can be used to inject an application provided header named `zephyr_custom_assert.h` at the end of include/zephyr/sys/__assert.h.

Build Assertions Zephyr provides a macro for performing build-time assertion checks. It is evaluated completely at compile-time and always checked.

BUILD_ASSERT() This has the same semantics as C's `_Static_assert` or C++'s `static_assert`. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike `__ASSERT()`, the message must be a static string, without `printf()`-like format codes or extra arguments.

For example, suppose this check fails:

```
BUILD_ASSERT(FOO == 2000, "Invalid value of FOO");
```

With GCC, the output resembles:

```
tests/kernel/fatal/src/main.c: In function 'test_main':
include/zephyr/toolchain/gcc.h:28:37: error: static assertion failed: "Invalid␣
↪value of FOO"
 #define BUILD_ASSERT(EXPR, MSG) _Static_assert(EXPR, "" MSG)
                                 ^~~~~~~~~~~~~~
tests/kernel/fatal/src/main.c:370:2: note: in expansion of macro 'BUILD_ASSERT'
  BUILD_ASSERT(FOO == 2000,
  ^~~~~~~~~~~~~~~~
```

Kernel Oops A kernel oops is a software triggered fatal error invoked by `k_oops()`. This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be `K_ERR_KERNEL_OOPS`.

Kernel Panic A kernel error is a software triggered fatal error invoked by `k_panic()`. This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of `k_sys_fatal_error_handler()` should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke `k_panic()`, and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be `K_ERR_KERNEL_PANIC`.

Exceptions

Spurious Interrupts If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with `IRQ_CONNECT()` or `irq_connect_dynamic()`, then the kernel will generate a fatal error with the reason code `K_ERR_SPURIOUS_IRQ()`.

Stack Overflows In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of `K_ERR_STACK_CHK_FAIL`.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if `CONFIG_USERSPACE` is not enabled, depending on configuration stack overflows may or may not be caught. `CONFIG_HW_STACK_PROTECTION` is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, `CONFIG_STACK_SENTINEL` is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via `CONFIG_STACK_CANARIES`. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwritten at function exit. If the check fails, the compiler invokes `__stack_chk_fail()`, whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.

Other Exceptions Any other type of unhandled CPU exception will generate an error code of `K_ERR_CPU_EXCEPTION`.

Fatal Error Handling The policy for what to do when encountering a fatal error is determined by the implementation of the `k_sys_fatal_error_handler()` function. This function has a default implementation with weak linkage that calls `LOG_PANIC()` to dump all pending logging messages and then unconditionally halts the system with `k_fatal_halt()`.

Applications are free to implement their own error handling policy by overriding the implementation of `k_sys_fatal_error_handler()`. If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

Fatal error APIs

Thread Local Storage (TLS)

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

Configuration To enable thread local storage in Zephyr, `CONFIG_THREAD_LOCAL_STORAGE` needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option `CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

`CONFIG_ERRNO_IN_TLS` can be enabled together with `CONFIG_ERRNO` to let the variable `errno` be a thread local variable. This allows user threads to access the value of `errno` without making a system call.

Declaring and Using Thread Local Variables The macro `Z_THREAD_LOCAL` can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```
extern Z_THREAD_LOCAL int i;
```

And to declare the actual variable in source files:

```
Z_THREAD_LOCAL int i;
```

Keyword `static` can also be used to limit the variable within a source file:

```
static Z_THREAD_LOCAL int j;
```

Using the thread local variable is the same as using other variable, for example:

```
void testing(void) {
    i = 10;
}
```

3.2 Device Driver Model

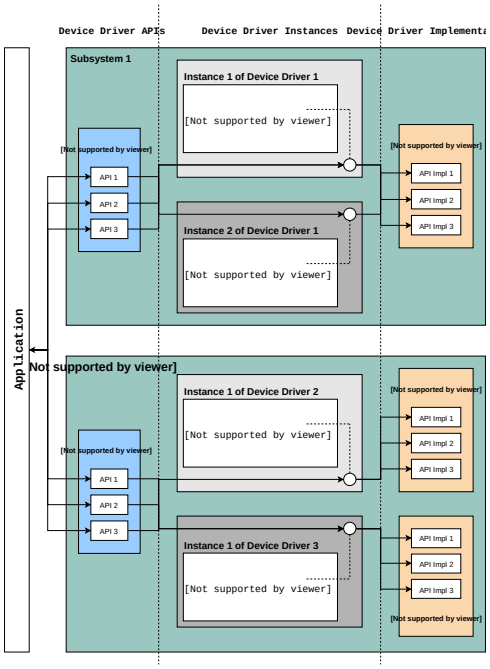
3.2.1 Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.



3.2.2 Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel's interrupt management subsystem.
- **Timer**: This device driver is used by the kernel's system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel's system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.

> **Important**
>
> Use the *random API functions* for random values. *Entropy functions* should not be directly used as a random number generator source as some hardware implementations are designed to be an entropy seed source for random number generators and will not provide cryptographically secure random number streams.

3.2.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.

High-level calls accessed through device-specific APIs, such as `i2c.h` or `spi.h`, are usually intended as synchronous. Thus, these calls should be blocking.

3.2.4 Driver APIs

The following APIs for device drivers are provided by `device.h`. The APIs are intended for use in device drivers only and should not be used in applications.

`DEVICE_DEFINE()`
: Create device object and related data structures including setting it up for boot-time initialization.

`DEVICE_NAME_GET()`
: Converts a device identifier to the global identifier for a device object.

`DEVICE_GET()`
: Obtain a pointer to a device object by name.

`DEVICE_DECLARE()`
: Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

`DEVICE_API()`
: Wrap a driver API declaration to assign it to its respective linker section.

3.2.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```
struct device {
      const char *name;
      const void *config;
      const void *api;
      void * const data;
};
```

The `config` member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the `config` pointer passed to `DEVICE_DEFINE()` and related macros.

The `data` struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The `api` struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.

3.2.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

If all driver API instances are assigned to their respective API linker section use `DEVICE_API_IS()` to verify the API's type.

A subsystem API definition typically looks like this:

```
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

__subsystem struct subsystem_driver_api {
      subsystem_do_this_t do_this;
      subsystem_do_that_t do_that;
```

(continues on next page)

(continued from previous page)

```
};

static inline int subsystem_do_this(const struct device *dev, int foo, int bar)
{
	return DEVICE_API_GET(subsystem, dev)->do_this(dev, foo, bar);
}

static inline void subsystem_do_that(const struct device *dev, void *baz)
{
	DEVICE_API_GET(subsystem, dev)->do_that(dev, baz);
}
```

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_driver_api structure using the `DEVICE_API()` wrapper:

```
static int my_driver_do_this(const struct device *dev, int foo, int bar)
{
	...
}

static void my_driver_do_that(const struct device *dev, void *baz)
{
	...
}

static DEVICE_API(subsystem, my_driver_api_funcs) = {
	.do_this = my_driver_do_this,
	.do_that = my_driver_do_that,
};
```

The driver would then pass `my_driver_api_funcs` as the `api` argument to `DEVICE_DEFINE()`.

Note

Since pointers to the API functions are referenced in the `api` struct, they will always be included in the binary even if unused; `gc-sections` linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.

3.2.7 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:

```
#include <zephyr/drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */
__syscall int specific_from_user(const struct device *dev, int bar);
```

(continues on next page)

(continued from previous page)

```
/* Only needed when extensions include syscalls */
#include <zephyr/syscalls/specific.h>
```

A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```
static int generic_do_this(const struct device *dev, void *arg)
{
   ...
}

static struct generic_api api {
   ...
   .do_this = generic_do_this,
   ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
   ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
   ...
}

#ifdef CONFIG_USERSPACE

#include <zephyr/internal/syscall_handler.h>

int z_vrfy_specific_from_user(const struct device *dev, int bar)
{
    K_OOPS(K_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
    return z_impl_specific_do_that(dev, bar)
}

#include <zephyr/syscalls/specific_from_user_mrsh.c>

#endif /* CONFIG_USERSPACE */
```

Applications use the device through both the subsystem and specific APIs.

3.2.8 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example there can be multiple GPIO banks, or multiple UARTS. Each instance of the driver will have a different `config` struct and `data` struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to `IRQ_CONNECT()` need to be resolvable at build time.

For example, let's say we need to configure two instances of `my_driver`, each with a different interrupt line. In `drivers/subsystem/subsystem_my_driver.h`:

```
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
	DEVICE_MMIO_ROM;
	my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```
void my_driver_isr(const struct device *dev)
{
	/* Handle interrupt */
	...
}

int my_driver_init(const struct device *dev)
{
	const struct my_driver_config *config = dev->config;

	DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);

	/* Do other initialization stuff */
	...

	config->config_func(dev);

	return 0;
}
```

Then when the particular instance is declared:

```
#if CONFIG_MY_DRIVER_0

DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(const struct device *dev)
{
	IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
		    DEVICE_GET(my_driver_0), MY_DRIVER_0_FLAGS);
}

const static struct my_driver_config my_driver_config_0 = {
	DEVICE_MMIO_ROM_INIT(DT_DRV_INST(0)),
	.config_func = my_driver_config_irq_0
}

static struct my_data_0;

DEVICE_DEFINE(my_driver_0, MY_DRIVER_0_NAME, my_driver_init,
	      NULL, &my_data_0, &my_driver_config_0,
	      POST_KERNEL, MY_DRIVER_0_PRIORITY, &my_api_funcs);

#endif /* CONFIG_MY_DRIVER_0 */
```

Note the use of `DEVICE_DECLARE()` to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

3.2.9 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. `DEVICE_DEFINE()` and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of three initialization levels:

PRE_KERNEL_1
: Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it's OK to set up interrupts. Init functions at this level run on the interrupt stack.

PRE_KERNEL_2
: Used for devices that rely on the initialization of devices initialized as part of the `PRE_KERNEL_1` level. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

POST_KERNEL
: Used for devices that require kernel services during configuration. Init functions at this level run in context of the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 999; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. `\#define MY_INIT_PRIO 32`); symbolic expressions are *not* permitted (e.g. `CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5`).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the `k_is_pre_kernel()` function.

3.2.10 Deferred initialization

Initialization of devices can also be deferred to a later time. In this case, the device is not automatically initialized by Zephyr at boot time. Instead, the device is initialized when the application calls `device_init()`. To defer a device driver initialization, add the property `zephyr,deferred-init` to the associated device node in the DTS file. For example:

```
/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>;
                zephyr,deferred-init;
        };
};
```

3.2.11 System Drivers

In some cases you may just need to run a function at boot. For such cases, the `SYS_INIT` can be used. This macro does not take any config or runtime data structures and there isn't a way to later get a device pointer by name. The same device policies for initialization level and priority apply.

3.2.12 Inspecting the initialization sequence

Device drivers declared with `DEVICE_DEFINE` (or any variations of it) and `SYS_INIT` are processed at boot time and the corresponding initialization functions are called sequentially according to their specified level and priority.

Sometimes it's useful to inspect the final sequence of initialization function call as produced by the linker. To do that, use the `initlevels` CMake target, for example `west build -t initlevels`.

3.2.13 Error handling

In general, it's best to use `__ASSERT()` macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.

When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX `errno.h` code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

3.2.14 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

- The I/O ranges must be probed at runtime from the bus, such as with PCI express
- A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver's init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function `device_map()`.

Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the `DEVICE_MMIO_ROM` and `DEVICE_MMIO_RAM` macros in the definitions for their `config_info` and `driver_data` structures, with initialization of the `config_info` from DTS using `DEVICE_MMIO_ROM_INIT`. A call to `DEVICE_MMIO_MAP()` is made within the init function:

```
struct my_driver_config {
   DEVICE_MMIO_ROM; /* Must be first */
   ...
}

struct my_driver_dev_data {
   DEVICE_MMIO_RAM; /* Must be first */
   ...
}

const static struct my_driver_config my_driver_config_0 = {
   DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
   ...
```

(continues on next page)

(continued from previous page)

```
}

int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO region */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev));
   ...
}
```

The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, `DEVICE_MMIO_MAP` and `DEVICE_MMIO_RAM` expand to nothing.

Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the `config_info` and `driver_data` structures.

This can be managed with the `DEVICE_MMIO_NAMED` variant macros. These require that `DEV_CFG()` and `DEV_DATA()` macros be defined to obtain a properly typed pointer to the driver's config_info or dev_data structs. For example:

```
struct my_driver_config {
   ...
     DEVICE_MMIO_NAMED_ROM(corge);
     DEVICE_MMIO_NAMED_ROM(grault);
   ...
}

struct my_driver_dev_data {
        ...
     DEVICE_MMIO_NAMED_RAM(corge);
     DEVICE_MMIO_NAMED_RAM(grault);
     ...
}

#define DEV_CFG(_dev) \
   ((const struct my_driver_config *)((_dev)->config))

#define DEV_DATA(_dev) \
   ((struct my_driver_dev_data *)((_dev)->data))

const static struct my_driver_config my_driver_config_0 = {
   ...
   DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_NAMED_MAP(dev, corge, K_MEM_CACHE_NONE);
   DEVICE_MMIO_NAMED_MAP(dev, grault, K_MEM_CACHE_NONE);
   ...
}
```

(continues on next page)

(continued from previous page)

```
int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO regions */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev, grault));
   sys_write32(0xF0CCAC1A, DEVICE_MMIO_GET(dev, corge));
   ...
}
```

Device Model Drivers with multiple MMIO regions in the same DT node

Some drivers may have multiple MMIO regions defined into the same DT device node using the `reg-names` property to differentiate them, for example:

```
/dts-v1/;

/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>,
                      <0x40001000 0x1000>;
                reg-names = "corge", "grault";
        };
};
```

This can be managed as seen in the previous section but this time using the `DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME` macro instead. So the only difference would be in the driver config struct:

```
const static struct my_driver_config my_driver_config_0 = {
   ...
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(grault, DT_DRV_INST(...)),
   ...
}
```

Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not use Zephyr's device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code.

This can be managed with the `DEVICE_MMIO_TOPLEVEL` set of macros, for example:

```
DEVICE_MMIO_TOPLEVEL_STATIC(my_regs, DT_DRV_INST(..));

void some_init_code(...)
{
   ...
   DEVICE_MMIO_TOPLEVEL_MAP(my_regs, K_MEM_CACHE_NONE);
   ...
}

void some_function(...)
   ...
   sys_write32(DEVICE_MMIO_TOPLEVEL_GET(my_regs), 0xDEADBEEF);
```

(continues on next page)

(continued from previous page)

```
    ...
}
```

Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the `device_map()` function may be used directly:

```
void some_init_code(...)
{
    ...
    struct pcie_bar mbar;
    bool bar_found = pcie_get_mbar(bdf, index, &mbar);

    device_map(DEVICE_MMIO_RAM_PTR(dev), mbar.phys_addr, mbar.size,␣
↪K_MEM_CACHE_NONE);
    ...
}
```

For these cases, DEVICE_MMIO_ROM directives may be omitted.

3.2.15 API Reference

Device Model

3.3 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see *Lifecycle*.

3.3.1 Overview

Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr's user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.
- The kernel can sandbox complex data parsers such as interpreters, network protocols, and filesystems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical "applications", each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

Design Goals For threads running in a non-privileged CPU state (hereafter referred to as 'user mode') we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    - A user thread will by default have read/write access to its own stack buffer.
    - A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
    - A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.
    - A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.
      - On MPU systems, threads may only access their own stack buffer.
      - On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.
  - By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.
  - User threads by default are not granted default access to any memory except what is noted above.
- We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.
- We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:
  - Using the wrong kernel object type.
  - Using parameters outside of proper bounds or with nonsensical values.
  - Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.
  - Use of kernel objects that are not in a proper initialization state.
- We ensure the detection and safe handling of user mode stack overflows.
- We prevent invoking system calls to functions excluded by the kernel configuration.
- We prevent disabling of or tampering with kernel-defined and hardware-enforced memory protections.
- We prevent re-entry from user to supervisor mode except through the kernel-defined system calls and interrupt handlers.
- We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

- The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.
- The toolchain and any supplemental programs used by the build system are assumed to be trusted.
- The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.

- We can't protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.
- It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.
- We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.
- There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
- Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

- Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the *Memory Protection Design* it belongs to. Access to any other RAM must be done on the thread's behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.
- User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.
- User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.
- For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.
- Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through predefined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

- Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.
- Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.
- Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

3.3.2 Memory Protection Design

Zephyr's memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures, such as x86, which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.

All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

Boot Time Memory Configuration

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a "background" mapping for any area of memory that doesn't have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities. See *Memory Attributes* for information on how to annotate the system map in the device tree.
- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.
- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

Hardware Stack Overflow

`CONFIG_HW_STACK_PROTECTION` is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has overflowed, and not individual stack frames, use compiler-assisted `CONFIG_STACK_CANARIES` for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it's still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a 'guard' MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

Thread Stack

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region or MMU page table entries will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn't have access to and a memory access violation exception will be generated.

Note that user threads have access to the stacks of other user threads in the same memory domain. This is the minimum required for architectures to support memory domains. Architecture can further restrict access to stacks so each user thread only has access to its own stack if such architecture advertises this capability via `CONFIG_ARCH_MEM_DOMAIN_SUPPORTS_ISOLATED_STACKS`. This behavior is enabled by default if supported and can be selectively disabled via `CONFIG_MEM_DOMAIN_ISOLATED_STACKS` if architecture supports both operating modes. However, some architectures may decide to enable this all the time, and thus this option cannot be disabled. Regardless of these kconfigs, user threads cannot access the stacks of other user threads outside of their memory domains.

Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a `k_heap` object. Memory is drawn from a thread's resource pool using `z_thread_malloc()` and freed with `k_free()`.

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- `k_stack_alloc_init()` sets up a k_stack with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_stacks that are automatically initialized at boot with `K_STACK_DEFINE()`, or to initialize the k_stack in supervisor mode with `k_stack_init()`.
- `k_msgq_alloc_init()` sets up a k_msgq object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a k_msgq that is automatically initialized at boot with `K_MSGQ_DEFINE()`, or to initialize the k_msgq in supervisor mode with `k_msgq_init()`.
- `k_poll()` when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when `k_poll()` returns for any reason.
- `k_queue_alloc_prepend()` and `k_queue_alloc_append()` allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.
- `k_object_alloc()` allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is `k_thread_heap_assign()` which assigns a k_heap to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with `k_thread_system_pool_assign()`, but it is preferable for different logical applications running on the system to have their own pools.

Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are *not* intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.

All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain `k_mem_domain_default` which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

Memory Partitions Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.
- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.
- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.
- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.
- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

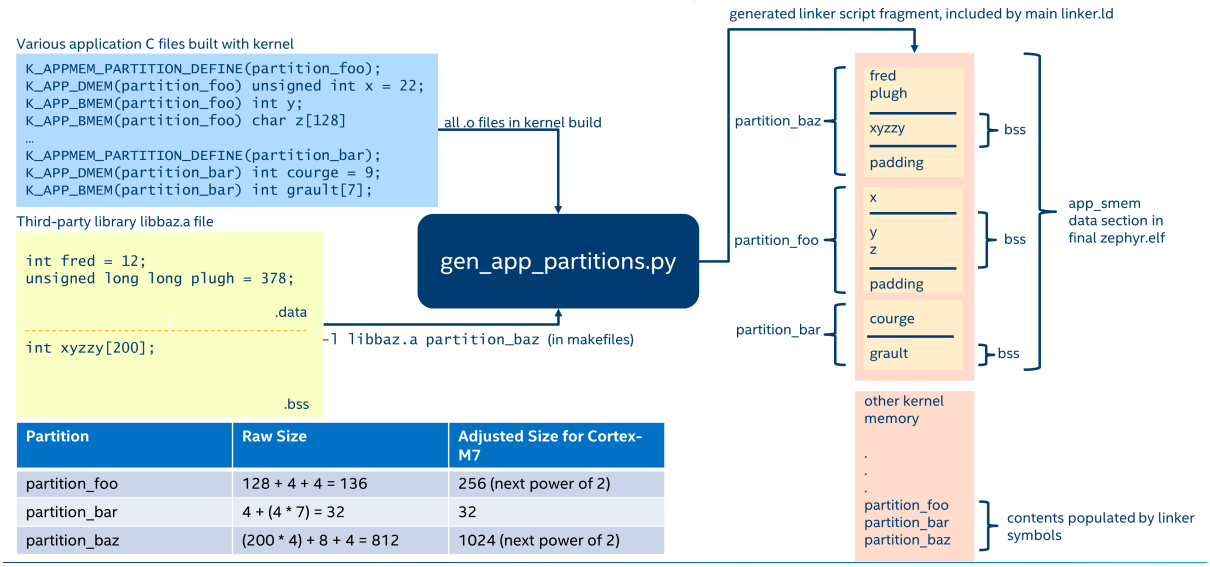
Manual Memory Partitions The following code declares a global array `buf`, and then declares a read-write partition for it which may be added to a domain:

```
uint8_t __aligned(32) buf[32];

K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf),
                       K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

Automatic Memory Partitions Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.



Partition	Raw Size	Adjusted Size for Cortex-M7
partition_foo	128 + 4 + 4 = 136	256 (next power of 2)
partition_bar	4 + (4 * 7) = 32	32
partition_baz	(200 * 4) + 8 + 4 = 812	1024 (next power of 2)

Fig. 2: Automatic Memory Domain build flow

Automatic memory partitions are only configured as read-write regions. They are defined with `K_APPMEM_PARTITION_DEFINE()`. Global variables are then routed to this partition using `K_APP_DMEM()` for initialized data and `K_APP_BMEM()` for BSS.

```
#include <zephyr/app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to
 * user mode. Note that we do not specify a base address or size.
 */
K_APPMEM_PARTITION_DEFINE(my_partition);

/* The global variable var1 will be inside the bounds of my_partition
 * and be initialized with 37 at boot.
 */
K_APP_DMEM(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition
 * and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS
 * variable.
 */
K_APP_BMEM(my_partition) int var2;
```

The build system will ensure that the base address of `my_partition` will be properly aligned,

and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in `app_macro_support.h`:

```
FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);
```

Automatic Partitions for Static Library Globals The build-time logic for setting up automatic memory partitions is in `scripts/build/gen_app_partitions.py`. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the `--library` argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in `z_libc_partition`. The invocation of the script in the top-level `CMakeLists.txt` adds the following:

```
gen_app_partitions.py ... --library libc.a z_libc_partition ..
```

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel `CMakeLists.txt` must be edited.

For Zephyr libraries created using `zephyr_library` or `zephyr_library_named` the `zephyr_library_app_memory` function can be used to specify the memory partition where all globals in the library should be placed.

Pre-defined Memory Partitions There are a few memory partitions which are pre-defined by the system:

- `z_malloc_partition` - This partition contains the system-wide pool of memory used by libc malloc(). Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various sys_heap objects and assign them to specific memory domains.
- `z_libc_partition` - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when `CONFIG_STACK_CANARIES` is enabled.

Library-specific partitions are listed in include/zephyr/app_memory/partitions.h. For example, to use the MBEDTLS library from user mode, the `k_mbedtls_partition` must be added to the domain.

Memory Domain Usage

Create a Memory Domain A memory domain is defined using a variable of type `k_mem_domain`. It must then be initialized by calling `k_mem_domain_init()`.

The following code defines and initializes an empty memory domain.

```
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

Add Memory Partitions into a Memory Domain There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
    app0_part0,
    app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);
```

Note

The maximum number of memory partitions is limited by the maximum number of MPU regions or the maximum number of MMU tables.

Memory Domain Assignment Any thread may join a memory domain, and any memory domain may have multiple threads assigned to it. Threads are assigned to memory domains with an API call:

```
k_mem_domain_add_thread(&app0_domain, app_thread_id);
```

If the thread was already a member of some other domain (including the default domain), it will be removed from it in favor of the new one.

In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will belong to the domain as well.

Remove a Memory Partition from a Memory Domain The following code shows how to remove a memory partition from a memory domain.

```
k_mem_domain_remove_partition(&app0_domain, &app0_part1);
```

The k_mem_domain_remove_partition() API finds the memory partition that matches the given parameter and removes that partition from the memory domain.

Available Partition Attributes When defining a partition, we need to set access permission attributes to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the available partition attributes would be architecture dependent.

The complete list of available partition attributes for a specific architecture is found in the architecture-specific include file `include/zephyr/arch/<arch name>/arch.h`, (for example, include/zephyr/arch/arm/arch.h.) Some examples of partition attributes are:

```
/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW
/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO
```

In almost all cases `K_MEM_PARTITION_P_RW_U_RW` is the right choice.

API Reference

The following memory domain APIs are provided by include/zephyr/kernel.h:

Memory domain APIs

3.3.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.
- A thread stack, which is an array of `z_thread_stack_element` and declared with `K_THREAD_STACK_DEFINE()`
- A device driver instance (const struct device) that belongs to one of a defined set of subsystems

The set of known kernel objects and driver subsystems is defined in include/zephyr/sys/kobject.h as `k_objects`.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the *scripts/build/gen_kobject_list.py* script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the `--verbose` flag, or if the build system is invoked with verbose output.

Dynamic Objects

Kernel objects may also be allocated at runtime if `CONFIG_DYNAMIC_OBJECTS` is enabled. In this case, the `k_object_alloc()` API may be used to instantiate an object from the calling thread's resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call `k_object_free()` to force a dynamic object to be released.
- If an object's references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with `k_object_release()`, and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using `k_object_access_revoke()`.

Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

Implementation Details The *scripts/build/gen_kobject_list.py* script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects generated by the 'gperf' tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of `device`, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of `z_object`, which has all the metadata for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the CONFIG_MAX_THREAD_BYTES option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of k_objects.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of z_object_data.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

Supervisor Thread Access Permission

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls k_thread_user_mode_enter(), the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the K_INHERIT_PERMS option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

User Thread Access Permission

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the K_INHERIT_PERMS, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the k_object_access_grant() API. The convenience pseudo-function k_thread_access_grant() may also be used, which accepts an arbitrary number of pointers to kernel objects and calls k_object_access_grant() on each of them. The thread being granted permission, or the object whose access is being granted, do not need to be in an initialized state. If the caller is from user mode, the caller must have permissions on both the kernel object and the target thread object.
- Supervisor threads may declare a particular kernel object to be a public object, usable by all current and future threads with the k_object_access_all_grant() API. You must assume that any untrusted or exploited code will then be able to access the object. Use this API with caution!
- If a thread was declared statically with K_THREAD_DEFINE(), then the K_THREAD_ACCESS_GRANT() may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the k_object_access_revoke() API. This API is not available to user threads, however user threads may use k_object_release() to relinquish their own permissions on an object.

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with `k_object_alloc()` implicitly grant permission on the allocated object to the calling thread.

Initialization State

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as `K_SEM_DEFINE` for semaphores) will be in an initialized state at build time.
- Device driver objects are considered initialized after their init function is run by the kernel early in the boot process.

If a kernel object is initialized with a private static initializer, the object must have `k_object_init()` called on it at some point by a supervisor thread, otherwise the kernel will consider the object uninitialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are embedded within some larger struct and initialized statically.

```
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
    ...
};

...
k_object_init(&my_foo.sem);
...
```

Creating New Kernel Object Types

When implementing new kernel features or driver subsystems, it may be necessary to define some new kernel object types. There are different steps needed for creating core kernel objects and new driver subsystems.

Creating New Core Kernel Objects

- In `scripts/build/gen_kobject_list.py`, add the name of the struct to the `kobjects` list.

Instances of the new struct should now be tracked.

Creating New Driver Subsystem Kernel Objects All driver instances are `device`. They are differentiated by what API struct they are set to.

- In `scripts/build/gen_kobject_list.py`, add the name of the API struct for the new subsystem to the `subsystems` list.

Driver instances of the new subsystem should now be tracked.

API Reference

User Mode APIs

3.3.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may not be used, and they have access to only a limited part of the memory map. System calls (may) allow user threads to perform operations not directly available to them.

When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the `k_queue` APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

Components

All system calls have the following components:

- A **C prototype** prefixed with `__syscall` for the API. It will be declared in some header under `include/` or in another `SYSCALL_INCLUDE_DIRS` directory. This prototype is never implemented manually, instead it gets created by the *scripts/build/gen_syscalls.py* script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).
- An **implementation function**, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.
- A **verification function**, which wraps the implementation function and does validation of all the arguments passed in.
- An **unmarshalling function**, which is an automatically generated handler that must be included by user source code.

C Prototype

The C prototype represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

```
__syscall void k_sem_init(struct k_sem *sem, unsigned int initial_count,
                          unsigned int limit);
```

The `__syscall` attribute is very special. To the C compiler, it simply expands to 'static inline'. However to the post-build *scripts/build/parse_syscalls.py* script, it indicates that this API is a system call. The *scripts/build/parse_syscalls.py* script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

- Array arguments must be passed in as pointers, not arrays. For example, `int foo[]` or `int foo[12]` is not allowed, but should instead be expressed as `int *foo`.
- Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.
- `__syscall` must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don't actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention `syscalls/<name of header file>`. For example, at the bottom of include/zephyr/drivers/sensor.h:

```
#include <zephyr/syscalls/sensor.h>
```

C prototype functions must be declared in one of the directories listed in the CMake variable `SYSCALL_INCLUDE_DIRS`. This list always contains `APPLICATION_SOURCE_DIR` when `CONFIG_APPLICATION_DEFINED_SYSCALL` is set, or `${ZEPHYR_BASE}/subsys/testsuite/ztest/include` when `CONFIG_ZTEST` is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before `find_package(Zephyr ...)` is run. `${ZEPHYR_BASE}/include` is always scanned for potential syscall prototypes.

Note that not all syscalls will be included in the final binaries. CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef` are used to specify which header files contain syscall prototypes where those syscalls must be present in the final binaries. Note that header files inside directories listed in CMake variable `SYSCALL_INCLUDE_DIRS` will always have their syscalls present in final binaries. To force all syscalls to be included in the final binaries, turn on `CONFIG_EMIT_ALL_SYSCALLS`.

Invocation Context Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros `__ZEPHYR_SUPERVISOR__` or `__ZEPHYR_USER__`, typically these will be added to the compiler flags in the build system for the related files.

- If `CONFIG_USERSPACE` is not enabled, all APIs just directly call the implementation function.
- Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.
- If `__ZEPHYR_SUPERVISOR__` is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn't allowed to do.
- If `__ZEPHYR_USER__` is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

Implementation Details Declaring an API with `__syscall` causes some code to be generated in C and header files by the *scripts/build/gen_syscalls.py* script, all of which can be found in the project out directory under `include/generated/`:

- The system call is added to the enumerated type of system call IDs, which is expressed in `include/generated/zephyr/syscall_list.h`. It is the name of the API in uppercase, prefixed with `K_SYSCALL_`.
- An entry for the system call is created in the dispatch table `_k_syscall_table`, expressed in `include/generated/zephyr/syscall_dispatch.c`
  - This table only contains syscalls where their corresponding prototypes are declared in header files when `CONFIG_EMIT_ALL_SYSCALLS` is enabled:
    * Indicated by CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef`, or

    * Under directories specified in CMake variable `SYSCALL_INCLUDE_DIRS`.

- A weak verification function is declared, which is just an alias of the 'unimplemented system call' verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.
- An unmarshalling function is defined in `include/generated/<name>_mrsh.c`

The body of the API is created in the generated system header. Using the example of `k_sem_init()`, this API is declared in include/zephyr/kernel.h. At the bottom of include/zephyr/kernel.h is:

```
#include <zephyr/syscalls/kernel.h>
```

Inside this header is the body of `k_sem_init()`:

```
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count,␣
↪unsigned int limit)
{
#ifdef CONFIG_USERSPACE
        if (z_syscall_trap()) {
                arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t␣
↪*)&initial_count, *(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
                return;
        }
        compiler_barrier();
#endif
        z_impl_k_sem_init(sem, initial_count, limit);
}
```

This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions `_arch_syscall_invoke0()` through `_arch_syscall_invoke6()`. These functions marshal arguments into designated CPU registers and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to `uintptr_t` which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters are split into lower and higher part and passed as two consecutive arguments. There is always a `uintptr_t` type return value, which may be neglected if not needed.

Some system calls may have more than six arguments, but number of arguments passed via registers is limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return `uintptr_t` type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered **untrusted** buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

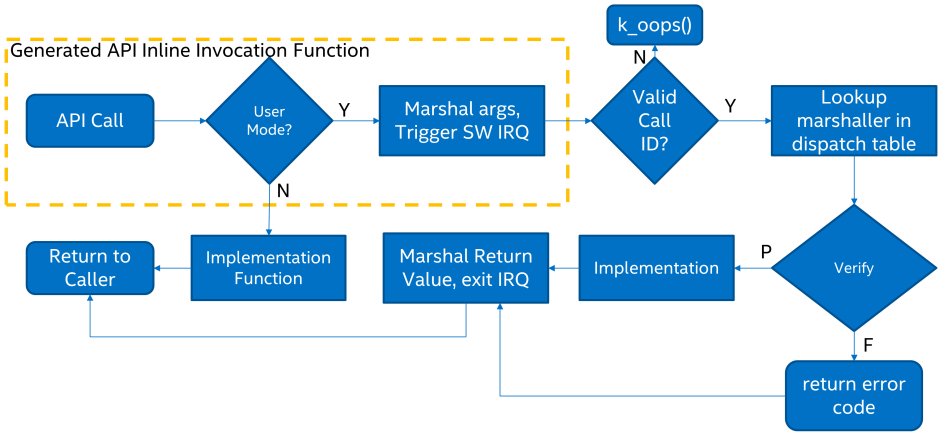

Fig. 3: System Call execution flow

Implementation Function

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with `z_impl_`. Implementation functions may be declared in the same header as the API as a static inline function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

Verification Function

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in include/zephyr/internal/syscall_handler.h. Verification functions should be declared using these macros.

Argument Validation Several macros exist to validate arguments:

- `K_SYSCALL_OBJ()` Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- `K_SYSCALL_OBJ_INIT()` is the same as `K_SYSCALL_OBJ()`, except that the provided object may be uninitialized. This is useful for verifiers of object init functions.

- K_SYSCALL_OBJ_NEVER_INIT() is the same as K_SYSCALL_OBJ(), except that the provided object must be uninitialized. This is not used very often, currently only for k_thread_create().
- K_SYSCALL_MEMORY_READ() validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.
- K_SYSCALL_MEMORY_WRITE() is the same as K_SYSCALL_MEMORY_READ() but the calling thread must additionally have write permissions.
- K_SYSCALL_MEMORY_ARRAY_READ() validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.
- K_SYSCALL_MEMORY_ARRAY_WRITE() is the same as K_SYSCALL_MEMORY_ARRAY_READ() but the calling thread must additionally have write permissions.
- K_SYSCALL_VERIFY_MSG() does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant K_SYSCALL_VERIFY exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.
- K_SYSCALL_DRIVER_OP() checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the K_SYSCALL_DRIVER_GPIO() macro.
- K_SYSCALL_SPECIFIC_DRIVER() is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro K_OOPS() can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

Verifier Definition All system calls are dispatched to a verifier function with a prefixed z_vrfy_ name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    K_OOPS(K_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <zephyr/syscalls/k_sem_take_mrsh.c>
```

Verification Memory Access Policies Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implementation functions get passed the copy and not the original data sent by the user. The `k_usermode_to_copy()` and `k_usermode_from_copy()` APIs exist for this purpose.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    K_OOPS(k_usermode_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated `local_out_param` on the stack, passed its address to the implementation function, and then used `k_usermode_to_copy()` to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```
int z_vrfy_some_syscall(int *out_param)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}
```

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it's not uncommon to see APIs which pass in a pointer to some `size_t` which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

```
int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;

    K_OOPS(k_usermode_from_copy(&size, size_ptr, sizeof(size));
    ret = z_impl_in_out_syscall(&size);
    K_OOPS(k_usermode_to_copy(size_ptr, &size, sizeof(size)));
    return ret;
}
```

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

```
struct bar {
    ...
};
```

(continues on next page)

(continued from previous page)

```
struct foo {
    ...
    struct bar *bar_left;
    struct bar *bar_right;
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;

    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));
    K_OOPS(k_usermode_from_copy(&bar_right_copy, foo_copy.bar_right,
                            sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    K_OOPS(k_usermode_from_copy(&bar_left_copy, foo_copy.bar_left,
                            sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;

    return z_impl_must_alloc(&foo_copy);
}
```

In some cases the amount of data isn't known at compile time or may be too large to allocate on the stack. In this scenario, it may be necessary to draw memory from the caller's resource pool via `z_thread_malloc()`. This should always be considered last resort. Functional safety programming guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly documented. Any issues with allocation must be reported, to a caller, with returning the `-ENOMEM` . The `K_OOPS()` should never be used to verify if resource allocation has been successful.

```
struct bar {
    ...
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }
```

(continues on next page)

(continued from previous page)

```
    /* Allocate RAM for the bar_list, replace the pointer in
     * foo_copy */
    bar_list_bytes = foo_copy.count * sizeof(struct bar);
    bar_list_copy = z_thread_malloc(bar_list_bytes);
    if (bar_list_copy == NULL) {
        return -ENOMEM;
    }
    K_OOPS(k_usermode_from_copy(bar_list_copy, foo_copy.bar_list,
                                bar_list_bytes));
    foo_copy.bar_list = bar_list_copy;

    ret = z_impl_must_alloc(&foo_copy);

    /* All done with the memory, free it and return */
    k_free(foo_copy.bar_list_copy);
    return ret;
}
```

Finally, we must consider large data buffers. These represent areas of user memory which either have data copied out of, or copied into. It is permitted to pass these pointers to the implementation function directly. The caller's access to the buffer still must be validated with K_SYSCALL_MEMORY APIs. The following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to write to some hardware destination, this data must be read without any processing. No conditional logic can be implemented due to the data buffer's contents. If such logic is required a copy must be made.
- The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

```
int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}
```

Verification Return Value Policies When verifying system calls, it's important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke K_OOPS() which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to handler_no_syscall() which invokes K_OOPS().
2. Any invalid access to memory found by the set of K_SYSCALL_MEMORY APIs, k_usermode_from_copy(), k_usermode_to_copy() should trigger a K_OOPS. This happens when the caller doesn't have appropriate permissions on the memory buffer or some size calculation overflowed.
3. Most system calls take kernel object pointers as an argument, checked either with one of the K_SYSCALL_OBJ functions, K_SYSCALL_DRIVER_nnnnn, or manually using k_object_validate(). These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke K_OOPS().

4. Any error resulting from a failed memory heap allocation, often from invoking `z_thread_malloc()`, should propagate `-ENOMEM` to the caller.
5. General parameter checks should be done in the implementation function, in most cases using `CHECKIF()`.
    - The behavior of `CHECKIF()` depends on the kernel configuration, but if user mode is enabled, `CONFIG_RUNTIME_ERROR_CHECKS` is enforced, which guarantees that these checks will be made and a return value propagated.
6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke `K_OOPS()` if not.
7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- `k_thread_join()` and `k_thread_abort()` are no-ops if the thread object isn't initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- `k_thread_create()` invokes `K_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- `k_thread_abort()` invokes `K_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `K_OOPS()` when bad parameters are passed in as they do not propagate errors.

Configuration Options

Related configuration options:

- `CONFIG_USERSPACE`
- `CONFIG_EMIT_ALL_SYSCALLS`

APIs

Helper macros for creating system call verification functions are provided in include/zephyr/internal/syscall_handler.h:

- `K_SYSCALL_OBJ()`
- `K_SYSCALL_OBJ_INIT()`
- `K_SYSCALL_OBJ_NEVER_INIT()`
- `K_OOPS()`
- `K_SYSCALL_MEMORY_READ()`
- `K_SYSCALL_MEMORY_WRITE()`
- `K_SYSCALL_MEMORY_ARRAY_READ()`
- `K_SYSCALL_MEMORY_ARRAY_WRITE()`
- `K_SYSCALL_VERIFY_MSG()`
- `K_SYSCALL_VERIFY`

Functions for invoking system calls are defined in include/zephyr/syscall.h:

- `_arch_syscall_invoke0()`
- `_arch_syscall_invoke1()`
- `_arch_syscall_invoke2()`
- `_arch_syscall_invoke3()`
- `_arch_syscall_invoke4()`
- `_arch_syscall_invoke5()`
- `_arch_syscall_invoke6()`

3.3.5 MPU Stack Objects

Thread Stack Creation

Thread stacks are declared statically with `K_THREAD_STACK_DEFINE()`.

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.

Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT` defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.

3.3.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread's access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

3.4 Memory Management

The following contains various topics regarding memory management.

3.4.1 Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap The simplest way to define a heap is statically, with the `K_HEAP_DEFINE` macro. This creates a static `k_heap` variable with a given name that manages a memory region of the specified size.

Heaps can also be created to manage arbitrary regions of application-controlled memory using `k_heap_init()`.

Allocating Memory Memory can be allocated from a heap using `k_heap_alloc()`, passing it the address of the heap object and the number of bytes desired. This functions similarly to standard C `malloc()`, returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a `k_timeout_t` timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values `K_NO_WAIT` or `K_FOREVER`.

Releasing Memory Memory allocated with `k_heap_alloc()` must be released using `k_heap_free()`. Similar to standard C `free()`, the pointer provided must be either a `NULL` value or a pointer previously returned by `k_heap_alloc()` for the same heap. Freeing a `NULL` value is defined to have no effect.

Low Level Heap Allocator

The underlying implementation of the `k_heap` abstraction is provided a data structure named `sys_heap`. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike `k_heap`, all calls to any `sys_heap` functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.

Implementation Internally, the sys_heap memory block is partitioned into "chunks" of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower ("left") chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a "free list" to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in "buckets" by their size, each bucket storing blocks within one power of two (i.e. a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the sys_heap structure itself.

The sys_heap functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All sys_heap API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that "might fit") has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This CONFIG_SYS_HEAP_ALLOC_LOOPS value may be chosen by the user at build time, and defaults to a value of 3.

Multi-Heap Wrapper Utility

The sys_heap utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a "heap". For example, the memory might exist as separate discontiguous regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc...

For those situations, Zephyr provides a sys_multi_heap utility. Effectively this is a simple wrapper around a set of one or more sys_heap objects. It should be initialized after its child heaps via sys_multi_heap_init(), after which each heap can be added to the managed set via sys_multi_heap_add_heap(). No destruction utility is provided; just as for sys_heap, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, sys_multi_heap_alloc() and sys_multi_heap_aligned_alloc(). These behave identically to the sys_heap functions with similar names, except that they also accept an opaque "configuration" parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

For modifying the size of an allocated buffer (whether shrinking or enlarging it), you can use the sys_multi_heap_realloc() and sys_multi_heap_aligned_realloc() APIs. If the buffer cannot be enlarged on the heap where it currently resides, any of the eligible heaps specified by the configuration parameter may be used.

When unused, a multi heap may be freed via sys_multi_heap_free(). The application does not need to pass a configuration parameter. Memory allocated from any of the managed sys_heap objects may be freed with in the same way.

System Heap

The *system heap* is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a `malloc()`-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.

A thread can dynamically allocate a chunk of heap memory by calling `k_malloc()`. The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found `NULL` is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling `k_free()`.

Defining the Heap Memory Pool The size of the heap memory pool is specified using the `CONFIG_HEAP_MEM_POOL_SIZE` configuration option.

By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

In addition, each subsystem (board, driver, library, etc) can set a custom requirement by defining a Kconfig option with the prefix `HEAP_MEM_POOL_ADD_SIZE_` (this value is in bytes). If multiple subsystems specify custom values, the sum of these will be used as the minimum requirement. If the application tries to set a value that's less than the minimum value, this will be ignored and the minimum value will be used instead.

To force a smaller than minimum value to be used, the application may enable the `CONFIG_HEAP_MEM_POOL_IGNORE_MIN` option. This can be useful when optimizing the heap size and the minimum requirement can be more accurately determined for a specific application.

Allocating Memory A chunk of heap memory is allocated by calling `k_malloc()`.

The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```
char *mem_ptr;

mem_ptr = k_malloc(200);
if (mem_ptr != NULL)) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```

Releasing Memory A chunk of heap memory is released by calling `k_free()`.

The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

```
char *mem_ptr;

mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
```

Suggested Uses Use the heap memory pool to dynamically allocate memory in a `malloc()`-like manner.

Heap Listener APIs

3.4.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque "attribute" value (an integer or enum value) that can be used by drivers or applications to request memory with certain capabilities.

This framework is commonly used as follow:

1. At boot time some platform code initialize the shared multi-heap framework using `shared_multi_heap_pool_init()` and add the memory regions to the pool with `shared_multi_heap_add()`, possibly gathering the needed information for the regions from the DT.
2. Each memory region encoded in a `shared_multi_heap_region` structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc...)

```
// Init the shared multi-heap pool
shared_multi_heap_pool_init()

// Fill the struct with the data for cacheable memory
struct shared_multi_heap_region cacheable_r0 = {
     .addr = addr_r0,
     .size = size_r0,
     .attr = SMH_REG_ATTR_CACHEABLE,
};

// Add the region to the pool
shared_multi_heap_add(&cacheable_r0, NULL);

// Add another cacheable region
struct shared_multi_heap_region cacheable_r1 = {
     .addr = addr_r1,
     .size = size_r1,
     .attr = SMH_REG_ATTR_CACHEABLE,
};
```

(continues on next page)

(continued from previous page)

```
shared_multi_heap_add(&cacheable_r1, NULL);

// Add a non-cacheable region
struct shared_multi_heap_region non_cacheable_r2 = {
     .addr = addr_r2,
     .size = size_r2,
     .attr = SMH_REG_ATTR_NON_CACHEABLE,
};

shared_multi_heap_add(&non_cacheable_r2, NULL);
```

3. When a driver or application needs some dynamic memory with a certain capability, it can use `shared_multi_heap_alloc()` (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

```
// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);
```

Adding new attributes

The API does not enforce any attributes, but at least it defines the two most common ones: `SMH_REG_ATTR_CACHEABLE` and `SMH_REG_ATTR_NON_CACHEABLE`.

Shared multi-heap interface

3.4.3 Memory Slabs

A *memory slab* is a kernel object that allows memory blocks to be dynamically allocated from a designated memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be allocated and released efficiently and avoiding memory fragmentation concerns.

- *Concepts*
  - *Internal Operation*
- *Implementation*
  - *Defining a Memory Slab*
  - *Allocating a Memory Block*
  - *Releasing a Memory Block*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts

Any number of memory slabs can be defined (limited only by available RAM). Each memory slab is referenced by its memory address.

A memory slab has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long on 32-bit platforms and at least 8N bytes long on 64-bit platforms, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least "block size" times "number of blocks" bytes long.

The memory slab's buffer must be aligned to an N-byte boundary, where N is a power of 2. N must be at least 4 on 32-bit platforms and at least 8 on 64-bit platforms. To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.

A thread that needs to use a memory block simply allocates it from a memory slab. When the thread finishes with a memory block, it must release the block back to the memory slab so the block can be reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any number of threads may wait on an empty memory slab simultaneously; when a memory block becomes available, it is given to the highest-priority thread that has waited the longest.

Unlike a heap, more than one memory slab can be defined, if needed. This allows for a memory slab with smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

Internal Operation A memory slab's buffer is an array of fixed-size blocks, with no wasted space between the blocks.

The memory slab keeps track of unallocated blocks using a linked list. 32-bit platforms use the first 4 bytes of each unused block to provide the necessary linkage, while 64-bit platforms use the first 8 bytes of each unused block.

Implementation

Defining a Memory Slab A memory slab is defined using a variable of type `k_mem_slab`. It must then be initialized by calling `k_mem_slab_init()`.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each of which is aligned to an 8-byte boundary.

```
struct k_mem_slab my_slab;
char __aligned(8) my_slab_buffer[6 * 400];

k_mem_slab_init(&my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling `K_MEM_SLAB_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the memory slab and its buffer.

```
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 8);
```

Similarly, you can define a memory slab in private scope:

```
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 8);
```

Allocating a Memory Block A memory block is allocated by calling `k_mem_slab_alloc()`.

The following code builds on the example above, and waits up to 100 milliseconds for a memory block to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```
char *block_ptr;

if (k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_MSEC(100)) == 0) {
    memset(block_ptr, 0, 400);
    ...
} else {
    printf("Memory allocation time-out");
}
```

Releasing a Memory Block A memory block is released by calling `k_mem_slab_free()`.

The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```
char *block_ptr;

k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_FOREVER);
... /* use memory block pointed at by block_ptr */
k_mem_slab_free(&my_slab, (void *)block_ptr);
```

Suggested Uses

Use a memory slab to allocate and free memory in fixed-size blocks.

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

3.4.4 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:

- All memory blocks have a single fixed size.
- Multiple blocks can be allocated or freed at the same time.
- A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.

- Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

- *Multi Memory Blocks Allocator Group*
- *Usage*
  - *Defining a Memory Blocks Allocator*
  - *Allocating Memory Blocks*
  - *Releasing a Memory Block*
  - *Using Multi Memory Blocks Allocator Group*
- *API Reference*

Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least "block size" times "number of blocks" bytes long.
- A **blocks bitmap** to keep track of which block has been allocated.

The buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation

Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the `sys_bitarray` interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group

The Multi Memory Blocks Allocator Group utility functions provide a convenient to manage a group of allocators. A custom allocator choosing function is used to choose which allocator to use among this group.

An allocator group should be initialized at runtime via `sys_multi_mem_blocks_init()`. Each allocator can then be added via `sys_multi_mem_blocks_add_allocator()`.

To allocate memory blocks from group, `sys_multi_mem_blocks_alloc()` is called with an opaque "configuration" parameter. This parameter is passed directly to the allocator choosing function so that an appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via `sys_mem_blocks_alloc()`.

Allocated memory blocks can be freed via `sys_multi_mem_blocks_free()`. The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via `sys_mem_blocks_free()`.

Usage

Defining a Memory Blocks Allocator A memory blocks allocator is defined using a variable of type `sys_mem_blocks_t`. It needs to be defined and initialized at compile time by calling `SYS_MEM_BLOCKS_DEFINE`.

The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory blocks allocator in private scope:

```
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the alignment of the buffer needs to be done at its definition.

```
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

Allocating Memory Blocks Memory blocks can be allocated by calling `sys_mem_blocks_alloc()`.

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

Releasing a Memory Block Memory blocks are released by calling `sys_mem_blocks_free()`.

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

(continues on next page)

(continued from previous page)

```
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

Using Multi Memory Blocks Allocator Group The following code demonstrates how to initialize an allocator group:

```
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
    ...
}

SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);

static sys_multi_mem_blocks_t alloc_group;

sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);
```

To allocate and free memory blocks from the group:

```
int ret;
uintptr_t blocks[1];
size_t blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                 1, blocks, &blk_size);

ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

3.4.5 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

- When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.
- When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using k_mem_page_in() and k_mem_page_out(). k_mem_page_in() can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. k_mem_page_out() can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.

Terminology

Data Page
A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be `void *` or in some cases `uint8_t *` when doing pointer arithmetic.

Page Frame
A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using `uintptr_t` for physical addresses. For every page frame, a `struct k_mem_page_frame` is instantiated to store metadata. Flags for each page frame:

- K_MEM_PAGE_FRAME_FREE indicates a page frame is unused and on the list of free page frames. When this flag is set, none of the other flags are meaningful and they must not be modified.
- K_MEM_PAGE_FRAME_PINNED indicates a page frame is pinned in memory and should never be paged out.
- K_MEM_PAGE_FRAME_RESERVED indicates a physical page reserved by hardware and should not be used at all.
- K_MEM_PAGE_FRAME_MAPPED is set when a physical page is mapped to virtual memory address.
- K_MEM_PAGE_FRAME_BUSY indicates a page frame is currently involved in a page-in/out operation.
- K_MEM_PAGE_FRAME_BACKED indicates a page frame has a clean copy in the backing store.

K_MEM_SCRATCH_PAGE
The virtual address of a special page provided to the backing store to: * Copy a data page from k_MEM_SCRATCH_PAGE to the specified location; or, * Copy a data page from the provided location to K_MEM_SCRATCH_PAGE. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

Paging Statistics

Paging statistics can be obtained via various function calls when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is enabled:

- Overall statistics via k_mem_paging_stats_get()
- Per-thread statistics via k_mem_paging_thread_stats_get() if CONFIG_DEMAND_PAGING_THREAD_STATS is enabled
- Execution time histogram can be obtained when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM is enabled, and CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is defined. Note that the timing is highly dependent on the architecture, SoC or board. It

is highly recommended that k_mem_paging_eviction_histogram_bounds[] and k_mem_paging_backing_store_histogram_bounds[] be defined for a particular application.

  - Execution time histogram of eviction algorithm via k_mem_paging_histogram_eviction_get()
  - Execution time histogram of backing store doing page-in via k_mem_paging_histogram_backing_store_page_in_get()
  - Execution time histogram of backing store doing page-out via k_mem_paging_histogram_backing_store_page_out_get()

Eviction Algorithm

The eviction algorithm is used to determine which data page and its corresponding page frame can be paged out to free up a page frame for the next page in operation. There are four functions which are called from the kernel paging code:

- k_mem_paging_eviction_init() is called to initialize the eviction algorithm. This is called at POST_KERNEL.
- k_mem_paging_eviction_add() is called each time a data page becomes eligible for future eviction.
- k_mem_paging_eviction_remove() is called when a data page is no longer eligible for eviction. This may happen if the given data page becomes pinned, gets unmapped or is about to be evicted.
- k_mem_paging_eviction_select() is called to select a data page to evict. A function argument dirty is written to signal the caller whether the selected data page has been modified since it is first paged in. If the dirty bit is returned as set, the paging code signals to the backing store to write the data page back into storage (thus updating its content). The function returns a pointer to the page frame corresponding to the selected data page.

There is one additional function which is called by the architecture's memory management code to flag data pages when they trigger an access fault: k_mem_paging_eviction_accessed(). This is used by the LRU algorithm to requeue "used" pages.

Two eviction algorithms are currently available:

- An NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a very simple algorithm which ranks data pages on whether they have been accessed and modified. The selection is based on this ranking.
- An LRU (Least-Recently-Used) eviction algorithm is also available. It is based on a sorted queue of data pages. The LRU code is more complex compared to the NRU code but also considerably more efficient. This is recommended for production use.

To implement a new eviction algorithm, k_mem_paging_eviction_init() and k_mem_paging_eviction_select() must be implemented. If CONFIG_EVICTION_TRACKING is enabled for an algorithm, these additional functions must also be implemented, k_mem_paging_eviction_add(), k_mem_paging_eviction_remove(), k_mem_paging_eviction_accessed().

Backing Store

Backing store is responsible for paging in/out data page between their corresponding page frames and storage. These are the functions which must be implemented:

- k_mem_paging_backing_store_init() is called to initialized the backing store at POST_KERNEL.

- `k_mem_paging_backing_store_location_get()` is called to reserve a backing store location so a data page can be paged out. This `location` token is passed to `k_mem_paging_backing_store_page_out()` to perform actual page out operation.
- `k_mem_paging_backing_store_location_free()` is called to free a backing store location (the `location` token) which can then be used for subsequent page out operation.
- `k_mem_paging_backing_store_location_query()` is called to obtain the `location` token corresponding to storage content to be virtually mapped and paged-in on demand. Most useful with `CONFIG_DEMAND_MAPPING`.
- `k_mem_paging_backing_store_page_in()` copies a data page from the backing store location associated with the provided `location` token to the page pointed by `K_MEM_SCRATCH_PAGE`.
- `k_mem_paging_backing_store_page_out()` copies a data page from `K_MEM_SCRATCH_PAGE` to the backing store location associated with the provided `location` token.
- `k_mem_paging_backing_store_page_finalize()` is invoked after `k_mem_paging_backing_store_page_in()` so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. `k_mem_paging_backing_store_page_finalize()` can be an empty function if so desired.

3.4.6 Virtual Memory

Virtual memory (VM) in Zephyr provides developers with the ability to fine tune access to memory. To utilize virtual memory, the platform must support Memory Management Unit (MMU) and it must be enabled in the build. Due to the target of Zephyr mainly being embedded systems, virtual memory support in Zephyr differs a bit from that in traditional operating systems:

Mapping of Kernel Image
: Default is to do 1:1 mapping for the kernel image (including code and data) between physical and virtual memory address spaces, if demand paging is not enabled. Deviation from this requires careful manipulation of linker script.

Secondary Storage
: Basic virtual memory support does not utilize secondary storage to extend usable memory. The maximum usable memory is the same as the physical memory.

  - *Demand Paging* enables utilizing secondary storage as a backing store for virtual memory, thus allowing larger usable memory than the available physical memory. Note that demand paging needs to be explicitly enabled.

- Although the virtual memory space can be larger than physical memory space, without enabling demand paging, all virtually mapped memory must be backed by physical memory.

Kconfigs

Required These are the Kconfigs that need to be enabled or defined for kernel to support virtual memory.

- `CONFIG_MMU`: must be enabled for virtual memory support in kernel.
- `CONFIG_MMU_PAGE_SIZE`: size of a memory page. Default is 4KB.
- `CONFIG_KERNEL_VM_BASE`: base address of virtual address space.
- `CONFIG_KERNEL_VM_SIZE`: size of virtual address space. Default is 8MB.
- `CONFIG_KERNEL_VM_OFFSET`: kernel image starts at this offset from `CONFIG_KERNEL_VM_BASE`.

Optional

- `CONFIG_KERNEL_DIRECT_MAP`: permits 1:1 mappings between virtual and physical addresses, instead of kernel choosing addresses within the virtual address space. This is useful for mapping device MMIO regions for more precise access control.

Memory Map Overview

This is an overview of the memory map of the virtual memory address space. Note that the `Z_*` macros, which are used in code, may have different meanings depending on architecture and Kconfigs, which will be explained below.

```
+--------------+ <- K_MEM_VIRT_RAM_START
| Undefined VM | <- architecture specific reserved area
+--------------+ <- K_MEM_KERNEL_VIRT_START
| Mapping for  |
| main kernel  |
| image        |
|              |
|              |
+--------------+ <- K_MEM_VM_FREE_START
|              |
| Unused,      |
| Available VM |
|              |
|..............| <- grows downward as more mappings are made
| Mapping      |
+--------------+
| Mapping      |
+--------------+
| ...          |
+--------------+
| Mapping      |
+--------------+ <- memory mappings start here
| Reserved     | <- special purpose virtual page(s) of size K_MEM_VM_RESERVED
+--------------+ <- K_MEM_VIRT_RAM_END
```

- `K_MEM_VIRT_RAM_START` is the beginning of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_BASE`.
- `K_MEM_VIRT_RAM_SIZE` is the size of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_SIZE`.

- K_MEM_VIRT_RAM_END is simply (K_MEM_VIRT_RAM_START + K_MEM_VIRT_RAM_SIZE).
- K_MEM_KERNEL_VIRT_START is the same as z_mapped_start specified in the linker script. This is the virtual address of the beginning of the kernel image at boot time.
- K_MEM_KERNEL_VIRT_END is the same as z_mapped_end specified in the linker script. This is the virtual address of the end of the kernel image at boot time.
- K_MEM_VM_FREE_START is the beginning of the virtual address space where addresses can be allocated for memory mapping. This depends on whether CONFIG_ARCH_MAPS_ALL_RAM is enabled.
  - If it is enabled, which means all physical memory are mapped in virtual memory address space, and it is the same as (CONFIG_SRAM_BASE_ADDRESS + CONFIG_SRAM_SIZE).
  - If it is disabled, K_MEM_VM_FREE_START is the same K_MEM_KERNEL_VIRT_END which is the end of the kernel image.
- K_MEM_VM_RESERVED is an area reserved to support kernel functions. For example, some addresses are reserved to support demand paging.

Virtual Memory Mappings

Setting up Mappings at Boot In general, most supported architectures set up the memory mappings at boot as following:

- .text section is read-only and executable. It is accessible in both kernel and user modes.
- .rodata section is read-only and non-executable. It is accessible in both kernel and user modes.
- Other kernel sections, such as .data, .bss and .noinit, are read-write and non-executable. They are only accessible in kernel mode.
  - Stacks for user mode threads are automatically granted read-write access to their corresponding user mode threads during thread creation.
  - Global variables, by default, are not accessible to user mode threads. Refer to *Memory Domains and Partitions* on how to use global variables in user mode threads, and on how to share data between user mode threads.

Caching modes for these mappings are architecture specific. They can be none, write-back, or write-through.

Note that SoCs have their own additional mappings required to boot where these mappings are defined under their own SoC configurations. These mappings usually include device MMIO regions needed to setup the hardware.

Mapping Anonymous Memory The unused physical memory can be mapped in virtual address space on demand. This is conceptually similar to memory allocation from heap, but these mappings must be aligned on page size and have finer access control.

- k_mem_map() can be used to map unused physical memory:
  - The requested size must be multiple of page size.
  - The address returned is inside the virtual address space between K_MEM_VM_FREE_START and K_MEM_VIRT_RAM_END.
  - The mapped region is not guaranteed to be physically contiguous in memory.
  - Guard pages immediately before and after the mapped virtual region are automatically allocated to catch access issue due to buffer underrun or overrun.
- The mapped region can be unmapped (i.e. freed) via k_mem_unmap():

– Caution must be exercised to give the pass the same region size to both `k_mem_map()` and `k_mem_unmap()`. The unmapping function does not check if it is a valid mapped region before unmapping.

API Reference

Kernel Memory Management

3.5 Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing "byte stream" data in a clean way.

Note that in general, the collections are implemented as "intrusive" data structures. The "node" data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is "owned" by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are generally unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user. Some of the provided data structures are thread safe in specific usage scenarios (see *Single Producer Single Consumer Lock Free Queue* and *Multi Producer Single Consumer Lock Free Queue*).

3.5.1 Single-linked List

Zephyr provides a `sys_slist_t` type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the "previous" pointer and thus can only be performed in linear time by searching the list.

The `sys_slist_t` struct may be instantiated by the user in any accessible memory. It should be initialized with either `sys_slist_init()` or by static assignment from SYS_SLIST_STATIC_INIT before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with `sys_slist_peek_head()` and `sys_slist_peek_tail()`, which will return NULL if the list is empty, otherwise a pointer to a `sys_snode_t` struct.

The `sys_snode_t` struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using `SYS_SLIST_CONTAINER`, passing it the struct name of the containing struct and the field name of the node. Internally, the `sys_snode_t` struct contains only a next pointer, which may be accessed with `sys_slist_peek_next()`.

Lists may be modified by adding a single node at the head or tail with `sys_slist_prepend()` and `sys_slist_append()`. They may also have a node added to an interior point with `sys_slist_insert()`, which inserts a new node after an existing one. Similarly `sys_slist_remove()` will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. `sys_slist_merge_slist()` will append an entire list to an existing one.

`sys_slist_append_list()` will append a bounded subset of an existing list in constant time. And `sys_slist_find_and_remove()` will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of "for each" macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. `SYS_SLIST_FOR_EACH_NODE` will enumerate every node in a list given a local variable to store the node pointer. `SYS_SLIST_FOR_EACH_NODE_SAFE` behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a "container" variant (`SYS_SLIST_FOR_EACH_CONTAINER` and `SYS_SLIST_FOR_EACH_CONTAINER_SAFE`) which assigns a local variable of a type that matches the user's container struct and not the node struct, performing the required offsets internally. And `SYS_SLIST_ITERATE_FROM_NODE` exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.

Single-linked List Internals

The slist code is designed to be minimal and conventional. Internally, a `sys_slist_t` struct is nothing more than a pair of "head" and "tail" pointer fields. And a `sys_snode_t` stores only a single "next" pointer.

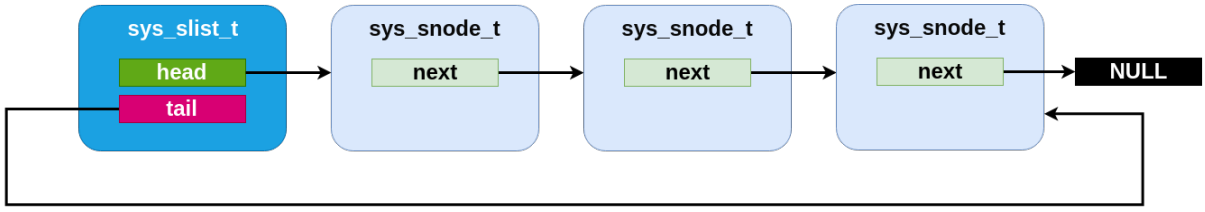

Fig. 4: An slist containing three elements.

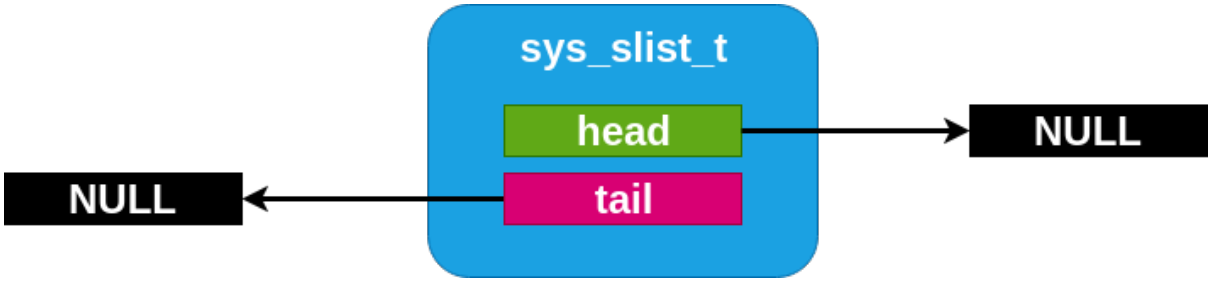

Fig. 5: An empty slist

The specific implementation of the list code, however, is done with an internal "Z_GENLIST" template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementer is responsible for a custom implementation of the primitive operations only: an "init" step for each struct, and a "get" and "set" primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

Only one such variant, sflist, exists in Zephyr at the moment.

Flagged List

The `sys_sflist_t` is implemented using the described genlist template API. With the exception of symbol naming ("sflist" instead of "slist") and the additional API described next, it operates in all ways identically to the slist API.

It adds the ability to associate exactly two bits of user defined "flags" with each list node. These can be accessed and modified with `sys_sfnode_flags_get()` and `sys_sfnode_flags_set()`. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

Single-linked list

Flagged List API Reference

Flagged Single-linked list

3.5.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A `sys_dlist_t` struct may be instantiated by the user in any accessible memory. It must be initialized with `sys_dlist_init()` or `SYS_DLIST_STATIC_INIT` before use. The `sys_dnode_t` struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with `sys_dnode_init()` before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with `sys_dlist_peek_head()`, `sys_dlist_peek_tail()`, `sys_dlist_peek_next()` and `sys_dlist_peek_prev()`. These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with `sys_dlist_remove()`, by adding a node to the head or tail of a list with `sys_dlist_prepend()` and `sys_dlist_append()`, or by inserting a node before an existing node with `sys_dlist_insert()`.

As for slist, each node in a dlist can be processed in a natural code block style using `SYS_DLIST_FOR_EACH_NODE`. This macro also exists in a "FROM_NODE" form which allows for iterating from a known starting point, a "SAFE" variant that allows for removing the node being inspected within the code block, a "CONTAINER" style that provides the pointer to a containing struct instead of the raw node, and a "CONTAINER_SAFE" variant that provides both properties.

Convenience utilities provided by dlist include `sys_dlist_insert_at()`, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and `sys_dnode_is_linked()`, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).

Double-linked List Internals

Internally, the dlist implementation is minimal: the `sys_dlist_t` struct contains "head" and "tail" pointer fields, the `sys_dnode_t` contains "prev" and "next" pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.

- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a "ring" of "N+1" nodes, where one node represents the list tracking struct.

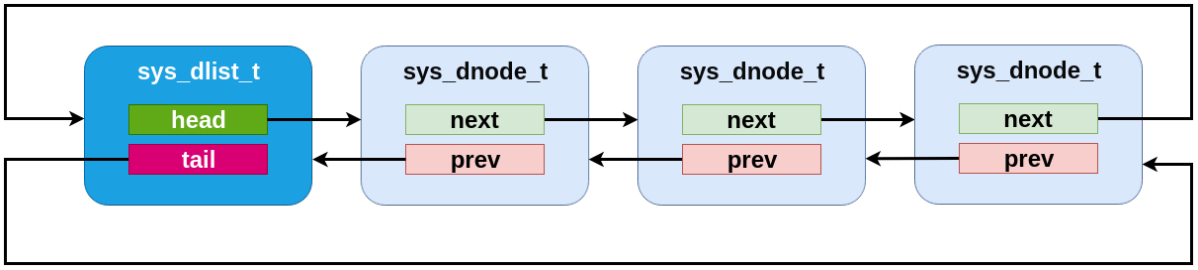

Fig. 6: A dlist containing three elements. Note that the list struct appears as a fourth "element" in the list.

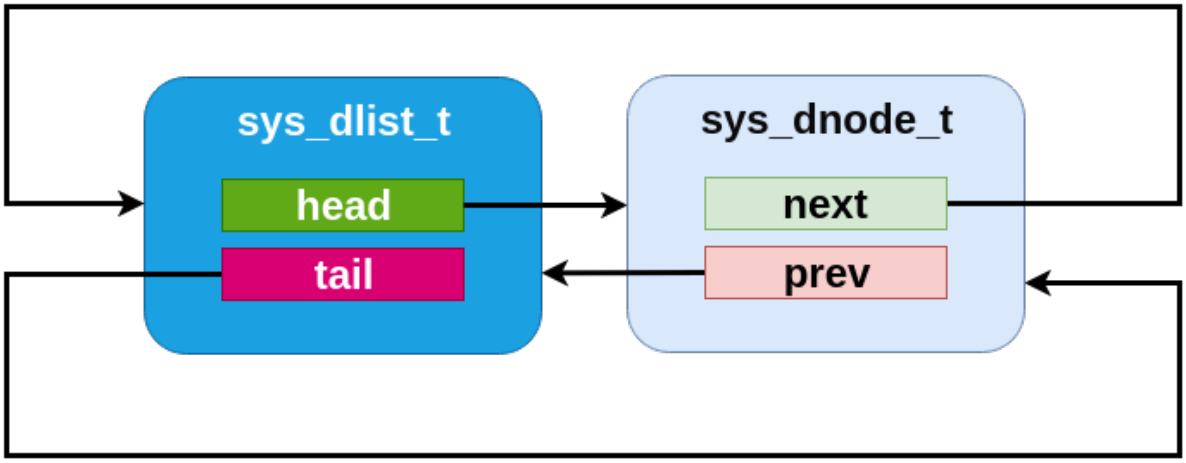

Fig. 7: An dlist containing just one element.

Doubly-linked list

3.5.3 Multi Producer Single Consumer Packet Buffer

A *Multi Producer Single Consumer Packet Buffer (MPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A *MPSC Packet Buffer* has the following key properties:

- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that contiguous memory of requested length is allocated.

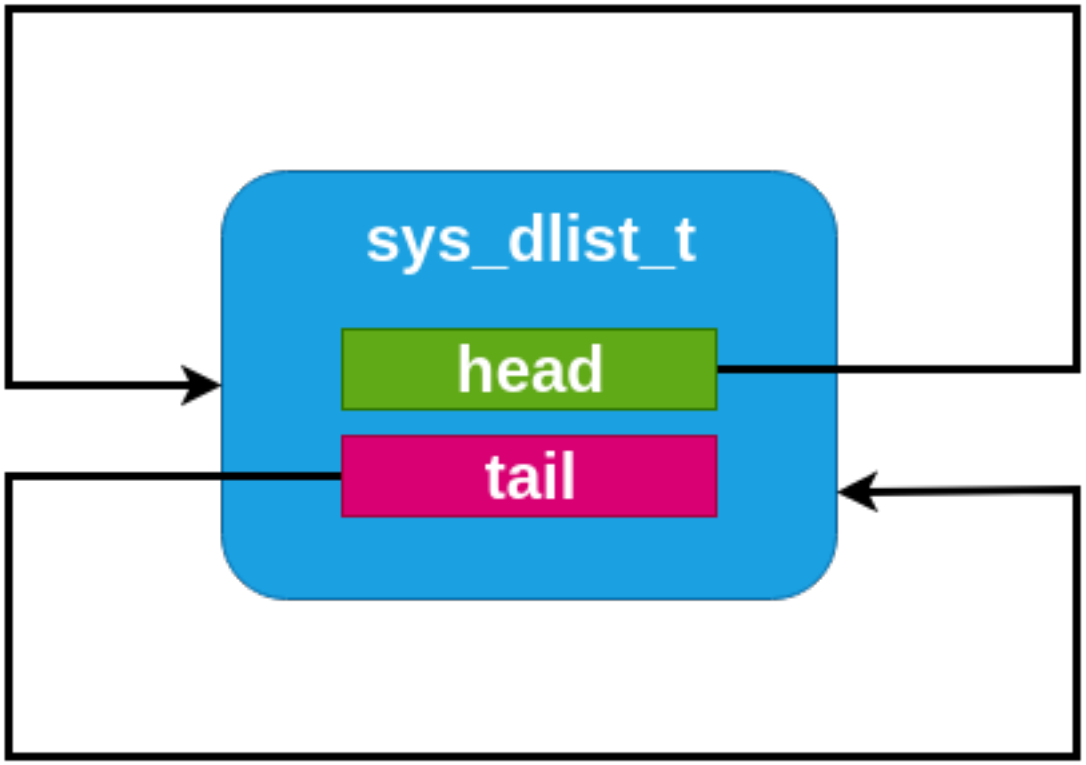

Fig. 8: An empty dlist.

- Following policies can be applied when requested space cannot be allocated:
  - **Overwrite** - oldest entries are dropped until requested amount of memory can be allocated. For each dropped packet user callback is called.
  - **No overwrite** - When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains `MPSC_PBUF` specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using `MPSC_PBUF_HDR` and remaining bits in the first word can be application specific. Header consists of following flags:

- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:

valid	busy	description
0	0	space is free
1	0	valid packet
1	1	claimed valid packet
0	1	internal skip packet

Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the end of the buffer.

Allocation Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space within buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then `NULL` pointer is returned or context blocks if allocation was with timeout.

Allocation with overwrite If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped `busy` flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

Usage

Packet header definition Packet header details can be found in include/zephyr/sys/mpsc_packet.h. API functions can be found in include/zephyr/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```
#include <zephyr/sys/mpsc_packet.h>

struct foo_header {
        MPSC_PBUF_HDR;
        uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

Packet buffer configuration Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

Packet producing Standard, two step method:

```
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);

fill_data(packet);

mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
- 32 bit word with pointer packet

Note that since packets are written by value, they should already contain `valid` bit set in the header.

```
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```

Packet consuming Two step method:

```
foo_packet *packet = mpsc_pbuf_claim(buffer);

process(packet);

mpsc_pbuf_free(buffer, packet);
```

3.5.4 Single Producer Single Consumer Packet Buffer

A *Single Producer Single Consumer Packet Buffer (SPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that produces packets and a single context that consumes the data.

Implementation is focused on performance and memory footprint.

Packets are added to the buffer using `spsc_pbuf_write()` which copies a data into the buffer. If the buffer is full error is returned.

Packets are copied out of the buffer using `spsc_pbuf_read()`.

3.5.5 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at O(log2(N)) for a tree of size N. This is implemented using a conventional red/black tree as described by multiple academic sources.

The `rbtree` tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type `rb_lessthan_t()` should be assigned to the `lessthan_fn` field of the `rbtree` struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is "less than" the second in the ordering desired by the tree. Note that "equal" is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as a `rbnode` structure which exists in user-managed memory, typically embedded within the data structure being tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and "manually" traverse the tree as it is for a list.

Nodes can be inserted into a tree with `rb_insert()` and removed with `rb_remove()`. Access to the "first" and "last" nodes within a tree (in the sense of the order defined by the comparison function) is provided by `rb_get_min()` and `rb_get_max()`. There is also a predicate, `rb_contains()`, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, `rb_walk()`, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C's `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a `RB_FOR_EACH` iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is

also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a `RB_FOR_EACH_CONTAINER` variant which enumerates using a pointer to a container field and not the raw node pointer.

Tree Internals

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of "color" with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of "extra" red nodes may be present). This rule is enforced by a set of rotation rules used to "fix" trees following modification.

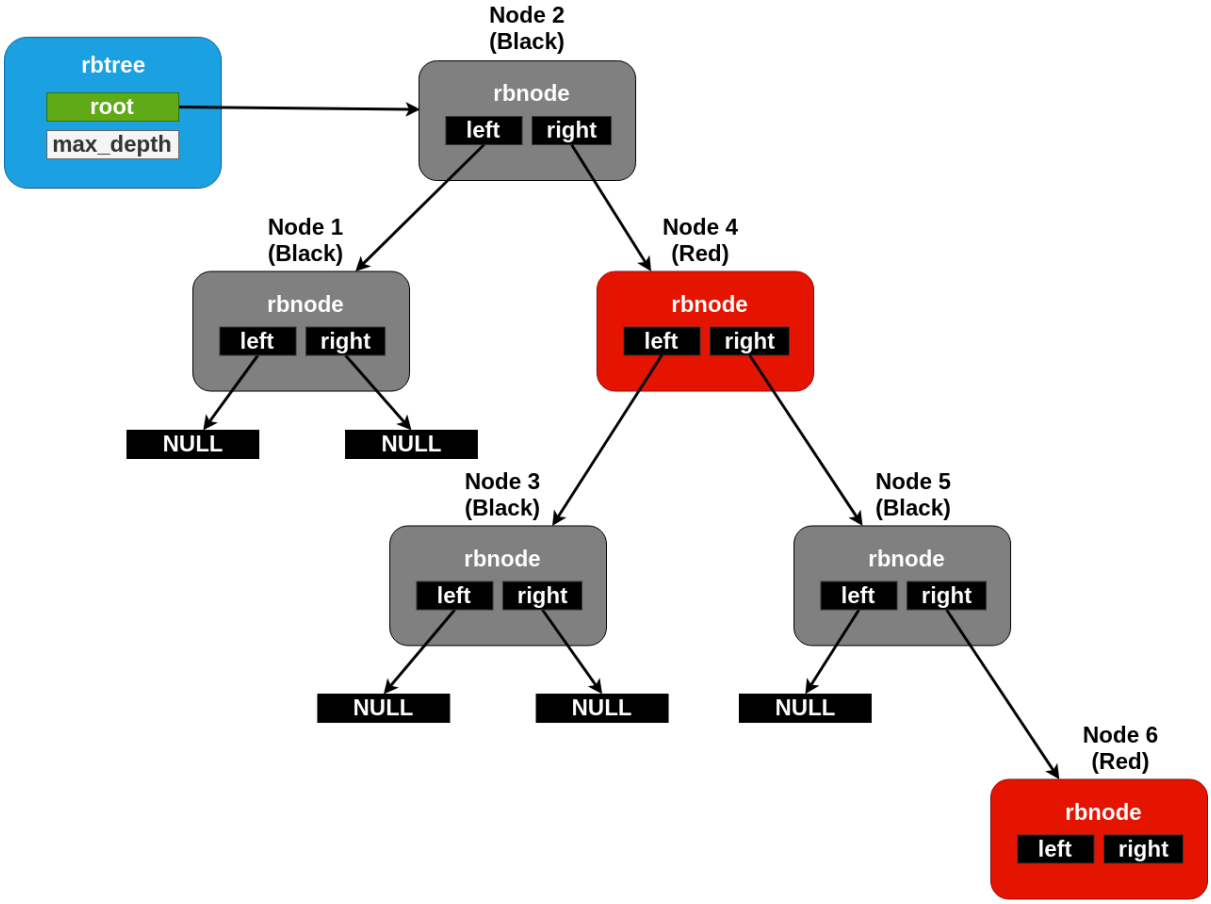

Fig. 9: A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.

These rotations are conceptually implemented on top of a primitive that "swaps" the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal "data" pointers, but because the Zephyr `rbnode` is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).

The `rbnode` struct for a Zephyr rbtree contains only two pointers, representing the "left", and "right" children of a node within the binary tree. Traversal of a tree for rebalancing following

modification, however, routinely requires the ability to iterate "upwards" from a node as well. It is very common for red/black trees in the industry to store a third "parent" pointer for this purpose. Zephyr avoids this requirement by building a "stack" of node pointers locally as it traverses downward through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

Red/Black Tree API Reference

Balanced Red/Black Tree

3.5.6 Ring Buffers

A *ring buffer* is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous "streaming" copying of data, Zephyr provides a `struct ring_buf` abstraction to manage copies of such data in and out of a shared buffer of memory.

Two content data modes are supported:

- **Byte mode**: raw bytes can be enqueued and dequeued.
- **Data item mode**: Multiple 32-bit word data items with metadata can be enqueued and dequeued from the ring buffer in chunks of up to 1020 bytes. Each data item also has two associated metadata values: a type identifier and a 16-bit integer value, both of which are application-specific.

While the underlying data structure is the same, it is not legal to mix these two modes on a single ring buffer instance. A ring buffer initialized with a byte count must be used only with the "bytes" API, one initialized with a word count must use the "items" calls.

- *Concepts*
  - *Byte mode*
  - *Data item mode*
  - *Concurrency*
  - *Internal Operation*
- *Implementation*
  - *Defining a Ring Buffer*
  - *Enqueuing Data*
  - *Retrieving Data*
- *Configuration Options*
- *API Reference*

Concepts

Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes or 32-bit words. The data buffer contains the raw bytes or 32-bit words that have been added to the ring buffer but not yet removed.
- A **data buffer size**, measured in bytes or 32-bit words. This governs the maximum amount of data (including possible metadata values) the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty.

A `struct ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with `ring_buf_init()` or `ring_buf_item_init()` before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. `RING_BUF_DECLARE` will declare and statically initialize a ring buffer with a specified byte count, where `RING_BUF_ITEM_DECLARE` will declare and statically initialize a buffer with a given count of 32 bit words. `RING_BUF_ITEM_SIZEOF` will compute the size in 32-bit words corresponding to a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

"Bytes" data may be copied into the ring buffer using `ring_buf_put()`, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise `ring_buf_get()` will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a "claim" API exists for byte mode. `ring_buf_put_claim()` takes a byte size value from the user and returns a pointer to memory internal to the ring buffer that can be used to receive those bytes, along with a size of the contiguous internal region (which may be smaller than requested). The user can then copy data into that region at a later time without assembling all the bytes in a single region first. When complete, `ring_buf_put_finish()` can be used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, `ring_buf_get_claim()` returns a pointer to internal ring buffer data from which the user can read without making a verbatim copy, and `ring_buf_get_finish()` signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

"Items" mode works similarly to bytes mode, except that all transfers are in units of 32 bit words and all memory is assumed to be aligned on 32 bit boundaries. The write and read operations are `ring_buf_item_put()` and `ring_buf_item_get()`, and work otherwise identically to the bytes mode APIs. There no "claim" API provided for items mode. One important difference is that unlike `ring_buf_put()`, `ring_buf_item_put()` will not do a partial transfer; it will return an error in the case where the provided data does not fit in its entirety.

The user can manage the capacity of a ring buffer without modifying it using either `ring_buf_space_get()` or `ring_buf_item_space_get()` which returns the number of free bytes or free 32-bit item words respectively, or by testing the `ring_buf_is_empty()` predicate.

Finally, a `ring_buf_reset()` call exists to immediately empty a ring buffer, discarding the tracking of any bytes or items already written to the buffer. It does not modify the memory contents of the buffer itself, however.

Byte mode A **byte mode** ring buffer instance is declared using `RING_BUF_DECLARE()` and accessed using: `ring_buf_put_claim()`, `ring_buf_put_finish()`, `ring_buf_get_claim()`, `ring_buf_get_finish()`, `ring_buf_put()` and `ring_buf_get()`.

Data can be copied into the ring buffer (see `ring_buf_put()`) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:

1. allocating the buffer (`ring_buf_put_claim()`) when user requests the destination location where data can be written.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer (`ring_buf_put_finish()`). The amount can be less than or equal to the allocated amount.

Data can be retrieved from a ring buffer through copying (see `ring_buf_get()`) or accessed directly by address. In the latter case, the operation is split into three stages:

1. retrieving source location with valid data written to a ring buffer (see `ring_buf_get_claim()`).
2. processing data
3. freeing processed data (see `ring_buf_get_finish()`). The amount freed can be less than or equal or to the retrieved amount.

Data item mode A **data item mode** ring buffer instance is declared using `RING_BUF_ITEM_DECLARE()` and accessed using `ring_buf_item_put()` and `ring_buf_item_get()`.

A ring buffer **data item** is an array of 32-bit words from 0 to 1020 bytes in length. When a data item is **enqueued** (`ring_buf_item_put()`) its contents are copied to the data buffer, along with its associated metadata values (which occupy one additional 32-bit word). If the ring buffer has insufficient space to hold the new data item the enqueue operation fails.

A data item is **dequeued** (`ring_buf_item_get()`) from a ring buffer by removing the oldest enqueued item. The contents of the dequeued data item, as well as its two metadata values, are copied to areas supplied by the retriever. If the ring buffer is empty, or if the data array supplied by the retriever is not large enough to hold the data item's data, the dequeue operation fails.

Concurrency The ring buffer APIs do not provide any concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

For the trivial case of one producer and one consumer, concurrency control shouldn't be needed.

Internal Operation Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the "ring" structure. Internally, the `struct ring_buf` contains its own buffer pointer and its size, and also a set of "head" and "tail" indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the "claim" API, because obviously no contiguous region can be returned that crosses the end of the buffer. This can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.

Implementation

Defining a Ring Buffer A ring buffer is defined using a variable of type `ring_buf`. It must then be initialized by calling `ring_buf_init()` or `ring_buf_item_init()`.

The following code defines and initializes an empty **data item mode** ring buffer (which is part of a larger data structure). The ring buffer's data buffer is capable of holding 64 words of data and metadata information.

```
#define MY_RING_BUF_WORDS 64

struct my_struct {
    struct ring_buf rb;
    uint32_t buffer[MY_RING_BUF_WORDS];
    ...
};
struct my_struct ms;
```

(continues on next page)

(continued from previous page)

```
void init_my_struct {
    ring_buf_item_init(&ms.rb, MY_RING_BUF_WORDS, ms.buffer);
    ...
}
```

Alternatively, a ring buffer can be defined and initialized at compile time using one of two macros at file scope. Each macro defines both the ring buffer itself and its data buffer.

The following code defines a **data item mode** ring buffer:

```
#define MY_RING_BUF_WORDS 93
RING_BUF_ITEM_DECLARE(my_ring_buf, MY_RING_BUF_WORDS);
```

The following code defines a ring buffer intended to be used for raw bytes:

```
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

Enqueuing Data Bytes are copied to a **byte mode** ring buffer by calling `ring_buf_put()`.

```
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;

ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {
    /* not enough room, partial copy. */
    ...
}
```

Data can be added to a **byte mode** ring buffer by directly accessing the ring buffer's memory. For example:

```
uint32_t size;
uint32_t rx_size;
uint8_t *data;
int err;

/* Allocate buffer within a ring buffer memory. */
size = ring_buf_put_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
rx_size = uart_rx(data, size);

/* Indicate amount of valid data. rx_size can be equal or less than size. */
err = ring_buf_put_finish(&ring_buf, rx_size);
if (err != 0) {
    /* This shouldn't happen unless rx_size > size */
    ...
}
```

A data item is added to a ring buffer by calling `ring_buf_item_put()`.

```
uint32_t data[MY_DATA_WORDS];
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_FOO, 0, data, MY_DATA_WORDS);
```

(continues on next page)

(continued from previous page)

```
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

If the data item requires only the type or application-specific integer value (i.e. it has no data array), a size of 0 and data pointer of `NULL` can be specified.

```
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_BAR, 17, NULL, 0);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

Retrieving Data Data bytes are copied out from a **byte mode** ring buffer by calling `ring_buf_get()`. For example:

```
uint8_t my_data[MY_DATA_BYTES];
size_t  ret;

ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
    ...
}
```

Data can be retrieved from a **byte mode** ring buffer by direct operations on the ring buffer's memory. For example:

```
uint32_t size;
uint32_t proc_size;
uint8_t *data;
int err;

/* Get buffer within a ring buffer memory. */
size = ring_buf_get_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
proc_size = process(data, size);

/* Indicate amount of data that can be freed. proc_size can be equal or less
 * than size.
 */
err = ring_buf_get_finish(&ring_buf, proc_size);
if (err != 0) {
    /* proc_size exceeds amount of valid data in a ring buffer. */
    ...
}
```

A data item is removed from a ring buffer by calling `ring_buf_item_get()`.

```
uint32_t my_data[MY_DATA_WORDS];
uint16_t my_type;
uint8_t  my_value;
uint8_t  my_size;
int ret;

my_size = MY_DATA_WORDS;
ret = ring_buf_item_get(&ring_buf, &my_type, &my_value, my_data, &my_size);
if (ret == -EMSGSIZE) {
    printk("Buffer is too small, need %d uint32_t\n", my_size);
} else if (ret == -EAGAIN) {
    printk("Ring buffer is empty\n");
} else {
    printk("Got item of type %u value &u of size %u dwords\n",
           my_type, my_value, my_size);
    ...
}
```

3.5.9 Min-Heap Data Structure

- *Heap Structure*
- *Use Cases*

- *Samples*
- *API Reference*

The Min-Heap implementation provides an efficient data structure for managing a dynamically changing list of elements while maintaining the ability to quickly extract the minimum value. It's a tree-based data structure that satisfies the heap property and supports common operations such as insertion, removal and popping the minimum element from the Min-Heap

This section explains the motivation behind the implementation, its internal structure, API usage, and example scenarios for embedded systems and real-time environments.

Heap Structure

The heap is maintained as a complete binary tree stored in an array. Each node satisfies the **min-heap** property:

- The value of each node is less than or equal to the values of its children.

This property ensures that the **minimum element is always at the root** (index 0).

```
Index:      0   1   2   3   4   5   6
Values:    [1,  3,  5,  8,  9, 10, 12]

               1
             /   \
           3       5
         / \     / \
        8   9  10  12
```

For any node at index `i`, its children are at indices:

- Left child: $2 * i + 1$
- Right child: $2 * i + 2$

Its parent is at index:

- Parent: $(i - 1)/2$

Use Cases

MinHeap is well suited for:

- Implementing priority queues
- Sorting data incrementally
- Resource arbitration (e.g., lowest-cost resource selection)
- Scheduling in cooperative multitasking systems
- Managing timeouts and delay queues
- Priority-based sensor or data sampling

In RTOS environments like Zephyr, this heap can be used in kernel-level or application-level modules where minimal latency to obtain the highest priority resource is needed.

Samples

min-heap sample demos the API usage of Min-Heap implementation in Zephyr RTOS.

Min-Heap service

3.6 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

3.6.1 Configuration

To allow using the timing functions, `CONFIG_TIMING_FUNCTIONS` needs to be enabled.

3.6.2 Usage

To gather timing information:

1. Call `timing_init()` to initialize the timer.
2. Call `timing_start()` to signal the start of gathering of timing information. This usually starts the timer.
3. Call `timing_counter_get()` to mark the start of code execution.
4. Call `timing_counter_get()` to mark the end of code execution.
5. Call `timing_cycles_get()` to get the number of timer cycles between start and end of code execution.
6. Call `timing_cycles_to_ns()` with total number of cycles to convert number of cycles to nanoseconds.
7. Repeat from step 3 to gather timing information for other blocks of code.
8. Call `timing_stop()` to signal the end of gathering of timing information. This usually stops the timer.

Example

This shows an example on how to use the timing functions:

```
#include <zephyr/timing/timing.h>

void gather_timing(void)
{
    timing_t start_time, end_time;
    uint64_t total_cycles;
    uint64_t total_ns;

    timing_init();
    timing_start();

    start_time = timing_counter_get();

    code_execution_to_be_measured();

    end_time = timing_counter_get();
```

(continues on next page)

(continued from previous page)

```
    total_cycles = timing_cycles_get(&start_time, &end_time);
    total_ns = timing_cycles_to_ns(total_cycles);

    timing_stop();
}
```

Arch specific Timing Measurement APIs

SoC specific Timing Measurement APIs

Board specific Timing Measurement APIs

3.7 Object Cores

Object cores are a kernel debugging tool that can be used to both identify and perform operations on registered objects.

- *Object Core Concepts*
- *Object Core Statistics Concepts*
- *Implementation*
  - *Defining a New Object Type*
  - *Initializing a New Object Core*
  - *Walking a List of Object Cores*
  - *Object Core Statistics Querying*
- *Configuration Options*
- *API Reference*

3.7.1 Object Core Concepts

Each instance of an object embeds an object core field named `obj_core`. Objects of the same type are linked together via their respective object cores to form a singly linked list. Each object core also links to the their respective object type. Each object type contains a singly linked list linking together all the object cores of that type. Object types are also linked together via a singly linked list. Together, this can allow debugging tools to traverse all the objects in the system.

Object cores have been integrated into following kernel objects:

- *Condition Variables*
- *Events*
- *FIFOs* and *LIFOs*
- *Mailboxes*
- *Memory Slabs*

- *Message Queues*
- *Mutexes*
- *Pipes*
- *Semaphores*
- *Threads*
- *Timers*
- *System Memory Blocks*

Developers are free to integrate them if desired into other objects within their projects.

3.7.2 Object Core Statistics Concepts

A variety of kernel objects allow for the gathering and reporting of statistics. Object cores provide a uniform means to retrieve that information via object core statistics. When enabled, the object type contains a pointer to a statistics descriptor that defines the various operations that have been enabled for interfacing with the object's statistics. Additionally, the object core contains a pointer to the "raw" statistical information associated with that object. Raw data is the raw, unmanipulated data associated with the statistics. Queried data may be "raw", but it may also have been manipulated in some way by calculation (such as determining an average).

The following table indicates both what objects have been integrated into the object core statistics as well as the structures used for both "raw" and "queried" data.

Object	Raw Data Type	Query Data Type
struct mem_slab	struct mem_slab_info	struct sys_memory_stats
struct sys_mem_blocks	struct sys_mem_blocks_info	struct sys_memory_stats
struct k_thread	struct k_cycle_stats	struct k_thread_runtime_stats
struct _cpu	struct k_cycle_stats	struct k_thread_runtime_stats
struct z_kernel	struct k_cycle_stats[num CPUs]	struct k_thread_runtime_stats

3.7.3 Implementation

Defining a New Object Type

An object type is defined using a global variable of type `k_obj_type`. It must be initialized before any objects of that type are initialized. The following code shows how a new object type can be initialized for use with object cores and object core statistics.

```
/* Unique object type ID */

#define K_OBJ_TYPE_MY_NEW_TYPE  K_OBJ_TYPE_ID_GEN("UNIQ")
struct k_obj_type  my_obj_type;

struct my_obj_type_raw_info {
    ...
};

struct my_obj_type_query_stats {
    ...
};

struct my_new_obj {
    ...
    struct k_obj_core obj_core;
```

(continues on next page)

(continued from previous page)

```
    struct my_obj_type_raw_info  info;
};

struct k_obj_core_stats_desc my_obj_type_stats_desc = {
    .raw_size = sizeof(struct my_obj_type_raw_stats),
    .query_size = sizeof(struct my_obj_type_query_stats),
    .raw = my_obj_type_stats_raw,
    .query = my_obj_type_stats_query,
    .reset = my_obj_type_stats_reset,
    .disable = NULL,    /* Stats gathering is always on */
    .enable = NULL,     /* Stats gathering is always on */
};

void my_obj_type_init(void)
{
    z_obj_type_init(&my_obj_type, K_OBJ_TYPE_MY_NEW_TYPE,
                    offsetof(struct my_new_obj, obj_core);
    k_obj_type_stats_init(&my_obj_type, &my_obj_type_stats_desc);
}
```

Initializing a New Object Core

Kernel objects that have already been integrated into the object core framework automatically have their object cores initialized when the object is initialized. However, developers that wish to add their own objects into the framework need to both initialize the object core and link it. The following code builds on the example above and initializes the object core.

```
void my_new_obj_init(struct my_new_obj *new_obj)
{
    ...
    k_obj_core_init(K_OBJ_CORE(new_obj), &my_obj_type);
    k_obj_core_link(K_OBJ_CORE(new_obj));
    k_obj_core_stats_register(K_OBJ_CORE(new_obj), &new_obj->raw_stats,
                              sizeof(struct my_obj_type_raw_info));
}
```

Walking a List of Object Cores

Two routines exist for walking the list of object cores linked to an object type. These are `k_obj_type_walk_locked()` and `k_obj_type_walk_unlocked()`. The following code builds upon the example above and prints the addresses of all the objects of that new object type.

```
int walk_op(struct k_obj_core *obj_core, void *data)
{
    uint8_t *ptr;

    ptr = obj_core;
    ptr -= obj_core->type->obj_core_offset;

    printk("%p\n", ptr);

    return 0;
}

void print_object_addresses(void)
```

(continues on next page)

(continued from previous page)

```
{
    struct k_obj_type *obj_type;

    /* Find the object type */

    obj_type = k_obj_type_find(K_OBJ_TYPE_MY_NEW_TYPE);

    /* Walk the list of objects */

    k_obj_type_walk_unlocked(obj_type, walk_op, NULL);
}
```

Object Core Statistics Querying

The following code builds on the examples above and shows how an object integrated into the object core statistics framework can both retrieve queried data and reset the stats associated with the object.

```
struct my_new_obj my_obj;

...

void my_func(void)
{
    struct my_obj_type_query_stats  my_stats;
    int  status;

    my_obj_type_init(&my_obj);

    ...

    status = k_obj_core_stats_query(K_OBJ_CORE(&my_obj),
                                    &my_stats, sizeof(my_stats));
    if (status != 0) {
        /* Failed to get stats */
        ...
    } else {
        k_obj_core_stats_reset(K_OBJ_CORE(&my_obj));
    }

    ...
}
```

3.7.4 Configuration Options

Related configuration options:

3.8 Time Utilities

3.8.1 Overview

Uptime in Zephyr is based on the a tick counter. With the default CONFIG_TICKLESS_KERNEL this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like CLOCK_MONOTONIC or, in Linux, CLOCK_MONOTONIC_RAW. k_uptime_get() provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time in different ways and may have discontinuities due to leap seconds and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a "real" civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- *converting between time representations*
- *synchronizing and aligning time scales*
- *comparing, adding, and subtracting representations*

For terminology and concepts that support these functions see *Concepts Underlying Time Support in Zephyr*.

3.8.2 Time Utility APIs

Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include `time_t` and `struct timespec`, which are generally interpreted as a representation of "UNIX Time" (see **RFC 8536 Section 2**).
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include `struct tm`.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, `time_t` measuring seconds since the POSIX EPOCH is converted to `struct tm` representing calendar time with gmtime(). Sub-second timestamps like `struct timespec` can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like `mktime()` expect information about time zones. Zephyr provides this transformation with `timeutil_timegm()` and `timeutil_timegm64()`.

To convert between `struct timespec` and `k_timeout_t` durations, use `timespec_to_timeout()` and `timespec_from_timeout()`.

```
k_timeout_t to;
struct timespec ts;

timespec_from_timeout(K_FOREVER, &ts);
to = timespec_to_timeout(&ts); /* to == K_FOREVER */

timespec_from_timeout(K_MSEC(100), &ts);
to = timespec_to_timeout(&ts); /* to == K_MSEC(100) */
```

Time Representation APIs

Time Scale Synchronization

There are several factors that affect synchronizing time scales:

- The rate of discrete instant representation change. For example Zephyr uptime is tracked in ticks which advance at events that nominally occur at `CONFIG_SYS_CLOCK_TICKS_PER_SEC` Hertz, while an external time source may provide data in whole or fractional seconds (e.g. microseconds).
- The absolute offset required to align the two scales at a single instant.
- The relative error between observable instants in each scale, required to align multiple instants consistently. For example a reference clock that's conditioned by a 1-pulse-per-second GPS signal will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250 ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

- An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a fixed nominal rate.
- `timeutil_sync_config` records the nominal rates of a reference time scale/source (e.g. TAI) and a local time source (e.g. `k_uptime_ticks()`).
- `timeutil_sync_instant` records the representation of a single instant in both the reference and local time scales.

- `timeutil_sync_state` provides storage for an initial instant, a recently received second observation, and a skew that can adjust for relative errors in the actual rate of each time scale.
- `timeutil_sync_ref_from_local()` and `timeutil_sync_local_from_ref()` convert instants in one time scale to another taking into account skew that can be estimated from the two instances stored in the state structure by `timeutil_sync_estimate_skew()`.

Time Synchronization APIs

`timespec` Manipulation

Checking the validity of a `timespec` can be done with `timespec_is_valid()`.

```
struct timespec ts = {
    .tv_sec = 0,
    .tv_nsec = -1, /* out of range! */
};

if (!timespec_is_valid(&ts)) {
    /* error-handing code */
}
```

In some cases, invalid `timespec` objects may be re-normalized using `timespec_normalize()`.

```
if (!timespec_normalize(&ts)) {
    /* error-handling code */
}

/* ts should be normalized */
__ASSERT(timespec_is_valid(&ts) == true, "expected normalized timespec");
```

It is possible to compare two `timespec` objects for equality using `timespec_equal()`.

```
if (timespec_equal(then, now)) {
    /* time is up! */
}
```

It is possible to compare and fully order (valid) `timespec` objects using `timespec_compare()`.

```
int cmp = timespec_compare(a, b);

switch (cmp) {
case 0:
    /* a == b */
    break;
case -1:
    /* a < b */
    break;
case +1:
    /* a > b */
    break;
}
```

It is possible to add, subtract, and negate `timespec` objects using `timespec_add()`, `timespec_sub()`, and `timespec_negate()`, respectively. Like `timespec_normalize()`, these functions will output a normalized `timespec` when doing so would not result in overflow. On success, these functions return `true`. If overflow would occur, the functions return `false`.

```
/* a += b */
if (!timespec_add(&a, &b)) {
    /* overflow */
}

/* a -= b */
if (!timespec_sub(&a, &b)) {
    /* overflow */
}

/* a = -a */
if (!timespec_negate(&a)) {
    /* overflow */
}
```

Timespec Utility APIs

3.8.3 Concepts Underlying Time Support in Zephyr

Terms from ISO/TC 154/WG 5 N0038 (ISO/WD 8601-1) and elsewhere:

- A *time axis* is a representation of time as an ordered sequence of instants.
- A *time scale* is a way of representing an instant relative to an origin that serves as the epoch.
- A time scale is *monotonic* (increasing) if the representation of successive time instants never decreases in value.
- A time scale is *continuous* if the representation has no abrupt changes in value, e.g. jumping forward or back when going between successive instants.
- Civil time generally refers to time scales that legally defined by civil authorities, like local governments, often to align local midnight to solar time.

Relevant Time Scales

International Atomic Time (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI is a monotonic and continuous time scale.

Universal Time (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it requires occasional adjustments (leap seconds) to maintain alignment to changes in Earth's rotation. Thus the difference between TAI and UT varies over time. There are several variants of UT, with UTC being the most common.

UT times are independent of location. UT is the basis for Standard Time (or "local time") which is the time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily influenced by longitude, but the offset may be adjusted ("daylight saving time") to align standard time to the local solar time. In a sense local time is "more discontinuous" than UT.

POSIX Time (see **RFC 8536 Section 2**) is a time scale that counts seconds since the "POSIX epoch" at 1970-01-01T00:00:00Z (i.e. the start of 1970 UTC). UNIX Time is an extension of POSIX time using negative values to represent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400 seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the discontinuity.

The continuous analogue is UNIX Leap Time which is UNIX time plus all leap-second corrections added after the POSIX epoch (when TAI-UTC was 8 s).

Example of Time Scale Differences A positive leap second was introduced at the end of 2016, increasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no

leap second introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The following table shows relevant civil and epoch times in several scales:

UTC Date	UNIX time	TAI Date	TAI-UTC	UNIX Leap Time
1970-01-01T00:00:00Z	0	1970-01-01T00:00:08	+8	0
1999-12-31T23:59:28Z	946684768	2000-01-01T00:00:00	+32	946684792
1999-12-31T23:59:59Z	946684799	2000-01-01T00:00:31	+32	946684823
2000-01-01T00:00:00Z	946684800	2000-01-01T00:00:32	+32	946684824
2016-12-31T23:59:59Z	1483228799	2017-01-01T00:00:35	+36	1483228827
2016-12-31T23:59:60Z	undefined	2017-01-01T00:00:36	+36	1483228828
2017-01-01T00:00:00Z	1483228800	2017-01-01T00:00:37	+37	1483228829

Functional Requirements The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around `timeutil_sync_state_update()` supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

Selecting an External Source and Time Scale If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth Mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.

The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

`timespec` Concepts

Originally from POSIX, `struct timespec` has been a part of the C standard since C11. The definition of `struct timespec` is as shown below.

```
struct timespec {
    time_t tv_sec;  /* seconds */
    long   tv_nsec; /* nanoseconds */
};
```

The `tv_nsec` field is only valid with values in the range `[0, 999999999]`. The `tv_sec` field is the number of seconds since the epoch. If `struct timespec` is used to express a difference, the `tv_sec` field may fall into a negative range.

3.9 Utilities

This page contains reference documentation for `<sys/util.h>`, which provides miscellaneous utility functions and macros.

Utility Functions

3.10 Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be used for defining iterable areas of equally-sized data structures, that can be iterated on using `STRUCT_SECTION_FOREACH`.

3.10.1 Usage

Iterable section elements are typically used by defining the data structure and associated initializer in a common header file, so that they can be instantiated anywhere in the code base.

```
struct my_data {
        int a, b;
};

#define DEFINE_DATA(name, _a, _b) \
        STRUCT_SECTION_ITERABLE(my_data, name) = { \
                .a = _a, \
                .b = _b, \
        }

...

DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
```

Then the linker has to be setup to place the structure in a contiguous segment using one of the linker macros such as `ITERABLE_SECTION_RAM` or `ITERABLE_SECTION_ROM`. Custom linker snippets are normally declared using one of the `zephyr_linker_sources()` CMake functions, using the appropriate section identifier, `DATA_SECTIONS` for RAM structures and `SECTIONS` for ROM ones.

```
# CMakeLists.txt
zephyr_linker_sources(DATA_SECTIONS iterables.ld)
```

```
# iterables.ld
#include <zephyr/linker/iterable_sections.h>
ITERABLE_SECTION_RAM(my_data, 4)
```

The data can then be accessed using `STRUCT_SECTION_FOREACH`.

```
STRUCT_SECTION_FOREACH(my_data, data) {
        printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
```

Note

The linker is going to place the entries sorted by name, so the example above would visit `d1`, `d2` and `d3` in that order, regardless of how they were defined in the code.

3.10.2 API Reference

Iterable Sections APIs

3.11 Code And Data Relocation

3.11.1 Overview

This feature will allow relocating .text, .rodata, .data, and .bss sections from required files and place them in the required memory region. The memory region and file are given to the *scripts/build/gen_relocate_app.py* script in the form of a string. This script is always invoked from inside cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the code. In simple terms this script will do the job of `__attribute__((section("name")))` for a bunch of files together.

A regular expression filter can be used to select only the required sections to be relocated.

3.11.2 Details

The memory region and file are given to the *scripts/build/gen_relocate_app.py* script through a file where each line specifies a list of files to be placed in the given region.

An example of such a file is:

```
SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c,
SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c,
```

This script is invoked with the following parameters: `python3 gen_relocate_app.py -i input_file -o generated_linker -c generated_code`

Kconfig `CONFIG_CODE_DATA_RELOCATION` option, when enabled in `prj.conf`, will invoke the script and do the required relocation.

This script also trigger the generation of `linker_relocate.ld` and `code_relocation.c` files. The `linker_relocate.ld` file creates appropriate sections and links the required functions or variables from all the selected files.

Note

The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

The code_relocation.c file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

The procedure to invoke this feature is:

- Enable CONFIG_CODE_DATA_RELOCATION in the prj.conf file
- Inside the CMakeLists.txt file in the project, mention all the files that need relocation.

  zephyr_code_relocate(FILES src/*.c LOCATION SRAM2)

  Where the first argument is the file/files and the second argument is the memory where it must be placed.

> **Note**
>
> function zephyr_code_relocate() can be called as many times as required.

Additional Configurations

This section shows additional configuration options that can be set in CMakeLists.txt.

- If the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections. For example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM)
```

- If the memory type is appended with _DATA, _TEXT, _RODATA, _BSS or _NOINIT, only the selected memory is placed in the required memory region. For example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_DATA)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM2_TEXT)
```

- Multiple regions can also be appended together such as: SRAM2_DATA_BSS_NOINIT. This will place all data: value-initialized, zero-initialized and uninitialized inside SRAM2.
- Multiple files can be passed to the FILES argument, or CMake generator expressions can be used to relocate a comma-separated list of files.

```
file(GLOB sources "file*.c")
zephyr_code_relocate(FILES ${sources} LOCATION SRAM)
zephyr_code_relocate(FILES $<TARGET_PROPERTY:my_tgt,SOURCES> LOCATION SRAM)
```

Section Filtering

By default, all sections of the specified files will be relocated. If FILTER is used, a regular expression is provided to select only the sections to be relocated.

The regular expression applies to sections names which can be used to select the file's symbols when this one has been built with -ffunction-sections and -fdata-sections which is the case by default.

```
zephyr_code_relocate(FILES src/file1.c FILTER ".*\\.func1|.*\\.func2"␣
↪LOCATION SRAM2_TEXT)
```

The example above will only relocate func1() and func2() of file src/file1.c

NOKEEP flag

By default, all relocated functions and variables will be marked with `KEEP()` when generating `linker_relocate.ld`. Therefore, if any input file happens to contain unused symbols, then they will not be discarded by the linker, even when it is invoked with `--gc-sections`. If you'd like to override this behavior, you can pass `NOKEEP` to your `zephyr_code_relocate()` call.

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_TEXT NOKEEP)
```

The example above will help ensure that any unused code found in the .text sections of `file1.c` will not stick to SRAM2.

NOCOPY flag

When a `NOCOPY` option is passed to the `zephyr_code_relocate()` function, the relocation code is not generated in `code_relocation.c`. This flag can be used when we want to move the content of a specific file (or set of files) to a XIP area.

This example will place the .text section of the `xip_external_flash.c` file to the `EXTFLASH` memory region where it will be executed from (XIP). The .data will be relocated as usual into SRAM.

```
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION␣
↪EXTFLASH_TEXT NOCOPY)
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION SRAM_DATA)
```

Relocating libraries

Libraries can be relocated using the LIBRARY argument to `zephyr_code_relocation()` with the library name. For example, the following snippet will relocate serial drivers to SRAM2:

```
zephyr_code_relocate(LIBRARY drivers__serial LOCATION SRAM2)
```

Tips

Take care if relocating kernel/arch files, some contain early initialization code that executes before code relocation takes place.

Additional MPU/MMU configuration may be required to ensure that the destination memory region is configured to allow code execution.

Samples/ Tests

A test showcasing this feature is provided at `$ZEPHYR_BASE/tests/application_development/code_relocation`

This test shows how the code relocation feature is used.

This test will place .text, .data, .bss from 3 files to various parts in the SRAM using a custom linker file derived from `include/zephyr/arch/arm/cortex_m/scripts/linker.ld`

A sample showcasing the NOCOPY flag is provided here: code_relocation_nocopy.

3.12 Scope-based Cleanup Helpers

- *Overview*
- *Core Concepts*

  - *Scoped Variables*
  - *Scoped Guards*
  - *Scoped Defers*
- *Defining Scoped Types*
  - *Custom Scoped Variables*
  - *Scoped Guards*
  - *Scoped Defers*
- *Usage Notes*
  - *Order of Cleanup*
  - *Scope Rules*
- *API Reference*

3.12.1 Overview

The Cleanup Helper API provides a mechanism for automatic resource cleanup when variables go out of scope. This is similar to RAII in C++ or defer statements in Go. By leveraging compiler support for the `__cleanup` attribute, this API helps prevent resource leaks and simplifies error handling by ensuring cleanup code is executed automatically.

It is required to set `CONFIG_SCOPE_CLEANUP_HELPERS` to enable this feature, which is particularly useful for:

- Automatic unlocking of mutexes and semaphores
- Automatic freeing of dynamically allocated memory
- Ensuring cleanup actions occur on all code paths (including early returns)
- Reducing boilerplate cleanup code

Warning

The cleanup mechanism is implemented using the `__cleanup` attribute. If the toolchain doesn't support this attribute, the API is not available.

For this reason this API is intended solely for user applications and not for the kernel itself or other subsystems.

3.12.2 Core Concepts

The cleanup API provides three main abstractions:

Scoped Variables

A scoped variable defines a type with automatic init and exit behavior. Variables declared with a scoped variable type are initialized using an init function and automatically cleaned up using an exit function when they go out of scope.

Scoped Guards

Scoped guards are specialized scoped variables that automatically acquire a lock or resource on initialization and release it when going out of scope. This pattern is commonly used with

mutexes, semaphores, and other synchronization primitives.

Scoped Defers

Scoped defers execute a specified function when the variable goes out of scope, without acquiring anything on initialization. This is similar to the `defer` statement in languages like Go.

3.12.3 Defining Scoped Types

Custom Scoped Variables

Use `SCOPE_VAR_DEFINE` to define a custom scoped variable type with init and exit functions:

```
static inline struct flash_area *flash_area_init(int area_id)
{
    struct flash_area *fa;

    if (flash_area_open(area_id, &fa) < 0) {
        return NULL;
    }

    return fa;
}

static inline void flash_area_exit(struct flash_area *fa)
{
    if (fa != NULL) {
        flash_area_close(fa);
    }
}

// Define the scoped variable type
SCOPE_VAR_DEFINE(flash_area, struct flash_area *, flash_area_exit(_T),
                 flash_area_init(area_id), int area_id);

static int some_function(void)
{
    // Declare 'fa' with automatic cleanup
    scope_var(flash_area, fa)(FIXED_PARTITION_ID(storage_partition));
    if (fa == NULL) {
        return -EINVAL;  // Exit function is still called
    }

    // Use fa normally
    printk("Has driver: %d\n", flash_area_has_driver(fa));

    // No need to manually close - exit function is called automatically
    return 0;
}
```

The `_T` variable in the exit function expression contains the value of the variable being cleaned up.

Scoped Guards

Use `SCOPE_GUARD_DEFINE` to define a guard that acquires a lock on initialization and releases it on scope exit:

```
// Example guard definition (already provided by kernel.h)
SCOPE_GUARD_DEFINE(k_mutex, struct k_mutex *,
                   (void)k_mutex_lock(_T, K_FOREVER),
                   (void)k_mutex_unlock(_T));

static K_MUTEX_DEFINE(lock);

void critical_section(void)
{
    scope_guard(k_mutex)(&lock);

    // Lock is held here
    // Perform critical operations

    // Lock is automatically released when guard goes out of scope
}
```

Scoped Defers

Use SCOPE_DEFER_DEFINE to define a defer that executes a cleanup function:

```
// Define a defer for a custom cleanup function
static void cleanup_resources(void)
{
    // Cleanup code here
}

SCOPE_DEFER_DEFINE(cleanup_resources);

void some_function(void)
{
    scope_defer(cleanup_resources)();

    // Do work...

    // cleanup_resources() is called automatically
}
```

For functions with parameters:

```
// Example deferred k_free (already provided by kernel.h)
SCOPE_DEFER_DEFINE(k_free, void *);

void allocate_and_use(void)
{
    void *ptr = k_malloc(100);
    scope_defer(k_free)(ptr);

    // Use ptr...

    // k_free(ptr) is called automatically
}
```

3.12.4 Usage Notes

Order of Cleanup

Cleanup functions are called in reverse order of declaration (LIFO - Last In, First Out), which matches the natural nesting of resources:

```
{
    scope_guard(k_mutex)(&lock);           // Acquired first
    void *ptr = k_malloc(100);
    scope_defer(k_free)(ptr);              // Registered second

    // Do work...

}  // ptr is freed first, then mutex is unlocked
```

Scope Rules

Cleanup occurs when the variable goes out of scope, which includes:

- Reaching the end of a block
- Early return statements
- Break or continue in loops
- Goto statements that jump out of scope

```
void example_with_early_exit(struct k_mutex *lock)
{
    scope_guard(k_mutex)(lock);

    if (error_condition) {
        return;  // Guard cleanup happens here
    }

    // Normal path

}  // Guard cleanup also happens here
```

3.12.5 API Reference

Cleanup Helper Interface

Chapter 4

OS Services

4.1 Binary Descriptors

Binary Descriptors are constant data objects storing information about the binary executable. Unlike "regular" constants, binary descriptors are linked to a known offset in the binary, making them accessible to other programs, such as a different image running on the same device or a host tool. A few examples of constants that would make useful binary descriptors are: kernel version, app version, build time, compiler version, environment variables, compiling host name, etc.

Binary descriptors are created by using the `DEFINE_BINDESC_*` macros. For example:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(my_string, 2, "Hello world!"); // Unique ID is 2
```

`my_string` could then be accessed using:

```
printk("my_string: %s\n", BINDESC_GET_STR(my_string));
```

But it could also be retrieved by `west bindesc`:

```
$ west bindesc custom_search STR 2 build/zephyr/zephyr.bin
"Hello world!"
```

4.1.1 Internals

Binary descriptors are implemented with a TLV (tag, length, value) header linked to a known offset in the binary image. This offset may vary between architectures, but generally the descriptors are linked as close to the beginning of the image as possible. In architectures where the image must begin with a vector table (such as ARM), the descriptors are linked right after the vector table. The reset vector points to the beginning of the text section, which is after the descriptors. In architectures where the image must begin with executable code (e.g. x86), a jump instruction is injected at the beginning of the image, in order to skip over the binary descriptors, which are right after the jump instruction.

Each tag is a 16 bit unsigned integer, where the most significant nibble (4 bits) is the type (currently uint, string or bytes), and the rest is the ID. The ID is globally unique to each descriptor. For example, the ID of the app version string is `0x800`, and a string is denoted by 0x1, making the app version tag `0x1800`. The length is a 16 bit number equal to the length of the data in bytes. The data is the actual descriptor value. All binary descriptor numbers (magic, tags, uints) are laid out in memory in the endianness native to the SoC. `west bindesc` assumes little endian by default, so if the image belongs to a big endian SoC, the appropriate flag should be given to the tool.

The binary descriptor header starts with the magic number `0xb9863e5a7ea46046`. It's followed by the TLVs, and ends with the `DESCRIPTORS_END` (`0xffff`) tag. The tags are always aligned to 32 bits. If the value of the previous descriptor had a non-aligned length, zero padding will be added to ensure that the current tag is aligned.

Putting it all together, here is what the example above would look like in memory (of a little endian SoC):

```
 46 60 a4 7e 5a 3e 86 b9 02 10  0d 00  48 65 6c 6c 6f 20 77 6f 72 6c 64 21 00 00␣
↪00 00 ff ff 00 00
|         magic         | tag |length| H  e  l  l  o     w  o  r  l  d  !    |  ␣
↪pad  |    end    |
```

4.1.2 Usage

Binary descriptors are always created by the `BINDESC_*_DEFINE` macros. As shown in the example above, a descriptor can be generated from any string or integer, with any ID. However, it is recommended to comply with the standard tags defined in `include/zephyr/bindesc.h`, as that would have the following benefits:

1. The `west bindesc` tool would be able to recognize what the descriptor means and print a meaningful tag
2. It would enforce consistency between various apps from various sources
3. It allows upstream-ability of descriptor generation (see Standard Descriptors)

To define a descriptor with a standard tag, just use the tags included from `bindesc.h`:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(app_version, BINDESC_ID_APP_VERSION_STRING, "1.2.3");
```

Standard Descriptors

Some descriptors might be trivial to implement, and could therefore be implemented in a standard way in upstream Zephyr. These could then be enabled via Kconfig, instead of requiring every user to reimplement them. These include build times, kernel version, and host info. For example, to add the build date and time as a string, the following configs should be enabled:

```
# Enable binary descriptors
CONFIG_BINDESC=y

# Enable definition of binary descriptors
CONFIG_BINDESC_DEFINE=y

# Enable default build time binary descriptors
CONFIG_BINDESC_DEFINE_BUILD_TIME=y
CONFIG_BINDESC_BUILD_DATE_TIME_STRING=y
```

To avoid collisions with user defined descriptors, the standard descriptors were allotted the range between `0x800-0xfff`. This leaves `0x000-0x7ff` to users. For more information read the `help` sections of these Kconfig symbols. By convention, each Kconfig symbol corresponds to a binary descriptor whose name is the Kconfig name (with `CONFIG_BINDESC_` removed) in lower case. For example, `CONFIG_BINDESC_KERNEL_VERSION_STRING` creates a descriptor that can be accessed using `BINDESC_GET_STR(kernel_version_string)`.

Reading Descriptors

It's also possible to read and parse binary descriptors from an application. This can be useful both for an image trying to read its own descriptors, and for an image trying to read another image's descriptors. Reading can be performed through one of three backends:

1. RAM - assuming the descriptors have been copied to RAM (e.g. by a bootloader), they can be read from the buffer they reside in.
2. Memory mapped flash - If the flash where the image to be read resides in flash and is accessible through the program's address space, it can be read directly from flash. This option uses the least amount of RAM, but will not work if the flash is not memory mapped, and is not recommended to read a bootloader's descriptors for security concerns.
3. Flash - Using an internal buffer, the descriptors are read one by one using the flash API, and given to the user while they're in the buffer.

To enable reading descriptors, enable `CONFIG_BINDESC_READ`. The three backends are enabled by these Kconfig symbols, respectively: `CONFIG_BINDESC_READ_RAM`, `CONFIG_BINDESC_READ_MEMORY_MAPPED_FLASH`, and `CONFIG_BINDESC_READ_FLASH`.

To read the descriptors, a handle to the descriptors should first be initialized:

```
struct bindesc_handle handle;

/* Assume buffer holds a copy of the descriptors */
bindesc_open_ram(&handle, buffer);
```

The `bindesc_open_*` functions are the only functions concerned with the backend used. The rest of the API is agnostic to where the data is. After the handle has been initialized, it can be used with the rest of the API:

```
char *version;
bindesc_find_str(&handle, BINDESC_ID_KERNEL_VERSION_STRING, &version);
printk("Kernel version: %s\n", version);
```

west bindesc tool

`west` is able to parse and display binary descriptors from a given executable image.

For more information refer to `west bindesc --help` or the *documentation*.

4.3 CPU Frequency Scaling

4.3.1 CPU Frequency Scaling Policies

On-Demand CPU Frequency Scaling Policy

The On-Demand policy evaluates the current CPU load using the *CPU Load metric*, and compares it to the trigger threshold defined by the SoC P-state definition.

The On-Demand policy will iterate through the defined P-states and select the first P-state for which the CPU load is greater than or equal to the defined threshold.

If no P-state matches (i.e., the CPU load is below all thresholds), the policy will select the last P-state in the soc_pstates array (the lowest performance state). This is intrinsic to the policy: P-states must be defined in decreasing threshold order in devicetree, and the last P-state will be used for loads below all thresholds.

For an example of the on-demand policy refer to the cpu_freq_on_demand sample.

This policy is reactive. Frequency adjustments occur only after a change in system load has been observed, so it cannot anticipate sudden high loads. The policy has no notion of task deadlines and should not be considered as a real-time policy.

Pressure based CPU Frequency Scaling Policy

The pressure policy evaluates the current pressure of the ready queue in order to inform system P-state transitions.

Thread pressure is calculated by the following formula:

$$P_{sys} = \frac{\sum_{t \in R}(P_{min} - prio_t + 1)}{\sum_{t \in T}(P_{min} - prio_t + 1)} \times 100$$

where

- R is the set of runnable (queued) threads
- T is the set of all threads considered for pressure
- $w_t = P_{min} - \text{prio}_t + 1$ is the weight of thread t
- P_{min} is the configured minimum priority to consider (the highest value numerically)

This produces a normalized system pressure between 0 and 100 which is then used to select an appropriate P-state as defined by the SoC or overlay file.

Once the normalized system pressure is calculated, it is treated as the system 'load' and the policy will then iterate through the available P-states of the SoC and select the first P-state for which the normalized pressure is greater than or equal to the defined threshold.

If no P-state matches (i.e., the normalized pressure is below all thresholds), the policy will select the last P-state in the soc_pstates array (the lowest performance state).

The user may tune the responsiveness of this policy by adjusting the `CONFIG_CPU_FREQ_POLICY_PRESSURE_LOWEST_PRIO` option which should be set the priority of

the lowest priority thread in the system (which numerically would be the highest number). The pressure policy will ignore threads of lower priority than this option, and due to the formulae above, will change the perceived impact of a high-priority thread running.

For an example of the pressure policy, refer to the cpu_freq_pressure sample.

This policy attempts to be proactive in evaluating queued tasks and adjusting the clock frequency ahead of their execution time, although this policy makes no guarentees on performance or determinism of threads achieving their deadlines and avoiding starvation.

Note that the `CONFIG_CPU_FREQ_POLICY_PRESSURE_LOWEST_PRIO` includes `CONFIG_TRACING` introduces overhead to context switching.

4.3.2 Overview

The CPU Frequency Scaling subsystem in Zephyr provides a framework for SoC's to dynamically adjust their processor frequency based on a monitored metric and performance state (P-state) policy algorithm.

4.3.3 Design Goals

The CPU Frequency Scaling subsystem aims to provide a framework that allows for any policy algorithm to work with any P-state driver and allows for each policy to make use of one, or many, metrics to determine an optimal CPU frequency. The subsystem should be flexible enough to allow for SoC vendors to define custom P-states, thresholds and metrics.

4.3.4 P-state Policies

A P-state policy is an algorithm that determines what the optimal P-state is for the CPU based on the metrics it consumes and the thresholds defined per P-state. A policy can consume one, or many, metrics to determine the optimal CPU frequency based on the desired statistics of the system.

See *policies* for a list of standard policies.

4.3.5 Metrics

A P-state policy should include one or more metrics to base decisions. Examples of metrics could include percent CPU load, SoC temperature, etc.

For an example of a metric in use, see the *on_demand* policy.

4.3.6 P-state Drivers

A SoC supporting the CPU Frequency Scaling subsystem must implement a P-state driver that implements `cpu_freq_pstate_set()` which applies the passed in `p_state` to the CPU when called.

A SoC must also provide the available P-states in devicetree by having a `zephyr,pstate` compatible node. The SoC may also define its own P-state binding, which extends `zephyr,pstate` to include additional properties that may be used by the SoC's P-state driver.

4.3.7 Usage considerations

The CPU Frequency Scaling subsystem is designed to work on both UP and SMP system. On SMP systems, it is assumed by default that each of the CPUs are clocked at the same rate. Thus, should one CPU undergo a P-state transition, then all other CPUs will also undergo the same P-state transition. This can be overridden by the SoC by enabling the `CONFIG_CPU_FREQ_PER_CPU_SCALING` configuration option to allow each CPU to be clocked independently.

The SoC supporting CPU Frequency Scaling must uphold Zephyr's requirement that the system timer frequency remains steady over the lifetime of the program. See *Kernel Timing* for more information.

The CPU Frequency Scaling subsystem runs as a handler function to a `k_timer`, which means it runs in interrupt context (IRQ). The SoC P-state driver must ensure that its implementation of `cpu_freq_pstate_set()` is IRQ context safe. If a P-state transition cannot be completed reasonably in an IRQ context, it is recommended that the P-state driver of the SoC implements its task as a workqueue item.

4.4 CPU Load

The CPU Load subsystem returns the CPU load as a percentage for the current CPU, since the last time it was called.

For an example of the CPU Load subsystem refer to cpu_freq_on_demand sample.

4.5 CRC

4.5.1 Overview

The CRC subsystem provides software implementations of various Cyclic Redundancy Check algorithms for data integrity verification. CRCs are commonly used to detect accidental changes to data in storage and communication systems.

The subsystem offers a comprehensive set of CRC algorithms including CRC-4, CRC-7, CRC-8, CRC-16, CRC-24, and CRC-32 variants, and provides optional hardware acceleration support when available.

> **Note**
>
> This library is distinct from the *CRC hardware driver API*, which provides an interface to hardware CRC acceleration peripherals.
>
> When a hardware CRC unit is available and the `zephyr,crc` property has been set in the `/chosen` node in Devicetree, the library functions will default to using hardware acceleration for improved performance (can be disabled by setting `CONFIG_CRC_HW_HANDLER` to `n`).

Usage

To compute a CRC, include the appropriate header and call the desired function:

```
#include <zephyr/sys/crc.h>

uint8_t data[] = {0x01, 0x02, 0x03, 0x04};
uint32_t checksum = crc32_ieee(data, sizeof(data));
```

For streaming data processed in chunks, use the "update" variants:

```
uint32_t crc = 0;
crc = crc32_ieee_update(crc, chunk1, len1);
crc = crc32_ieee_update(crc, chunk2, len2);
/* Final CRC value is in 'crc' */
```

The generic `crc_by_type()` function provides a unified interface to select the CRC algorithm at runtime.

4.5.2 Configuration

Related configuration options:

- `CONFIG_CRC` - Enable CRC support
- `CONFIG_CRC_HW_HANDLER` - Enable hardware CRC acceleration
- `CONFIG_CRC_SHELL` - Enable CRC shell commands
- `CONFIG_CRC[0-9].*` - Enable software implementations of specific CRC algorithms

4.5.3 API Reference

Related code samples

- Cyclic Redundancy Check Subsystem (CRC Subsys)Compute and verify a CRC computation using the CRC subsys API.

4.6 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

4.6.1 PSA Crypto

Overview

The PSA (Platform Security Architecture) Crypto API offers a portable programming interface for cryptographic operations and key storage across a wide range of hardware. It is designed to be user-friendly while still providing access to the low-level primitives essential for modern cryptography.

It is created and maintained by Arm. Arm developed the PSA as a comprehensive security framework to address the increasing security needs of connected devices.

In Zephyr, the PSA Crypto API is implemented using Mbed TLS, an open-source cryptographic library that provides the underlying cryptographic functions.

Design Goals

The interface is suitable for a vast range of devices: from special-purpose cryptographic processors that process data with a built-in key, to constrained devices running custom application code, such as microcontrollers, and multi-application devices, such as servers. It follows the principle of cryptographic agility.

Algorithm Flexibility
: The PSA Crypto API supports a wide range of cryptographic algorithms, allowing developers to switch between different cryptographic methods as needed. This flexibility is crucial for maintaining security as new algorithms emerge and existing ones become obsolete.

Key Management
: The PSA Crypto API includes robust key management features that support the creation, storage, and use of cryptographic keys in a secure and flexible manner. It uses opaque

key identifiers, which allows for easy key replacement and updates without exposing key material.

Implementation Independence
The PSA Crypto API abstracts the underlying cryptographic library, meaning that the specific implementation can be changed without affecting the application code. This abstraction supports cryptographic agility by enabling the use of different cryptographic libraries or hardware accelerators as needed.

Future-Proofing
By adhering to cryptographic agility, PSA Crypto ensures that applications can quickly adapt to new cryptographic standards and practices, enhancing long-term security and compliance.

Examples of Applications

Network Security (TLS)
The API provides all of the cryptographic primitives needed to establish TLS connections.

Secure Storage
The API provides all primitives related to storage encryption, block or file-based, with master encryption keys stored inside a key store.

Network Credentials
The API provides network credential management inside a key store, for example, for X.509-based authentication or pre-shared keys on enterprise networks.

Device Pairing
The API provides support for key agreement protocols that are often used for secure pairing of devices over wireless channels. For example, the pairing of an NFC token or a Bluetooth device might use key agreement protocols upon first use.

Secure Boot
The API provides primitives for use during firmware integrity and authenticity validation, during a secure or trusted boot process.

Attestation
The API provides primitives used in attestation activities. Attestation is the ability for a device to sign an array of bytes with a device private key and return the result to the caller. There are several use cases; ranging from attestation of the device state, to the ability to generate a key pair and prove that it has been generated inside a secure key store. The API provides access to the algorithms commonly used for attestation.

Factory Provisioning
Most IoT devices receive a unique identity during the factory provisioning process, or once they have been deployed to the field. This API provides the APIs necessary for populating a device with keys that represent that identity.

Usage considerations

Always check for errors
Most functions in the PSA Crypto API can return errors. All functions that can fail have the return type `psa_status_t`. A few functions cannot fail, and thus, return void or some other type.

If an error occurs, unless otherwise specified, the content of the output parameters is undefined and must not be used.

Some common causes of errors include:

- In implementations where the keys are stored and processed in a separate environment from the application, all functions that need to access the cryptography process-

ing environment might fail due to an error in the communication between the two environments.

- If an algorithm is implemented with a hardware accelerator, which is logically separate from the application processor, the accelerator might fail, even when the application processor keeps running normally.
- Most functions might fail due to a lack of resources. However, some implementations guarantee that certain functions always have sufficient memory.
- All functions that access persistent keys might fail due to a storage failure.
- All functions that require randomness might fail due to a lack of entropy. Implementations are encouraged to seed the random generator with sufficient entropy during the execution of `psa_crypto_init()`. However, some security standards require periodic reseeding from a hardware random generator, which can fail.

Shared memory and concurrency

Some environments allow applications to be multithreaded, while others do not. In some environments, applications can share memory with a different security context. In environments with multithreaded applications or shared memory, applications must be written carefully to avoid data corruption or leakage. This specification requires the application to obey certain constraints.

In general, the PSA Crypto API allows either one writer or any number of simultaneous readers, on any given object. In other words, if two or more calls access the same object concurrently, then the behavior is only well-defined if all the calls are only reading from the object and do not modify it. Read accesses include reading memory by input parameters and reading keystore content by using a key. For more details, refer to Concurrent calls

If an application shares memory with another security context, it can pass shared memory blocks as input buffers or output buffers, but not as non-buffer parameters. For more details, refer to Stability of parameters.

Cleaning up after use

To minimize impact if the system is compromised, it is recommended that applications wipe all sensitive data from memory when it is no longer used. That way, only data that is currently in use can be leaked, and past data is not compromised.

Wiping sensitive data includes:

- Clearing temporary buffers in the stack or on the heap.
- Aborting operations if they will not be finished.
- Destroying keys that are no longer used.

References

- PSA Crypto
- Mbed TLS

4.6.2 Random Number Generation

Overview

The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

- Use `sys_rand_get()` and related functions for non-cryptographic purposes such as randomizing delays, shuffling data, or general-purpose randomization. These functions are faster but not suitable for security applications.

- Use `sys_csrand_get()` for cryptographic purposes such as generating encryption keys, nonces, initialization vectors, or any data that must be unpredictable to an attacker.

Warning

Never use the non-cryptographic random functions (`sys_rand_get()`, `sys_rand8_get()`, `sys_rand16_get()`, `sys_rand32_get()`, `sys_rand64_get()`) for security-sensitive operations. These functions do not provide cryptographically secure random numbers.

API Usage

Non-Cryptographic Random Numbers The following functions provide non-cryptographically secure random numbers:

- `sys_rand_get()` - Fill a buffer with random bytes
- `sys_rand8_get()` - Get a random 8-bit value
- `sys_rand16_get()` - Get a random 16-bit value
- `sys_rand32_get()` - Get a random 32-bit value
- `sys_rand64_get()` - Get a random 64-bit value

Example usage:

```
#include <zephyr/random/random.h>

void example_random_usage(void)
{
    uint8_t buffer[16];
    uint32_t random_value;

    /* Fill buffer with random bytes */
    sys_rand_get(buffer, sizeof(buffer));

    /* Get a single random 32-bit value */
    random_value = sys_rand32_get();
}
```

Cryptographically Secure Random Numbers For cryptographic purposes, use `sys_csrand_get()`:

```
#include <zephyr/random/random.h>

int generate_encryption_key(uint8_t *key, size_t key_len)
{
    int ret;

    ret = sys_csrand_get(key, key_len);
    if (ret != 0) {
        /* Handle error - entropy source may have failed */
        return ret;
    }

    return 0;
}
```

Note

`sys_csrand_get()` returns 0 on success, or `-EIO` if the entropy source fails. Always check the return value when generating cryptographic material.

Kconfig Options

All configuration options can be found in subsys/random/Kconfig.

General Options

`CONFIG_TEST_RANDOM_GENERATOR`
: For testing, this option allows a non-random number generator to be used and permits random number APIs to return values that are not truly random.

  Warning

  This option is intended only for testing on platforms that lack hardware entropy support. The random numbers generated when this option is enabled are predictable and not suitable for any security-sensitive use.

Non-Cryptographic Random Generator Selection

`CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR`
: Uses the hardware entropy driver directly to generate random numbers. This provides high-quality random numbers but may be slower than pseudo-random alternatives. Select this option when your hardware entropy source has sufficient performance for your application's needs.

`CONFIG_XOSHIRO_RANDOM_GENERATOR`
: Uses the Xoshiro128++ pseudo-random number generator, seeded from the hardware entropy source. This is a fast, general-purpose PRNG with a 128-bit state that passes all standard randomness tests.

  This is the recommended choice for most applications that need fast non-cryptographic random numbers.

`CONFIG_TIMER_RANDOM_GENERATOR`
: Uses the system timer to generate pseudo-random numbers. This generator produces predictable values and is intended **only for testing** on platforms without hardware entropy support.

  Requires `CONFIG_TEST_RANDOM_GENERATOR` to be enabled.

Cryptographically Secure Random Generator Selection The `CSPRNG_GENERATOR_CHOICE` kconfig choice selects the source for cryptographically secure random number generation.

To override the default in a board or SoC configuration file:

```
choice CSPRNG_GENERATOR_CHOICE
        default PSA_CSPRNG_GENERATOR
endchoice
```

Available generators:

`CONFIG_HARDWARE_DEVICE_CS_GENERATOR`
: Uses the hardware entropy driver directly as the source for cryptographically secure random numbers. Select this when your hardware random number generator is certified or validated for cryptographic use.

`CONFIG_PSA_CSPRNG_GENERATOR`
: enables a cryptographically secure random number generator that uses the PSA Crypto API. This CSPRNG implementation leverages the underlying PSA Crypto library's secure random number generation capabilities, which may use hardware entropy sources when available. The PSA CSPRNG provides cryptographically secure random numbers suitable for security-sensitive applications.

`CONFIG_TEST_CSPRNG_GENERATOR`
: Routes calls to `sys_csrand_get()` through `sys_rand_get()`. This allows testing libraries that require CSPRNG on platforms without hardware entropy support.

  Requires `CONFIG_TEST_RANDOM_GENERATOR` to be enabled.

> **Warning**
>
> This option provides **no cryptographic security**. Use only for testing.

CTR-DRBG Personalization

`CONFIG_CS_CTR_DRBG_PERSONALIZATION`
: A personalization string used during CTR-DRBG initialization. This string is mixed with the entropy source during seeding to make the DRBG state as unique as possible.

  Consider customizing this value for your application to add additional uniqueness to the DRBG initialization.

Helper Configuration Options

Devicetree Configuration

The random subsystem uses the `zephyr,entropy` chosen node to identify the hardware entropy device:

```
/ {
    chosen {
        zephyr,entropy = &rng;
    };
};
```

Ensure your board's devicetree correctly specifies this chosen node if your platform has a hardware random number generator.

4.7 Debugging

4.7.1 Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g. thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls `thread_analyzer_run()` or `thread_analyzer_print()`.

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/synchronization/ -- -
↪DCONFIG_QEMU_ICOUNT=n -DCONFIG_THREAD_ANALYZER=y \
-DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
-DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```

When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
 thread_b            : STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %
 thread_analyzer     : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
 thread_a            : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 98 %
 idle                : STACK: unused 204 usage 116 / 320 (36 %); CPU: 0 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:

thread_b: Hello World from cpu 0 on qemu_x86!
```

Configuration

Configure this module using the following options.

`CONFIG_THREAD_ANALYZER`
: Enable the module.

`CONFIG_THREAD_ANALYZER_USE_PRINTK`
: Use printk for thread statistics.

`CONFIG_THREAD_ANALYZER_USE_LOG`
: Use the logger for thread statistics.

`CONFIG_THREAD_ANALYZER_AUTO`
: Run the thread analyzer automatically. You do not need to add any code to the application when using this option.

`CONFIG_THREAD_ANALYZER_AUTO_INTERVAL`
: The time for which the module sleeps between consecutive printing of thread analysis in automatic mode.

`CONFIG_THREAD_ANALYZER_AUTO_STACK_SIZE`
: The stack for thread analyzer automatic thread.

`CONFIG_THREAD_NAME`
: Print the name of the thread instead of its ID.

`CONFIG_THREAD_RUNTIME_STATS`
: Print thread runtime data such as utilization. This options is automatically selected by `CONFIG_THREAD_ANALYZER`.

`CONFIG_THREAD_ANALYZER_LONG_FRAME_PER_INTERVAL`
: Reset Longest Frame value statistics after printing. When using `SCHED_THREAD_USAGE_ANALYSIS` to get average and longest frame thread statistics, reset the Longest Frame value to zero after each time printing the thread statistics. This enables observation of the longest frame during the most recent interval rather than longest frame since startup.

API documentation

Thread analyzer

4.7.2 CPU load

Module can be used to track how much time is spent in idle. It is using tracing hooks which are called before and after CPU goes to idle. Compared to *Thread analyzer* it is more accurate since it takes into account time spent in the interrupt context as well.

Function `cpu_load_get()` is used to get the latest value. It is also used to reset the measurement. By default, module is using `k_cycle_get_32()` but in cases when higher precision is needed a *Counter* device can be used.

Load can also be reported periodically using a logging message. Period is configured using `CONFIG_CPU_LOAD_LOG_PERIODICALLY`.

Using counter device

In order to use *Counter* device `CONFIG_CPU_LOAD_USE_COUNTER` must be enabled and chosen in devicetree must be set.

```
chosen {
  zephyr,cpu-load-counter = &counter_device;
};
```

4.7.3 Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when a fatal error is encountered and prints or stores data according to which backends are enabled.

Configuration

Configure this module using the following options.

- `DEBUG_COREDUMP`: enable the module.

Here are the options to enable output backends for core dump:

- `DEBUG_COREDUMP_BACKEND_LOGGING`: use log module for core dump output.
- `DEBUG_COREDUMP_BACKEND_FLASH_PARTITION`: use flash partition for core dump output.
- `DEBUG_COREDUMP_BACKEND_NULL`: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- `DEBUG_COREDUMP_MEMORY_DUMP_MIN`: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in the debugger. Use this only if absolute minimum of data dump is desired.
- `DEBUG_COREDUMP_MEMORY_DUMP_THREADS`: Dumps the thread struct and stack of all threads and all data required to debug threads.
- `DEBUG_COREDUMP_MEMORY_DUMP_LINKER_RAM`: Dumps the memory region between _image_ram_start[] and _image_ram_end[]. This includes at least data, noinit, and BSS sections. This is the default.

Additional memory can be included in a dump (even with the "DEBUG_COREDUMP_MEMORY_DUMP_MIN" config selected) through one or more *coredump devices*

Usage

When the core dump module is enabled, during a fatal error, CPU registers and memory content are printed or stored according to which backends are enabled. This core dump data can be fed into a custom-made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.
2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, scripts/coredump/coredump_serial_log_parser.py can be used to convert the serial console log into a binary file.
3. Start the custom GDB server using the script scripts/coredump/coredump_gdbserver.py with the core dump binary log file, and the Zephyr ELF file as parameters. The GDB server can also be started from within GDB, see below.
4. Start the debugger corresponding to the target architecture.

Note

Developers for Intel ADSP CAVS 15-25 platforms using `ZEPHYR_TOOLCHAIN_VARIANT=zephyr` should use the debugger in the `xtensa-intel_apl_adsp` toolchain of the SDK.

5. When `DEBUG_COREDUMP_BACKEND_FLASH_PARTITION` is enabled the core dump data is stored in the flash partition. The flash partition must be defined in the device tree:

```
&flash0 {
        partitions {
                coredump_partition: partition@255000 {
                        label = "coredump-partition";
                        reg = <0x255000 DT_SIZE_K(4)>;
                };
};
```

Example This example uses the log module backend tied to serial console. This was done on qemu_x86 where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in `coredump.log`:

```

E: Halting system
```

1. Run the core dump serial log converter:

   ```
   ./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin
   ```

2. Start the custom GDB server:

   ```
   ./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin
   ```

3. Start GDB:

   ```
   <path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb␣
   ↪build/zephyr/zephyr.elf
   ```

4. Inside GDB, connect to the GDB server via port 1234:

   ```
   (gdb) target remote localhost:1234
   ```

5. Examine the CPU registers:

```
(gdb) info registers
```

Output from GDB:

```
eax            0x0                 0
ecx            0x119d74            1154420

es             <unavailable>
fs             <unavailable>
gs             <unavailable>
```

6. Examine the backtrace:

```
(gdb) bt
```

Output from GDB:

```
#0  0x00100459 in func_3 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:14
#1  0x00100477 in func_2 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:21
#2  0x00100492 in func_1 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:28
#3  0x001004c8 in main () at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:42
```

Starting the GDB server from within GDB You can use `target remote |` to start the custom GDB server from inside GDB, instead of in a separate shell.

1. Start GDB:

```
<path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb␣
↪build/zephyr/zephyr.elf
```

2. Inside GDB, start the GDB server using the `--pipe` option:

```
(gdb) target remote | ./scripts/coredump/coredump_gdbserver.py --pipe␣
↪build/zephyr/zephyr.elf coredump.bin
```

File Format

The core dump binary file consists of one file header, one architecture-specific block, zero or one threads metadata block(s), and multiple memory blocks. All numbers in the headers below are little endian.

File Header The file header consists of the following fields:

Table 1: Core dump binary file header

Field	Data Type	Description
ID	`char[2]`	`Z`, `E` as identifier of file.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Target code	`uint16_`	Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.
Pointer size	'uint8_t'	Size of `uintptr_t` in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.
Flags	`uint8_t`	
Fatal error reason	`unsigned int`	Reason for the fatal error, as the same in `enum k_fatal_error_reason` defined in include/zephyr/fatal.h

Architecture-specific Block The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

Table 2: Architecture-specific Block

Field	Data Type	Description
ID	`char`	`A` to indicate this is a architecture-specific block.
Header version	`uint16_`	Identify the version of this block. To be interpreted by the target architecture specific block parser.
Number of bytes	`uint16_`	Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.
Register byte stream	`uint8_t`	Contains target architecture specific data.

Threads Metadata Block The threads metadata block contains the byte stream of data necessary for debugging threads.

Table 3: Threads Metadata Block

Field	Data Type	Description
ID	`char`	`T` to indicate this is a threads metadata block.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Number of bytes	`uint16_`	Number of bytes following the header which contains the byte stream for target data.
Byte stream	`uint8_t`	Contains data necessary for debugging threads.

Memory Block The memory block contains the start and end addresses and the data within the memory region.

Table 4: Memory Block

Field	Data Type	Description
ID	`char`	`M` to indicate this is a memory block.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Start address	`uintptr`	The start address of the memory region.
End address	`uintptr`	The end address of the memory region.
Memory byte stream	`uint8_t`	Contains the memory content between the start and end addresses.

Adding New Target

The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the `enum coredump_tgt_code` in include/zephyr/debug/coredump.h.
2. Implement `arch_coredump_tgt_code_get()` simply to return the newly introduced target code.
3. Implement `arch_coredump_info_dump()` to construct a target architecture block and call `coredump_buffer_output()` to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under `scripts/coredump/gdbstubs/`
    1. Extends the `gdbstubs.gdbstub.GdbStub` class.
    2. During `__init__`, store the GDB signal corresponding to the exception reason in `self.gdb_signal`.
    3. Parse the architecture-specific block from `self.logfile.get_arch_data()`. This needs to match the format as implemented in step 3 (inside `arch_coredump_info_dump()`).
    4. Implement the abstract method `handle_register_group_read_packet` where it returns the register group as GDB expected. Refer to GDB's code and documentation on what it is expecting for the new target.
    5. Optionally implement `handle_register_single_read_packet` for registers not covered in the `g` packet.
5. Extend `get_gdbstub()` in scripts/coredump/gdbstubs/__init__.py to return the newly implemented GDB stub.

4.7.4 GDB stub

- *Overview*
- *Features*

- *Enabling GDB Stub*
  - *Using Serial Backend*
- *Debugging*
  - *Using Serial Backend*
- *Example*

Overview

The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as a client while the Zephyr gdbstub acts as a server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

Features

The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

Enabling GDB Stub

GDB stub can be enabled with the `CONFIG_GDBSTUB` option.

Using Serial Backend The serial backend for GDB stub can be enabled with the `CONFIG_GDBSTUB_SERIAL_BACKEND` option.

Since serial backend utilizes UART devices to send and receive GDB commands,

- If there are spare UART devices on the board, set `zephyr,gdbstub-uart` property of the chosen node to the spare UART device so that `printk()` and log messages are not being printed to the same UART device used for GDB.
- For boards with only one UART device, `printk()` and logging must be disabled if they are also using the same UART device for output. GDB related messages may interleave with log messages which may have unintended consequences. Usually this can be done by disabling `CONFIG_PRINTK` and `CONFIG_LOG`.

Debugging

Using Serial Backend

1. Build with GDB stub and serial backend enabled.
2. Flash built image onto board and reset the board.
   - Execution should now be paused at `gdb_init()`.

3. Execute GDB on development machine and connect to the GDB stub.

   ```
   target remote <serial device>
   ```

   For example,

   ```
   target remote /dev/ttyUSB1
   ```

4. GDB commands can be used to start debugging.

Example

There is a test application tests/subsys/debug/gdbstub with one of its test cases `debug.gdbstub.breakpoints` demonstrating how the Zephyr GDB stub can be used. The test also has a case to connect to the QEMU's GDB stub implementation (at a custom port `tcp:1235`) as a reference to validate the test script itself.

Run the test with the following command from your *ZEPHYR_BASE* directory:

```
./scripts/twister -p qemu_x86 -T tests/subsys/debug/gdbstub
```

The test should run successfully, and now let's do something similar step-by-step to demonstrate how the Zephyr GDB stub works from the GDB user's perspective.

In the snippets below use and expect your appropriate directories instead of `<SDK install directory>`, `<build_directory>`, `<ZEPHYR_BASE>`.

1. Open two terminal windows.
2. On the first terminal, build and run the test application:

   ```
   # From the root of the zephyr repository
   west build -b qemu_x86 tests/subsys/debug/gdbstub -- '-
   ↪DCONFIG_QEMU_EXTRA_FLAGS="-serial tcp:localhost:5678,server"'
   west build -t run
   ```

   Note how we set `CONFIG_QEMU_EXTRA_FLAGS` to direct QEMU serial console port to the `localhost` TCP port `5678` to wait for a connection from the GDB `remote` command we are going to do on the next steps.

3. On the second terminal, start GDB:

   ```
   <SDK install directory>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb
   ```

   1. Tell GDB where to look for the built ELF file:

      ```
      (gdb) symbol-file <build directory>/zephyr/zephyr.elf
      ```

      Response from GDB:

      ```
      Reading symbols from <build directory>/zephyr/zephyr.elf...
      ```

   2. Tell GDB to connect to the Zephyr gdbstub serial backend which is exposed earlier as a server through the TCP port `-serial` redirection at QEMU.

      ```
      (gdb) target remote localhost:5678
      ```

      Response from GDB:

      ```
      Remote debugging using localhost:5678
      arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
      252     }
      ```

GDB also shows where the code execution is stopped. In this case, it is at arch/x86/core/ia32/gdbstub.c, line 252.

3. Use command `bt` or `backtrace` to show the backtrace of stack frames.

```
(gdb) bt
#0  arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
#1  0x00104140 in gdb_init () at
↪<ZEPHYR_BASE>/zephyr/subsys/debug/gdbstub.c:852
#2  0x00109c13 in z_sys_init_run_level (level=INIT_LEVEL_PRE_KERNEL_2) at
↪<ZEPHYR_BASE>/kernel/init.c:360
#3  0x00109e73 in z_cstart () at <ZEPHYR_BASE>/kernel/init.c:630
#4  0x00104422 in z_prep_c (arg=0x1245bc <x86_cpu_boot_arg>) at
↪<ZEPHYR_BASE>/arch/x86/core/prep_c.c:80
#5  0x001000c9 in __csSet () at
↪<ZEPHYR_BASE>/arch/x86/core/ia32/crt0.S:290
#6  0x001245bc in uart_dev ()
#7  0x00134988 in z_interrupt_stacks ()
#8  0x00000000 in ?? ()
```

4. Use command `list` to show the source code and surroundings where code execution is stopped.

```
(gdb) list
247             __asm__ volatile ("int3");
248
249     #ifdef CONFIG_GDBSTUB_TRACE
250             printk("gdbstub:%s GDB is connected\n", __func__);
251     #endif
252     }
253
254     /* Hook current IDT. */
255     _EXCEPTION_CONNECT_NOCODE(z_gdb_debug_isr, IV_DEBUG, 3);
256     _EXCEPTION_CONNECT_NOCODE(z_gdb_break_isr, IV_BREAKPOINT, 3);
```

5. Use command `s` or `step` to step through program until it reaches a different source line. Now that it finished executing `arch_gdb_init()` and is continuing in `gdb_init()`.

```
(gdb) s
gdb_init () at <ZEPHYR_BASE>/subsys/debug/gdbstub.c:857
857     return 0;
```

```
(gdb) list
852             arch_gdb_init();
853
854     #ifdef CONFIG_GDBSTUB_TRACE
855             printk("gdbstub:%s exit\n", __func__);
856     #endif
857             return 0;
858     }
859
860     #ifdef CONFIG_XTENSA
861     /*
```

6. Use command `br` or `break` to setup a breakpoint. For this example set up a breakpoint at `main()`, and let code execution continue without any intervention using command `c` (or `continue`).

```
(gdb) break main
Breakpoint 1 at 0x10064d: file
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c, line 27.
```

```
(gdb) continue
Continuing.
```

Once code execution reaches `main()`, execution will be stopped and GDB prompt returns.

```
Breakpoint 1, main () at
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:27
27              printk("%s():enter\n", __func__);
```

Now GDB is waiting at the beginning of `main()`:

```
(gdb) list
22
23      int main(void)
24      {
25              int ret;
26
27              printk("%s():enter\n", __func__);
28              ret = test();
29              printk("ret=%d\n", ret);
30              return 0;
31      }
```

7. To examine the value of `ret`, the command `p` or `print` can be used.

```
(gdb) p ret
$1 = 1273788
```

Since `ret` has not been initialized, it contains some random value.

8. If step (`s` or `step`) is used here, it will continue execution skipping the interior of `test()`. To examine code execution inside `test()`, a breakpoint can be set for `test()`, or simply using `si` (or `stepi`) to execute one machine instruction, where it has the side effect of going into the function. The GDB command `finish` can be used to continue execution without intervention until the function returns.

```
(gdb) finish
Run till exit from #0  test () at
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:17
0x00100667 in main () at
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:28
28              ret = test();
Value returned is $2 = 30
```

9. Examine `ret` again which should have the return value from `test()`. Sometimes, the assignment is not done until another `step` is issued, as in this case. This is due to the assignment code is done after returning from function. The assignment code is generated by the toolchain as machine instructions which are not visible when viewing the corresponding C source file.

```
(gdb) p ret
$3 = 1273788
(gdb) step
```

(continues on next page)

(continued from previous page)

```
29              printk("ret=%d\n", ret);
(gdb) p ret
$4 = 30
```

10. If `continue` is issued here, code execution will continue indefinitely as there are no breakpoints to further stop execution. Breaking execution in GDB via `Ctrl-C` does not currently work as the Zephyr gdbstub does not support this functionality yet. Switch to the first console with QEMU running the Zephyr image and stop it manually with `Ctrl+a x`. When the same test is executed by Twister, it automatically takes care of stopping the QEMU instance.

4.7.5 Cortex-M Debug Monitor

Monitor mode debugging is a Cortex-M feature, that provides a non-halting approach to debugging. With this it's possible to continue the execution of high-priority interrupts, even when waiting on a breakpoint. This strategy makes it possible to debug time-sensitive software, that would otherwise crash when the core halts (e.g. applications that need to keep communication links alive).

Zephyr provides support for enabling and configuring the Debug Monitor exception. It also contains a ready implementation of the interrupt, which can be used with SEGGER J-Link debuggers.

Configuration

Configure this module using the following options.

- `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`: enable the module. This option, by itself, requires an implementation of debug monitor interrupt that will be executed every time the program enters a breakpoint.

With a SEGGER debug probe, it's possible to use a ready, SEGGER-provided implementation of the interrupt.

- `CONFIG_SEGGER_DEBUGMON`: enables SEGGER debug monitor interrupt. Can be used with SEGGER JLinkGDBServer and a SEGGER debug probe.

Usage

When monitor mode debugging is enabled, entering a breakpoint will not halt the processor, but rather generate an interrupt with ISR implemented under `z_arm_debug_monitor` symbol. `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK` config configures this interrupt to be the lowest available priority, which will allow other interrupts to execute while processor spins on a breakpoint.

Using SEGGER-provided ISR The ready implementation provided with `CONFIG_SEGGER_DEBUGMON` provides functionality required to debug in the monitor mode using regular GDB commands. Steps to configure SEGGER debug monitor:

1. Build a sample with `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`` and `CONFIG_SEGGER_DEBUGMON` configs enabled.
2. Attach JLink GDB server to the target. Example linux command: `JLinkGDBServerCLExe -device <device> -if swd`.
3. Connect to the server with your GDB installation. Example linux command: `arm-none-eabi-gdb --ex="file build/zephyr.elf" --ex="target remote localhost:2331"`.
4. Enable monitor mode debugging in GDB using command: `monitor exec SetMonModeDebug=1`.

After these steps use regular gdb commands to debug your program.

Using other custom ISR In order to provide a custom debug monitor interrupt, override `z_arm_debug_monitor` symbol. Additionally, manual configuration of some registers is required (see debugmon sample).

4.7.6 MIPI STP Decoder

The MIPI System Trace Protocol (MIPI STP) was developed as a generic base protocol that can be shared by multiple application-specific trace protocols. It serves as a wrapper protocol that merges disparate streams that typically contain different trace protocols from different trace sources. Stream consists of opcode (shortest is 4 bit long) followed by optional data and optional timestamp. There are opcodes for data (8, 16, 32, 64 bit data marked/not marked, with or without timestamp), stream recognition (master and channel), synchronization (ASYNC opcode) and others.

One example where protocol is used is ARM Coresight STM (System Trace Macrocell) where data written to Stimulus Port registers maps directly to STP stream.

This module can be used to perform on-chip decoding of the data stream. STP v2 is used.

Usage

Decoder is initialized with a callback. A callback is called on each decoded opcode. Decoder has internal state since there are dependency between opcodes (e.g. timestamp can be relative). Decoder can be in synchronization or not. Initial state is configurable. If decoder is not synchronized to the stream then it decodes each nibble in search for ASYNC opcode. Loss of synchronization can be indicated to the decoder by calling `mipi_stp_decoder_sync_loss()`. `mipi_stp_decoder_decode()` is used to decode the data.

Limitations

There are following limitations:

- Decoder supports only little endian architectures.
- When decoding nibbles, it is more efficient when core supports unaligned memory access. Implementation supports optimized version with unaligned memory access and generic one. Optimized version is used for ARM Cortex-M (expect for M0).
- Limited set of the most common opcodes is implemented.

API documentation

STP Decoder API

4.7.7 Symbol Table (Symtab)

The Symtab module, when enabled, will generate full symbol table during the Zephyr linking stage that keep tracks of the information about the functions' name and address, for advanced application with a lot of functions, this is expected to consume a sizable amount of ROM.

Currently, this is being used to look up the function names during a stack trace in supported architectures.

Usage

Application can gain access to the symbol table data structure by including the `symtab.h` header file and call `symtab_get()`. For now, we only provide `symtab_find_symbol_name()` function to look-up the symbol name and offset of an address. More advanced functionalities and be achieved by directly accessing the members of the data structure.

Configuration

Configure this module using the following options.

- `CONFIG_SYMTAB`: enable the generation of the symbol table.

API documentation

Symbol Table API

4.7.8 ARM Coresight Trace Deformatter

Formatter is a method of wrapping multiple trace streams (specified by 7 bit ID) into a single output stream. Formatter is using 16 byte frames which wraps up to 15 bytes of data. It is used, for example, by ETR (Embedded Trace Router) which is a circular RAM buffer where data from various trace streams can be saved. Typically tracing data is decoded offline by the host but deformatter can be used on-chip to decode the data during application runtime.

Usage

Deformatter is initialized with a user callback. Data is decoded using `cs_trace_defmt_process()` in 16 bytes chunks. Callback is called whenever stream changes or end of chunk is reached. Callback contains stream ID and the data.

API documentation

Coresight Trace Deformatter

4.7.9 Zyclictest

The zyclictest module enables estimation of worst case latencies of realtime threads. It can measure the time from the hardware interrupt to the service routine and further to the Zephyr thread.

This module and its name is inspired from the cyclictest program on Linux. That's why it's a Zephyr cyclictest.

The idea is to use the timer interrupt as interrupt source as we know exactly the point of time when it occurred. In the interrupt service routine we take the time and calculate the difference to the programmed time of the timer interrupt.

Further a thread is also synchronizing itself on the timer and also measures the difference to the programmed timer.

Both times are put into an array which serves as data source of the histogram printed out at the end of the measurement.

This measurement is done in a cyclic manner with a certain interval time.

If someone wants to know the worst case latency of a task with priority <p> then the application needs to be running. While it is running we can start zyclictest with a priority at least one digit less than the application thread probed. For example if our application with the thread of interrest has the priority -10 than we need to start zyclictest with a priority of -11 or less.

Another important argument is the interval time. It's not meant to have an interval less than the measured worst case latency. Therefore it's recommended to set up an interval with at least double the time of the expected or measured worst case latency.

If there are overflows indicated at the end of the measurement than this means that there is no deterministic worst case latency inside the range of the histogram.

For a meaningful output it's recommended to set up CONFIG_SYS_CLOCK_TICKS_PER_SEC to at least 1000000 as this means a minimum resolution of 1 microsecond. A tickless kernel is also needed (CONFIG_TICKLESS_KERNEL:).

Mode of operation

Zyclictest can be started free running without a fixed number of cycles. This is the default. When stopped the result so far is printed out.

In the loop mode (option start with -l <loops>) zyclictest is running for a predefined number of cycles. When the number of cycles is reached there is a message on the shell indicating the end of the test. But the test can be canceled prematurely with zyclictest stop -c.

Configuration

Configure this module using the following options.

- CONFIG_ZYCLICTEST_SHELL: enable the shell command.

Usage

zyclictest start [options]

-i <interval>	Interval in microseconds
-l <loops>	Use loop mode with predefined number of cycles
-p <prio>	Setup priority of Thread

zyclictest stop [options]

-c	Cancel loop mode prematurely
-q	Quiet mode, print summary, but no histogram data

Example

In this example we want to know the worst case latency of a thread which is woken up by an interrupt and running as cooperative task with priority -10. We expect a latency of less then 200 us. We are using the free running mode.

1. Start the zyclictest thread with an interval of 400 us (double of expected worst case latency) and a priority of -11 (one digit higher than the application thread):

```
zyclictest start -i 400 -p -11
```

2. Do whatever should be tested....
3. Stop the measurement:

```
zyclictest stop
```

Output from zyclictest:

```
Count: 547329
                    IRQ  Thread
Max-Latency:         21      27
Errors:               0       0
Overflow:             0       0
Histogram:
[...]
 23                   0  547306
 24                   0       2
```

(continues on next page)

(continued from previous page)

```
 25                   0       5
 26                   0       5
 27                   0       2
 28                   0       0
[...]
```

4. Interpret the result:

   Where are no errors and no overflows which means the measurement can be used. There were 547329 cycles in the test. Worst case interrupt latency is 21 us and for threads it's 27 us.

4.8 Device Management

4.8.1 MCUmgr

Overview

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- Image management
- File System management
- OS management
- Settings (config) management
- Shell management
- Statistic management
- Zephyr management

over the following transports:

- Bluetooth Low Energy (LE)
- Serial (UART)
- UDP over IP

The management subsystem is based on the Simple Management Protocol (SMP) provided by MCUmgr, an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is located in subsys/mgmt/ inside of the Zephyr tree.

Additionally, there is a sample server that provides management functionality over Bluetooth LE and serial.

Tools/libraries

There are various tools and libraries available which enable usage of MCUmgr functionality on a device which are listed below. Note that these tools are not part of or related to the Zephyr project.

Table 5: Tools and Libraries for MCUmgr

Name	OS support	Transports	Groups								Type	Language
			OS	IMG	Stat	Settings	FS	Shell	Enur	Zephyr		
AuTerm	Windows, Linux, macOS	Serial, Bluetooth, UDP, LoRaWAN	✓	✓	✓	✓	✓	✓	✓	✓	App	C++ (Qt)
mcumgr-client	Windows, Linux, macOS	Serial	×	✓	×	×	×	×	×	×	App	Rust
mcumgr-web	Windows, Linux, macOS	Bluetooth	×	✓	×	×	×	×	×	×	Web (chrome only)	Javascript
nRF Connect Device Manager: Android and iOS	iOS, Android	Bluetooth	✓	✓	✓	✓	✓	✓	×	✓	Library, App	Java, Kotlin, Swift
smp	Windows, Linux, macOS, iOS, Android	N/A	✓	✓	✓	✓	✓	✓	✓	✓	Library	Python
smpclient	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	✓	✓	✓	✓	✓	Library	Python
smpmgr	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	×	✓	✓	✓	×	App	Python
mcumgr-toolkit	Windows, Linux, macOS	Serial	✓	✓	×	×	✓	✓	×	✓	Library, App	Rust, Python
Zephyr MCUmgr client (in-tree)	Linux, Zephyr	Serial, Bluetooth, UDP	✓	✓	×	×	×	×	×	×	Library	C

Note that a tick for a particular group indicates basic support for that group in the code, it is possible that not all commands/features of a group are supported by the implementation.

J-Link Virtual MSD Interaction Note

On boards where a J-Link OB is present which has both CDC and MSC (virtual Mass Storage Device, also known as drag-and-drop) support, the MSD functionality can prevent MCUmgr commands over the CDC UART port from working due to how USB endpoints are configured in the J-Link firmware (for example on the nrf52840dk board) because of limiting the maximum packet size (most likely to occur when using image management commands for updating firmware). This issue can be resolved by disabling MSD functionality on the J-Link device, follow the instructions on nordic_segger_msd to disable MSD support.

Bootloader Integration

The *Device Firmware Upgrade* subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See *MCUboot* for more information.

Discord channel

Developers welcome!

API Reference

Management

4.8.2 MCUmgr handlers

Overview

MCUmgr functions by having group handlers which identify a group of functions relating to a specific management area, which is addressed with a 16-bit identification value, `mcumgr_group_t` contains the management groups available in Zephyr with their corresponding group ID values. The group ID is included in SMP headers to identify which group a command belongs to, there is also an 8-bit command ID which identifies the function of that group to execute - see *SMP Protocol Specification* for details on the SMP protocol and header. There can only be one registered group per unique ID.

Implementation

MCUmgr handlers can be added externally by application code or by module code, they do not have to reside in the upstream Zephyr tree to be usable. The first step to creating a handler is to create the folder structure for it, the typical Zephyr MCUmgr group layout is as follows:

```
<dir>/grp/<grp_name>_mgmt/
├── CMakeLists.txt
├── Kconfig
├── include
├──── <grp_name>_mgmt.h
├──── <grp_name>_mgmt_callbacks.h
├── src
└──── <grp_name>_mgmt.c
```

Note that the header files in upstream Zephyr MCUmgr handlers reside in the `zephyr/include/zephyr/mgmt/mcumgr/grp/<grp_name>_mgmt` directory to allow the files to be globally included by applications.

Initial header <grp_name>_mgmt.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_EXAMPLE_MGMT_
#define H_EXAMPLE_MGMT_

#ifdef __cplusplus
extern "C" {
#endif

/**
 * Group ID for example management group.
 */
#define MGMT_GROUP_ID_EXAMPLE  MGMT_GROUP_ID_PERUSER

/**
 * Command IDs for example management group.
 */
#define EXAMPLE_MGMT_ID_TEST   0
#define EXAMPLE_MGMT_ID_OTHER  1

/**
 * Command result codes for example management group.
 */
enum example_mgmt_err_code_t {
        /** No error, this is implied if there is no ret value in the response */
        EXAMPLE_MGMT_ERR_OK = 0,

        /** Unknown error occurred. */
        EXAMPLE_MGMT_ERR_UNKNOWN,

        /** The provided value is not wanted at this time. */
        EXAMPLE_MGMT_ERR_NOT_WANTED,

        /** The provided value was rejected by a hook. */
        EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK,
};

#ifdef __cplusplus
}
#endif

#endif
```

This provides the defines for 2 command `test` and `other` and sets up the SMP version 2 error responses (which have unique error codes per group as opposed to the legacy SMP version 1 error responses that return a `mcumgr_err_t` - there should always be an OK error code with the value 0 and an unknown error code with the value 1. The above example then adds an error code

of `not wanted` with value 2. In addition, the group ID is set to be `MGMT_GROUP_ID_PERUSER`, which is the start group ID for user-defined groups, note that group IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute group IDs more easily.

Initial header <grp_name>_mgmt_callbacks.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#define H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#include <stdint.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#ifdef __cplusplus
extern "C" {
#endif

/* This is the event ID for the example group */
#define MGMT_EVT_GRP_EXAMPLE MGMT_EVT_GRP_USER_CUSTOM_START

/* MGMT event opcodes for example management group */
enum example_mgmt_group_events {
        /* Callback when the other command is received, data is␣
↪example_mgmt_other_data */
        MGMT_EVT_OP_EXAMPLE_OTHER = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_EXAMPLE, 0),

        /* Used to enable all smp_group events */
        MGMT_EVT_OP_EXAMPLE_MGMT_ALL  = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_EXAMPLE),
};

/* Structure provided in the #MGMT_EVT_OP_EXAMPLE_OTHER notification callback */
struct example_mgmt_other_data {
        /* Contains the user supplied value */
        uint32_t user_value;
};

#ifdef __cplusplus
}
#endif

#endif
```

This sets up a single event which application (or module) code can register for to receive a callback when the function handler is executed, which allows the flow of the handler to be changed (i.e. to return an error instead of continuing). The event group ID is set to `MGMT_EVT_GRP_USER_CUSTOM_START`, which is the start event ID for user-defined groups, note that event IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute event IDs more easily.

Initial source <grp_name>_mgmt.c The purpose of this source file is to handle the incoming MCUmgr commands, provide responses, and register the transport with MCUmgr so that commands will be sent to it. An example file would look similar to:

```c
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */

        },
        [EXAMPLE_MGMT_ID_OTHER] = {
                .mh_read = NULL,
                .mh_write = example_mgmt_other,
        },
};

static struct mgmt_group example_mgmt_group = {
        .mg_handlers = example_mgmt_handlers,
        .mg_handlers_count = ARRAY_SIZE(example_mgmt_handlers),
        .mg_group_id = MGMT_GROUP_ID_EXAMPLE,
#ifdef CONFIG_MCUMGR_SMP_SUPPORT_ORIGINAL_PROTOCOL
        .mg_translate_error = example_mgmt_translate_error_code,
#endif
};

static void example_mgmt_register_group(void)
{
        /* This function is called during system init before main() is invoked, if␣
↪the
         * handler needs to set anything up before it can be used, it should do it␣
↪here.
         * This register the group so that clients can call the function handlers.
         */
        mgmt_register_group(&example_mgmt_group);
}

MCUMGR_HANDLER_DEFINE(example_mgmt, example_mgmt_register_group);
```

The above code creates 2 function handlers, `test` which supports read requests and takes 2 required parameters, and `other` which supports write requests and takes 1 optional parameter, this function handler has an optional notification callback feature that allows other parts of the code to listen for the event and take any required actions that are necessary or prevent further execution of the function by returning an error, further details on MCUmgr callback functionality can be found on *MCUmgr Callbacks*.

Note that other code referencing callbacks for custom MCUmgr handlers needs to include both the base Zephyr callback include file and the custom handler callback file, only in-tree Zephyr

handler headers are included when including the upstream Zephyr callback header file.

Initial Kconfig The purpose of the Kconfig file is to provide options which users can enable or change relating to the functionality of the handler being implemented. An example file would look similar to:

```
# Copyright Nordic Semiconductor ASA 2023. All rights reserved.
# SPDX-License-Identifier: Apache-2.0
# The Kconfig file is dedicated to example management group of
# of MCUmgr subsystem and provides Kconfig options to configure
# group commands behaviour and other aspects.
#
# Options defined in this file should be prefixed:
#  MCUMGR_GRP_EXAMPLE_ -- general group options;
#
# When adding Kconfig options, that control the same feature,
# try to group them together by the same stem after prefix.
if MCUMGR

menuconfig MCUMGR_GRP_EXAMPLE_APP
        bool "MCUmgr handlers for example management (app)"
        select MCUMGR_SMP_CBOR_MIN_DECODING_LEVEL_2
        default y
        help
          Enables MCUmgr handlers for example management. This demonstrates the
          file at application-level.

if MCUMGR_GRP_EXAMPLE_APP
config MCUMGR_GRP_EXAMPLE_OTHER_HOOK
        bool "Other hook"
        depends on MCUMGR_MGMT_NOTIFICATION_HOOKS
        help
          Allows applications to receive callback when the "other" example
          management function is called

module = MCUMGR_GRP_EXAMPLE
module-str = mcumgr_grp_example
source "subsys/logging/Kconfig.template.log_config"

endif

endif

source "Kconfig.zephyr"
```

Initial CMakeLists.txt The CMakeLists.txt file is used by the build system to setup files to compile, include directories to add and specify options that can be changed. A basic file only need to include the source files if the Kconfig options are enabled. An example file would look similar to:

Zephyr module

```
# Copyright (c) 2023 Nordic Semiconductor ASA
# SPDX-License-Identifier: Apache-2.0

if(CONFIG_MCUMGR_GRP_EXAMPLE_MODULE)
  zephyr_library()
```

(continues on next page)

(continued from previous page)

```
  # The below should be updated with the real name of the file
  zephyr_library_sources(src/example_mgmt.c)
  zephyr_include_directories(include)
endif()
```

Application

```
if(CONFIG_MCUMGR_GRP_EXAMPLE_APP)
  target_sources(app PRIVATE example_as_module/src/example_mgmt.c)
  zephyr_include_directories(example_as_module/include)
endif()
```

Including from application

Application-specific MCUmgr handlers can be added by creating/editing application build files. Example modifications are shown below.

Example CMakeLists.txt The application `CMakeLists.txt` file can load the CMake file for the example MCUmgr handler by adding the following:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig The application Kconfig file can include the Kconfig file for the example MCUmgr handler by adding the following to the `Kconfig` file in the application directory (or creating it if it does not exist):

```
rsource "mcumgr/grp/<grp_name>/Kconfig"

# Include Zephyr's Kconfig
source "Kconfig.zephyr"
```

Including from Zephyr Module

Zephyr *Modules (External projects)* can be used to add custom MCUmgr handlers to multiple different applications without needing to duplicate the code in each application's source tree, see *Module yaml file description* for details on how to set up the module files. Example files are shown below.

Example zephyr/module.yml This is an example file which can be used to load the Kconfig and CMake files from the root of the module directory, and would be placed at `zephyr/module.yml`:

```
build:
  kconfig: Kconfig
  cmake: .
```

Example CMakeLists.txt This is an example CMakeLists.txt file which loads the CMake file for the example MCUmgr handler, and would be placed at `CMakeLists.txt`:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig This is an example Kconfig file which loads the Kconfig file for the example MCUmgr handler, and would be placed at `Kconfig`:

```
rsource "mcumgr/grp/<grp_name>/Kconfig"
```

Demonstration handler

There is a demonstration project which includes configuration for both application and zephyr module-MCUmgr handlers which can be used as a basis for created your own in tests/subsys/mgmt/mcumgr/handler_demo/.

4.8.3 MCUmgr Callbacks

Overview

MCUmgr has a customisable callback/notification system that allows application (and module) code to receive callbacks for MCUmgr events that they are interested in and react to them or return a status code to the calling function that provides control over if the action should be allowed or not. An example of this is with the fs_mgmt group, whereby file access can be gated, the callback allows the application to inspect the request path and allow or deny access to said file, or it can rewrite the provided path to a different path for transparent file redirection support.

Implementation

Enabling The base callback/notification system can be enabled using CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS which will compile the registration and notification system into the code. This will not provide any callbacks by default as the callbacks that are supported by a build must also be selected by enabling the Kconfig's for the required callbacks (see *Events* for further details). A callback function with the mgmt_cb type definition can then be declared and registered by calling mgmt_callback_register() for the desired event inside of a mgmt_callback structure. Handlers are called in the order that they were registered.

With the system enabled, a basic handler can be set up and defined in application code as per:

```
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    if (event == MGMT_EVT_OP_CMD_DONE) {
        /* This is the event we registered for */
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_CMD_DONE;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the MGMT_EVT_OP_CMD_DONE event, which will be called after a

MCUmgr command has been processed and output generated, note that this requires that CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS be enabled to receive this callback.

Multiple callbacks can be setup to use a single function as a common callback, and many different functions can be used for each event by registering each group once, or all notifications for a whole group can be enabled by using one of the MGMT_EVT_OP_*_ALL events, alternatively a handler can setup for every notification by using MGMT_EVT_OP_ALL. When setting up handlers, events can be combined that are in the same group only, for example 5 img_mgmt callbacks can be setup with a single registration call, but to also setup a callback for an os_mgmt callback, this must be done as a separate registration. Group IDs are numerical increments, event IDs are bitmask values, hence the restriction.

As an example, the following registration is allowed, which will register for 3 SMP events with a single callback function in a single registration:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_CMD_RECV |
                        MGMT_EVT_OP_CMD_STATUS |
                        MGMT_EVT_OP_CMD_DONE);
mgmt_callback_register(&my_callback);
```

The following code is not allowed, and will cause undefined operation, because it mixes the IMG management group with the OS management group whereby the group is **not** a bitmask value, only the event is:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_IMG_MGMT_DFU_STARTED |
                        MGMT_EVT_OP_OS_MGMT_RESET);
mgmt_callback_register(&my_callback);
```

Events Events can be selected by enabling their corresponding Kconfig option:

- **CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS**
  MCUmgr command status (MGMT_EVT_OP_CMD_RECV, MGMT_EVT_OP_CMD_STATUS, MGMT_EVT_OP_CMD_DONE)
- **CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK**
  fs_mgmt file access (MGMT_EVT_OP_FS_MGMT_FILE_ACCESS)
- **CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK**
  img_mgmt upload check (MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK)
- **CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS**
  img_mgmt upload status (MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED, MGMT_EVT_OP_IMG_MGMT_DFU_STARTED, MGMT_EVT_OP_IMG_MGMT_DFU_PENDING, MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED)
- **CONFIG_MCUMGR_GRP_OS_RESET_HOOK**
  os_mgmt reset check (MGMT_EVT_OP_OS_MGMT_RESET)
- **CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK**
  settings_mgmt access (MGMT_EVT_OP_SETTINGS_MGMT_ACCESS)

Actions Some callbacks expect a return status to either allow or disallow an operation, an example is the fs_mgmt access hook which allows for access to files to be allowed or denied. With these handlers, the first non-OK error code returned by a handler will be returned to the MCUmgr client.

An example of selectively denying file access:

```c
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>
#include <string.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    /* Only run this handler if a previous handler has not failed */
    if (event == MGMT_EVT_OP_FS_MGMT_FILE_ACCESS && prev_status == MGMT_CB_OK) {
        struct fs_mgmt_file_access *fs_data = (struct fs_mgmt_file_access *)data;

        /* Check if this is an upload and deny access if it is, otherwise check
         * the path and deny if is matches a name
         */
        if (fs_data->access == FS_MGMT_FILE_ACCESS_WRITE) {
            /* Return an access denied error code to the client and abort calling
             * further handlers
             */
            *abort_more = true;
            *rc = MGMT_ERR_EACCESSDENIED;

            return MGMT_CB_ERROR_RC;
        } else if (strcmp(fs_data->filename, "/lfs1/false_deny.txt") == 0) {
            /* Return a no entry error code to the client, call additional handlers
             * (which will have failed set to true)
             */
            *rc = MGMT_ERR_ENOENT;

            return MGMT_CB_ERROR_RC;
        }
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_FS_MGMT_FILE_ACCESS;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` event, which will be called after a fs_mgmt file read/write command has been received to check if access to the file should be allowed or not, note that this requires that `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` be enabled to receive this callback. Two types of errors can be returned, the `rc` parameter can be set to an `mcumgr_err_t` error code and `MGMT_CB_ERROR_RC` can be returned, or a group error code (introduced with version 2 of the MCUmgr protocol) can be set by setting the `group` value to the group and `rc` value to the group error code and returning `MGMT_CB_ERROR_ERR`.

MCUmgr Command Callback Usage/Adding New Event Types To add a callback to a MCUmgr command, `mgmt_callback_notify()` can be called with the event ID and, optionally, a data struct

to pass to the callback (which can be modified by handlers). If no data needs to be passed back, NULL can be used instead, and size of the data set to 0.

An example MCUmgr command handler:

```
#include <zephyr/kernel.h>
#include <zcbor_common.h>
#include <zcbor_encode.h>
#include <zephyr/mgmt/mcumgr/smp/smp.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#define MGMT_EVT_GRP_USER_ONE MGMT_EVT_GRP_USER_CUSTOM_START

enum user_one_group_events {
    /** Callback on first post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_FIRST  = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 0),

    /** Callback on second post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_SECOND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 1),

    /** Used to enable all user_one events. */
    MGMT_EVT_OP_USER_ONE_ALL    = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_USER_ONE),
};

struct test_struct {
    uint8_t some_value;
};

static int test_command(struct mgmt_ctxt *ctxt)
{
    int rc;
    int err_rc;
    uint16_t err_group;
    zcbor_state_t *zse = ctxt->cnbe->zs;
    bool ok;
    struct test_struct test_data = {
        .some_value = 8,
    };

    rc = mgmt_callback_notify(MGMT_EVT_OP_USER_ONE_FIRST, &test_data,
                              sizeof(test_data), &err_rc, &err_group);

    if (rc != MGMT_CB_OK) {
        /* A handler returned a failure code */
        if (rc == MGMT_CB_ERROR_RC) {
            /* The failure code is the RC value */
            return err_rc;
        }

        /* The failure is a group and ID error value */
        ok = smp_add_cmd_err(zse, err_group, (uint16_t)err_rc);
        goto end;
    }

    /* All handlers returned success codes */
    ok = zcbor_tstr_put_lit(zse, "output_value") &&
         zcbor_int32_put(zse, 1234);
```

(continues on next page)

(continued from previous page)

```
end:
    rc = (ok ? MGMT_ERR_EOK : MGMT_ERR_EMSGSIZE);

    return rc;
}
```

If no response is required for the callback, the function call be called and casted to void.

Migration

If there is existing code using the previous callback system(s) in Zephyr 3.2 or earlier, then it will need to be migrated to the new system. To migrate code, the following callback registration functions will need to be migrated to register for callbacks using `mgmt_callback_register()` (note that `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` will need to be set to enable the new notification system in addition to any migrations):

- **mgmt_evt**
  Using `MGMT_EVT_OP_CMD_RECV`, `MGMT_EVT_OP_CMD_STATUS`, or `MGMT_EVT_OP_CMD_DONE` as drop-in replacements for events of the same name, where the provided data is `mgmt_evt_op_cmd_arg`. `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set.
- **fs_mgmt_register_evt_cb**
  Using `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` where the provided data is `fs_mgmt_file_access`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.
- **img_mgmt_register_callbacks**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_STARTED` if `dfu_started_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED` if `dfu_stopped_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_PENDING` if `dfu_pending_cb` was used or `MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED` if `dfu_confirmed_cb` was used. These callbacks do not have any return status. `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.
- **img_mgmt_set_upload_cb**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK` where the provided data is `img_mgmt_upload_check`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK` needs to be set.
- **os_mgmt_register_reset_evt_cb**
  Using `MGMT_EVT_OP_OS_MGMT_RESET`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set.

4.8.4 SMP Protocol Specification

This is description of Simple Management Protocol, SMP, that is used by MCUmgr to pass requests to devices and receive responses from them.

SMP is an application layer protocol. The underlying transport layer is not in scope of this documentation.

> **Note**
>
> SMP in this context refers to SMP for MCUmgr (Simple Management Protocol), it is unrelated to SMP in Bluetooth (Security Manager Protocol), but there is an MCUmgr SMP transport for Bluetooth.

Frame: The envelope

Each frame consists of a header and data. The `Data Length` field in the header may be used for reassembly purposes if underlying transport layer supports fragmentation. Frames are encoded in "Big Endian" (Network endianness) when fields are more than one byte long, and takes the following form:

3								2								1								0							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
Res			Ver		OP			Flags								Data Length															
Group ID																Sequence Num								Command ID							
Data ...																															

> **Note**
>
> The original specification states that SMP should support receiving both the "Little-endian" and "Big-endian" frames but in reality the MCUmgr library is hardcoded to always treat "Network" side as "Big-endian".

Data is optional and is not present when `Data Length` is zero. The encoding of data depends on the target of group/ID.

A description of the various fields and their meaning:

Field	Description
Res	This is reserved, not-used field and must be always set to 0.
Ver (Version)	This indicates the version of the protocol being used, this should be set to 0b01 to use the newer SMP transport where error codes are more detailed and returned in the map, otherwise left as 0b00 to use the legacy SMP protocol. Versions 0b10 and 0b11 are reserved for future use and should not be used.
OP	mcumgr_op_t, determines whether information is written to a device or requested from it and whether a packet contains request to an SMP server or response from it.
Flags	Reserved for flags; there are no flags defined yet, the field should be set to 0
Data Length	Length of the Data field
Group ID	mcumgr_group_t, see *Management Group ID's* for further details.
Sequence Num	This is a frame sequence number. The number is increased by one with each request frame. The Sequence Num of a response should match the one in the request.
Command ID	This is a command, within Group.
Data	This is data payload of the Data Length size. It is optional as Data Length may be set to zero, which means that no data follows the header.

Note

Contents of Data depends on a value of an OP, a Group ID, and a Command ID.

Management Group ID's The SMP protocol supports predefined common groups and allows user defined groups. The following table presents a list of common groups:

Decimal ID	Group description
0	*Default/OS Management Group*
1	*Application/software image management group*
2	*Statistics management*
3	*Settings (Config) Management Group*
4	Application/system log management (currently not used by Zephyr)
5	Run-time tests (unused by Zephyr)
6	Split image management (unused by Zephyr)
7	Test crashing application (unused by Zephyr)
8	*File management*
9	*Shell management*
63	*Zephyr Management Group*
64	This is the base group for defining an application specific management groups.

The payload for above groups, except for user groups (64 and above) is always CBOR encoded. The group 64, and above can define their own scheme for data communication.

Minimal response

Regardless of a command issued, as long as there is SMP client on the other side of a request, a response should be issued containing the header followed by CBOR map container. Lack of response is only allowed when there is no SMP service or device is non-responsive.

Minimal response SMP data Minimal response is:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note that in the case of a successful command, an empty map will be returned (`rc`/`err` is only returned if there is an error condition, therefore if only an empty map is returned or a response lacks these, the request can be considered as being successful. For SMP version 2, errors relating to SMP itself that are not group specific will still be returned as `rc` errors, SMP version 2 clients must therefore be able to handle both types of errors.

Specifications of management groups supported by Zephyr

Default/OS Management Group OS management group defines following commands:

Command ID	Command description
0	Echo
1	Console/Terminal echo control; unimplemented by Zephyr
2	Task Statistics
3	Memory pool statistics
4	Date-time string
5	System reset
6	MCUMGR parameters
7	OS/Application info
8	Bootloader information

Echo command Echo command responses by sending back string that it has received.

Echo request Echo request header fields:

OP	Group ID	Command ID
0 or 2	0	0

CBOR data of request:

```
{
    (str)"d" : (str)
}
```

where:

“d”	string to be replied by echo service.

Echo response Echo response header fields:

OP	Group ID	Command ID	Note
1	0	0	When request OP was 0
3	0	0	When request OP was 2

CBOR data of successful response:

```
{
    (str)"r"        : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“r”	replying echo string.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Task statistics command The command responds with some system statistics.

Task statistics request Task statistics request header fields:

OP	Group ID	Command ID
0	0	2

The command sends an empty CBOR map as data.

Task statistics response Task statistics response header fields:

OP	Group ID	Command ID
1	0	2

CBOR data of successful response:

```
{
    (str)"tasks" : {
        (str)<task_name> : {
            (str)"prio"          : (uint)
            (str)"tid"           : (uint)
            (str)"state"         : (uint)
            (str)"stkuse"        : (uint)
            (str)"stksiz"        : (uint)
            (str)"cswcnt"        : (uint)
            (str)"runtime"       : (uint)
            (str)"last_checkin" : (uint)
            (str)"next_checkin" : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<task_nam	string identifying task.
“prio”	task priority.
“tid”	numeric task ID.
“state”	numeric task state.
“stkuse”	task’s/thread’s stack usage.
“stksiz”	task’s/thread’s stack size.
“cswcnt”	task’s/thread’s context switches.
“run-time”	task’s/thread’s runtime in “ticks”.
“last_check	set to 0 by Zephyr.
“next_chec	set to 0 by Zephyr.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

The unit for “stkuse” and “stksiz” is system dependent and in case of Zephyr this is number of 4 byte words.

Memory pool statistics The command is used to obtain information on memory pools active in running system.

Memory pool statistic request Memory pool statistics request header fields:

OP	Group ID	Command ID
0	0	3

The command sends an empty CBOR map as data.

Memory pool statistics response Memory pool statistics response header fields:

OP	Group ID	Command ID
1	0	3

CBOR data of successful response:

```
{
    (str)<pool_name> {
        (str)"blksiz"   : (int)
        (str)"nblks"    : (int)
        (str)"nfree"    : (int)
        (str)"min'      : (int)
    }
    ...
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<pool_nam	string representing the pool name, used as a key for dictionary with pool statistics data.
“blksiz”	size of the memory block in the pool.
“nblks”	number of blocks in the pool.
“nfree”	number of free blocks.
“min”	lowest number of free blocks the pool reached during run-time.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time command The command allows to obtain string representing current time-date on a device or set a new time to a device. The time format used, by both set and get operations, is:

“yyyy-MM-dd’T’HH:mm:ss.SSSSSSZZZZZ”

Date-time get The command allows to obtain date-time from a device.

Date-time get request Date-time request header fields:

OP	Group ID	Command ID
0	0	4

The command sends an empty CBOR map as data.

Date-time get response Date-time get response header fields:

OP	Group ID	Command ID
1	0	4

CBOR data of successful response:

```
{
    (str)"datetime" : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“datetime”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time set The command allows to set date-time to a device.

Date-time set request Date-time set request header fields:

OP	Group ID	Command ID
2	0	4

CBOR data of response:

```
{
    (str)"datetime" : (str)
}
```

where:

“datetime”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.

Date-time set response Date-time set response header fields:

OP	Group ID	Command ID
3	0	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

System reset Performs reset of system. The device should issue response before resetting so that the SMP client could receive information that the command has been accepted. By default, this command is accepted in all conditions, however if the `CONFIG_MCUMGR_GRP_OS_RESET_HOOK` is enabled and an application registers a callback, the callback will be called when this command is issued and can be used to perform any necessary tidy operations prior to the module rebooting, or to reject the reset request outright altogether with an error response. For details on this functionality, see *MCUmgr Callbacks*.

System reset request System reset request header fields:

OP	Group ID	Command ID
2	0	5

Normally the command sends an empty CBOR map as data, but if a previous reset attempt has responded with "rc" equal to `MGMT_ERR_EBUSY` then the following map may be sent to force a reset:

```
{
    (opt)"force"        : (int)
    (opt)"boot_mode"    : (uint)
}
```

where:

"force"	Force reset if value > 0, optional if 0.
"boot_mo	Specifies boot mode for image or application mode/selection, requires `CONFIG_MCUMGR_GRP_OS_RESET_BOOT_MODE` to be enabled.

System reset response System reset response header fields

OP	Group ID	Command ID
3	0	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

MCUmgr Parameters Used to obtain parameters of mcumgr library.

MCUmgr Parameters Request MCUmgr parameters request header fields:

OP	Group ID	Command ID
0	0	6

The command sends an empty CBOR map as data.

MCUmgr Parameters Response MCUmgr parameters response header fields

OP	Group ID	Command ID
1	0	6

CBOR data of successful response:

```
{
    (str)"buf_size"     : (uint)
    (str)"buf_count"    : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“buf_size”	Single SMP buffer size, this includes SMP header and CBOR payload.
“buf_count	Number of SMP buffers supported.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

OS/Application Info Used to obtain information on running image, similar functionality to the linux uname command, allowing details such as kernel name, kernel version, build date/time, processor type and application-defined details to be returned. This functionality can be enabled with `CONFIG_MCUMGR_GRP_OS_INFO`.

OS/Application Info Request OS/Application info request header fields:

OP	Group ID	Command ID
0	0	7

CBOR data of request:

```
{
    (str,opt)"format"       : (str)
}
```

where:

“format’	Format specifier of returned response, fields are appended in their natural ascending index order, not the order of characters that are received by the command. Format specifiers: * `s` Kernel name * `n` Node name * `r` Kernel release * `v` Kernel version * `b` Build date and time (requires `CONFIG_MCUMGR_GRP_OS_INFO_BUILD_DATE_TIME`) * `m` Machine * `p` Processor * `i` Hardware platform * `o` Operating system * `a` All fields (shorthand for all above options) If this option is not provided, the `s` Kernel name option will be used.

OS/Application Info Response OS/Application info response header fields

OP	Group ID	Command ID
1	0	7

CBOR data of successful response:

```
{
    (str)"output"       : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“output”	Text response including requested parameters.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information Allows retrieving information about the on-board bootloader and its parameters.

Bootloader Information Request Bootloader information request header:

OP	Group ID	Command ID
0	0	8

CBOR data of request:

```
{
    (str,opt)"query"  : (str)
}
```

where:

“que	Is string representing query for parameters, with no restrictions how the query looks like as processing of query is left for bootloader backend. If there is no query, then response will return string identifying the bootloader.

Bootloader Information Response Bootloader information response header:

OP	Group ID	Command ID
1	0	8

In case when no “query” has been provided in request, CBOR data of response:

```
{
    (str)"bootloader"      : (str)
}
```

where:

“bootloader”	String representing bootloader name

In case when “query” is provided:

```
{
    (str,opt)<response>   : ()
    ...
}
```

where:

<re-spor	Response to “query”. This is optional and may be left out in case when query yields no response, SMP version 2 error code of *OS_MGMT_ERR_QUERY_YIELDS_NO_ANSWER* is expected. Response may have more than one parameter reported back or it may be a map, that is dependent on bootloader backednd and query.
...	Parameter characteristic information.

Parameter may be accompanied by additional, parameter specific, information keywords with assigned values.

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information: MCUboot In case when MCUboot is application bootloader, empty request will be responded with:

```
{
    (str)"bootloader"       : (str)"MCUboot"
}
```

Currently “MCUboot” supports querying for mode of operation:

```
{
    (str)"query"            : (str)"mode"
}
```

Response to “mode” is:

```
{
    (str)"mode"                     : (int)
    (str,opt)"no-downgrade"         : (bool)
}
```

where “mode” is one of:

-1	Unknown mode of MCUboot.
0	MCUboot is in single application mode.
1	MCUboot is in swap using scratch partition mode.
2	MCUboot is in overwrite (upgrade-only) mode.
3	MCUboot is in swap without scratch mode.
4	MCUboot is in DirectXIP without revert mode.
5	MCUboot is in DirectXIP with revert mode.
6	MCUboot is in RAM loader mode.

The `no-downgrade` field is a flag, which is always sent when true, indicating that MCUboot has downgrade prevention enabled; downgrade prevention means that if the uploaded image has a lower version than the currently running application, it will not be used for an update by MCUboot.

MCUmgr may reject images with a lower version in this configuration.

Application/software image management group Application/software image management group defines following commands:

Command ID	Command description
0	State of images
1	Image upload
2	File (reserved but not supported by Zephyr)
3	Corelist (reserved but not supported by Zephyr)
4	Coreload (reserved but not supported by Zephyr)
5	Image erase
6	Slot info

Notion of "slots" and "images" in Zephyr The "slot" and "image" definition comes from mcuboot where "image" would consist of two "slots", further named "primary" and "secondary"; the application is supposed to run from the "primary slot" and update is supposed to be uploaded to the "secondary slot"; the mcuboot is responsible in swapping slots on boot. This means that pair of slots is dedicated to single upgradable application. In case of Zephyr this gets a little bit confusing because DTS will use "slot0_partition" and "slot1_partition", as label of `fixed-partition` dedicated to single application, but will name them as "image-0" and "image-1" respectively.

Currently Zephyr supports at most two images, in which case mapping is as follows:

Image	Slot labels	Slot Names
1	"slot0_partition" "slot1_partition"	"image-0" "image-1"
2	"slot2_partition" "slot3_partition"	"image-2" "image-3"

State of images The command is used to set state of images and obtain list of images with their current state.

Get state of images request Get state of images request header fields:

OP	Group ID	Command ID
0	1	0

The command sends an empty CBOR map as data.

Get state of images response Get state of images response header fields:

OP	Group ID	Command ID
1	1	0

Note

Below definition of the response contains "image" field that has been marked as optional(opt): the field may not appear in response when target application does not support more than one image. The field is mandatory when application supports more than one application image to allow identifying which image information is listed.

A response will only contain information for valid images, if an image can not be identified as valid it is simply skipped.

CBOR data of successful response:

```
{
    (str)"images" : [
        {
            (str,opt)"image"        : (uint)
            (str)"slot"             : (uint)
            (str)"version"          : (str)
            (str,opt*)"hash"        : (byte str)
            (str,opt)"bootable"     : (bool)
            (str,opt)"pending"      : (bool)
            (str,opt)"confirmed"    : (bool)
            (str,opt)"active"       : (bool)
            (str,opt)"permanent"    : (bool)
        }
        ...
    ]
    (str,opt)"splitStatus" : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"image"	semi-optional image number; the field is not required when only one image is supported by the running application.
"slot"	slot number within "image"; each image has two slots : primary (running one) = 0 and secondary (for DFU dual-bank purposes) = 1.
"version"	string representing image version, as set with `imgtool`.
"hash"	SHA256 hash of the image header and body. Note that this will not be the same as the SHA256 of the whole file, it is the field in the MCUboot TLV section that contains a hash of the data which is used for signature verification purposes. This field is optional but only optional when using MCUboot's serial recovery feature with one pair of image slots, Kconfig `CONFIG_BOOT_SERIAL_IMG_GRP_HASH` can be disabled to remove support for hashes in this configuration. MCUmgr in applications must support sending hashes. **Note** See `IMAGE_TLV_SHA256` in the MCUboot image format documentation link below.
"bootable"	true if image has bootable flag set; this field does not have to be present if false.
"pending"	true if image is set for next swap; this field does not have to be present if false.
"confirmed"	true if image has been confirmed; this field does not have to be present if false.
"active"	true if image is currently active application; this field does not have to be present if false.
"permanent"	true if image is to stay in primary slot after the next boot; this does not have to be present if false.
"splitStatus"	states whether loader of split image is compatible with application part; this is unused by Zephyr.
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

Note

For more information on how does image/slots function, please refer to the MCUBoot documentation https://docs.mcuboot.com/design.html#image-slots For information on MCUboot image format, please reset to the MCUboot documentation https://docs.mcuboot.com/design.html#image-format

Set state of image request Set state of image request header fields:

OP	Group ID	Command ID
2	1	0

CBOR data of request:

```
{
    (str,opt)"hash"     : (str)
    (str)"confirm"      : (bool)
}
```

If “confirm” is false or not provided, an image with the “hash” will be set for test, which means that it will not be marked as permanent and upon hard reset the previous application will be restored to the primary slot. In case when “confirm” is true, the “hash” is optional as the currently running application will be assumed as target for confirmation.

Set state of image response The response takes the same format as *Get state of images response*

Image upload The image upload command allows to update application image.

Image upload request The image upload request is sent for each chunk of image that is uploaded, until complete image gets uploaded to a device.

Image upload request header fields:

OP	Group ID	Command ID
2	1	1

CBOR data of request:

```
{
    (str,opt)"image"    : (uint)
    (str,opt)"len"      : (uint)
    (str)"off"          : (uint)
    (str,opt)"sha"      : (byte str)
    (str)"data"         : (byte str)
    (str,opt)"upgrade"  : (bool)
}
```

where:

“image”	optional image number, it does not have to appear in request at all, in which case it is assumed to be 0. Should only be present when “off” is 0.
“len”	optional length of an image. Must appear when “off” is 0.
“off”	offset of image chunk the request carries.
“sha	SHA256 hash of an upload; this is used to identify an upload session (e.g. to allow MCUmgr to continue a broken session), and for image verification purposes. This must be a full SHA256 hash of the whole image being uploaded, or not included if the hash is not available (in which case, upload session continuation and image verification functionality will be unavailable). Should only be present when “off” is 0.
“dat	image data to write at provided offset.
“upgrad	optional flag that states that only upgrade should be allowed, so if the version of uploaded software is not higher then already on a device, the image upload will be rejected. Zephyr compares major, minor and revision (x.y.z) by default unless `CONFIG_MCUMGR_GRP_IMG_VERSION_CMP_USE_BUILD_NUMBER` is set, whereby it will compare build numbers too. Should only be present when “off” is 0.

Note

There is no field representing size of chunk that is carried as “data” because that information is embedded within “data” field itself.

Note

It is possible that a server will respond to an upload with “off” of 0, this may happen if an upload on another transport (or outside of MCUmgr entirely) is started, if the device has re-booted or if a packet has been lost. If this happens, a client must re-send all the required and optional fields that it sent in the original first packet so that the upload state can be re-created by the server. If the original fields are not included, the upload will be unable to continue.

The MCUmgr library uses “sha” field to tag ongoing update session, to be able to continue it in case when it gets broken, and for upload verification purposes. If library gets request with “off” equal zero it checks stored “sha” within its state and if it matches it will respond to update client application with offset that it should continue with. If this hash is not available (e.g. because a file is being streamed) then it must not be provided, image verification and upload session continuation features will be unavailable in this case.

Image upload response Image upload response header fields:

OP	Group ID	Command ID
3	1	1

CBOR data of successful response:

```
{
    (str,opt)"off"    : (uint)
    (str,opt)"match"  : (bool)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

“off”	offset of last successfully written byte of update.
“match”	indicates if the uploaded data successfully matches the provided SHA256 hash or not, only sent in the final packet if `CONFIG_IMG_ENABLE_IMAGE_CHECK` is enabled.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
“rsn”	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

The “off” field is only included in responses to successfully processed requests; if “rc” is negative then “off” may not appear.

Image erase The command is used for erasing image slot on a target device.

> **Note**
>
> This is synchronous command which means that a sender of request will not receive response until the command completes, which can take a long time.

Image erase request Image erase request header fields:

OP	Group ID	Command ID
2	1	5

CBOR data of request:

```
{
    (str,opt)"slot"     : (uint)
}
```

where:

“slot”	optional slot number, it does not have to appear in the request at all, in which case it is assumed to be 1.

Image erase response Image erase response header fields:

OP	Group ID	Command ID
3	1	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
```

(continues on next page)

(continued from previous page)

```
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

Note

Response from Zephyr running device may have "rc" value of `MGMT_ERR_EBADSTATE`, which means that the secondary image has been marked for next boot already and may not be erased.

Slot info The command is used for fetching information on slots that are available. This command can be enabled with `CONFIG_MCUMGR_GRP_IMG_SLOT_INFO`.

Slot info request Slot info request header fields:

OP	Group ID	Command ID
0	1	6

The command sends an empty CBOR map as data.

Slot info response Slot info response header fields:

OP	Group ID	Command ID
1	1	6

CBOR data of successful response:

```
{
    (str)"images" : [
        {
            (str)"image"                        : (uint)
```

(continues on next page)

(continued from previous page)

```
            (str)"slots" : [
                {
                    (str)"slot"                 : (uint)
                    (str)"size"                 : (uint)
                    (str,opt)"upload_image_id"  : (uint)
                }
                ...
            ]
            (str,opt)"max_image_size"           : (uint)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“image”	the image number being enumerated.
“slot”	the slot inside the image being enumerated (note: this will be 0 or 1, it is the slot of the image not the physical slot number).
“size”	the size of the slot.
“upload_im	optional field (only present if `CONFIG_MCUMGR_GRP_IMG_DIRECT_UPLOAD` is enabled to allow direct image uploads) which specifies the image ID that can be used by external tools to upload an image to that slot.
“max_ir	optional field (only present if `CONFIG_MCUMGR_GRP_IMG_TOO_LARGE_SYSBUILD` or `CONFIG_MCUMGR_GRP_IMG_TOO_LARGE_BOOTLOADER_INFO` are enabled) which specifies the maximum size of an application that can be uploaded to that image number.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears ifnon-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Statistics management Statistics management allows to obtain data gathered by Statistics subsystem of Zephyr, enabled with `CONFIG_STATS`.

Statistics management group defines commands:

Command ID	Command description
0	Group data
1	List groups

Statistics: group data The command is used to obtain data for group specified by a name. The name is one of group names as registered, with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function call, within module that gathers the statistics.

Statistics: group data request Statistics group data request header:

OP	Group ID	Command ID
0	2	0

CBOR data of request:

```
{
    (str)"name" :  (str)
}
```

where:

“name”	group name.

Statistics: group data response Statistics group data response header:

OP	Group ID	Command ID
1	2	0

CBOR data of successful response:

```
{
    (str)"name"     : (str)
    (str)"fields"   : {
        (str)<entry_name> : (uint)
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“name”	this is name of group the response contains data for.
“fields”	this is map of entries within groups that consists of pairs where the entry name is mapped to value it represents in statistics.
<entry_name>	single entry to value mapping; value is hardcoded to unsigned integer type, in a CBOR meaning.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Statistics: list of groups The command is used to obtain list of groups of statistics that are gathered on a device. This is a list of names as given to groups with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function calls, within module that gathers the statistics; this means that this command may be considered optional as it is known during compilation what groups will be included into build and listing them is not needed prior to issuing a query.

Statistics: list of groups request Statistics group list request header:

OP	Group ID	Command ID
0	2	1

The command sends an empty CBOR map as data.

Statistics: list of groups response Statistics group list request header:

OP	Group ID	Command ID
1	2	1

CBOR data of successful response:

```
{
    (str)"stat_list" :  [
        (str)<stat_group_name>, ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
```

(continues on next page)

(continued from previous page)

```
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“stat_list”	array of strings representing group names; this array may be empty if there are no groups.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings (Config) Management Group Settings management group (known as Configuration Manager in the original MCUmgr repository) defines the following commands:

Command ID	Command description
0	Read/write setting
1	Delete setting
2	Commit settings
3	Load/Save settings

Note that the Zephyr version adds additional commands and features which are not supported by the original upstream version, however, the original client functionality should work for read/write functionality.

Read/write setting command Read/write setting command allows updating a setting entry on a device or getting the current value of a setting from a device.

Read setting request Read setting request header fields:

OP	Group ID	Command ID
0	3	0

CBOR data of request:

```
{
    (str)"name"         : (str)
    (str,opt)"max_size" : (uint)
}
```

where:

“name”	string of the setting to retrieve
“max_size”	optional maximum size of data to return

Read setting response Read setting response header fields:

OP	Group ID	Command ID
1	3	0

CBOR data of successful response:

```
{
    (str)"val"          : (bstr)
    (str,opt)"max_size" : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“val”	binary string of the returned data, note that the underlying data type cannot be specified through this and must be known by the client.
“max_s	will be set if the maximum supported data size is smaller than the maximum requested data size, and contains the maximum data size which the device supports, equivalent to kconfig:option:*CONFIG_MCUMGR_GRP_SETTINGS_NAME_LEN*.
“err” -> “group	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Write setting request Write setting request header fields:

OP	Group ID	Command ID
2	3	0

CBOR data of request:

```
{
    (str)"name"     : (str)
```

(continues on next page)

(continued from previous page)

```
    (str)"val"      : (bstr)
}
```

where:

“name”	string of the setting to update/set
“val”	value to set the setting to

Write setting response Write setting response header fields:

OP	Group ID	Command ID
3	3	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Delete setting command Delete setting command allows deleting a setting on a device.

Delete setting request Delete setting request header fields:

OP	Group ID	Command ID
2	3	1

CBOR data of request:

```
{
    (str)"name"   : (str)
}
```

where:

“name”	string of the setting to delete

Delete setting response Delete setting response header fields:

OP	Group ID	Command ID
3	3	1

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Commit settings command Commit settings command allows committing all settings that have been set but not yet applied on a device.

Commit settings request Commit settings request header fields:

OP	Group ID	Command ID
2	3	2

The command sends an empty CBOR map as data.

Commit settings response Commit settings response header fields:

OP	Group ID	Command ID
3	3	2

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Load/Save settings command Load/Save settings command allows loading/saving all serialized items from/to persistent storage on a device.

Load settings request Load settings request header fields:

OP	Group ID	Command ID
0	3	3

The command sends an empty CBOR map as data.

Load settings response Load settings response header fields:

OP	Group ID	Command ID
1	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Save settings request Save settings request header fields:

OP	Group ID	Command ID
2	3	3

CBOR data of request:

```
{
    (str,opt)"name" : (str)
}
```

where:

“nan	If provided, contains the settings subtree name to save (can also be a single setting name if `CONFIG_SETTINGS_SAVE_SINGLE_SUBTREE_WITHOUT_MODIFICATION` is enabled), if not then will save all settings.

Save settings response Save settings response header fields:

OP	Group ID	Command ID
3	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings access callback There is a settings access MCUmgr callback available (see *MCUmgr Callbacks* for details on callbacks) which allows for applications/modules to know when settings management commands are used and, optionally, block access (for example through the use of a security mechanism). This callback can be enabled with `CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK`, registered with the event `MGMT_EVT_OP_SETTINGS_MGMT_ACCESS`, whereby the supplied callback data is `settings_mgmt_access`.

File management The file management group provides commands that allow to upload and download files to/from a device.

File management group defines following commands:

Command ID	Command description
0	File download/upload
1	File status
2	File hash/checksum
3	Supported file hash/checksum types
4	File close

File download Command allows to download contents of an existing file from specified path of a target device. Client applications must keep track of data they have already downloaded and where their position in the file is (MCUmgr will cache these also), and issue subsequent requests, with modified offset, to gather the entire file. Request does not carry size of requested chunk, the size is specified by application itself. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File download request File download request header:

OP	Group ID	Command ID
0	8	0

CBOR data of request:

```
{
    (str)"off" :  (uint)
    (str)"name" : (str)
}
```

where:

“off”	offset to start download at
“name”	absolute path to a file

File download response File download response header:

OP	Group ID	Command ID
1	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (byte str)
    (str,opt)"len"  : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“off”	offset the response is for.
“data”	chunk of data read from file; it is CBOR encoded stream of bytes with embedded size; “data” appears only in responses where “rc” is 0.
“len”	length of file, this field is only mandatory when “off” is 0.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File upload Allows to upload a file to a specified location. Command will automatically overwrite existing file or create a new one if it does not exist at specified path. The protocol supports stateless upload where each requests carries different chunk of a file and it is client side responsibility to track progress of upload.

Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached, but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

Weirdly, the current Zephyr implementation is half-stateless as is able to hold single upload context, holding information on ongoing upload, that consists of bool flag indicating in-progress upload, last successfully uploaded offset and total length only.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File upload request File upload request header:

OP	Group ID	Command ID
2	8	0

CBOR data of request:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (str)
    (str)"name"     : (str)
    (str,opt)"len"  : (uint)
}
```

where:

“off”	offset to start/continue upload at.
“data”	chunk of data to write to the file; it is CBOR encoded with length embedded.
“name”	absolute path to a file.
“len”	length of file, this field is only mandatory when “off” is 0.

File upload response File upload response header:

OP	Group ID	Command ID
3	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
}
```

In case of error the CBOR data takes the form:

where:

“off”	offset of last successfully written data.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File status Command allows to retrieve status of an existing file from specified path of a target device.

File status request File status request header:

OP	Group ID	Command ID
0	8	1

CBOR data of request:

```
{
    (str)"name" : (str)
}
```

where:

“name”	absolute path to a file.

File status response File status response header:

OP	Group ID	Command ID
1	8	1

CBOR data of successful response:

```
{
    (str)"len"      : (uint)
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"len"	length of file (in bytes).
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File hash/checksum Command allows to generate a hash/checksum of an existing file at a specified path on a target device. Note that kernel heap memory is required for buffers to be allocated for this to function, and large stack memory buffers are required for generation of the output hash/checksum. Requires `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH` to be enabled for the base functionality, supported hash/checksum are opt-in with `CONFIG_MCUMGR_GRP_FS_CHECKSUM_IEEE_CRC32` or `CONFIG_MCUMGR_GRP_FS_HASH_SHA256`.

File hash/checksum request File hash/checksum request header:

OP	Group ID	Command ID
0	8	2

CBOR data of request:

```
{
    (str)"name"     : (str)
    (str,opt)"type" : (str)
    (str,opt)"off"  : (uint)
    (str,opt)"len"  : (uint)
}
```

where:

"name"	absolute path to a file.
"type"	type of hash/checksum to perform *Hash/checksum types* or omit to use default.
"off"	offset to start hash/checksum calculation at (optional, 0 if not provided).
"len"	maximum length of data to read from file to generate hash/checksum with (optional, full file size if not provided).

Hash/checksum types

String name	Hash/checksum	Byte string	Size (bytes)
crc32	IEEE CRC32 checksum	No	4
sha256	SHA256 (Secure Hash Algorithm)	Yes	32

Note that the default type will be crc32 if it is enabled, or sha256 if crc32 is not enabled.

File hash/checksum response File hash/checksum response header:

OP	Group ID	Command ID
1	8	2

CBOR data of successful response:

```
{
    (str)"type"     : (str)
    (str,opt)"off"  : (uint)
    (str)"len"      : (uint)
    (str)"output"   : (uint or bstr)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“type”	type of hash/checksum that was performed *Hash/checksum types*.
“off”	offset that hash/checksum calculation started at (only present if not 0).
“len”	length of input data used for hash/checksum generation (in bytes).
“output”	output hash/checksum.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Supported file hash/checksum types Command allows listing which hash and checksum types are available on a device. Requires Kconfig `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH_SUPPORTED_CMD` to be enabled.

Supported file hash/checksum types request Supported file hash/checksum types request header:

OP	Group ID	Command ID
0	8	3

The command sends empty CBOR map as data.

Supported file hash/checksum types response Supported file hash/checksum types response header:

OP	Group ID	Command ID
1	8	3

CBOR data of successful response:

```
{
    (str)"types" : {
        (str)<hash_checksum_name> : {
            (str)"format"       : (uint)
            (str)"size"         : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<hash_checksur	name of the hash/checksum type *Hash/checksum types*.
“format”	format that the hash/checksum returns where 0 is for numerical and 1 is for byte array.
“size”	size (in bytes) of output hash/checksum response.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File close Command allows closing any open file handles held by fs_mgmt upload/download requests that might have stalled or be incomplete.

File close request File close request header:

OP	Group ID	Command ID
2	8	4

The command sends empty CBOR map as data.

File close response File close response header:

OP	Group ID	Command ID
3	8	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Shell management Shell management allows passing commands to the shell subsystem over the SMP protocol.

Shell management group defines following commands:

Command ID	Command description
0	Shell command line execute

Shell command line execute The command allows to execute command line in a similar way to typing it into a shell, but both a request and a response are transported over SMP.

Shell command line execute request Execute command request header:

OP	Group ID	Command ID
2	9	0

CBOR data of request:

```
{
    (str)"argv"     : [
        (str)<cmd>
        (str,opt)<arg>
        ...
    ]
}
```

where:

“argv”	array consisting of strings representing command and its arguments.
<cmd>	command to be executed.
<arg>	optional arguments to command.

Shell command line execute response Command line execute response header fields:

OP	Group ID	Command ID
3	9	0

CBOR data of successful response:

```
{
    (str)"o"            : (str)
    (str)"ret"          : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“o”	command output.
“ret”	return code from shell command execution.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

In older versions of Zephyr, “rc” was used for both the mcumgr status code and shell command execution return code, this legacy behaviour can be restored by enabling `CONFIG_MCUMGR_GRP_SHELL_LEGACY_RC_RETURN_CODE`

Enumeration Management Group Enumeration management group defines the following commands:

Command ID	Command description
0	Count of supported groups
1	List supported groups
2	Fetch single group ID
3	Details on supported groups

Count of supported groups command Count of supported groups returns the total number of MCUmgr command groups that a device supports.

Count of supported groups request Read setting request header fields:

OP	Group ID	Command ID
0	10	0

The command sends an empty CBOR map as data.

Count of supported groups response Count of supported groups response header fields:

OP	Group ID	Command ID
1	10	0

CBOR data of successful response:

```
{
    (str)"count"        : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"count"	contains the total number of supported MCUmgr groups on the device.
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

List supported groups command List supported groups command allows listing the group IDs of supported MCUmgr groups on the device.

List supported groups request List supported groups request header fields:

OP	Group ID	Command ID
0	10	1

The command sends an empty CBOR map as data.

List supported groups response List supported groups response header fields:

OP	Group ID	Command ID
1	10	1

CBOR data of successful response:

```
{
    (str)"groups" : [
        (uint)
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“groups”	contains a list of the supported MCUmgr group IDs on the device.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Fetch single group ID command Fetch single group ID command allows listing the group IDs of supported MCUmgr groups on the device, one by one.

Fetch single group ID request Fetch single group ID request header fields:

OP	Group ID	Command ID
0	10	2

CBOR data of request:

```
{
    (str,opt)"index" : (uint)
}
```

where:

“index”	contains the (0-based) index of the group to return information on, can be omitted to return the first group’s details.

Fetch single group ID response Fetch single group ID response header fields:

OP	Group ID	Command ID
1	10	2

CBOR data of successful response:

```
{
    (str)"group"    : (uint)
```

(continues on next page)

(continued from previous page)

```
    (str,opt)"end"  : (bool)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“group”	contains the list of the supported MCUmgr group IDs on the device.
“end”	will be set to true if the listed group is the final supported group on the device, otherwise will be omitted.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on supported groups command Details on supported groups command allows fetching details on each supported MCUmgr group, such as the name and number of handlers. A device can specify an allow list of groups to return details on or details on all groups can be returned.

This command is optional, it can be enabled using `CONFIG_MCUMGR_GRP_ENUM_DETAILS`. The optional name and number of handlers can be enabled/disabled with `CONFIG_MCUMGR_GRP_ENUM_DETAILS_NAME` and `CONFIG_MCUMGR_GRP_ENUM_DETAILS_HANDLERS`.

Details on supported groups request Details on supported groups request header fields:

OP	Group ID	Command ID
0	10	3

Details on all groups

The command sends an empty CBOR map as data.

Details on specified groups

CBOR data of request:

```
{
    (str)"groups" : [
        (uint)
        ...
    ]
}
```

where:

“groups”	contains a list of the MCUmgr group IDs to fetch details on.

Details on supported groups response Details on supported groups response header fields:

OP	Group ID	Command ID
1	10	3

CBOR data of successful response:

```
{
    (str)"groups" : [
        {
            (str)"group"          : (uint)
            (str,opt)"name"       : (str)
            (str,opt)"handlers"   : (uint)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“group”	the group ID of the MCUmgr command group.
“name”	the name of the MCUmgr command group.
“handlers”	the number of handlers that the MCUmgr command group supports.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on supported groups callback There is a details on supported groups MCUmgr callback available (see *MCUmgr Callbacks* for details on callbacks) which allows for applications/modules to add additional fields to this response. This callback can be enabled with `CONFIG_MCUMGR_GRP_ENUM_DETAILS_HOOK`, registered with the event `MGMT_EVT_OP_ENUM_MGMT_DETAILS`, whereby the supplied callback data is `enum_mgmt_detail_output`. Note that `CONFIG_MCUMGR_GRP_ENUM_DETAILS_STATES` will need incrementing by the number of additional extra fields that are added.

Zephyr Management Group Zephyr management group defines the following commands:

Command ID	Command description
0	Erase storage

Erase storage command Erase storage command allows clearing the `storage_partition` flash partition on a device, generally this is used when switching to a new application build if the application uses storage that should be cleared (application dependent).

Erase storage request Erase storage request header fields:

OP	Group ID	Command ID
2	63	0

The command sends sends empty CBOR map as data.

Erase storage response Read setting response header fields:

OP	Group ID	Command ID
3	63	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

4.8.5 SMP Transport Specification

The documents specifies information needed for implementing server and client side SMP transports.

Bluetooth Low Energy (LE)

MCUmgr Clients need to use following Bluetooth Characteristics, when implementing SMP client:

- **Service UUID**: `8D53DC1D-1DB7-4CD3-868B-8A527460AA84`
- **Characteristic UUID**: `DA2E7828-FBCE-4E01-AE9E-261174997C48`

All SMP communication utilizes a single GATT characteristic. An SMP request is sent via a GATT Write Without Response command. An SMP response is sent in the form of a GATT Notification

If an SMP request or response is too large to fit in a single GATT command, the sender fragments it across several packets. No additional framing is introduced when a request or response is fragmented; the payload is simply split among several packets. Since GATT guarantees ordered delivery of packets, the SMP header in the first fragment contains sufficient information for reassembly.

UART/serial and console

SMP protocol specification by MCUmgr subsystem of Zephyr uses basic framing of data to allow multiplexing of UART channel. Multiplexing requires prefixing each frame with two byte marker and terminating it with newline. Currently MCUmgr imposes a 127 byte limit on frame size, although there are no real protocol constraints that require that limit. The limit includes the prefix and the newline character, so the allowed payload size is actually 124 bytes.

Although no such transport exists in Zephyr, it is possible to implement MCUmgr client/server over UART transport that does not have framing at all, or uses hardware serial port control, or other means of framing.

Frame fragmenting SMP protocol over serial is fragmented into MTU size frames; each frame consists of two byte start marker, body and terminating newline character.

There are four types of types of frames: initial, partial, partial-final and initial-final; each frame type differs by start marker and/or body contents.

Frame formats Initial frame requires to be followed by optional sequence of partial frames and finally by partial-final frame. Body is always Base64 encoded, so the body size, here described as MTU - 3, is able to actually carry N = (MTU - 3) / 4 * 3 bytes of raw data.

Body of initial frame is preceded by two byte total packet length, encoded in Big Endian, and equals size of a raw body plus two bytes, size of CRC16; this means that actual body size allowed into an initial frame is N - 2.

If a body size is smaller than N - 4, than it is possible to carry entire body with preceding length and following it CRC in a single frame, here called initial-final; for the description of initial-final frame look below.

Initial frame format:

Content	Size	Description
0x06 0x09	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

<base64-i> is Base64 encoded body of format:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 5	Raw body data fragment

Initial-final frame format is similar to initial frame format, but differs by <base64-i> definition.

<base64-i> of initial-final frame, is Base64 encoded data taking form:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 7	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

Partial frame is continuation after previous initial or other partial frame. Partial frame takes form:

Content	Size	Description
0x04 0x14	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

The <base64-i> of partial frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 3	Raw body data fragment

The <base64-i> of partial-final frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 5	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

CRC Details The CRC16 included in final type frames is calculated over only raw data and does not include packet length. CRC16 polynomial is 0x1021 and initial value is 0.

Raw UART/serial (without console)

In Zephyr, an alternative transport is available for UART which does not use Base64 as the SMP over console transport does, this allows for smaller code size and faster transfers - but cannot be used on devices which have shell or log output on the same UART or are connected to terminals that are displaying ASCII data, as all communication is done using the raw binary SMP protocol.

To use this protocol, use `CONFIG_MCUMGR_TRANSPORT_RAW_UART`, it requires the MCUmgr UART console driver to be enabled in raw mode.

Timeout Because there is no framing when using this transport, it is possible that there might be invalid data received on the UART which causes the system to wait for e.g. a very long packet which is not going to arrive. To prevent this, a timeout system exists whereby if the full packet is not received within a specific timeframe, the whole receive buffer is cleared. It is recommended that this option should be enabled on UART ports, for transports like USB CDC whereby it is a "virtual" UART and the data can be verified before being passed, this option is not needed. The option can be enabled with `CONFIG_MCUMGR_TRANSPORT_RAW_UART_INPUT_TIMEOUT`, the timeout for this can be set with `CONFIG_MCUMGR_TRANSPORT_RAW_UART_INPUT_TIMEOUT_TIME_MS`.

SMP transport

4.8.6 Device Firmware Upgrade

Overview

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- subsys/dfu/boot/: Interface code to bootloaders
- subsys/dfu/img_util/: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

Flash Image The flash image API as part of the Device Firmware Upgrade (DFU) subsystem provides an abstraction on top of Flash Stream to simplify writing firmware image chunks to flash.

API Reference

Flash image API

MCUBoot API The MCUboot API is provided to get version information and boot status of application images. It allows to select application image and boot type for the next boot.

API Reference
MCUboot image control API

Bootloaders

MCUboot Zephyr is directly compatible with the open source, cross-RTOS MCUboot boot loader. It interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted in the MCUboot GitHub Project page.

In order to use MCUboot with Zephyr you need to take the following into account:

1. You will need to define the flash partitions required by MCUboot; see *Flash map* for details.
2. You will have to specify your flash partition as the chosen code partition

```
/ {
   chosen {
      zephyr,code-partition = &slot0_partition;
   };
};
```

3. Your application's `.conf` file needs to enable the `CONFIG_BOOTLOADER_MCUBOOT` Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner
4. You need to build and flash MCUboot itself on your device
5. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader)

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

4.8.7 Over-the-Air Update

Overview

Over-the-Air (OTA) Update is a method for delivering firmware updates to remote devices using a network connection. Although the name implies a wireless connection, updates received over a wired connection (such as Ethernet) are still commonly referred to as OTA updates. This approach requires server infrastructure to host the firmware binary and implement a method of signaling when an update is available. Security is a concern with OTA updates; firmware binaries should be cryptographically signed and verified before upgrading.

The *Device Firmware Upgrade* section discusses upgrading Zephyr firmware using MCUboot. The same method can be used as part of OTA. The binary is first downloaded into an unoccupied code partition, usually named `slot1_partition`, then upgraded using the *MCUboot* process.

Examples of OTA

Golioth Golioth is an IoT management platform that includes OTA updates. Devices are configured to observe your available firmware revisions on the Golioth Cloud. When a new version is available, the device downloads and flashes the binary. In this implementation, the connection between cloud and device is secured using TLS/DTLS, and the signed firmware binary is confirmed by MCUboot before the upgrade occurs.

1. A working sample can be found on the Golioth Firmware SDK repository

2. The Golioth OTA documentation includes complete information about the versioning process

Eclipse hawkBit™ Eclipse hawkBit™ is an update server framework that uses polling on a REST api to detect firmware updates. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is a hawkbit-api sample included in the Zephyr mgmt section.

UpdateHub UpdateHub is a platform for remotely updating embedded devices. Updates can be manually triggered or monitored via polling. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is an updatehub-fota sample included in the Zephyr mgmt section.

SMP Server A Simple Management Protocol (SMP) server can be used to update firmware via Bluetooth Low Energy (LE) or UDP. *MCUmgr* is used to send a signed firmware binary to the remote device where it is verified by MCUboot before the upgrade occurs.

There is an smp-svr sample included in the Zephyr mgmt section.

Lightweight M2M (LWM2M) The *Lightweight M2M (LWM2M)* protocol includes support for firmware update via `CONFIG_LWM2M_FIRMWARE_UPDATE_OBJ_SUPPORT`. Devices securely connect to an LwM2M server using DTLS. A lwm2m-client sample is available but it does not demonstrate the firmware update feature.

mender-mcu mender-mcu enables robust firmware updates on resource-constrained devices by integrating with Zephyr. It implements an Update Module interface and provides a default Update Module that integrates with MCUboot to provide A/B updates. This allows microcontroller units (MCUs) to perform atomic, fail-safe OTA updates with automatic rollback on failure.

See external_module_mender_mcu for integration details and examples.

Memfault and nRF Cloud powered by Memfault Memfault is a IoT observability platform that includes OTA management. Devices check-in with Memfault's service periodically for an OTA update, and when an update is available, download and install the binary.

See external_module_memfault_firmware_sdk for overall integration details and examples.

4.8.8 EC Host Command

Overview

The host command protocol defines the interface for a host, or application processor, to communicate with a target embedded controller (EC). The EC Host command subsystem implements the target side of the protocol, generating responses to commands sent by the host. The host command protocol interface supports multiple versions, but this subsystem implementation only support protocol version 3.

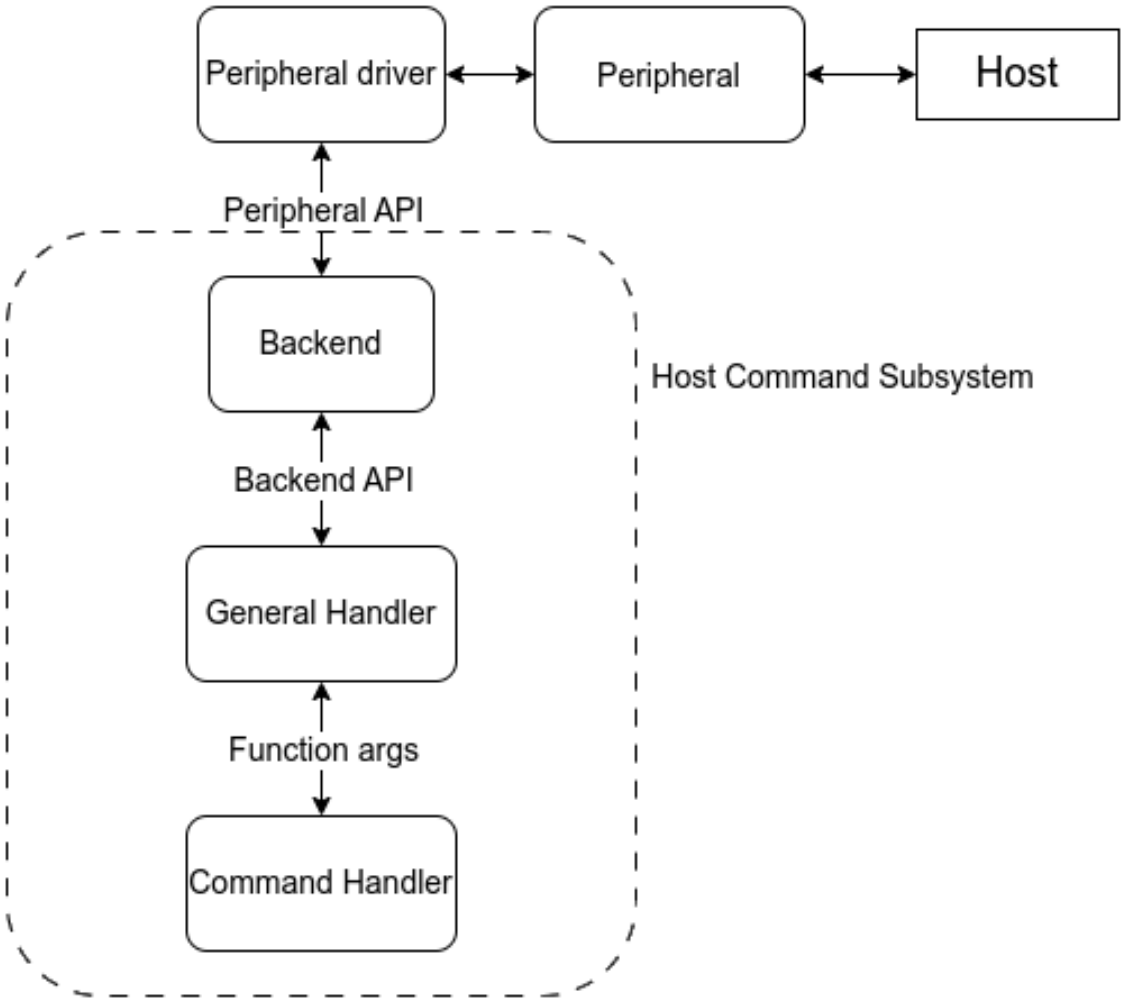
Architecture

The Host Command subsystem contains a few components:

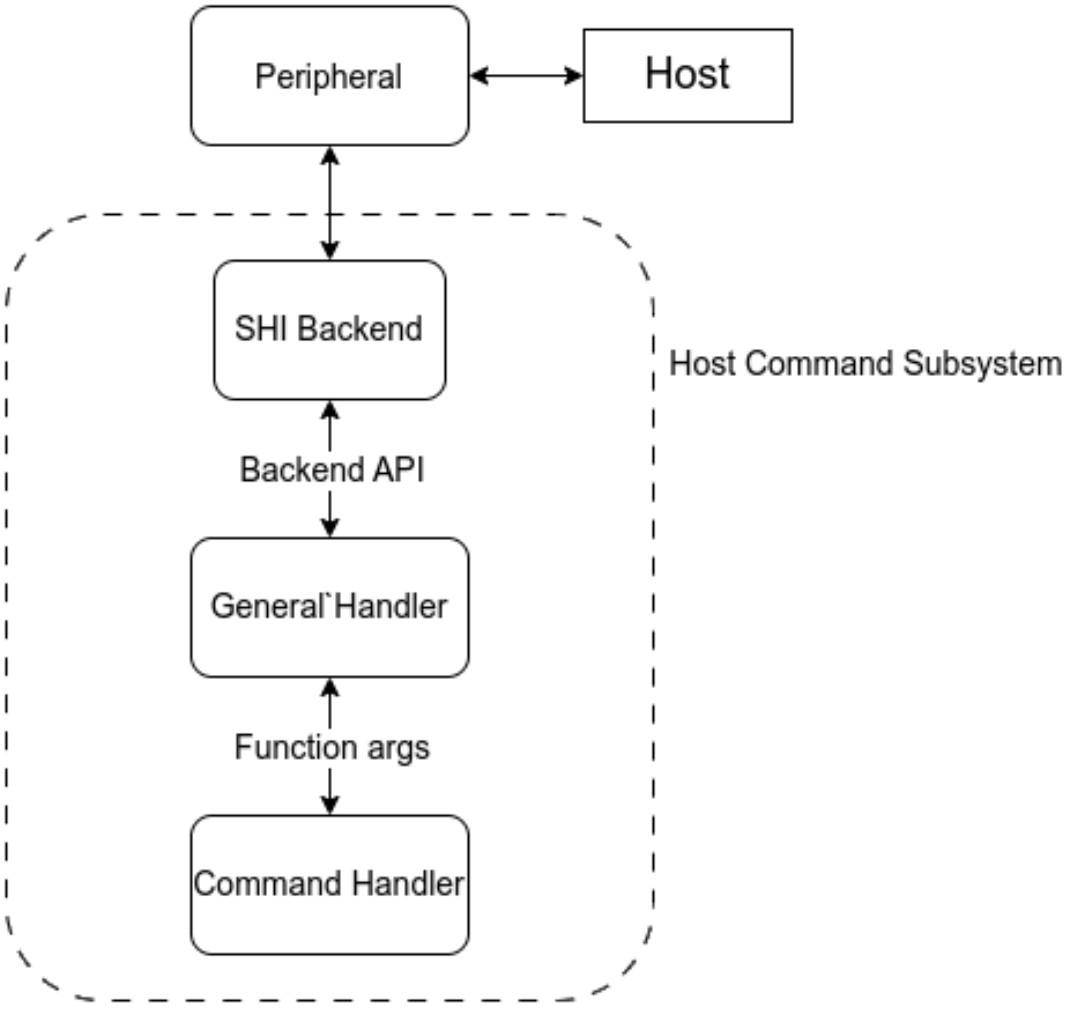
- Backend
- General handler
- Command handler

The backend is a layer between a peripheral driver and the general handler. It is responsible for sending and receiving commands via chosen peripheral.

The general handler validates data from the backend e.g. check sizes, checksum, etc. If the command is valid and the user has provided a handler for a received command id, the command handler is called.



SHI (Serial Host Interface) is different to this because it is used only for communication with a host. SHI does not have API itself, thus the backend and peripheral driver layers are combined into one backend layer.



Another case is SPI. Unfortunately, the current SPI API can't be used to handle the host commands communication. The main issues are unknown command size sent by the host (the SPI transaction sends/receives specific number of bytes) and need to constant sending status byte (the SPI module is enabled and disabled per transaction). It forces implementing the SPI driver within a backend, as it is done for SHI. That means a SPI backend has to be implemented per chip family. However, it can be changed in the future once the SPI API is extended to host command needs. Please check the discussion.

That approach requires configuring the SPI dts node in a special way. The main compatible string of a SPI node has changed to use the Host Command version of a SPI driver. The rest of the properties should be configured as usual. Example of the SPI node for STM32:

```
&spi1 {
        /* Change the compatible string to use the Host Command version of the
         * STM32 SPI driver
         */
        compatible = "st,stm32-spi-host-cmd";
        status = "okay";

        dmas = <&dma2 3 3 0x38440 0x03>,
             <&dma2 0 3 0x38480 0x03>;
        dma-names = "tx", "rx";
        /* This field is used to point at our CS pin */
```

(continues on next page)

(continued from previous page)

```
        cs-gpios = <&gpioa 4 (GPIO_ACTIVE_LOW | GPIO_PULL_UP)>;
};
```

The STM32 SPI host command backend driver supports the `st,stm32h7-spi` and `st,stm32-spi-fifo` variant implementations. To enable these variants, append the corresponding compatible string. For example, to enable FIFO support and support for the STM32H7 SoCs, modify the compatible string as shown.

```
&spi1 {
    compatible = "st,stm32h7-spi", "st,stm32-spi-fifo", "st,stm32-spi-host-cmd";
    ...
};
```

The chip that runs Zephyr is a SPI slave and the `cs-gpios` property is used to point our CS pin. For the SPI, it is required to set the backend chosen node `zephyr,host-cmd-spi-backend`.

The supported backend and peripheral drivers:

- Simulator
- SHI - ITE and NPCX
- eSPI - any eSPI slave driver that support `CONFIG_ESPI_PERIPHERAL_EC_HOST_CMD` and `CONFIG_ESPI_PERIPHERAL_CUSTOM_OPCODE`
- UART - any UART driver that supports the asynchronous API
- SPI - STM32

Initialization

If the application configures one of the following backend chosen nodes and `CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT` is set, then the corresponding backend initializes the host command subsystem by calling `ec_host_cmd_init()`:

- `zephyr,host-cmd-espi-backend`
- `zephyr,host-cmd-shi-backend`
- `zephyr,host-cmd-uart-backend`
- `zephyr,host-cmd-spi-backend`

If no backend chosen node is configured, the application must call the `ec_host_cmd_init()` function directly. This way of initialization is useful if a backend is chosen in runtime based on e.g. GPIO state.

Buffers

The host command communication requires buffers for rx and tx. The buffers are be provided by the general handler if `CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE` > 0 for rx buffer and `CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE` > 0 for the tx buffer. The shared buffers are useful for applications that use multiple backends. Defining separate buffers by every backend would increase the memory usage. However, some buffers can be defined by a peripheral driver e.g. eSPI. These ones should be reused as much as possible.

Logging

The host command has an embedded logging system of the ongoing communication. The are a few logging levels:

- `LOG_INF` is used to log a command id of a new command and not success responses. Repeats of the same command are not logged

- `LOG_DBG` logs every command, even repeats
- `LOG_DBG` + `CONFIG_EC_HOST_CMD_LOG_DBG_BUFFERS` logs every command and responses with the data buffers

API Reference

EC Host Command Interface

4.9 Digital Signal Processing (DSP)

- *Using zDSP*
- *Optimizing for your architecture*
- *API Reference*

The DSP API provides an architecture agnostic way for signal processing. Currently, the API will work on any architecture but will likely not be optimized. The status of the various architectures can be found below:

Architecture	Status
ARC	Optimized
ARM	Optimized
ARM64	Optimized
MIPS	Unoptimized
POSIX	Unoptimized
RISCV	Unoptimized
RISCV64	Unoptimized
SPARC	Unoptimized
X86	Unoptimized
XTENSA	Unoptimized

4.9.1 Using zDSP

zDSP provides various backend options which are selected automatically for the application. By default, including the CMSIS module will enable all architectures to use the zDSP APIs. This can be done by setting:

```
CONFIG_CMSIS_DSP=y
```

If your application requires some additional customization, it's possible to enable `CONFIG_DSP_BACKEND_CUSTOM` which means that the application is responsible for providing the implementation of the zDSP library.

4.9.2 Optimizing for your architecture

If your architecture is showing as `Unoptimized`, it's possible to add a new zDSP backend to better support it. To do that, a new Kconfig option should be added to `subsys/dsp/Kconfig` along with the required dependencies and the `default` set for `DSP_BACKEND` Kconfig choice.

Next, the implementation should be added at `subsys/dsp/<backend>/` and linked in at `subsys/dsp/CMakeLists.txt`. To add architecture-specific attributes, its corresponding Kconfig option should be added to `subsys/dsp/Kconfig` and use them to update `DSP_DATA` and `DSP_STATIC_DATA` in `include/zephyr/dsp/dsp.h`.

4.9.3 API Reference

DSP (Digital Signal Processing)

4.10 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library `*printf()` functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to store the formatted output.

Internal Zephyr API traditionally provided this both for `printk()` and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The `cbprintf()` public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of `s*printf()` C libraries in Zephyr can be converted to `snprintfcb()` to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- `CONFIG_CBPRINTF_FULL_INTEGRAL` or `CONFIG_CBPRINTF_REDUCED_INTEGRAL`
- `CONFIG_CBPRINTF_FP_SUPPORT`
- `CONFIG_CBPRINTF_FP_A_SUPPORT`
- `CONFIG_CBPRINTF_FP_ALWAYS_A`
- `CONFIG_CBPRINTF_N_SPECIFIER`

`CONFIG_CBPRINTF_LIBC_SUBSTS` can be used to provide functions that behave like standard libc functions but use the selected cbprintf formatter rather than pulling in another formatter from libc.

In addition `CONFIG_CBPRINTF_NANO` can be used to revert back to the very space-optimized but limited formatter used for `printk()` before this capability was added.

4.10.1 Cbprintf Packaging

Typically, strings are formatted synchronously when a function from `printf` family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package may contain copies of strings which are part of a format string (format string or any `%s` argument). Package primary content resembles va_list stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as va_list frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can have following variants:

- **Self-contained** - non read-only strings appended to the package. String can be formatted from such package as long as there is access to read-only string locations. Package may contain information where read-only strings are located within the package. That information can be used to convert packet to fully self-contained package.
- **Fully self-contained** - all strings are appended to the package. String can be formatted from such package without any external data.

- **Transient**- only arguments are stored. Package contain information where pointers to non read-only strings are located within the package. Optionally, it may contain read-only string location information. String can be formatted from such package as long as non read-only strings are still valid and read-only strings are accessible. Alternatively, package can be converted to **self-contained** package or **fully self-contained** if information about read-only string locations is present in the package.

Package can be created using two methods:

- runtime - using `cbprintf_package()` or `cbvprintf_package()`. This method scans format string and based on detected format specifiers builds the package.
- static - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has following limitations: requires `_Generic` keyword (C11 feature) to be supported by the compiler and cannot distinguish between `%p` and `%s` if char pointer is used. It treats all (unsigned) char pointers as `%s` thus it will attempt to append string to a package. It can be handled correctly during conversion from **transient** package to **self-contained** package using `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag. However, it requires access to the format string and it is not always possible thus it is recommended to cast char pointers used for `%p` to `void *`. There is a logging warning generated by `cbprintf_package_convert()` called with `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag when char pointer is used with `%p`.

Several Kconfig options control behavior of the packaging:

- `CONFIG_CBPRINTF_PACKAGE_LONGDOUBLE`
- `CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT`

Cbprintf package conversion

It is possible to convert package to a variant which contains more information, e.g **transient** package can be converted to **self-contained**. Conversion to **fully self-contained** package is possible if `CBPRINTF_PACKAGE_ADD_RO_STR_POS` flag was used when package was created.

`cbprintf_package_copy()` is used to calculate space needed for the new package and to copy and convert a package.

Cbprintf package format

Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles *va_list* stack frame. It is followed by data associated with character pointer arguments used by the string which are not appended to the string (but may be appended later by `cbprinf_package_convert()`). Finally, package, optionally, contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

Header sizeof(void *)	1 byte: Argument list size including header and *fmt* (in 32 bit words)
	1 byte: Number of strings appended to the package
	1 byte: Number of read-only string argument locations
	1 byte: Number of transient string argument locations
	platform specific padding to sizeof(void *)
Arguments	Pointer to *fmt* (or null if *fmt* is appended to the package)
	(optional padding for platform specific alignment)
	argument 0
	(optional padding for platform specific alignment)
	argument 1
	...
String location information (optional)	Indexes of words within the package where read-only strings are located
	Pairs of argument index and argument location index where transient strings are located
Appended strings (optional)	1 byte: Index within the package to the location of associated argument
	Null terminated string
	...

Warning

If `CONFIG_MINIMAL_LIBC` is selected in combination with `CONFIG_CBPRINTF_NANO` formatting with C standard library functions like `printf` or `snprintf` is limited. Among other things the `%n` specifier, most format flags, precision control, and floating point are not supported.

Limitations and recommendations

- C11 `_Generic` support is required by the compiler to use static (fast) packaging.
- It is recommended to cast any character pointer used with `%p` format specifier to other pointer type (e.g. `void *`). If format string is not accessible then only static packaging is possible and it will append all detected strings. Character pointer used for `%p` will be considered as string pointer. Copying from unexpected location can have serious consequences (e.g., memory fault or security violation).

4.10.2 API Reference

Formatted Output APIs

4.11 Input

The input subsystem provides an API for dispatching input events from input devices to the application.

4.11.1 Input Events

The subsystem is built around the `input_event` structure. An input event represents a change in an individual event entity, for example the state of a single button, or a movement in a single axis.

The input_event structure describes the specific event, and includes a synchronization bit to indicate that the device reached a stable state, for example when the events corresponding to multiple axes of a multi-axis device have been reported.

4.11.2 Input Devices

An input device can report input events directly using input_report() or any related function; for example buttons or other on-off input entities would use input_report_key().

Complex devices may use a combination of multiple events, and set the sync bit once the output is stable.

The input_report* functions take a device pointer, which is used to indicate which device reported the event and can be used by subscribers to only receive events from a specific device. If there's no actual device associated with the event, it can be set to NULL, in which case only subscribers with no device filter will receive the event.

4.11.3 Application API

An application can register a callback using the INPUT_CALLBACK_DEFINE macro. If a device node is specified, the callback is only invoked for events from the specific device, otherwise the callback will receive all the events in the system. This is the only type of filtering supported, any more complex filtering logic has to be implemented in the callback itself.

The subsystem can operate synchronously or by using an event queue, depending on the CONFIG_INPUT_MODE option. If the input thread is used, all the events are added to a queue and executed in a common input thread. If the thread is not used, the callback are invoked directly in the input driver context.

The synchronous mode can be used in a simple application to keep a minimal footprint, or in a complex application with an existing event model, where the callback is just a wrapper to pipe back the event in a more complex application specific event system.

4.11.4 HID code mapping

A common use case for input devices is to use them to generate HID reports. For this purpose, the input_to_hid_code() and input_to_hid_modifier() functions can be used to map input codes to HID codes and modifiers.

4.11.5 General Purpose Drivers

- adc-keys: for buttons connected to a resistor ladder.
- analog-axis: for absolute position devices connected to an ADC input (thumbsticks, sliders...).
- gpio-kbd-matrix: for GPIO-connected keyboard matrices.
- gpio-keys: for switches directly connected to a GPIO, implements button debouncing.
- gpio-qdec: for GPIO-connected quadrature encoders.
- input-keymap: maps row/col/touch events from a keyboard matrix to key events.
- zephyr,input-longpress: listens for key events, emits events for short and long press.
- zephyr,input-double-tap: listens for key events, emits events for input double taps
- zephyr,lvgl-button-input zephyr,lvgl-encoder-input zephyr,lvgl-keypad-input zephyr,lvgl-pointer-input: listens for input events and translates those to various types of LVGL input devices.

4.11.6 Detailed Driver Documentation

GPIO Keyboard Matrix

The `gpio-kbd-matrix` driver supports a large variety of keyboard matrix hardware configurations and has numerous options to change its behavior. This is an overview of some common setups and how they can be supported by the driver.

The conventional configuration for all of these is that the driver reads on the row GPIOs (inputs) and selects on the columns GPIOs (output).

Base use case, no isolation diodes, interrupt capable GPIOs This is the common configuration found on consumer keyboards with membrane switches and flexible circuit boards, no isolation diodes, requires ghosting detection (which is enabled by default).

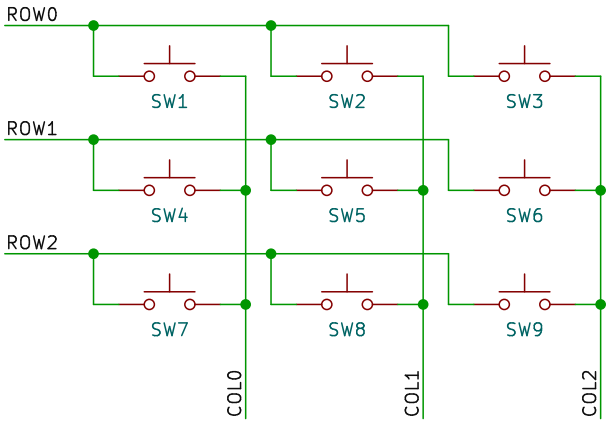


Fig. 1: A 3x3 matrix, no diodes

The system must support GPIO interrupts, and the interrupt can be enabled on all row GPIOs at the same time.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
};
```

In this configuration the matrix scanning library enters idle mode once all keys are released, and the keyboard matrix thread only wakes up when a key has been pressed.

GPIOs for columns that are not currently selected are configured in high impedance mode. This means that the row state may need some time to settle to avoid misreading the key state from a column to the following one. The settle time can be tweaked by changing the `settle-time-us` property.

Isolation diodes If the matrix has isolation diodes for every key, then it's possible to:

- disable ghosting detection, allowing any key combination to be detected
- configuring the driver to drive unselected columns GPIO to inactive state rather than high impedance, this allows to reduce the settle time (potentially down to 0), and use the more efficient port wide GPIO read APIs (happens automatically if the GPIO pins are sequential)

Matrixes with diodes going from rows to columns must use pull-ups on rows and active low columns.

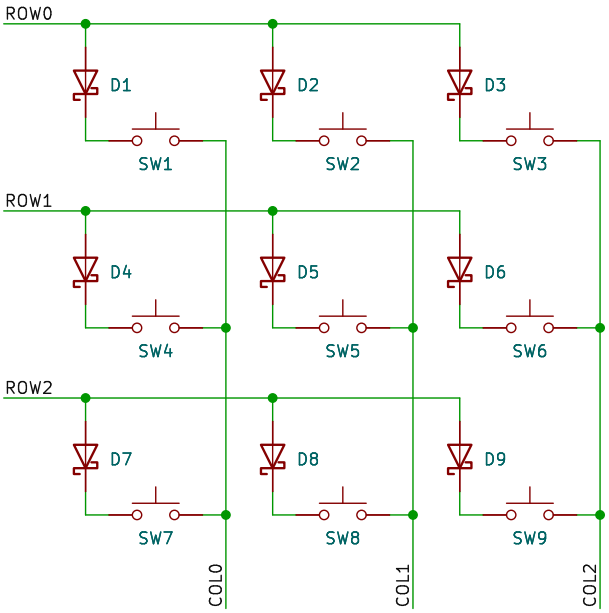

Fig. 2: A 3x3 matrix with row to column isolation diodes.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
     col-drive-inactive;
     settle-time-us = <0>;
     no-ghostkey-check;
};
```

Matrixes with diodes going from columns to rows must use pull-downs on rows and active high columns.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
                 <&gpio0 1 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
                 <&gpio0 2 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_HIGH>,
                 <&gpio0 4 GPIO_ACTIVE_HIGH>,
                 <&gpio0 5 GPIO_ACTIVE_HIGH>;
     col-drive-inactive;
     settle-time-us = <0>;
     no-ghostkey-check;
};
```

GPIO with no interrupt support Some GPIO controllers have limitations on GPIO interrupts, and may not support enabling interrupts on all row GPIOs at the same time.

In this case, the driver can be configured to not use interrupt at all, and instead idle by selecting

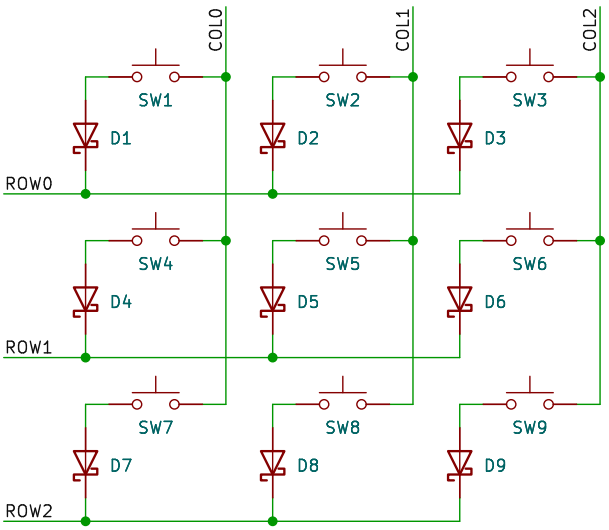

Fig. 3: A 3x3 matrix with column to row isolation diodes.

all columns and keep polling on the row GPIOs, which is a single GPIO API operation if the pins are sequential.

This configuration can be enabled by setting the `idle-mode` property to `poll`:

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     idle-mode = "poll";
};
```

GPIO multiplexer In more extreme cases, such as if the columns are using a multiplexer and it's impossible to select all of them at the same time, the driver can be configured to scan continuously.

This can be done by setting `idle-mode` to `scan` and `poll-timeout-ms` to `0`.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     poll-timeout-ms = <0>;
     idle-mode = "scan";
};
```

Row and column GPIO selection If the row GPIOs are sequential and on the same gpio controller, the driver automatically switches API to read from the whole GPIO port rather than the individual pins. This is particularly useful if the GPIOs are not memory mapped, for example on an I2C or SPI port expander, as this significantly reduces the number of transactions on the corresponding bus.

The same is true for column GPIOs, but only if the matrix is configured for `col-drive-inactive`, so that is only usable for matrixes with isolation diodes.

16-bit row support The driver uses an 8-bit datatype to store the row state by default, which limits the matrix row size to 8. This can be increased to 16 by enabling the `CONFIG_INPUT_KBD_MATRIX_16_BIT_ROW` option.

Actual key mask configuration If the key matrix is not complete, a map of the keys that are actually populated can be specified using the `actual-key-mask` property. This allows the matrix state to be filtered to remove keys that are not present before ghosting detection, potentially allowing key combinations that would otherwise be blocked by it.

For example for a 3x3 matrix missing a key:

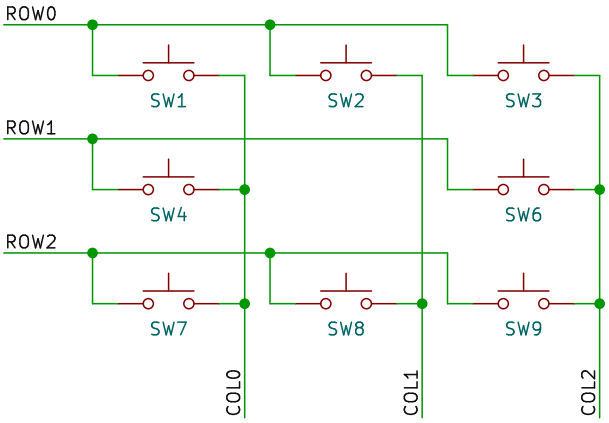

Fig. 4: A 3x3 matrix missing a key.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     actual-key-mask = <0x07 0x05 0x07>;
};
```

This would allow, for example, to detect pressing `Sw1`, `SW2` and `SW4` at the same time without triggering anti ghosting.

The actual key mask can be changed at runtime by enabling `CONFIG_INPUT_KBD_ACTUAL_KEY_MASK_DYNAMIC` and the using the `input_kbd_matrix_actual_key_mask_set()` API.

Keymap configuration Keyboard matrix devices report a series of x/y/touch events. These can be mapped to normal key events using the `input-keymap` driver.

For example, the following would setup a `keymap` device that take the x/y/touch events as an input and generate corresponding key events as an output:

```
kbd {
    ...
    keymap {
        compatible = "input-keymap";
        keymap = <
            MATRIX_KEY(0, 0, INPUT_KEY_1)
            MATRIX_KEY(0, 1, INPUT_KEY_2)
            MATRIX_KEY(0, 2, INPUT_KEY_3)
            MATRIX_KEY(1, 0, INPUT_KEY_4)
            MATRIX_KEY(1, 1, INPUT_KEY_5)
            MATRIX_KEY(1, 2, INPUT_KEY_6)
            MATRIX_KEY(2, 0, INPUT_KEY_7)
            MATRIX_KEY(2, 1, INPUT_KEY_8)
            MATRIX_KEY(2, 2, INPUT_KEY_9)
        >;
        row-size = <3>;
        col-size = <3>;
```

(continues on next page)

(continued from previous page)

```
    };
};
```

Keymap utilities

Keyboard matrix shell commands The shell command `kbd_matrix_state_dump` can be used to test the functionality of any keyboard matrix driver implemented using the keyboard matrix library. Once enabled it logs the state of the matrix every time it changes, and once disabled it prints an or-mask of any key that has been detected, which can be used to set the `actual-key-mask` property.

The command can be enabled using the `CONFIG_INPUT_SHELL_KBD_MATRIX_STATE`.

Example usage:

```
uart:~$ device list
devices:
- kbd-matrix (READY)
uart:~$ input kbd_matrix_state_dump kbd-matrix
Keyboard state logging enabled for kbd-matrix
[00:01:41.678,466] <inf> input: kbd-matrix state [01 -- -- --] (1)
[00:01:41.784,912] <inf> input: kbd-matrix state [-- -- -- --] (0)
...
press more buttons
...
uart:~$ input kbd_matrix_state_dump off
Keyboard state logging disabled
[00:01:47.967,651] <inf> input: kbd-matrix key-mask [07 05 07 --] (8)
```

Keyboard matrix library The GPIO keyboard matrix driver is based on a generic keyboard matrix library, which implements the core functionalities such as scanning delays, debouncing, idle mode etc. This can be reused to implement other keyboard matrix drivers, potentially application specific.

4.12 Instrumentation

4.12.1 Overview

The instrumentation subsystem provides compiler-managed runtime system instrumentation capabilities for Zephyr applications. It enables developers to trace function calls, observe context switches, and profile application performance with minimal manual instrumentation effort.

Unlike the *tracing* subsystem, which provides RTOS-aware tracing with structured event APIs, the instrumentation subsystem works at a lower level by leveraging compiler instrumentation hooks. This approach makes it possible to capture virtually any function entry and exit events without requiring manual tracing calls in the code.

Tracing vs. Instrumentation

When to use Tracing: Choose the tracing subsystem when you need RTOS-aware event tracing (e.g. thread switches, semaphore operations, etc.) and want to minimize overhead.

When to use Instrumentation: Choose instrumentation when you need a detailed view of function-level execution to better understand code flow, or to identify performance bottlenecks without adding manual trace points.

The instrumentation subsystem relies on compiler support for automatic function instrumentation. When enabled, the compiler automatically inserts calls to special instrumentation handler functions at the entry and exit of every function in your application (excluding those explicitly marked with `__no_instrumentation__`). Currently, only GCC is supported with the `-finstrument-functions` compiler flag.

The subsystem initializes automatically after RAM initialization and uses trigger/stopper functions to control when recording is active. The default trigger and stopper functions are both set to `main()` (configurable via Kconfig), meaning instrumentation captures the entire execution from when `main()` starts until it returns.

The recorded data is stored in RAM and can be accessed from a host computer thanks to a UART backend that exposes a set of simple commands. scripts/instrumentation/zaru.py script allows to execute these commands through a high-level command-line interface and makes it easy to obtain data in a format suitable for further analysis (e.g. using Perfetto).

4.12.2 Operational Modes

The instrumentation subsystem supports two modes that can be enabled independently or together:

Callgraph Mode (Tracing)

In callgraph mode (enabled with `CONFIG_INSTRUMENTATION_MODE_CALLGRAPH`), the subsystem records function entry and exit events along with timestamps and context information in a memory buffer. This enables:

- Reconstruction of the complete function call graph
- Observation of thread context switches
- Analysis of execution flow and timing relationships

The trace buffer can operate in ring buffer mode (default, overwrites old entries) or fixed buffer mode (stops when full). Buffer size is configurable via `CONFIG_INSTRUMENTATION_MODE_CALLGRAPH_TRACE_BUFFER_SIZE`.

Listing 1: Example of callgraph mode output. See *zaru.py Usage* for more details.

```
$ ./scripts/instrumentation/zaru.py trace

       ... (truncated) ...
```

Statistical Mode (Profiling)

In statistical mode (enabled with `CONFIG_INSTRUMENTATION_MODE_STATISTICAL`), the subsystem accumulates timing statistics for each unique function executed between the trigger and stopper points. This provides total execution time per function and helps identify performance bottlenecks. The subsystem tracks up to `CONFIG_INSTRUMENTATION_MODE_STATISTICAL_MAX_NUM_FUNC` unique functions.

Listing 2: Example of statistical mode output (top 10 most expensive functions). See *zaru.py Usage* for more details.

```
$ ./scripts/instrumentation/zaru.py profile -n 10

2.67% 0000d361 sys_clock_announce
```

4.12.3 Configuration

Enable instrumentation with:

```
CONFIG_INSTRUMENTATION=y
CONFIG_INSTRUMENTATION_MODE_CALLGRAPH=y    # For tracing
CONFIG_INSTRUMENTATION_MODE_STATISTICAL=y  # For profiling
```

The instrumentation subsystem uses *retained memory* to persist trigger/stopper function addresses across reboots. This must be configured in the devicetree:

```
/ {
    sram@2003FC00 {
        compatible = "zephyr,memory-region", "mmio-sram";
        reg = <0x2003FC00 DT_SIZE_K(1)>;
        zephyr,memory-region = "RetainedMem";

        retainedmem {
            compatible = "zephyr,retained-ram";
            status = "okay";

            instrumentation_triggers: retention@0 {
                compatible = "zephyr,retention";
                status = "okay";
                reg = <0x0 0x10>;
            };
        };
    };
};

/* Adjust main SRAM to exclude retained region */
&sram0 {
    reg = <0x20000000 DT_SIZE_K(255)>;
};
```

See the instrumentation sample for complete configuration examples. Additional options include buffer sizes, trigger functions, and function/file exclusion lists (see Kconfig options starting with `CONFIG_INSTRUMENTATION_*`).

4.12.4 `zaru.py` Usage

The `zaru.py` command-line tool (located in scripts/instrumentation/zaru.py) provides an interface for controlling instrumentation and extracting data from the target over UART.

The tool offers several commands:

- `status`: Check if the target device supports callgraph (tracing) and statistical (profiling) modes.
- `trace`: Capture and display function call traces.
- `profile`: Capture and display function profiling data.
- `reboot`: Reboot the target device.

You can get help for each command by running `zaru.py <command> --help`.

By default, `zaru.py` attempts to connect to the target device using `/dev/ttyACM0`. You can specify a different serial port using the `--serial` option:

```
$ ./scripts/instrumentation/zaru.py --serial /dev/ttyACM1 status
```

The `--build-dir` option can be used to specify the Zephyr build directory, which is needed to locate the ELF file for symbol resolution. If not provided, `zaru.py` will attempt to find it automatically.

See the instrumentation sample documentation for detailed usage instructions.

4.12.5 Limitations and Considerations

Compiler support
: The instrumentation subsystem requires GCC with `-finstrument-functions` support. Other compilers are not supported.

Stack size requirements
: Instrumentation adds overhead to every function call, which increases stack usage. You will likely need to increase thread stack sizes to accommodate the additional space required by instrumentation handlers and nested function calls.

Execution overhead
: All function calls incur instrumentation overhead. Code size will increase due to added instrumentation calls, and performance will be impacted.

Initialization constraints
: Code that runs before RAM initialization (e.g., early boot functions) is not captured as it runs before the instrumentation subsystem is initialized.

To reduce overhead, use trigger/stopper functions to instrument only code regions of interest, and exclude performance-critical functions via `CONFIG_INSTRUMENTATION_EXCLUDE_FUNCTION_LIST` and `CONFIG_INSTRUMENTATION_EXCLUDE_FILE_LIST`.

4.13 Interprocessor Communication (IPC)

4.13.1 IPC service

- *Overview*
- *Simple data exchange*
- *Data exchange using the no-copy API*
- *Backends*
- *API Reference*

- *IPC service API*
- *IPC service backend API*

The IPC service API provides an interface to exchange data between two domains or CPUs.

Overview

An IPC service communication channel consists of one instance and one or several endpoints associated with the instance.

An instance is the external representation of a physical communication channel between two domains or CPUs. The actual implementation and internal representation of the instance is peculiar to each backend.

An individual instance is not used to send data between domains/CPUs. To send and receive the data, the user must create (register) an endpoint in the instance. This allows for the connection of the two domains of interest.

It is possible to have zero or multiple endpoints for one single instance, possibly with different priorities, and to use each to exchange data. Endpoint prioritization and multi-instance ability highly depend on the backend used.

The endpoint is an entity the user must use to send and receive data between two domains (connected by the instance). An endpoint is always associated to an instance.

The creation of the instances is left to the backend, usually at init time. The registration of the endpoints is left to the user, usually at run time.

The API does not mandate a way for the backend to create instances but it is strongly recommended to use the devicetree to retrieve the configuration parameters for an instance. Currently, each backend defines its own DT-compatible configuration that is used to configure the interface at boot time.

The following usage scenarios are supported:

- Simple data exchange.
- Data exchange using the no-copy API.

Simple data exchange

To send data between domains or CPUs, an endpoint must be registered onto an instance.

See the following example:

Note

Before registering an endpoint, the instance must be opened using the `ipc_service_open_instance()` function.

```
#include <zephyr/ipc/ipc_service.h>

static void bound_cb(void *priv)
{
   /* Endpoint bounded */
}

static void recv_cb(const void *data, size_t len, void *priv)
{
```

(continues on next page)

(continued from previous page)

```
    /* Data received */
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
    .cb = {
        .bound    = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    struct ipc_ept ept0;
    int ret;

    inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
    ret = ipc_service_open_instance(inst0);
    ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

    /* Wait for endpoint bound (bound_cb called) */

    unsigned char message[] = "hello world";
    ret = ipc_service_send(&ept0, &message, sizeof(message));
}
```

Data exchange using the no-copy API

If the backend supports the no-copy API you can use it to directly write and read to and from shared memory regions.

See the following example:

```
#include <zephyr/ipc/ipc_service.h>
#include <stdint.h>
#include <string.h>

static struct ipc_ept ept0;

static void bound_cb(void *priv)
{
    /* Endpoint bounded */
}

static void recv_cb_nocopy(const void *data, size_t len, void *priv)
{
    int ret;

    ret = ipc_service_hold_rx_buffer(&ept0, (void *)data);
    /* Process directly or put the buffer somewhere else and release. */
    ret = ipc_service_release_rx_buffer(&ept0, (void *)data);
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
```

(continues on next page)

(continued from previous page)

```
    .cb = {
        .bound    = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    int ret;

    inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
    ret = ipc_service_open_instance(inst0);
    ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

    /* Wait for endpoint bound (bound_cb called) */
    void *data;
    unsigned char message[] = "hello world";
    uint32_t len = sizeof(message);

    ret = ipc_service_get_tx_buffer(&ept0, &data, &len, K_FOREVER);

    memcpy(data, message, len);

    ret = ipc_service_send_nocopy(&ept0, data, sizeof(message));
}
```

Backends

The requirements needed for implementing backends give flexibility to the IPC service. These allow for the addition of dedicated backends having only a subsets of features for specific use cases.

The backend must support at least the following:

- The init-time creation of instances.
- The run-time registration of an endpoint in an instance.

Additionally, the backend can also support the following:

- The run-time deregistration of an endpoint from the instance.
- The run-time closing of an instance.
- The no-copy API.

Each backend can have its own limitations and features that make the backend unique and dedicated to a specific use case. The IPC service API can be used with multiple backends simultaneously, combining the pros and cons of each backend.

ICMsg backend The inter core messaging backend (ICMsg) is a lighter alternative to the heavier RPMsg static vrings backend. It offers a minimal feature set in a small memory footprint. The ICMsg backend is build on top of *Single Producer Single Consumer Packet Buffer*.

Overview The ICMsg backend uses shared memory and MBOX devices for exchanging data. Shared memory is used to store the data, MBOX devices are used to signal that the data has been written.

The backend supports the registration of a single endpoint on a single instance. If the application requires more than one communication channel, you must define multiple instances, each having its own dedicated endpoint.

Configuration The backend is configured via Kconfig and devicetree. When configuring the backend, do the following:

- If at least one of the cores uses data cache on shared memory, set the `dcache-alignment` value. This must be the largest value of the invalidation or the write-back size for both sides of the communication. You can skip it if none of the communication sides is using data cache on shared memory.
- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define MBOX devices which are used to send the signal that informs the other domain (or CPU) that data has been written. Ensure that the other domain (or CPU) is able to receive the signal.

Caution

Make sure that you set correct value of the `dcache-alignment`. At first, wrong value may not show any signs, which may give a false impression that everything works. Unstable behavior will appear sooner or later.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
};

   ipc {
      ipc0: ipc0 {
         compatible = "zephyr,ipc-icmsg";
         dcache-alignment = <32>;
         tx-region = <&tx>;
         rx-region = <&rx>;
         mboxes = <&mbox 0>, <&mbox 1>;
         mbox-names = "tx", "rx";
         status = "okay";
      };
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU) but you must swap the MBOX channels and memory regions (`tx-region` and `rx-region`).

Bonding When the endpoint is registered, the following happens on each domain (or CPU) connected through the IPC instance:

1. The domain (or CPU) writes a magic number to its `tx-region` of the shared memory.

2. It then sends a signal to the other domain or CPU, informing that the data has been written. Sending the signal to the other domain or CPU is repeated with timeout.
3. When the signal from the other domain or CPU is received, the magic number is read from `rx-region`. If it is correct, the bonding process is finished and the backend informs the application by calling `ipc_service_cb.bound` callback.

Samples

- ipc-icmsg

Detailed Protocol Specification The ICMsg uses two shared memory regions and two MBOX channels. The region and channel pair are used to transfer messages in one direction. The other pair is symmetric and transfers messages in the opposite direction. For this reason, the specification below focuses on one such pair. The other pair is identical.

The ICMsg provides just one endpoint per instance.

Shared Memory Region Organization If data caching is enabled, the shared memory region provided to ICMsg must be aligned according to the cache requirement. If cache is not enabled, the required alignment is 4 bytes.

The shared memory region is entirely used by a single FIFO. It contains read and write indexes followed by the data buffer. The detailed structure is contained in the following table:

Field name	Size (bytes)	Byte order	Description
`rd_idx`	4	little-endian	Index of the first incoming byte in the `data` field.
`padding`	depends on cache alignment	n/a	Padding added to align `wr_idx` to the cache alignment.
`wr_idx`	4	little-endian	Index of the byte after the last incoming byte in the `data` field.
`data`	everything to the end of the region	n/a	Circular buffer containing actual bytes to transfer.

This is usual FIFO with a circular buffer:

- The Indexes (`rd_idx` and `wr_idx`) are wrapped around when they reach the end of the `data` buffer.
- The FIFO is empty if `rd_idx == wr_idx`.
- The FIFO has one byte less capacity than the `data` buffer length.

Packets Packets are sent over the FIFO described in the above section. One packet can be wrapped around if it occurs at the end of the FIFO buffer.

The following is the packet structure:

Field name	Size (bytes)	Byte order	Description
`len`	2	big-endian	Length of the `data` field.
`reserved`	2	n/a	Reserved for the future use. It must be 0 for the current protocol version.
`data`	`len`	n/a	Packet data.
`padding`	0-3	n/a	Padding is added to align the total packet size to 4 bytes.

The packet send procedure is the following:

1. Check if the packet fits into the buffer.
2. Write the packet to `data` FIFO buffer starting at `wr_idx`. Wrap it if needed.
3. Write a new value of the `wr_idx`.
4. Notify the receiver over the MBOX channel.

Initialization The initialization sequence is the following:

1. Set the `wr_idx` and `rd_idx` to zero.
2. Push a single packet to FIFO containing magic data: `45 6d 31 6c 31 4b 30 72 6e 33 6c 69 34`. The MBOX is not used yet.
3. Initialize the MBOX.
4. Repeat the notification over the MBOX channel using some interval, for example, 1 ms.
5. Wait for an incoming packet containing the magic data. It will arrive over the other pair (shared memory region and MBOX).
6. Stop repeating the MBOX notification.

After this, the ICMsg is bound, and it is ready to transfer packets.

ICMsg with dynamically allocated buffers backend This backend is built on top of the *ICMsg backend*. Data transferred over this backend travels in dynamically allocated buffers on shared memory. The ICMsg just sends references to the buffers. It also supports multiple endpoints.

This architecture allows for overcoming some common problems with other backends (mostly related to multithread access and zero-copy). This backend provides an alternative with no significant limitations.

Overview The shared memory is divided into two parts. One is reserved for the ICMsg and the other contains equal-sized blocks. The number of blocks is configured in the devicetree.

The data sending process is following:

- The sender allocates one or more blocks. If there are not enough sequential blocks, it waits using the timeout provided in the parameter that also includes K_FOREVER and K_NO_WAIT.
- The allocated blocks are filled with data. For the zero-copy case, this is done by the caller, otherwise, it is copied automatically. During this time other threads are not blocked in any way as long as there are enough free blocks for them. They can allocate, send data and receive data.
- A message containing the block index is sent over ICMsg to the receiver. The size of the ICMsg queue is large enough to hold messages for all blocks, so it will never overflow.
- The receiver can hold the data as long as desired. Again, other threads are not blocked as long as there are enough free blocks for them.
- When data is no longer needed, the backend sends a release message over ICMsg.
- When the backend receives this message, it deallocates all blocks. It is done internally by the backend and it is invisible to the caller.

Configuration The backend is configured using Kconfig and devicetree. When configuring the backend, do the following:

- If at least one of the cores uses data cache on shared memory, set the `dcache-alignment` value. This must be the largest value of the invalidation or the write-back size for both sides of the communication. You can skip it if none of the communication sides is using data cache on shared memory.
- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define the number of allocable blocks for each region with `tx-blocks` and `rx-blocks`.
- Define MBOX devices for sending a signal that informs the other domain (or CPU) of the written data. Ensure that the other domain (or CPU) can receive the signal.

Caution

Make sure that you set correct value of the `dcache-alignment`. At first, wrong value may not show any signs, which may give a false impression that everything works. Unstable behavior will appear sooner or later.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
};

ipc {
   ipc0: ipc0 {
      compatible = "zephyr,ipc-icbmsg";
      dcache-alignment = <32>;
      tx-region = <&tx>;
      rx-region = <&rx>;
      tx-blocks = <16>;
      rx-blocks = <32>;
      mboxes = <&mbox 0>, <&mbox 1>;
      mbox-names = "tx", "rx";
      status = "okay";
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU). Swap the MBOX channels, memory regions (`tx-region` and `rx-region`), and block count (`tx-blocks` and `rx-blocks`).

Samples

- ipc_multi_endpoint

Detailed Protocol Specification The ICBMsg protocol transfers messages using dynamically allocated blocks of shared memory. Internally, it uses ICMsg for control messages.

Shared Memory Organization The ICBMsg uses two shared memory regions, `rx-region` for message receiving, and `tx-region` for message transmission. The regions do not need to be next to each other, placed in any specific order, or be of the same size. Those regions are interchanged on each core.

Each shared memory region is divided into following two parts:

- **ICMsg area** - An area reserved by ICMsg instance and used to transfer the control messages.
- **Blocks area** - An area containing allocatable blocks carrying the content of the messages. This area is divided into even-sized blocks aligned to cache boundaries.

The location of each area is calculated to fulfill cache boundary requirements and allow optimal region usage. It is calculated using the following algorithm:

Inputs:

- `region_begin`, `region_end` - Boundaries of the region.
- `local_blocks` - Number of blocks in this region.
- `remote_blocks` - Number of blocks in the opposite region.
- `alignment` - Memory cache alignment.

The algorithm:

1. Align region boundaries to cache:
   - `region_begin_aligned = ROUND_UP(region_begin, alignment)`
   - `region_end_aligned = ROUND_DOWN(region_end, alignment)`
   - `region_size_aligned = region_end_aligned - region_begin_aligned`
2. Calculate the minimum size required for ICMsg area `icmsg_min_size`, which is a sum of:
   - ICMsg header size (refer to the ICMsg specification)
   - ICMsg message size for 4 bytes of content (refer to the ICMsg specification) multiplied by `local_blocks + remote_blocks + 2`
3. Calculate available size for block area. Note that the actual size may be smaller because of block alignment:

   ```
   blocks_area_available_size = region_size_aligned - icmsg_min_size
   ```

4. Calculate single block size:

   ```
   block_size = ROUND_DOWN(blocks_area_available_size / local_blocks, alignment)
   ```

5. Calculate actual block area size:

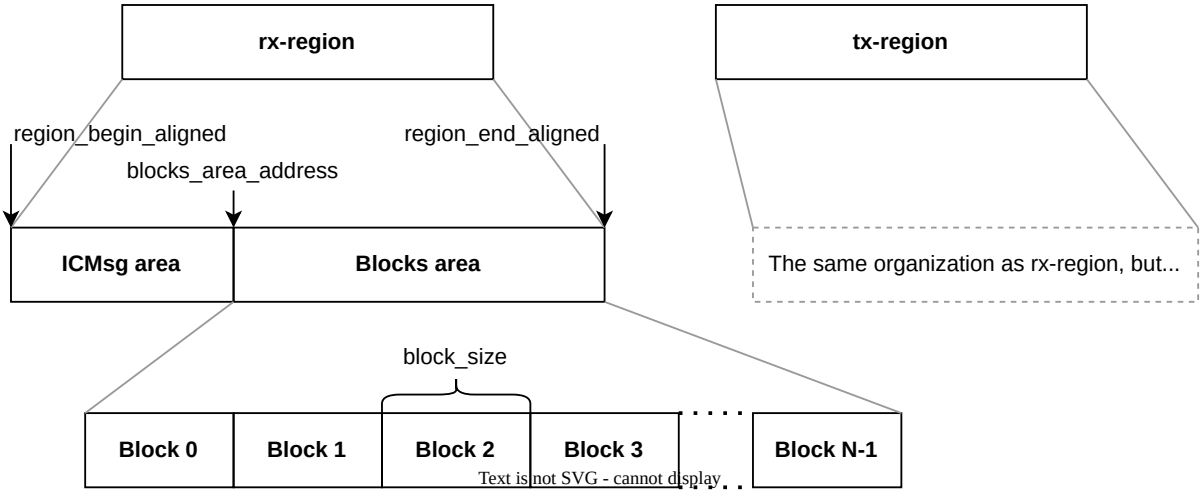
   ```
   blocks_area_size = block_size * local_blocks
   ```

6. Calculate block area start address:

   ```
   blocks_area_begin = region_end_aligned - blocks_area_size
   ```

The result:

- `region_begin_aligned` - The start of ICMsg area.
- `blocks_area_begin` - End of ICMsg area and the start of block area.
- `block_size` - Single block size.
- `region_end_aligned` - End of blocks area.

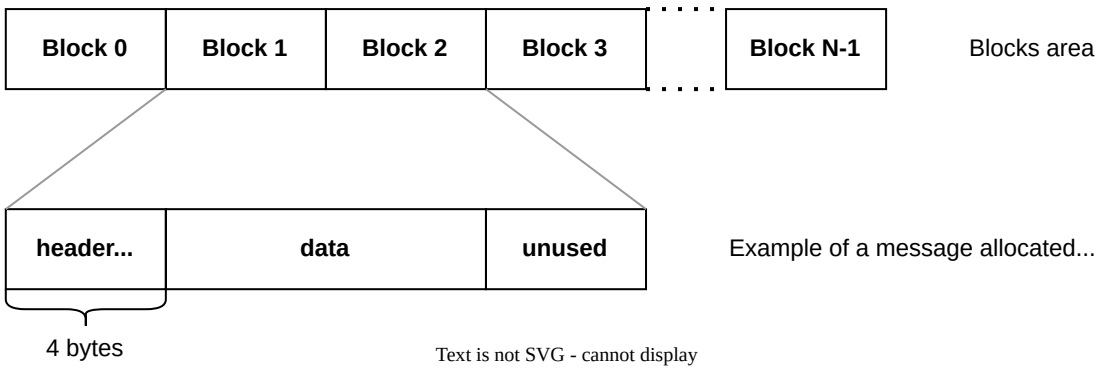


Message Transfer The ICBMsg uses following two types of messages:

- **Binding message** - Message exchanged during endpoint binding process (described below).
- **Data message** - Message carrying actual data from a user.

They serve different purposes, but their lifetime and flow are the same. The following steps describe it:

1. The sender wants to send a message that contains `K` bytes.
2. The sender reserves blocks from his `tx-region` blocks area that can hold at least `K + 4` bytes. The additional `+ 4` bytes are reserved for the header, which contains the exact size of the message. The blocks must be continuous (one after another). The sender is responsible for block allocation management. It is up to the implementation to decide what to do if no blocks are available.
3. The sender fills the header with a 32-bit integer value, `K` (little-endian).
4. The sender fills the remaining part of the blocks with his data. Unused space is ignored.
5. The sender sends an `MSG_DATA` or `MSG_BOUND` control message over ICMsg that contains starting block number (where the header is located). Details about the control message are in the next section.
6. The control message travels to the receiver.
7. The receiver reads message size and data from his `rx-region` starting from the block number received in the control message.
8. The receiver processes the message.
9. The receiver sends `MSG_RELEASE_DATA` or `MSG_RELEASE_BOUND` control message over ICMsg containing the starting block number (the same as inside received control message).
10. The control message travels back to the sender.
11. The sender releases the blocks starting from the block number provided in the control message. The number of blocks to release can be calculated using a size from the header.



Control Messages The control messages are transmitted over ICMsg. Each control message contains three bytes. The first byte tells what kind of message it is.

The allocated size for ICMsg ensures that the maximum possible number of control messages will fit into its ring buffer, so sending over the ICMsg will never fail because of buffer overflow.

MSG_DATA

byte 0	byte 1	byte 2
MSG_DATA	endpoint address	block number
0x00	0x00 ÷ 0xFD	0x00 ÷ N-1

The `MSG_DATA` control message indicates that a new data message was sent. The data message starts with a header inside `block number`. The data message was sent over the endpoint specified in `endpoint address`. The endpoint binding procedure must be finished before sending this control message.

MSG_RELEASE_DATA

byte 0	byte 1	byte 2
MSG_RELEASE_DATA	unused	block number
0x01		0x00 ÷ N-1

The `MSG_RELEASE_DATA` control message is sent in response to `MSG_DATA`. It informs us that the data message starting with `block number` was received and is no longer needed. When this control message is received, the blocks containing the message must be released.

MSG_BOUND

byte 0	byte 1	byte 2
MSG_BOUND	endpoint address	block number
0x02	0x00 ÷ 0xFD	0x00 ÷ N-1

The `MSG_BOUND` control message is similar to the `MSG_DATA` except the blocks carry binding information. See the next section for details on the binding procedure.

MSG_RELEASE_BOUND

byte 0	byte 1	byte 2
MSG_RELEASE_BOUND	endpoint address	block number
0x03	0x00 ÷ 0xFD	0x00 ÷ N-1

The MSG_RELEASE_BOUND control message is sent in response to MSG_BOUND. It is similar to the MSG_RELEASE_DATA except the endpoint address is required. See the next section for details on the binding procedure.

Initialization The ICBMsg initialization calls ICMsg to initialize. When it is done, no further initialization is required. Blocks can be left uninitialized.

After ICBMsg initialization, you are ready for the endpoint binding procedure.

Endpoint Binding So far, the protocol is symmetrical. Each side of the connection was the same. The binding process is not symmetrical. There are following two roles:

- **Initiator** - It assigns endpoint addresses and sends binding messages.
- **Follower** - It waits for a binding message.

The roles are determined based on the addresses of the rx-region and tx-region.

- If address of rx-region < address of tx-region, then it is initiator.
- If address of rx-region > address of tx-region, then it is follower.

The binding process needs an endpoint name and is responsible for following two things:

- To establish a common endpoint address,
- To make sure that two sides are ready to exchange messages over that endpoint.

After ICMsg is initialized, both sides can start the endpoint binding. There are no restrictions on the order in which the sides start the endpoint binding.

Initiator Binding Procedure The initiator sends a binding message. It contains a single null-terminated string with an endpoint name. As usual, it is preceded by a message header containing the message size (including null-terminator).

Example of the binding message for example endpoint name:

Header	Endpoint name	Null-terminator
bytes 0-3	bytes 4-10	byte 11
0x00000008	example	0x00

The binding message is sent using the MSG_BOUND control message and released with the MSG_RELEASE_BOUND control message.

The endpoint binding procedure from the initiator's point of view is the following:

1. The initiator assigns an endpoint address to this endpoint.
2. The initiator sends a binding message containing the endpoint name and address.
3. The initiator waits for any message from the follower using this endpoint address. Usually, it will be MSG_RELEASE_BOUND, but MSG_DATA is also allowed.
4. The initiator is bound to an endpoint, and it can send data messages using this endpoint.

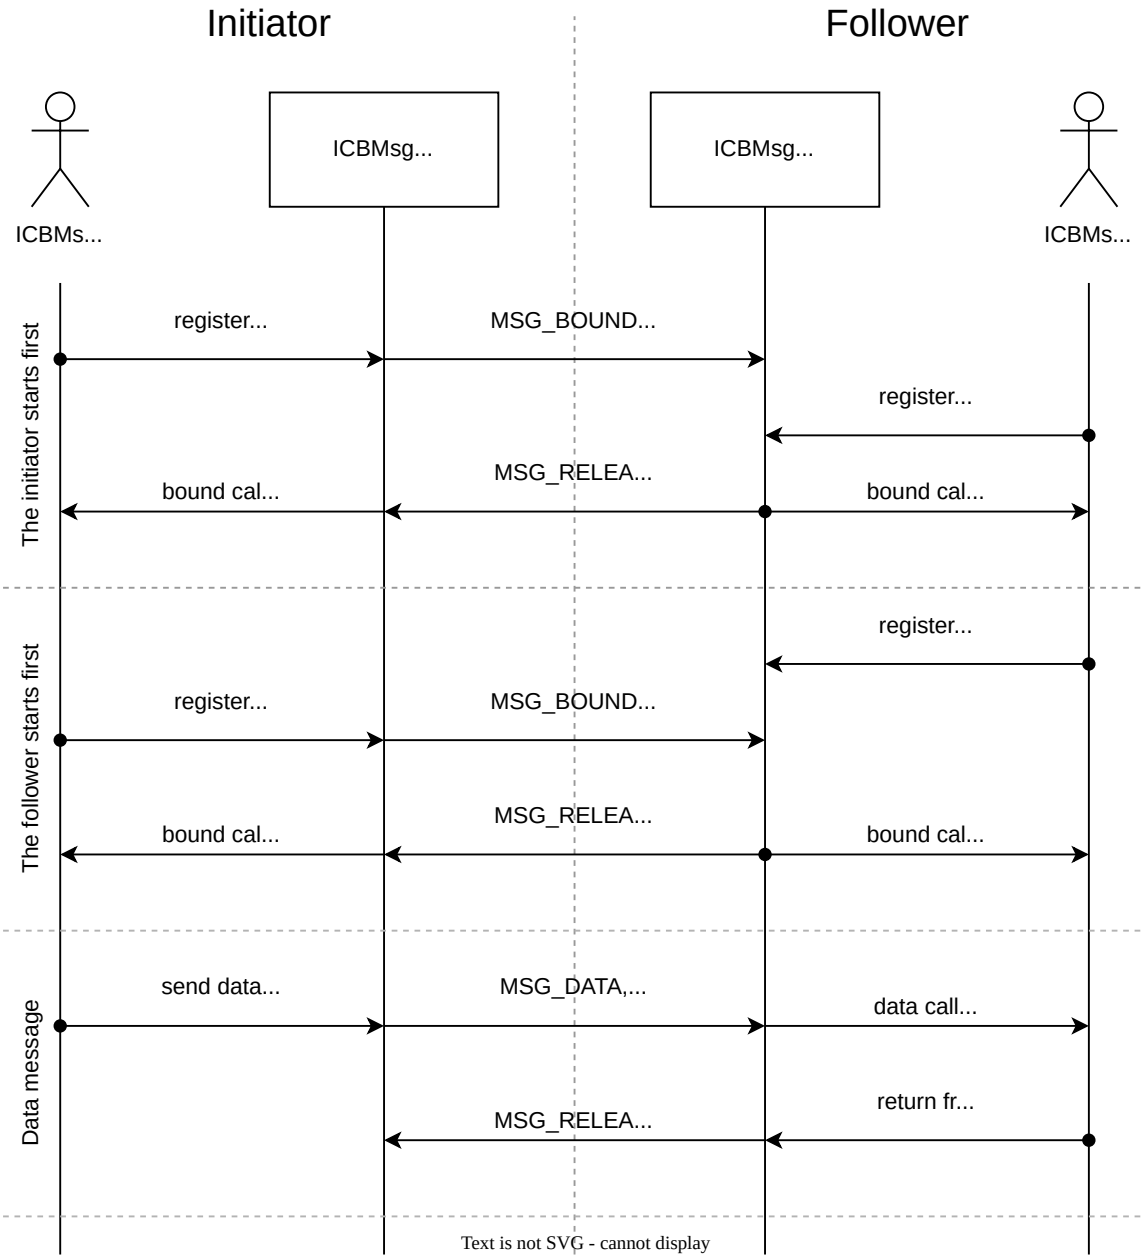
Follower Binding Procedure If the follower receives a binding message before it starts the binding procedure on that endpoint, it should store the message for later. It should not send the MSG_RELEASE_BOUND yet.

The endpoint binding procedure from the follower's point of view is the following:

1. The follower waits for a binding message containing its endpoint name. The message may be a newly received message or a message stored before the binding procedure started.

2. The follower stores the endpoint address assigned to this endpoint by the initiator.
3. The follower sends the `MSG_RELEASE_BOUND` control message.
4. The follower is bound to an endpoint, and it can send data messages using this endpoint.

Example sequence diagrams The following diagram shows a few examples of how the messages flow between two ends. There is a binding of two endpoints and one fully processed data message exchange.



Protocol Versioning The protocol allows improvements in future versions. The newer implementations should be able to work with older ones in backward compatible mode. To allow it, the current protocol version has the following restrictions:

- If the receiver receives a longer control message, it should use only the first three bytes and ignore the remaining.
- If the receiver receives a control message starting with a byte that does not match any of the messages described here, it should ignore it.
- If the receiver receives a binding message with additional bytes at the end, it should ignore the additional bytes.

4.14 JSON Web Token (JWT)

4.14.1 Overview

JSON Web Tokens (JWT) are an open, industry standard (**RFC 7519**) method for representing claims securely between two parties. Although JWT is fairly flexible, this API is limited to creating the simplistic tokens needed to authenticate with the Google Core IoT infrastructure.

At a high level, a JWT is just a signed blob of JSON that a client can present as a token instead of sending, for example, their username/password every time.

Usage

To use the JWT API, include the header file:

```
#include <zephyr/data/jwt.h>
```

Generating a JWT The JWT subsystem provides a lightweight, builder-based API for constructing JSON Web Tokens (JWT). It allows for the creation of tokens where the payload (claims) contains: expiration time, issued-at time, and audience. The token is then signed using a provided private key.

```
#include <zephyr/data/jwt.h>

struct jwt_builder builder;
char buffer[1024];
int ret;

/* Initialize the builder */
ret = jwt_init_builder(&builder, buffer, sizeof(buffer));
if (ret < 0) {
    /* Handle error */
}

/* Add payload: expiration, issued at, audience */
ret = jwt_add_payload(&builder, 1767221999, 1764605987, "project-id");
if (ret < 0) {
    /* Handle error */
}
```

(continues on next page)

(continued from previous page)

```
/* Sign the token using a DER-encoded private key */
ret = jwt_sign(&builder, private_key_der, private_key_der_len);
if (ret < 0) {
    /* Handle error */
}

/*
 * buffer now contains the JWT; it can be passed to a third-party service that
↪will be able
 * to validate it against the public key associated with `private_key_der`.
 */
```

4.14.2 Configuration

Related configuration options:

- CONFIG_JWT
- CONFIG_JWT_.*

4.14.3 API Reference

JSON Web Token (JWT)

4.15 Linkable Loadable Extensions (LLEXT)

The LLEXT subsystem provides a toolbox for extending the functionality of an application at runtime with linkable loadable code.

Extensions are precompiled executables in ELF format that can be verified, loaded, and linked with the main Zephyr binary. Extensions can be manipulated and introspected to some degree, as well as unloaded when no longer needed.

4.15.1 Configuration

The following Kconfig options are available for the LLEXT subsystem:

Heap size

The LLEXT subsystem needs a heap to be allocated for extension related data. The following option controls this allocation, when allocating a static heap.

CONFIG_LLEXT_HEAP_SIZE

Size of the LLEXT heap in kilobytes.

For boards using the Harvard architecture, the LLEXT heap is split into two: one heap in instruction memory and another in data memory. The following options control these allocations.

CONFIG_LLEXT_INSTR_HEAP_SIZE

Size of the LLEXT heap in instruction memory in kilobytes.

CONFIG_LLEXT_DATA_HEAP_SIZE

Size of the LLEXT heap in data memory in kilobytes.

Alternatively the application can configure a dynamic heap using the following option.

CONFIG_LLEXT_HEAP_DYNAMIC

Some applications require loading extensions into the memory which does not exist during the boot time and cannot be allocated statically. Make the application responsible for LLEXT heap allocation. Do not allocate LLEXT heap statically.

Application must call `llext_heap_init()` in order to assign a buffer to be used as the LLEXT heap, otherwise LLEXT modules will not load. When the application does not need LLEXT functionality any more, it should call `llext_heap_uninit()` which releases control of the buffer back to the application.

Note

When *user mode* is enabled, the heap size must be large enough to allow the extension sections to be allocated with the alignment required by the architecture.

Note

On Harvard architectures, applications must call `llext_heap_init_harvard()`.

The backing data structure for the LLEXT heap is by default a `k_heap`, but it can be changed to `sys_mem_blocks_t` for non-metadata (i.e., extension regions) by selecting CONFIG_LLEXT_HEAP_MEMBLK for CONFIG_LLEXT_HEAP_MANAGEMENT.

CONFIG_LLEXT_HEAP_MANAGEMENT

Select the memory management API used to store extension regions in LLEXT heap memory. This choice does not affect LLEXT metadata, which is always managed with `k_heap`.

CONFIG_LLEXT_HEAP_MEMBLK

Use `sys_mem_blocks_t` API to manage LLEXT heap memory for extension regions. A minimum of one block will be allocated per region. Block size must be selected with care to ensure proper alignment for extension regions.

Note

CONFIG_LLEXT_HEAP_MEMBLK does not support CONFIG_LLEXT_HEAP_DYNAMIC.

The heap will be split into two, the size of each sub-heap controlled by the following options:

CONFIG_LLEXT_EXT_HEAP_SIZE

Heap size in kilobytes available for LLEXT extension sections. Must be a multiple of CONFIG_LLEXT_HEAP_MEMBLK_BLOCK_SIZE. Replaced by CONFIG_LLEXT_INSTR_HEAP_SIZE and CONFIG_LLEXT_DATA_HEAP_SIZE if CONFIG_HARVARD is selected.

CONFIG_LLEXT_METADATA_HEAP_SIZE

Heap size in kilobytes available for LLEXT metadata.

Another option controls block size.

CONFIG_LLEXT_HEAP_MEMBLK_BLOCK_SIZE

Block size in bytes for LLEXT `sys_mem_blocks_t` heap(s). Must be equal to or a multiple of LLEXT_PAGE_SIZE. The block size must also be equal to or a

multiple of the largest alignment needed for any extension region. If CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT is selected and regions are large, an unreasonably large block size may be needed to satisfy alignment requirements.

Heap placement

The LLEXT heap(s) have custom sections. Non-Harvard heap sections (.llext_heap or .llext_metadata_heap and .llext_ext_heap if CONFIG_LLEXT_HEAP_MEMBLK is selected) are placed alongside .noinit sections by default. Harvard instruction and data heap sections (.llext_instr_heap and .llext_data_heap) are placed in instruction and data memory respectively. These default placements can be overridden by providing a custom linker script.

CONFIG_CUSTOM_LINKER_SCRIPT

Path to the linker script to be used instead of the one defined by the board.

The linker script must be based on a version provided by Zephyr since the kernel can expect a certain layout/certain regions.

This is useful when an application needs to add sections into the linker script and avoid having to change the script provided by Zephyr.

Warning

LLEXT will be unable to load extensions if the instruction memory .llext_instr_heap is placed in is not writable at the time the extensions are loaded and linked.

ELF object type

The LLEXT subsystem supports loading different types of extensions; the type can be set by choosing among the following Kconfig options:

CONFIG_LLEXT_TYPE_ELF_OBJECT

Build and expect relocatable files as binary object type for the LLEXT subsystem. A single compiler invocation is used to generate the object file.

CONFIG_LLEXT_TYPE_ELF_RELOCATABLE

Build and expect relocatable (partially linked) files as the binary object type for the LLEXT subsystem. These object files are generated by the linker by combining multiple object files into a single one.

CONFIG_LLEXT_TYPE_ELF_SHAREDLIB

Build and expect shared libraries as binary object type for the LLEXT subsystem. The standard linking process is used to generate the shared library from multiple object files.

Note

This is not currently supported on ARM architectures.

Minimize allocations

The LLEXT subsystem loading mechanism, by default, uses a seek/read abstraction and copies all data into allocated memory; this is done to allow the extension to be loaded from any storage medium. Sometimes, however, data is already in a buffer in RAM and copying it is not necessary. The following option allows the LLEXT subsystem to optimize memory footprint in this case.

CONFIG_LLEXT_STORAGE_WRITABLE

Allow the extension to be loaded by directly referencing section data into the ELF buffer. To be effective, this requires the use of an ELF loader that supports the peek functionality, such as the `llext_buf_loader`.

Warning

The application must ensure that the buffer used to load the extension remains allocated until the extension is unloaded.

Note

This will directly modify the contents of the buffer during the link phase. Once the extension is unloaded, the buffer must be reloaded before it can be used again in a call to `llext_load()`.

Note

This is currently required by the Xtensa architecture. Further information on this topic is available on GitHub issue #75341.

Symbol Groups

All LLEXT symbols belong to a group, with the inclusion of each group in the exported symbol table controlled by a corresponding Kconfig symbol. Exporting a symbol as part of a group is done with the `EXPORT_GROUP_SYMBOL` and `EXPORT_GROUP_SYMBOL_NAMED` macros. For example the following exports the symbol `memcpy` as part of the `LIBC` group:

```
EXPORT_GROUP_SYMBOL(LIBC, memcpy);
```

Group names are arbitrary, but they must be all uppercase. For each group used in C code, there **MUST** be a corresponding Kconfig symbol of the form:

```
config LLEXT_EXPORT_SYMBOL_GROUP_{GROUP_NAME}
   bool "Export all symbols from the {GROUP_NAME} group"
```

The default group for symbols (those declared with `EXPORT_SYMBOL` or `EXPORT_SYMBOL_NAMED`) is the `UNASSIGNED` group. As per the above rules, the inclusion of this group is controlled by `CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_UNASSIGNED`.

The groups currently defined by Zephyr are:

Table 6: Zephyr LLEXT symbol groups

Group Name	Kconfig Symbol	Description
UNASSIGNED	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_UNAS	Symbols without an explicit group
SYSCALL	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_SYSC	Zephyr kernel system calls
LIBC	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_LIBC	C standard library functions (memcpy() etc)
DEVICE	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_DEVI	Devicetree devices

Using SLID for symbol lookups

When an extension is loaded, the LLEXT subsystem must find the address of all the symbols residing in the main application that the extension references. To this end, the main binary contains a LLEXT-dedicated symbol table, filled with one symbol-name-to-address mapping entry for each symbol exported by the main application to extensions. This table can then be searched into by the LLEXT linker at extension load time. This process is pretty slow due to the nature of string comparisons, and the size consumed by the table can become significant as the number of exported symbols increases.

`CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID`

> Perform an extra processing step on the Zephyr binary and on all extensions being built, converting every string in the symbol tables to a pointer-sized hash called Symbol Link Identifier (SLID), which is stored in the binary.
>
> This speeds up the symbol lookup process by allowing usage of integer-based comparisons rather than string-based ones. Another benefit of SLID-based linking is that storing symbol names in the binary is no longer necessary, which provides a significant decrease in symbol table size.

Note

This option is not currently compatible with the *LLEXT EDK*.

Note

Using a different value for this option in the main binary and in extensions is not supported. For example, if the main application is built with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=y`, it is forbidden to load an extension that was compiled with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=n`.

EDK configuration

Options influencing the generation and behavior of the LLEXT EDK are described in *LLEXT EDK Kconfig options*.

4.15.2 Building extensions

The LLEXT subsystem allows for the creation of extensions that can be loaded into a running Zephyr application. When building these extensions, it's very often useful to have access to the headers and compiler flags used by the main Zephyr application.

The easiest path to achieve this is to build the extension as part of the Zephyr application, using the *native Zephyr CMake features*. This will result in a single build providing both the main Zephyr application and the extension(s), which will all automatically be built with the same parameters.

In some cases, involving the full Zephyr build system may not be feasible or convenient; maybe the extension is built using a different compiler suite or as part of a different project altogether. In this case, the extension developer needs to export the headers and compiler flags used by the main Zephyr application. This can be done using the *LLEXT Extension Development Kit*.

Using the Zephyr CMake features

The Zephyr build system provides a set of features that can be used to build extensions as part of the Zephyr application. This is the simplest way to build extensions, as it requires minimal additions to an application build system.

Building the extension An extension can be defined in the app's `CMakeLists.txt` by invoking the `add_llext_target` function, providing the target name, the output and the source files. Usage is similar to the standard `add_custom_target` CMake function:

```
add_llext_target(
    <target_name>
    OUTPUT <ext_file.llext>
    SOURCES <src1> [<src2>...]
)
```

where:

- `<target_name>` is the name of the final CMake target that will result in the LLEXT binary being created;
- `<ext_file.llext>` is the name of the output file that will contain the packaged extension;
- `<src1> [<src2>...]` is the list of source files that will be compiled to create the extension.

The exact steps of the extension building process depend on the currently selected *ELF object format*.

The following custom properties of `<target_name>` are defined and can be retrieved using the `get_target_property()` CMake function:

`lib_target`

Target name for the source compilation and/or link step.

`lib_output`

The binary file resulting from compilation and/or linking steps.

`pkg_input`

The file to be used as input for the packaging step.

`pkg_output`

The final extension file name.

Tweaking the build process The following CMake functions can be used to modify the build system behavior during the extension build process to a fine degree. Each of the below functions takes the LLEXT target name as its first argument; it is otherwise functionally equivalent to the common Zephyr `target_*` version.

- `llext_compile_definitions`
- `llext_compile_features`
- `llext_compile_options`
- `llext_include_directories`
- `llext_link_options`

Custom build steps The `add_llext_command` CMake function can be used to add custom build steps that will be executed during the extension build process. The command will be run at the specified build step and can refer to the properties of the target for build-specific details.

The function signature is:

```
add_llext_command(
    TARGET <target_name>
    [PRE_BUILD | POST_BUILD | POST_PKG]
    COMMAND <command> [args...]
)
```

The different build steps are:

`PRE_BUILD`

: Before the extension code is linked, if the architecture uses dynamic libraries. This step can access `lib_target` and its own properties.

`POST_BUILD`

: After the extension code is built, but before packaging it in an `.llext` file. This step is expected to create a `pkg_input` file by reading the contents of `lib_output`.

`POST_PKG`

: After the extension output file has been created. The command can operate on the final llext file `pkg_output`.

Anything else after `COMMAND` will be passed to `add_custom_command()` as-is (including multiple commands and other options).

LLEXT Extension Development Kit (EDK)

When building extensions as a standalone project, outside of the main Zephyr build system, it's important to have access to the same set of generated headers and compiler flags used by the main Zephyr application, since they have a direct impact on how Zephyr headers are interpreted and the extension is compiled in general.

This can be achieved by asking Zephyr to generate an Extension Development Kit (EDK) from the build artifacts of the main Zephyr application, by running the following command which uses the `llext-edk` target:

```
west build -t llext-edk
```

The generated EDK can be found in the build directory under the `zephyr` directory. It's a tarball that contains the headers and compile flags needed to build extensions. The extension developer can then include the headers and use the compile flags in their build system to build the extension.

EDK definition files The EDK includes several convenience files which define a set of variables that contain the compile flags needed by the project, as well as other build-related information, when enabled. The information is currently exported in the following formats:

- `Makefile.cflags`, for Makefile-based projects;
- `cmake.cflags`, for CMake-based projects.

Paths to the headers and flags are prefixed by the EDK root directory. This is automatically obtained for CMake projects from `CMAKE_CURRENT_LIST_DIR`; other formats refer to an `LLEXT_EDK_INSTALL_DIR` variable, which must be set by the user with the path where the EDK is installed before including the generated file.

> **Note**
>
> The `LLEXT_EDK` prefix in the variable name may be changed with the `CONFIG_LLEXT_EDK_NAME` option.

Compile flags The full list of flags needed to build an extension is provided by `LLEXT_CFLAGS`. Also provided is a more granular set of flags that can be used in support of different use cases, such as when building mocks for unit tests:

`LLEXT_INCLUDE_CFLAGS`

Compiler flags to add directories containing non-autogenerated headers to the compiler's include search paths.

`LLEXT_GENERATED_INCLUDE_CFLAGS`

Compiler flags to add directories containing autogenerated headers to the compiler's include search paths.

`LLEXT_ALL_INCLUDE_CFLAGS`

Compiler flags to add all directories containing headers used in the build to the compiler's include search paths. This is a combination of `LLEXT_INCLUDE_CFLAGS` and `LLEXT_GENERATED_INCLUDE_CFLAGS`.

`LLEXT_GENERATED_IMACROS_CFLAGS`

Compiler flags for autogenerated headers that must be included in the build via `-imacros`.

`LLEXT_BASE_CFLAGS`

Other compiler flags that control code generation for the target CPU. None of these flags are included in the above lists.

`LLEXT_CFLAGS`

All flags required to build an extension. This is a combination of `LLEXT_ALL_INCLUDE_CFLAGS`, `LLEXT_GENERATED_IMACROS_CFLAGS` and `LLEXT_BASE_CFLAGS`.

Target information The EDK includes information that identifies the target of the current Zephyr build. The following variables are currently defined and mirror the information available in the Zephyr build system:

`LLEXT_EDK_BOARD_NAME`
The board name used in the Zephyr build.

`LLEXT_EDK_BOARD_QUALIFIERS`
The board qualifiers, if provided, used in the Zephyr build.

`LLEXT_EDK_BOARD_REVISION`
The board revision, if provided, used in the Zephyr build.

`LLEXT_EDK_BOARD_TARGET`
The fully qualified board target used in the Zephyr build.

Note

The `LLEXT_EDK` prefix in the variable names may be changed with the `CONFIG_LLEXT_EDK_NAME` option.

LLEXT EDK Kconfig options The LLEXT EDK can be configured using the following Kconfig options:

`CONFIG_LLEXT_EDK_NAME`
The name of the generated EDK tarball. This is also used as the prefix for several variables defined in the EDK files.

`CONFIG_LLEXT_EDK_USERSPACE_ONLY`
If set, the EDK will include headers that do not contain code to route syscalls to the kernel. This is useful when building extensions that will run exclusively in user mode.

EDK Sample Refer to llext-edk for an example of how to use the LLEXT EDK.

4.15.3 Loading extensions

Once an extension is built and the ELF file is available, it can be loaded into the Zephyr application using the LLEXT API, which provides a way to load the extension into memory, access its symbols and call its functions.

Loading an extension

An extension may be loaded using any implementation of a `llext_loader` which has a set of function pointers that provide the necessary functionality to read the ELF data. A loader also provides some minimal context (memory) needed by the `llext_load()` function. Several loaders are already provided:

- An implementation over a buffer containing an ELF in addressable memory in memory is available as `llext_buf_loader`. To use this kind of loader, it is helpful to use one of the `LLEXT_TEMPORARY_BUF_LOADER`, `LLEXT_PERSISTENT_BUF_LOADER`, or `LLEXT_WRITABLE_BUF_LOADER` macros to tell LLEXT the appropriate type of memory buffer.
- An implementation that reads data from a file in the filesystem is available as the `llext_fs_loader`. The path to the file must be provided when creating the loader with the `LLEXT_FS_LOADER` macro.

The extensions are loaded with a call to the `llext_load()` function, passing in the extension name and the configured loader. Once that completes successfully, the extension is loaded into memory and is ready to be used.

Note

When *User Mode* is enabled, the extension will not be included in any user memory domain. To allow access from user mode, the `llext_add_domain()` function must be called.

Initializing and cleaning up the extension

The extension may define a number of initialization functions that must be called after loading but before any function in it can be used; this is typical in languages such as C++ that provide the concept of object constructors. The same is true for cleanup functions that must be called before unloading the extension.

LLEXT supports calling the functions listed in the `.preinit_array` and `.init_array` sections of the ELF file with the `llext_bringup()` function, and the functions listed in the `.fini_array` section with the `llext_teardown()` function. These APIs are compatible with *User Mode*, and thus can be called from either kernel or user context.

Important

The code run by these functions is fully determined by the contents of the ELF file. This may have security implications if its origin is untrusted.

If the extension requires a dedicated thread, the `llext_bootstrap()` function can be used to minimize boilerplate code. This function has a signature that is compatible with the `k_thread_create()` API, and will call `llext_bringup()`, then a user-specified function in the same context, and finally `llext_teardown()` before returning.

Accessing code and data

To interact with the newly loaded extension, the host application must use the `llext_find_sym()` function to get the address of the exported symbol. The returned `void *` can then be cast to the appropriate type and used.

A wrapper for calling a function with no arguments is provided in `llext_call_fn()`.

Advanced users that need direct access to areas of the newly loaded extension may want to refer to `llext_get_section_info()` and other LLEXT inspection APIs.

Cleaning up after use

The `llext_unload()` function must be called to free the memory used by the extension once it is no longer required. After this call completes, all pointers to symbols in the extension that were obtained will be invalid.

4.15.4 Troubleshooting

This feature is being actively developed and as such it is possible that some issues may arise. Since linking does modify the binary code, in case of errors the results are difficult to predict. Some common issues may be:

- Results from `llext_find_sym()` point to an invalid address;
- Constants and variables defined in the extension do not have the expected values;
- Calling a function defined in an extension results in a hard fault, or memory in the main application is corrupted after returning from it.

If any of this happens, the following tips may help understand the issue:

- Make sure `CONFIG_LLEXT_LOG_LEVEL` is set to `DEBUG`, then obtain a log of the `llext_load()` invocation.
- If possible, disable memory protection (MMU/MPU) and see if this results in different behavior.
- Try to simplify the extension to the minimum possible code that reproduces the issue.
- Use a debugger to inspect the memory and registers to try to understand what is happening. See *Debugging extensions* for more details.

If the issue persists, please open an issue in the GitHub repository, including all the above information.

4.15.5 Debugging extensions

Debugging extensions is a complex task. Since the extension code is by definition not built with the Zephyr application, the final Zephyr ELF file does not contain the symbols for extension code. Furthermore, the extension is dynamically relocated by `llext_load()` at runtime, so even if the symbols were available, it would be impossible for the debugger to know the final locations of the symbols in the extension code.

Setting up the debugger session properly in this case requires a few manual steps. The following sections will provide some tips on how to do it with the Zephyr SDK and the debug features provided by `west`, but the instructions can be adapted to any GDB-based debugging environment.

Extension debugging process

1. Make sure the project is set up to display the verbose LLEXT debug output (`CONFIG_LOG` and `CONFIG_LLEXT_LOG_LEVEL_DBG` are set).
2. Build the Zephyr application and the extensions.

   For each target `name` included in the current build, two files will be generated into the `llext` subdirectory of the build root:

   `name_ext_debug.elf`

   : An intermediate ELF file with full debugging information.

`name.llext`

The final extension binary, stripped to the essential data required for loading into the Zephyr application.

Other files may be present, depending on the target architecture and the build configuration.

3. Start a debugging session of the main Zephyr application. This is described in the *Debugging* section of the documentation; on supported boards it is as easy as running `west debug`, perhaps with some additional arguments.
4. Set a breakpoint just after the `llext_load()` function in your code and let it run. This will load the extension into memory and relocate it. The output logs will contain a line with `gdb add-symbol-file flags:`, followed by lines all starting with `-s`.
5. Type this command in the GDB console to load this extension's symbols:

```
add-symbol-file <path-to-debug.elf> <load-addresses>
```

where `<path-to-debug.elf>` is the full path of the ELF file with debug information identified in step 2, and `<load-addresses>` is a space separated list of all the `-s` lines collected from the log in the previous step.

6. The extension symbols are now available to the debugger. You can set breakpoints, inspect variables, and step through the code as usual.

Steps 4-6 can be repeated for every extension that is loaded by the application, if there are several.

Symbol lookup issues

Warning

It is almost certain that the loaded symbols will be shadowed by others in the main application; for example, they may be located inside the memory area of the ELF buffer or the LLEXT heap.

In this case GDB chooses the first known symbol and therefore associates the addresses to some `elf_buffer+0x123` instead of an expected `ext_fn`. This further confuses its high-level operations like source stepping or inspecting locals, since they are meaningless in that context.

Two possible solutions to this problem are discussed in the following paragraphs.

Discard all Zephyr symbols The simplest option is to drop all the Zephyr application symbols from GDB by invoking `add-symbol-file` with no arguments, before step 5. This will however focus the debugging session to the llext only, as all information about the Zephyr application will be lost. For example, the debugger may not be able to properly follow stack traces outside the extension code.

It is possible to use the same technique multiple times in the same session to switch between the main and extension symbol tables as required, but it rapidly becomes cumbersome.

Edit the ELF file This alternative is more complex but allows for a more seamless debugging experience. The idea is to edit the main Zephyr ELF file to remove information about the symbols that overlap with the extension that is to be debugged, so that when the extension symbols are loaded, GDB will not have any ambiguity. This can be done by using `objcopy` with the `-N <symbol>` option.

Identifying the offending symbols is however an iterative trial-and-error procedure, as there can be many different layers; for example, the ELF buffer may be itself contained in a symbol for the

data segment. Fortunately, this knowledge can then be used several times as the list is unlikely to change for a given project.

Example debugging session

This example demonstrates how to debug the `detached_fn` extension in the `tests/subsys/llext` project (specifically, the `writable` case), on an emulated `mps2/an385` board which is based on an ARM Cortex-M3.

> **Note**
>
> The logs below have been obtained using Zephyr version 4.1 and the Zephyr SDK version 0.17.0. However, the exact addresses may still vary between runs even when using the same versions. Adjust the commands below to match the results of your own session.

The following command will build the project and start the emulator in debugging mode:

Listing 3: Terminal 1 (build, QEMU emulator, GDB server)

```
zephyr$ west build -p -b mps2/an385 tests/subsys/llext/ -T llext.writable -t␣
↪debugserver_qemu

↪p3=0x0 <cbvprintf_package>) at zephyr/lib/os/thread_entry.c:48
#6  0x00000000 in ?? ()
```

The symbol associated with the breakpoint location and the last stack frames mistakenly reference the ELF buffer in the Zephyr application instead of the extension symbols. Note that GDB however knows both:

Listing 8: Terminal 2 (GDB client)

```
(gdb) info sym 0x200001d0
test_detached_ext + 464 in section datas of zephyr/build/zephyr/zephyr.elf
detached_entry in section .detach of zephyr/build/llext/detached_fn_ext_debug.elf
(gdb) info sym 0x200000ac
test_detached_ext + 172 in section datas of zephyr/build/zephyr/zephyr.elf
test_entry + 8 in section .text of zephyr/build/llext/detached_fn_ext_debug.elf
```

It is also impossible to inspect the variables in the extension or step through code properly:

Listing 9: Terminal 2 (GDB client)

```
(gdb) print bss_cnt
No symbol "bss_cnt" in current context.
(gdb) print data_cnt
No symbol "data_cnt" in current context.
(gdb) next
Single stepping until exit from function test_detached_ext,
which has no line number information.

Breakpoint 2, 0x200001ea in test_detached_ext ()
(gdb)
```

Discarding symbols Discarding the Zephyr symbols and only focusing on the extension restores full debugging functionality at the cost of losing the global context (note the backtrace stops outside the extension):

Listing 10: Terminal 2 (GDB client)

```
(gdb) symbol-file

Editing the ELF file In this alternative approach, the patches to the Zephyr ELF file must be performed after building the Zephyr binary and starting the emulator on Terminal 1, but before starting the GDB client on Terminal 2.

The above debugging session already identified `test_detached_ext`, the char array that holds the ELF file, as an offending symbol, so that will be removed in a first pass. Performing the same steps multiple times, `__data_start` and `__data_region_start` can also be found to overlap the memory area of interest.

The following commands will remove all of these from the Zephyr ELF file, then start a debugging session on the modified file:

Listing 11: Terminal 2 (GDB client)

```
zephyr$ export LLEXT_SDK_INSTALL_DIR=/opt/zephyr-sdk-0.17.0
zephyr$ ${LLEXT_SDK_INSTALL_DIR}/arm-zephyr-eabi/bin/arm-zephyr-eabi-objcopy -N␣
↪test_detached_ext -N __data_start -N __data_region_start build/zephyr/zephyr.elf␣
↪build/zephyr/zephyr-edit.elf
zephyr$ ${LLEXT_SDK_INSTALL_DIR}/arm-zephyr-eabi/bin/arm-zephyr-eabi-gdb␣
↪build/zephyr/zephyr-edit.elf
GNU gdb (Zephyr SDK 0.17.0) 12.1
[...]
Reading symbols from build/zephyr/zephyr-edit.elf...
(gdb)
```

The same steps used in the previous run can be performed again to attach to the GDB server and load both the extension and its debug symbols. This time, however, the result is rather different:

- the `break` command includes line number information;
- the output from `backtrace` contains functions from both the extension and the Zephyr application;
- the local variables can be properly inspected.

  - *Logger output formatting*

The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and are then processed by active backends. Custom frontend and backends can be used if needed.

Summary of the logging features:

- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context instead of processing and sending the log message when

called.

- Multiple backends supported (up to 9 backends).
- Custom frontend support. It can work together with backends.
- Compile time filtering on module level.
- Run time filtering independent for each backend.
- Additional run time filtering on module instance level.
- Timestamping with user provided function. Timestamp can have 32 or 64 bits.
- Dedicated API for dumping data.
- Dedicated API for handling transient strings.
- Panic support - in panic mode logging switches to blocking, synchronous processing.
- Printk support - printk message can be redirected to the logging.
- Design ready for multi-domain/multi-processor system.
- Support for logging floating point variables and long long arguments.
- Built-in copying of transient strings used as arguments.
- Support for multi-domain logging.
- Rate-limited logging macros to prevent log flooding when messages are generated frequently.

Logging API is highly configurable at compile time as well as at run time. Using Kconfig options (see *Global Kconfig Options*) logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation logs can be filtered out on module basis and severity level.

Logs can also be compiled in but filtered on run time using dedicate API. Run time filtering is independent for each backend and each source of log messages. Source of log messages can be a module or specific instance of the module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level the logging API (include/zephyr/logging/log.h) has set of dedicated macros. Logger API also has macros for logging data.

For each level the following set of macros are available:

- `LOG_X` for standard printf-like messages, e.g. `LOG_ERR`.
- `LOG_HEXDUMP_X` for dumping data, e.g. `LOG_HEXDUMP_WRN`.
- `LOG_INST_X` for standard printf-like message associated with the particular instance, e.g. `LOG_INST_INF`.
- `LOG_INST_HEXDUMP_X` for dumping data associated with the particular instance, e.g. `LOG_INST_HEXDUMP_DBG`

The warning level also exposes the following additional macro:

- `LOG_WRN_ONCE` for warnings where only the first occurrence is of interest.

Rate-limited logging macros are also available for all severity levels to prevent log flooding:

- `LOG_X_RATELIMIT` for rate-limited standard printf-like messages using default rate, e.g. `LOG_ERR_RATELIMIT`.
- `LOG_X_RATELIMIT_RATE` for rate-limited standard printf-like messages with custom rate, e.g. `LOG_ERR_RATELIMIT_RATE`.
- `LOG_HEXDUMP_X_RATELIMIT` for rate-limited data dumping using default rate, e.g. `LOG_HEXDUMP_WRN_RATELIMIT`.

- LOG_HEXDUMP_X_RATELIMIT_RATE for rate-limited data dumping with custom rate, e.g. LOG_HEXDUMP_WRN_RATELIMIT_RATE.

The convenience macros use the default rate specified by CONFIG_LOG_RATELIMIT_INTERVAL_MS, while the explicit rate macros take a rate parameter (in milliseconds) that specifies the minimum interval between log messages.

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it works for modules. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the LOG_LEVEL macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If module consists of more than one file, registration is performed in one file but each file must define a module name.

Logger's default frontend is designed to be thread safe and minimizes time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when logging API is called. When logging API is called a message is created and added to the list. Dedicated, configurable buffer for pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contain source ID (module or instance ID and domain ID which might be used for multiprocessor systems), timestamp and severity level. Standard message contains pointer to the string and arguments. Hexdump message contains copied data and string.

4.16.1 Global Kconfig Options

These options can be found in the following path subsys/logging/Kconfig.

CONFIG_LOG: Global switch, turns on/off the logging.

Mode of operations:

CONFIG_LOG_MODE_DEFERRED: Deferred mode.

CONFIG_LOG_MODE_IMMEDIATE: Immediate (synchronous) mode.

CONFIG_LOG_MODE_MINIMAL: Minimal footprint mode.

Filtering options:

CONFIG_LOG_RUNTIME_FILTERING: Enables runtime reconfiguration of the filtering.

CONFIG_LOG_DEFAULT_LEVEL: Default level, sets the logging level used by modules that are not setting their own logging level.

CONFIG_LOG_OVERRIDE_LEVEL: It overrides module logging level when it is not set or set lower than the override value.

CONFIG_LOG_MAX_LEVEL: Maximal (lowest severity) level which is compiled in.

Processing options:

CONFIG_LOG_MODE_OVERFLOW: When new message cannot be allocated, oldest one are discarded.

CONFIG_LOG_BLOCK_IN_THREAD: If enabled and new log message cannot be allocated thread context will block for up to CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS or until log message is allocated.

CONFIG_LOG_PRINTK: Redirect printk calls to the logging.

CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD: When the number of buffered log messages reaches the threshold, the dedicated thread (see log_thread_set()) is woken up. If CONFIG_LOG_PROCESS_THREAD is enabled then this threshold is used by the internal thread.

CONFIG_LOG_PROCESS_THREAD: When enabled, logging thread is created which handles log processing.

CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS: Delay in milliseconds after which logging thread is started.

CONFIG_LOG_BUFFER_SIZE: Number of bytes dedicated for the circular packet buffer.

CONFIG_LOG_FRONTEND: Direct logs to a custom frontend.

CONFIG_LOG_FRONTEND_ONLY: No backends are used when messages goes to frontend.

CONFIG_LOG_FRONTEND_OPT_API: Optional API optimized for the most common simple messages.

CONFIG_LOG_CUSTOM_HEADER: Injects an application provided header into log.h

CONFIG_LOG_TIMESTAMP_64BIT: 64 bit timestamp.

CONFIG_LOG_SIMPLE_MSG_OPTIMIZE: Optimizes simple log messages for size and performance. Option available only for 32 bit architectures.

Formatting options:

CONFIG_LOG_FUNC_NAME_PREFIX_ERR: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_WRN: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_INF: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_DBG: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_BACKEND_SHOW_TIMESTAMP: Enables backend to print timestamps with log.

CONFIG_LOG_BACKEND_SHOW_LEVEL: Enables backend to print levels with log.

CONFIG_LOG_BACKEND_SHOW_COLOR: Enables coloring of errors (red) and warnings (yellow).

CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP: If enabled timestamp is formatted to *hh:mm:ss:mmm,uuu*. Otherwise is printed in raw format.

Backend options:

CONFIG_LOG_BACKEND_UART: Enable built-in UART backend.

CONFIG_LOG_BACKEND_NET: Enable built-in Networking backend to send syslog messages to a network server.

4.16.2 Usage

Logging in a module

In order to use logging in the module, a unique name of a module must be specified and module must be registered using LOG_MODULE_REGISTER. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
```

If the module consists of multiple files, then LOG_MODULE_REGISTER() should appear in exactly one of them. Each other file should use LOG_MODULE_DECLARE to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>
/* In all files comprising the module but one */
LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
```

In order to use logging API in a function implemented in a header file LOG_MODULE_DECLARE macro must be used in the function body before logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```
#include <zephyr/logging/log.h>

static inline void foo(void)
{
	LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);

	LOG_INF("foo");
}
```

Dedicated Kconfig template (subsys/logging/Kconfig.template.log_config) can be used to create local log level configuration.

Example below presents usage of the template. As a result CONFIG_FOO_LOG_LEVEL will be generated:

```
module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"
```

Logging in a module instance

In case of modules which are multi-instance and instances are widely used across the system enabling logs will lead to flooding. The logger provides the tools which can be used to provide filtering on instance level rather than module level. In that case logging can be enabled for particular instance.

In order to use instance level filtering following steps must be performed:

- a pointer to specific logging structure is declared in instance structure. LOG_INSTANCE_PTR_DECLARE is used for that.

```
#include <zephyr/logging/log_instance.h>

struct foo_object {
	LOG_INSTANCE_PTR_DECLARE(log);
	uint32_t id;
}
```

- module must provide macro for instantiation. In that macro, logging instance is registered and log instance pointer is initialized in the object structure.

```
#define FOO_OBJECT_DEFINE(_name)                                \
	LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO_LOG_LEVEL) \
	struct foo_object _name = {                             \
		LOG_INSTANCE_PTR_INIT(log, foo, _name)          \
	}
```

Note that when logging is disabled logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using LOG_LEVEL_SET.

```
LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

void foo_init(foo_object *f)
{
	LOG_INST_INF(f->log, "Initialized.");
}
```

In order to use the instance logging API in a header file, a compile-time log level must be set using LOG_LEVEL_SET.

```
static inline void foo_init(foo_object *f)
{
	LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

	LOG_INST_INF(f->log, "Initialized.");
}
```

Controlling the logging

By default, logging processing in deferred mode is handled internally by the dedicated task which starts automatically. However, it might not be available if multithreading is disabled. It can also be disabled by unsetting CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD. In that case, logging can be controlled using the API defined in include/zephyr/logging/log_ctrl.h. Logging must be initialized before it can be used. Optionally, the user can provide a function which returns the timestamp value. If not provided, k_cycle_get or k_cycle_get_32 is used for timestamping. The log_process() function is used to trigger processing of one log message (if pending), and returns true if there are more messages pending. However, it is recommended to use macro wrappers (LOG_INIT and LOG_PROCESS) which handle the case where logging is disabled.

The following snippet shows how logging can be processed in simple forever loop.

```
#include <zephyr/logging/log_ctrl.h>

int main(void)
{
	LOG_INIT();
	/* If multithreading is enabled provide thread id to the logging. */
	log_thread_set(k_current_get());

	while (1) {
		if (LOG_PROCESS() == false) {
			/* sleep */
		}
	}
}
```

If logs are processed from a thread (user or internal) then it is possible to enable a feature which will wake up processing thread when certain amount of log messages are buffered (see CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD).

4.16.3 Rate-limited logging

Rate-limited logging macros provide a way to prevent log flooding when messages are generated frequently. These macros ensure that log messages are not output more frequently than a

specified interval, similar to Linux's `printk_ratelimited` functionality.

The rate-limited logging system provides two types of macros:

Convenience macros (using default rate): - `LOG_ERR_RATELIMIT` - Rate-limited error messages - `LOG_WRN_RATELIMIT` - Rate-limited warning messages - `LOG_INF_RATELIMIT` - Rate-limited info messages - `LOG_DBG_RATELIMIT` - Rate-limited debug messages - `LOG_HEXDUMP_ERR_RATELIMIT` - Rate-limited error hexdump - `LOG_HEXDUMP_WRN_RATELIMIT` - Rate-limited warning hexdump - `LOG_HEXDUMP_INF_RATELIMIT` - Rate-limited info hexdump - `LOG_HEXDUMP_DBG_RATELIMIT` - Rate-limited debug hexdump

Explicit rate macros (with custom rate): - `LOG_ERR_RATELIMIT_RATE` - Rate-limited error messages with custom rate - `LOG_WRN_RATELIMIT_RATE` - Rate-limited warning messages with custom rate - `LOG_INF_RATELIMIT_RATE` - Rate-limited info messages with custom rate - `LOG_DBG_RATELIMIT_RATE` - Rate-limited debug messages with custom rate - `LOG_HEXDUMP_ERR_RATELIMIT_RATE` - Rate-limited error hexdump with custom rate - `LOG_HEXDUMP_WRN_RATELIMIT_RATE` - Rate-limited warning hexdump with custom rate - `LOG_HEXDUMP_INF_RATELIMIT_RATE` - Rate-limited info hexdump with custom rate - `LOG_HEXDUMP_DBG_RATELIMIT_RATE` - Rate-limited debug hexdump with custom rate

The convenience macros use the default rate specified by `CONFIG_LOG_RATELIMIT_INTERVAL_MS` (5000ms by default). The explicit rate macros take a rate parameter (in milliseconds) that specifies the minimum interval between log messages. The rate limiting is per-macro-call-site, meaning that each unique call to a rate-limited macro has its own independent rate limit.

Example usage:

```
#include <zephyr/logging/log.h>
#include <zephyr/kernel.h>

LOG_MODULE_REGISTER(my_module, CONFIG_LOG_DEFAULT_LEVEL);

void process_data(void)
{
    /* Convenience macros using default rate (CONFIG_LOG_RATELIMIT_INTERVAL_MS) */
    LOG_WRN_RATELIMIT("Data processing warning: %d", error_code);
    LOG_ERR_RATELIMIT("Critical error occurred: %s", error_msg);
    LOG_INF_RATELIMIT("Processing status: %d items", item_count);
    LOG_HEXDUMP_WRN_RATELIMIT(data_buffer, data_len, "Data buffer:");

    /* Explicit rate macros with custom intervals */
    LOG_WRN_RATELIMIT_RATE(1000, "Fast rate warning: %d", error_code);
    LOG_ERR_RATELIMIT_RATE(30000, "Slow rate error: %s", error_msg);
    LOG_INF_RATELIMIT_RATE(2000, "Custom rate status: %d items", item_count);
    LOG_HEXDUMP_ERR_RATELIMIT_RATE(5000, data_buffer, data_len, "Error data:");
}
```

Rate-limited logging is particularly useful for:

- Error conditions that might occur frequently but don't need to flood the logs
- Status updates in tight loops or high-frequency callbacks
- Debug information that could overwhelm the logging system
- Network or I/O operations that might fail repeatedly

Configuration

Rate-limited logging can be configured using the following Kconfig options:

- `CONFIG_LOG_RATELIMIT` - Master switch to enable/disable rate-limited logging
- `CONFIG_LOG_RATELIMIT_INTERVAL_MS` - Default interval for convenience macros (5000ms)

When CONFIG_LOG_RATELIMIT is disabled, the behavior of rate-limited macros is controlled by the CONFIG_LOG_RATELIMIT_FALLBACK choice:

- CONFIG_LOG_RATELIMIT_FALLBACK_LOG - All rate-limited macros behave as regular logging macros
- CONFIG_LOG_RATELIMIT_FALLBACK_DROP - All rate-limited macros expand to no-ops (default)

This allows you to control whether rate-limited log macros should always print or be completely suppressed when rate limiting is not available.

The rate limiting is implemented using static variables and k_uptime_get_32() to track the last log time for each call site.

4.16.4 Logging panic

In case of error condition system usually can no longer rely on scheduler or interrupts. In that situation deferred log message processing is not an option. Logger controlling API provides a function for entering into panic mode (log_panic()) which should be called in such situation.

When log_panic() is called, _panic_ notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. Since that moment all logs are processed in a blocking way.

4.16.5 Printk

Typically, logging and printk() use the same output, which they compete for. This can lead to issues if the output does not support preemption but it may also result in corrupted output because logging data is interleaved with printk data. However, it is possible to redirect printk messages to the logging subsystem by enabling CONFIG_LOG_PRINTK. In that case, printk entries are treated as log messages with level 0 (they cannot be disabled). When enabled, logging manages the output so there is no interleaving. However, in deferred mode the printk behaviour is changed since the output is delayed until the logging thread processes the data. CONFIG_LOG_PRINTK is enabled by default.

4.16.6 Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

Log message is generated by a source of logging which can be a module or instance of a module.

Default Frontend

Default frontend is engaged when the logging API is called in a source of logging (e.g. LOG_INF) and is responsible for filtering a message (compile and run time), allocating a buffer for the message, creating the message and committing that message. Since the logging API can be called in an interrupt, the frontend is optimized to log the message as fast as possible.

Log message A log message contains a message descriptor (source, domain and level), timestamp, formatted string details (see *Cbprintf Packaging*) and optional data. Log messages are stored in a continuous block of memory. Memory is allocated from a circular packet buffer (*Multi Producer Single Consumer Packet Buffer*), which has a few consequences:

- Each message is a self-contained, continuous block of memory thus it is suited for copying the message (e.g. for offline processing).

- Messages must be sequentially freed. Backend processing is synchronous. Backend can make a copy for deferred processing.

A log message has following format:

Message Header	2 bits: MPSC packet buffer header
	1 bit: Trace/Log message flag
	3 bits: Domain ID
	3 bits: Level
	10 bits: Cbprintf Package Length
	12 bits: Data length
	1 bit: Reserved
	pointer: Pointer to the source descriptor[1]
	32 or 64 bits: Timestamp[1]
	Optional padding[2]
Cbprintf package (optional)	Header
	Arguments
	Appended strings
Hexdump data (optional)	
Alignment padding (optional)	

Log message allocation It may happen that the frontend cannot allocate a message. This happens if the system is generating more log messages than it can process in certain time frame. There are two strategies to handle that case:

- No overflow - the new log is dropped if space for a message cannot be allocated.
- Overflow - the oldest pending messages are freed, until the new message can be allocated. Enabled by `CONFIG_LOG_MODE_OVERFLOW`. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Run-time filtering If run-time filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such filter is using 32 bits divided into ten 3 bit slots. Except *slot 0*, each slot stores current filter for one backend in the system. *Slot 0* (bits 0-2) is used to aggregate maximal filter setting for given source of logging. Aggregate slot determines if log message is created for given entry since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when message is processed by the core to determine if message is accepted by the given backend. Contrary to compile time filtering, binary footprint is increased because logs are compiled in.

In the example below backend 1 is set to receive errors (*slot 1*) and backend 2 up to info level (*slot 2*). Slots 3-9 are not used. Aggregated filter (*slot 0*) is set to info level and up to this level message from that particular source will be buffered.

slot 0	slot 1	slot 2	slot 3	...	slot 9
INF	ERR	INF	OFF	...	OFF

Custom Frontend

Custom frontend is enabled using `CONFIG_LOG_FRONTEND`. Logs are directed to functions declared in include/zephyr/logging/log_frontend.h. If option `CONFIG_LOG_FRONTEND_ONLY` is enabled then

[1] Depending on the platform and the timestamp size fields may be swapped.
[2] It may be required for cbprintf package alignment

log message is not created and no backend is handled. Otherwise, custom frontend can coexist with backends.

In some cases, logs need to be redirected at the macro level. For these cases, `CONFIG_LOG_CUSTOM_HEADER` can be used to inject an application provided header named `zephyr_custom_log.h` at the end of include/zephyr/logging/log.h.

Frontend using ARM Coresight STM (System Trace Macrocell) For more details about logging using ARM Coresight STM see *Multi-domain logging using ARM Coresight STM*.

Logging strings

String arguments are handled by *Cbprintf Packaging*. See *Limitations and recommendations* for limitations and recommendations.

Multi-domain support

More complex systems can consist of multiple domains where each domain is an independent binary. Examples of domains are a core in a multicore SoC or one of the binaries (Secure or Nonsecure) on an ARM TrustZone core.

Tracing and debugging on a multi-domain system is more complex and requires an efficient logging system. Two approaches can be used to structure this logging system:

- Log inside each domain independently. This option is not always possible as it requires that each domain has an available backend (for example, UART). This approach can also be troublesome to use and not scalable, as logs are presented on independent outputs.
- Use a multi-domain logging system where log messages from each domain end up in one root domain, where they are processed exactly as in a single domain case. In this approach, log messages are passed between domains using a connection between domains created from the backend on one side and linked to the other.

  The Log link is an interface introduced in this multi-domain approach. The Log link is responsible for receiving any log message from another domain, creating a copy, and putting that local log message copy (including remote data) into the message queue. This specific log link implementation matches the complementary backend implementation to allow log messages exchange and logger control like configuring filtering, getting log source names, and so on.

There are three types of domains in a multi-domain system:

- The *end domain* has the logging core implementation and a cross-domain backend. It can also have other backends in parallel.
- The *relay domain* has one or more links to other domains but does not have backends that output logs to the user. It has a cross-domain backend either to another relay or to the root domain.
- The *root domain* has one or multiple links and a backend that outputs logs to the user.

See the following image for an example of a multi-domain setup:

In this architecture, a link can handle multiple domains. For example, let's consider an SoC with two ARM Cortex-M33 cores with TrustZone: cores A and B (see the example illustrated above). There are four domains in the system, as each core has both a Secure and a Nonsecure domain. If *core A nonsecure* (A_NS) is the root domain, it has two links: one to *core A secure* (A_NS-A_S) and one to *core B nonsecure* (A_NS-B_NS). *B_NS* domain has one link, to *core B secure B_NS-B_S*), and a backend to *A_NS*.

Since in all instances there is a standard logging subsystem, it is always possible to have multiple backends and simultaneously output messages to them. An example of this is shown in the illustration above as a dotted UART backend on the *B_NS* domain.

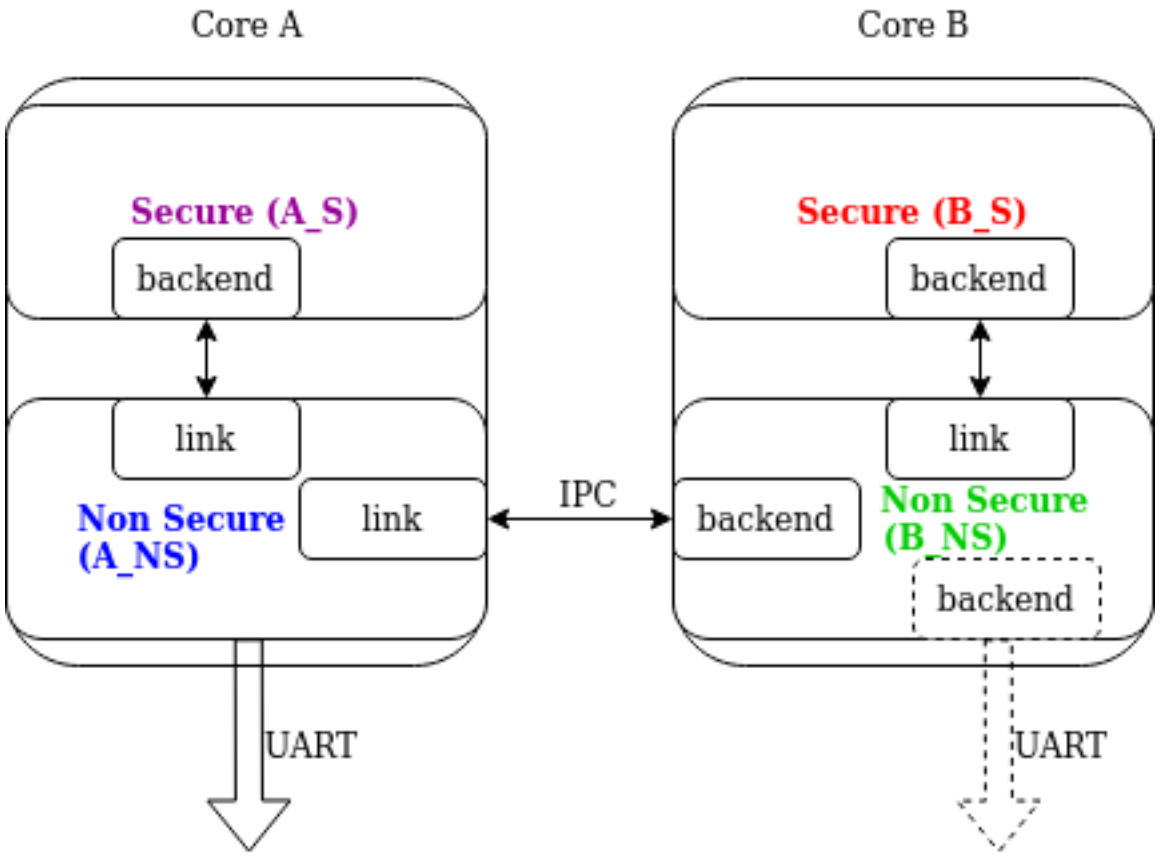

Fig. 5: Multi-domain example

Domain ID The source of each log message can be identified by the following fields in the header: `source_id` and `domain_id`.

The value assigned to the `domain_id` is relative. Whenever a domain creates a log message, it sets its `domain_id` to `0`. When a message crosses the domain, `domain_id` changes as it is increased by the link offset. The link offset is assigned during the initialization, where the logger core is iterating over all the registered links and assigned offsets.

The first link has the offset set to 1. The following offset equals the previous link offset plus the number of domains in the previous link.

The following example is shown below, where the assigned `domain_ids` are shown for each domain:

Let's consider a log message created on the *B_S* domain:

1. Initially, it has its `domain_id` set to `0`.
2. When the *B_NS*-*B_S* link receives the message, it increases the `domain_id` to 1 by adding the *B_NS*-*B_S* offset.
3. The message is passed to *A_NS*.
4. When the *A_NS*-*B_NS* link receives the message, it adds the offset (2) to the `domain_id`. The message ends up with the `domain_id` set to 3, which uniquely identifies the message originator.

Cross-domain log message In most cases, the address space of each domain is unique, and one domain cannot access directly the data in another domain. For this reason, the backend can partially process the message before it is passed to another domain. Partial processing can

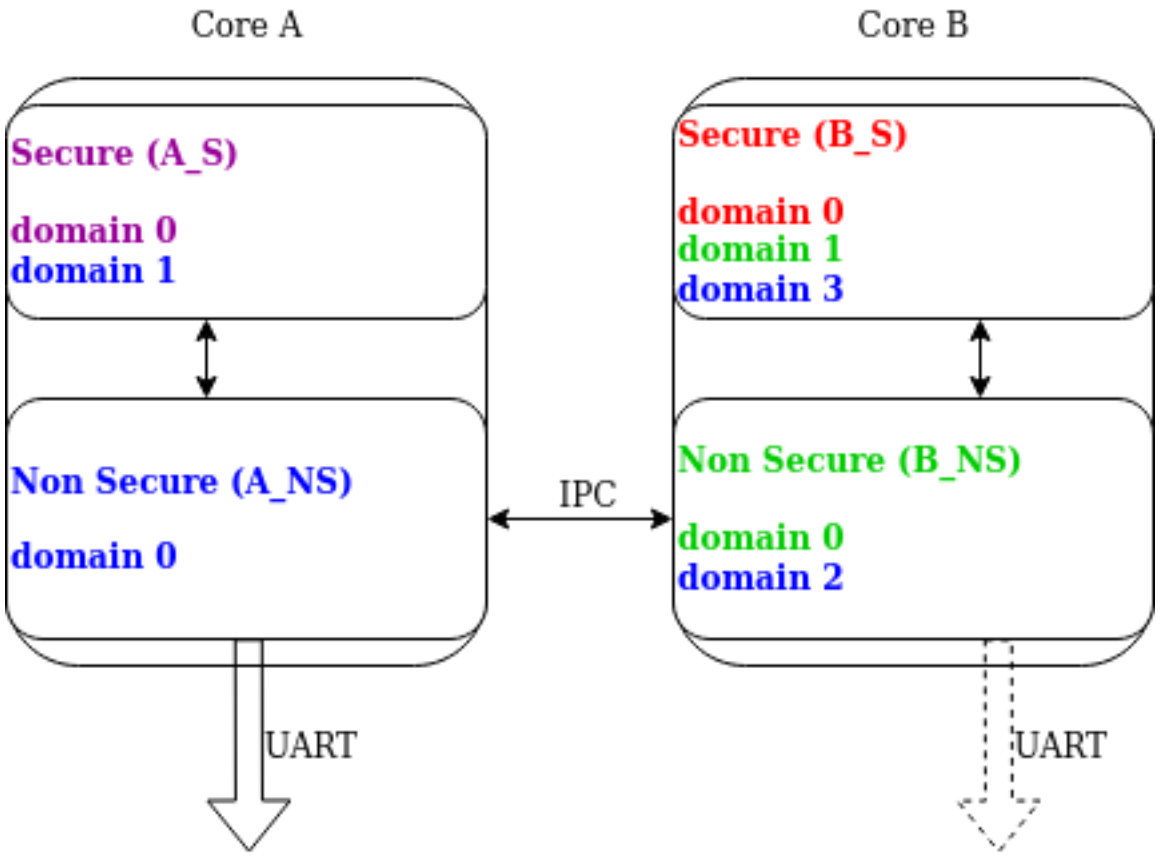

Fig. 6: Domain IDs assigning example

include converting a string package to a *fully self-contained* version (copying read-only strings to the package body).

Each domain can have a different timestamp source in terms of frequency and offset. Logging does not perform any timestamp conversion.

Runtime filtering In the single-domain case, each log source has a dedicated variable with runtime filtering for each backend in the system. In the multi-domain case, the originator of the log message is not aware of the number of backends in the root domain.

As such, to filter logs in multiple domains, each source requires a runtime filtering setting in each domain on the way to the root domain. As the number of sources in other domains is not known during the compilation, the runtime filtering of remote sources must use dynamically allocated memory (one word per source). When a backend in the root domain changes the filtering of the module from a remote domain, the local filter is updated. After the update, the aggregated filter (the maximum from all the local backends) is checked and, if changed, the remote domain is informed about this change. With this approach, the runtime filtering works identically in both multi-domain and single-domain scenarios.

Message ordering Logging does not provide any mechanism for synchronizing timestamps across multiple domains:

- If domains have different timestamp sources, messages will be processed in the order of arrival to the buffer in the root domain.
- If domains have the same timestamp source or if there is an out-of-bound mechanism that recalculates timestamps, there are 2 options:
  - Messages are processed as they arrive in the buffer in the root domain. Messages are

unordered but they can be sorted by the host as the timestamp indicates the time of the message generation.

- Links have dedicated buffers. During processing, the head of each buffer is checked and the oldest message is processed first.

  With this approach, it is possible to maintain the order of the messages at the cost of a suboptimal memory utilization (since the buffer is not shared) and increased processing latency (see CONFIG_LOG_PROCESSING_LATENCY_US).

Logging backends

Logging backends are registered using LOG_BACKEND_DEFINE. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (log_backend_enable()) and disabled. When *Run-time filtering* is enabled, log_filter_set() can be used to dynamically change filtering of a module logs for given backend. Module is identified by source ID and domain ID. Source ID can be retrieved if source name is known by iterating through all registered sources.

Logging supports up to 9 concurrent backends. Log message is passed to the each backend in processing phase. Additionally, backend is notified when logging enter panic mode with log_backend_panic(). On that call backend should switch to synchronous, interrupt-less operation or shut down itself if that is not supported. Occasionally, logging may inform backend about number of dropped messages with log_backend_dropped(). Message processing API is version specific.

log_backend_msg_process() is used for processing message. It is common for standard and hexdump messages because log message hold string with arguments and data. It is also common for deferred and immediate logging.

Message formatting Logging provides set of function that can be used by the backend to format a message. Helper functions are available in include/zephyr/logging/log_output.h.

Example message formatted using log_output_msg_process().

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

Dictionary-based Logging

Dictionary-based logging, instead of human readable texts, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that `long double` is not supported by Python's `struct` module. Therefore, log messages with `long double` will not display the correct values.

Configuration Here are kconfig options related to dictionary-based logging:

- CONFIG_LOG_DICTIONARY_SUPPORT enables dictionary-based logging support. This should be selected by the backends which require it.
- The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:

  - CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  - CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN tells the UART backend to output binary data.

Usage When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named `log_dictionary.json`, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

To use the log parser:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log␣
↪data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument `--hex` to the end if the log data file contains hexadecimal characters (e.g. when CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y). This tells the parser to convert the hexadecimal characters to binary before parsing.

Please refer to the logging-dictionary sample to learn more on how to use the log parser.

4.16.7 Recommendations and limitations

The are following recommendations:

- Enable CONFIG_LOG_SPEED to slightly speed up deferred logging at the cost of slight increase in memory footprint.
- Compiler with C11 `_Generic` keyword support is recommended. Logging performance is significantly degraded without it. See *Cbprintf Packaging*.
- It is recommended to cast pointer to `const char *` when it is used with %s format specifier and it points to a constant string.
- It is recommended to cast pointer to `char *` when it is used with %s format specifier and it points to a transient string.
- It is required to cast a character pointer to non character pointer (e.g., `void *`) when it is used with %p format specifier.

```
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

There are following limitations:

- Logging does not support string format specifier with width (e.g., %.*s or %8s). That is because format string content is not used to build a log message, only argument types.
- If deferred logging is used and log messages are prefixed with the thread name (Kconfig option CONFIG_LOG_THREAD_ID_PREFIX=y and CONFIG_THREAD_NAME=y), it is assumed that the corresponding `k_thread` structure is still valid when the log message is formatted. This can be an issue when that structure is allocated dynamically, using `k_malloc()` or `malloc()` for instance. In this case, if the thread logs some messages and then gets stopped and its `struct k_thread` is freed, the log system will still try to access that structure when handling the message later. This creates a use-after-free scenario. To avoid this, a solution consists in calling `log_flush()` before freeing the structure.

```
struct k_thread *thread = k_malloc(sizeof(*thread)); /* struct allocated␣
↪dynamically */
k_thread_create(thread, ...);
k_thread_name_set(thread, "foobar");

/* Thread calls LOG_*(...) */

k_thread_join(thread, K_FOREVER);
log_flush();  /* flush log buffer before freeing the struct k_thread */
k_free(thread); /* avoid a potential use-after-free scenario if deferred logging␣
↪is used */
```

4.16.8 Benchmark

Benchmark numbers from tests/subsys/logging/log_benchmark performed on `qemu_x86`. It is a rough comparison to give a general overview.

Feature	
Kernel logging	7us[3]/11us
User logging	13us
kernel logging with overwrite	10us[3]/15us
Logging transient string	42us
Logging transient string from user	50us
Memory utilization[4]	518
Memory footprint (test)[5]	2k
Memory footprint (application)[6]	3.5k
Message footprint[7]	47[3]/32 bytes

Benchmark details

4.16.9 Stack usage

When logging is enabled it impacts stack usage of the context that uses logging API. If stack is optimized it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when `CONFIG_LOG_MODE_DEFERRED` is used stack usage is smaller since logging is limited to creating and storing log message. When `CONFIG_LOG_MODE_IMMEDIATE` is used then log message is processed by the backend which includes string formatting. In case of that mode, stack usage will depend on which backends are used.

Some of the platforms characterization for log message with two `integer` arguments listed below:

[3] `CONFIG_LOG_SPEED` enabled.
[4] Number of log messages with various number of arguments that fits in 2048 bytes dedicated for logging.
[5] Logging subsystem memory footprint in tests/subsys/logging/log_benchmark where filtering and formatting features are not used.
[6] Logging subsystem memory footprint in samples/subsys/logging/logger.
[7] Average size of a log message (excluding string) with 2 arguments on `Cortex M3`

Platform	Deferred	Deferred (no optimization)	Immediate	Immediate (no optimization)
ARM Cortex-M3	40	152	412	783
x86	12	224	388	796
riscv32	24	208	456	844
xtensa	72	336	504	944
x86_64	32	528	1088	1440

Log output API

Multi-domain logging using ARM Coresight STM The Arm CoreSight SoC-400 is a comprehensive library of components for the creation of debug and trace functionality within a system. The STM (System Trace Macrocell) is a trace source that is integrated into a CoreSight system, designed primarily for high-bandwidth trace of instrumentation embedded into software. This instrumentation is made up of memory-mapped writes to the STMESP (STM Extended Stimulus Port) peripheral registers. Multiple cores can share and directly access the STM without being aware of each other. Each core has 65536 stimulus ports (identical register sets) which can be independently accessed thus there is no need for locking when various contexts want to log the data.

STM Extended Stimulus Port (STMESP) Local domain (each core) has access to its own set of STMESP peripherals. Each set has registers for writing data (with or without timestamp and with or without marking) and writing a flag. Each write to STMESP register results in the user data being encoded into MIPI System Trace Protocol v2 (STPv2). Hardware manages multiplexing of data from different STMESP register sets and from different cores by adding Major and Channel opcodes into the stream when necessary. Timestamp (from common source for all cores) and synchronization opcodes are autonomously added by the STM.

Data stream generated by STM can end up in various sinks. For example it can be directly send to TPIU (Trace Port Interface Unit) or saved in the RAM Circular Buffer which is called ETR (Embedded Trace Router). TPIU is a 5 pin interface (4 data pins and clock) and external tool is required to capture the data (e.g. J-Trace PRO). When ETR is used then one core in the system is responsible for processing that data, for example dumping it over UART to the host.

ARM Coresight Embedded Trace Router (ETR) ETR is a circular RAM buffer to which tracing data is saved. Since it may contain data from various sources additional wrapping protocol is used to multiplex them. `Coresight Trace Formatter` is used for that. Data is encoded into 16 bytes frames which holds up to 15 byte of data. Circular RAM buffer size is limited to 4k thus there is a risk of data overflow. If overflow occurs then data is lost but due to presence of synchronization opcodes in the STPv2 data stream synchronization can be restored.

Data from ETR is handled on the device. It can be forwarded as-is to the host (e.g. using UART), where a host tool is decoding the data or data can be decoded on-chip to output the data in human readable format.

Nordic Semiconductor NRF54H20 implementation instead of using ETR peripheral for getting buffer busyness is using own wrapper: Trace Buffer Monitor (TBM).

STMESP Logging frontend *Custom Frontend* API is implemented. Custom frontend assumes that all required operations are executed in the context of the logging macro call. It is also assumed that frontend provides the timestamp. Frontend utilizes a fact that there are multiple STMESP register sets and use multiple sets to avoid locking context. The atomically incremented channel counter is used to pick unique STMESP set and whole message is written to that STMESP. Limited pool of sets is used leaving most of channels for other purposes.

Early logging STMESP cannot be used before STM or ETR/TPIU is setup. In order to support early logging, before infrastructure is ready a dedicated RAM buffer is used to which data is written. When STM infrastructure readiness is notified (`log_frontend_stmesp_etr_ready()`)

then RAM buffer content is written to STMESP. Early logging is applicable only to the core which owns and configures Coresight infrastructure (e.g. in case of NRF54H20 it is the Secure core).

Trace points There may be cases when logging is too slow (even though it is very fast). For cases like that a dedicated `trace point` API is added. It is extremely fast because it is just a single write to one STMESP register. There are 2 functions in the API:

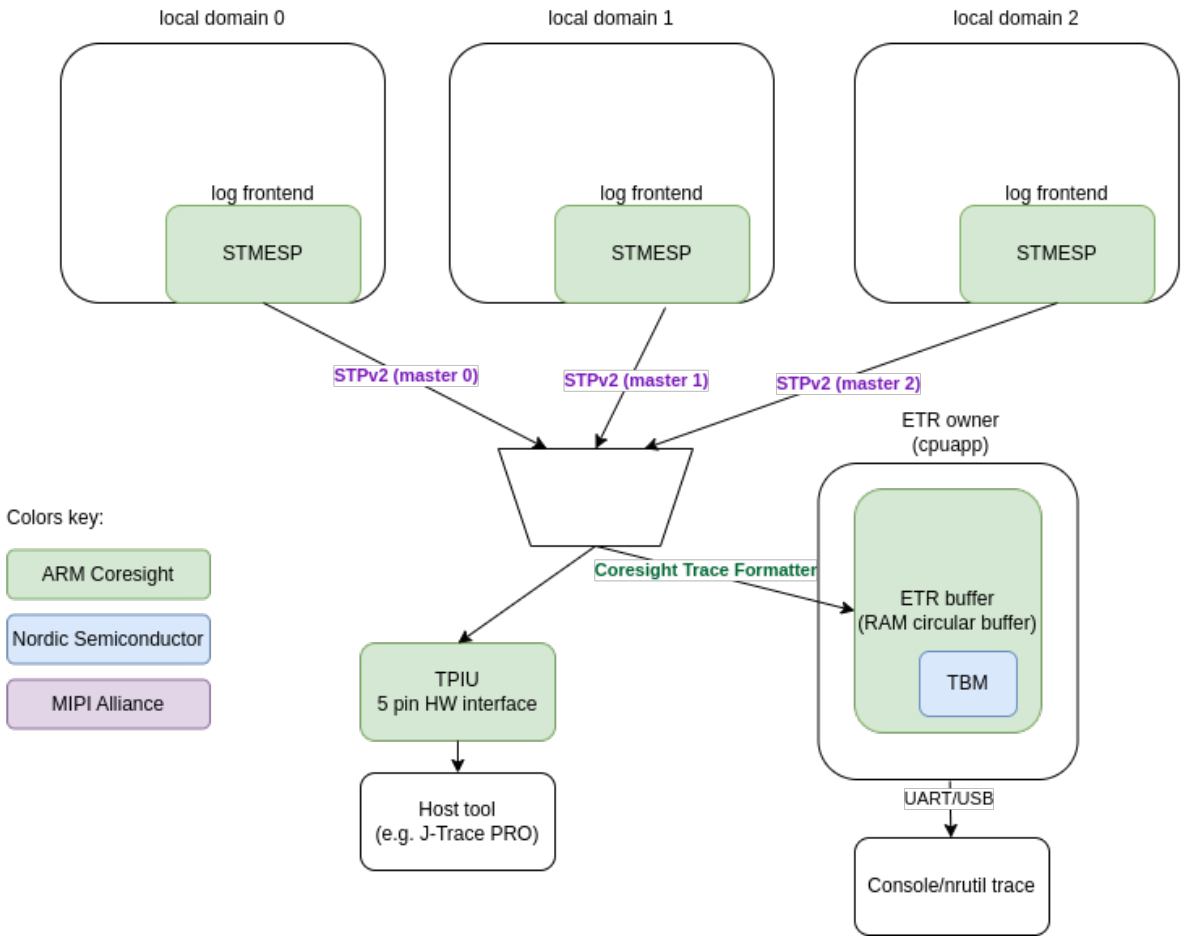
- `log_frontend_stmesp_tp()` - It accepts single argument - index. Index is between 0 and 65280.
- `log_frontend_stmesp_tp_d32()` - It accepts two arguments - index and user data. Index is between 0 and 65280. User data is 32 bit word.

It takes less than 100 ns to log a single trace point on NRF54H20 and it is approx. 7 times faster than the fastest log message.

Logging using STM STM logging has 2 modes of operations:

- Dictionary-based - assisted mode which is using dictionary-based logging. In this mode logging strings can be removed from the binary because they are only needed for decoding and decoding is performed by the host tool. This mode takes less memory and is faster (2-3 times faster). There is less data written so there is less chance of data overflow in ETR buffer.
- Standalone - data is decoded on chip and human-readable strings are printed. This mode requires more device resources and processing power.

Following figure presents multi-domain logging using ARM Coresight STM.



Each core (local domain) is using logging frontend which writes logging data to STMESP registers.

If TPIU is used as the output then there is no more software components needed. STPv2 stream of data is composed by STM and send over TPIU.

If ETR RAM buffer is used then buffer owner core (`proxy`) is responsible for handling that data. If dictionary-based logging is used then proxy just sends data as-is over UART. If standalone logging is used then proxy is using *ARM Coresight Trace Deformatter* and *MIPI STP Decoder* to decode data and demultiplex messages. Messages are formatted to human readable strings using logging *Message formatting*.

Dictionary-based logging Assisted multicore logging uses dictionary-based logging to send messages without redundant strings to STM, and is based on the *Dictionary-based Logging* feature of the logging API provided by Zephyr. Instead of including the format strings in the log messages, it logs the addresses (message IDs) where the strings are stored, which reduces the size of the logging subsystem. If the data goes to the ETR buffer, the proxy core's responsibility is to dump this data. The host PC, equipped with a decoder tool, translates these addresses back into human-readable text using a JSON database generated during the build process.

When using logs, this method has the following advantages:

- It reduces the size of the binary, as the strings used in the log messages are not stored in the binary itself. Logging infrastructure is also very limited. On local domains it is just the frontend. There is even no need to have string formatting function.
- It reduces the amount of data that needs to be sent to and processed by the application core, as the string formatting is offloaded to the host side.
- Logging is fast. It takes less than 1 us to log a simple message (up to 2 arguments) on NRF54H20.

Proxy core is using Nordic specific peripheral (TBM) to get ETR buffer busyness and send data over UART. Nordic specific driver for ETR buffer is located in drivers/debug/debug_nrf_etr.c.

Configuration For Nordic SoC a dedicated snippet (*Nordic Dictionary-based STM logging snippet (nordic-log-stm-dict)*) shall be used to enable logging. Each core shall be build with that snippet. If any core wants to use it then application core is required to have it enabled too since it acts as the proxy (ETR buffer processing). All cores must use the same configuration of the logging.

Reading the logs To read the dictionary-based STM log output, do the following:

1. Set up the log capture.

   Use the `nrfutil trace stm` command to start capturing logs from the device, specifying the database configuration for each domain ID, as well as the serial port, the baud rate, and the output file name:

   ```
   nrfutil trace stm --database-config␣
   ↪34:build/zephyr/log_dictionary.json,35:build_rad/zephyr/log_dictionary.json␣
   ↪--input-serialport /dev/ttyACM1 --baudrate 115200 --output-ascii out.txt
   ```

2. Capture and decode the logs.

   nrfutil will capture the log data from the specified UART port and use the provided dictionary databases to decode the logs into a human-readable format. The decoded logs will be saved in the specified output file (the `out.txt` file in the previous example).

3. Open the output file to review the decoded log messages.

   The file will contain timestamps and the log messages in a format that is human-readable.

If the log capture fails to find a sync, rerun the capture process.

Note

Decoding artifacts or incorrect timestamps might occur when rerunning the process.

Each log line contains a domain-related or core-related prefix between the log level and the module name, indicating the core that generated the log entry. The following are the prefixes used to indicate the cores:

Table 7: nRF54H20 log prefixes

Core	Prefix	ID
Secure Domain	sec	0x21
Application core	app	0x22
Radio core	rad	0x23
System Controller (SysCtrl)	sys	0x2c
Fast Lightweight Processor (FLPR)	flpr	0x2d
Peripheral Processor (PPR)	ppr	0x2e
	mod	0x24

Stand-alone logging Frontend is writing to STMESP registers. Message format is aligned with the on chip decoder in subsys/logging/frontends/log_frontend_stmesp_demux.c.

`Proxy` is using Nordic specific peripheral (TBM) to get ETR buffer busyness and read and decode data and send human-readable data over UART. Nordic specific driver for ETR buffer is located in drivers/debug/debug_nrf_etr.c. It is using *ARM Coresight Trace Deformatter* and *MIPI STP Decoder* and above-mentioned demultiplexer to decode messages.

Logging messages contains read-only format string used in the logging macros thus they cannot be removed from the binary. This mode uses more read-only memory and has lower throughput because messages are longer and processing is time consuming. Compared to the dictionary-based mode logging is 2-3 slower.

Configuration For Nordic SoC a dedicated snippet (*Nordic Standalone STM logging snippet (nordic-log-stm)*) shall be used to enable logging. Each core shall be build with that snippet. If any core wants to use it then application core is required to have it enabled too since it acts as the proxy (ETR buffer processing). All cores must use the same configuration of the logging.

Reading the logs Logs are printed using Console UART.

Note

To use UART in your application, the UART's node must be described in devicetree. For more details, see *Introduction to devicetree*.

The following is an example log output:

```
[00:00:00.154,790] <inf> app/spsc_pbuf: alloc in 0x2f0df800
[00:00:00.163,319] <inf> app/spsc_pbuf: alloc 0x2f0df800 wr_idx:20

[00:00:00.189,090] <inf> app/spsc_pbuf: commit 0x2f0df800, len:20 wr_idx: 44
[00:00:00.202,577] <inf> rad/icmsg: mbox_callback
[00:00:00.214,750] <inf> rad/spsc_pbuf: claim 0x2f0df800 rd_idx:20
[00:00:00.235,823] <inf> rad/spsc_pbuf: free 0x2f0df800 len:20 rd_idx: 44
[00:00:00.244,507] <inf> rad/spsc_pbuf: read done 0x2f0df800 len:20
```

(continues on next page)

(continued from previous page)

```
[00:00:00.272,444] <inf> rad/host: ep recv 0x330021f0, len:20
[00:00:00.283,939] <inf> rad/host: rx:00 exp:00
[00:00:00.292,200] <inf> rad/icmsg: read 0
[00:00:05.077,026] <inf> rad/spsc_pbuf: alloc in 0x2f0df000
[00:00:05.077,068] <inf> rad/spsc_pbuf: alloc 0x2f0df000 wr_idx:44
[00:00:05.077,098] <inf> rad/spsc_pbuf: commit in 0x2f0df000
[00:00:05.077,134] <inf> rad/spsc_pbuf: commit 0x2f0df000, len:20 wr_idx
```

Each log line contains a domain-related or core-related prefix between the log level and the module name, indicating the core that generated the log entry. The following are the prefixes used to indicate the cores:

Table 8: nRF54H20 log prefixes

Core	Prefix
Secure Domain	`sec`
Application core	`app`
Radio core	`rad`
System Controller (SysCtrl)	`sys`
Fast Lightweight Processor (FLPR)	`flpr`
Peripheral Processor (PPR)	`ppr`

Additional considerations When using STM logging, consider the following:

- Use optimized log macros (having up to 2 word size numeric arguments, like `LOG_INF("%d %c", (int)x, (char)y)`) to improve the size and speed of logging.
- For memory constrained applications (for example, when running on the PPR core), disable the `printk()` function by setting both the `CONFIG_PRINTK` and `CONFIG_BOOT_BANNER` Kconfig options to `n` in your project configuration.
- When working with multiple domains, such as the Radio core and Application core, ensure that each database is prefixed with the correct domain ID.
- Some log messages might be dropped due to the limited size of the RAM buffer that stores STM logs.

4.17 Tracing

4.17.1 Overview

The tracing feature provides hooks that permits you to collect data from your application and allows *Tracing Tools* running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in include/zephyr/tracing/tracing.h.

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the *I/O taxonomy* section below.

4.17.2 Named Trace Events

Although the user can extend any of the supported serialization formats to enable additional tracing functions (or provide their own backend), zephyr also provides one generic named tracing function for convenience purposes, as well as to demonstrate how tracing frameworks could be extended.

Users can generate a custom trace event by calling `sys_trace_named_event()`, which takes an event name as well as two arbitrary 4 byte arguments. Tracing backends may truncate the provided event name if it is too long for the serialization format they support.

4.17.3 Serialization Formats

Common Trace Format (CTF) Support

Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.

CTF should look familiar to C programmers but adds stronger typing. See CTF - A Flexible, High-performance Binary Trace Format.

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

A Generic Interface In CTF, an event is serialized to a packet containing one or more fields. As seen from *I/O taxonomy* section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

CTF Top-Layer Example The CTF_EVENT macro will serialize each argument to a field:

```
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
  CTF_EVENT(
    CTF_LITERAL(uint8_t, 42),
    thread_id,
    name,
    "hello, I was emitted from function: ",
    __func__  /* __func__ is standard since C99 */
  );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

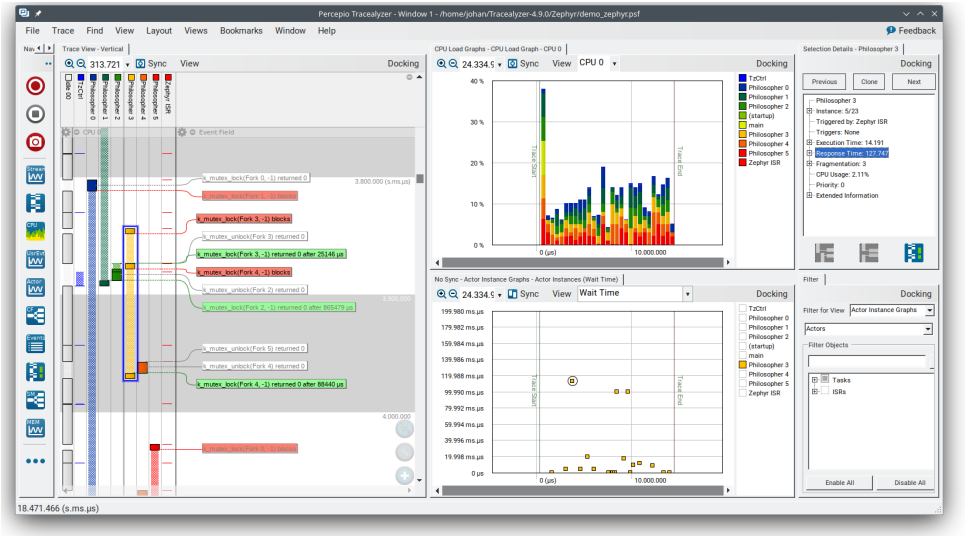
The CTF top layer is enabled using the configuration option `CONFIG_TRACING_CTF` and can be used with the different transport backends both in synchronous and asynchronous modes.

4.17.4 Tracing Tools

Zephyr includes support for several popular tracing tools, presented below in alphabetical order.

Percepio Tracealyzer Support

Zephyr includes support for Percepio Tracealyzer that offers trace visualization for simplified analysis, report generation and other analysis features. Tracealyzer allows for trace streaming over various interfaces and also snapshot tracing, where the events are kept in a RAM buffer.



Zephyr kernel events are captured automatically when Tracealyzer tracing is enabled. Tracealyzer also provides extensive support for application logging, where you call the tracing library from your application code. This lets you visualize kernel events and application events together, for example as data plots or state diagrams on logged variables. Learn more in the Tracealyzer User Manual provided with the application.

Percepio TraceRecorder and Stream Ports The tracing library for Tracealyzer (TraceRecorder) is included in the Zephyr manifest and provided under the same license (Apache 2.0). This is enabled by adding the following configuration options in your prj.conf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
```

Or using menuconfig:

- Enable *Subsystems and OS Services* ▸ *Tracing Support*
- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*

Some additional settings are needed to configure TraceRecorder. The most important configuration is to select the right "stream port". This specifies how to output the trace data. As of July 2024, the following stream ports are available in the Zephyr configuration system:

- **Ring Buffer**: The trace data is kept in a circular RAM buffer.
- **RTT**: Trace streaming via Segger RTT on J-Link debug probes.
- **ITM**: Trace streaming via the ITM function on Arm Cortex-M devices.
- **Semihost**: For tracing on QEMU. Streams the trace data to a host file.

Select the stream port in menuconfig under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*.

Or simply add one of the following options in your prj.conf:

```
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ZEPHYR_SEMIHOST=y
```

Make sure to only include ONE of these configuration options.

The stream port modules have individual configuration options. In menuconfig these are found under *Modules ▸ percepio ▸ TraceRecorder ▸ (Stream Port) Config*. The most important options for each stream port are described below.

Tracealyzer Snapshot Tracing (Ring Buffer) The "Ring Buffer" stream port keeps the trace data in a RAM buffer on the device. By default, this is a circular buffer, meaning that it always contains the most recent data. This is used to dump "snapshots" of the trace data, e.g. by using the debugger. This usually only allows for short traces, unless you have megabytes of RAM to spare, so it is not suitable for profiling. However, it can be quite useful for debugging in combination with breakpoints. For example, if you set a breakpoint in an error handler, a snapshot trace can show the sequence of events leading up to the error. Snapshot tracing is also easy to begin with, since it doesn't depend on any particular debug probe or other development tool.

To use the Ring Buffer option, make sure to have the following configuration options in your prj.cnf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER_SIZE=<size in bytes>
```

Or if using menuconfig:

- Enable *Subsystems and OS Services ▸ Tracing Support*
- Under *Subsystems and OS Services ▸ Tracing Support ▸ Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Recorder Start Mode*, select *Start*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Stream Port*, select *Ring Buffer*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Ring Buffer Config ▸ Buffer Size*, set the buffer size in bytes.

The default buffer size can be reduced if you are tight on RAM, or increased if you have RAM to spare and want longer traces. You may also optimize the Tracing Configuration settings to get longer traces by filtering out less important events. In menuconfig, see *Subsystems and OS Services ▸ Tracing Support ▸ Tracing Configuration*.

To view the trace data, the easiest way is to start your debugger (west debug) and run the following GDB command:

```
dump binary value trace.bin *RecorderDataPtr
```

The resulting file is typically found in the root of the build folder, unless a different path is specified. Open this file in Tracealyzer by selecting *File ▸ Open ▸ Open File*.

Tracealyzer Streaming with SEGGER RTT Tracealyzer has built-in support for SEGGER RTT to receive trace data using a J-Link probe. This allows for recording very long traces. To configure Zephyr for RTT streaming to Tracealyzer, add the following configuration options in your prj.cnf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START_FROM_HOST=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT_UP_BUFFER_SIZE=<size in bytes>
```

Or if using menuconfig:

- Enable *Subsystems and OS Services ▸ Tracing Support*
- Under *Subsystems and OS Services ▸ Tracing Support ▸ Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Recorder Start Mode*, select *Start From Host*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Stream Port*, select *RTT*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ RTT Config*, set the size of the RTT "up" buffer in bytes.

The setting *RTT buffer size up* sets the size of the RTT transmission buffer. This is important for throughput. By default this buffer is quite large, 5000 bytes, to give decent performance also on onboard J-Link debuggers (they are not as fast as the stand-alone probes). If you are tight on RAM, you may consider reducing this setting. If using a regular J-Link probe it is often sufficient with a much smaller buffer, e.g. 1 KB or less.

Learn more about RTT streaming in the Tracealyzer User Manual. See Creating and Loading Traces -> Percepio TraceRecorder -> Using TraceRecorder v4.6 or later -> Stream ports (or search for RTT).

Tracealyzer Streaming with Arm ITM This stream port is for Arm Cortex-M devices featuring the ITM unit. It is recommended to use a fast debug probe that allows for SWO speeds of 10 MHz or higher. To use this stream port, apply the following configuration options:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM_PORT=1
```

Or if using menuconfig:

- Enable *Subsystems and OS Services ▸ Tracing Support*
- Under *Subsystems and OS Services ▸ Tracing Support ▸ Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Recorder Start Mode*, select *Start*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Stream Port*, select *ITM*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ ITM Config*, set the ITM port to 1.

The main setting for the ITM stream port is the ITM port (0-31). A dedicated channel is needed for Tracealyzer. Port 0 is usually reserved for printf logging, so channel 1 is used by default.

The option *Use internal buffer* should typically remain disabled. It buffers the data in RAM before transmission and defers the data transmission to the periodic TzCtrl thread.

The host-side setup depends on what debug probe you are using. Learn more in the Tracealyzer User Manual. See *Creating and Loading Traces ▸ Percepio TraceRecorder ▸ Using TraceRecorder v4.6 or later ▸ Stream ports (or search for ITM)*.

Tracealyzer Streaming from QEMU (Semihost) This stream port is designed for Zephyr tracing in QEMU. This can be an easy way to get started with tracing and try out streaming trace without needing a fast debug probe. The data is streamed to a host file using semihosting. To use this option, apply the following configuration options:

```
CONFIG_SEMIHOST=y
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ZEPHYR_SEMIHOST=y
```

Using menuconfig

- Enable *General Architecture Options ▸ Semihosting support for Arm and RISC-V targets*
- Enable *Subsystems and OS Services ▸ Tracing Support*
- Under *Subsystems and OS Services ▸ Tracing Support ▸ Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Recorder Start Mode*, select *Start*
- Under *Modules ▸ percepio ▸ TraceRecorder ▸ Stream Port*, select *Semihost*

By default, the resulting trace file is found in `./trace.psf` in the root of the build folder, unless a different path is specified. Open this file in Percepio Tracealyzer by selecting *File ▸ Open ▸ Open File*.

Recorder Start Mode You may have noticed the *Recorder Start Mode* option in the Tracealyzer examples above. This decides when the tracing starts. With the option *Start*, the tracing begins directly at startup, once the TraceRecorder library has been initialized. This is recommended when using the Ring Buffer and Semihost stream ports.

For streaming via RTT or ITM you may also use *Start From Host* or *Start Await Host*. Both listens for start commands from the Tracealyzer application. The latter option, *Start Await Host*, causes the TraceRecorder initialization to block until the start command is received from the Tracealyzer application.

Custom Stream Ports for Tracealyzer The stream ports are small modules within TraceRecorder that define what functions to call to output the trace data and (optionally) how to read start/stop commands from Tracealyzer. It is fairly easy to make custom stream ports to implement your own data transport and Tracealyzer can receive trace streams over various interfaces, including files, sockets, COM ports, named pipes and more. Note that additional stream port modules are available in the TraceRecorder repo (e.g. lwIP), although they might require modifications to work with Zephyr.

Learning More Learn more about how to get started in the Tracealyzer Getting Started Guides.

Percepio View for Zephyr

Percepio View is a free-of-charge tracing tool based on Percepio Tracealyzer, intended for debugging and verification of Zephyr applications.

Percepio View can be used side-by-side with a traditional debugger and complements your debugger by visualising the real-time execution of threads, ISRs, syscalls and your own "User Events".

To learn more about Percepio View, how to get started and upgrade options, check out Percepio's product page.

Percepio View provides snapshot tracing, meaning the data is stored to a ring-buffer in target RAM and is saved to host using the regular debugger connection. For trace streaming support,

Percepio offers (paid-for) upgrades to Percepio Profile or Percepio Tracealyzer. No modifications of the Zephyr source code are needed, only enabling the TraceRecorder library in Kconfig. Percepio View runs on Windows and Linux hosts.

SEGGER SystemView Support

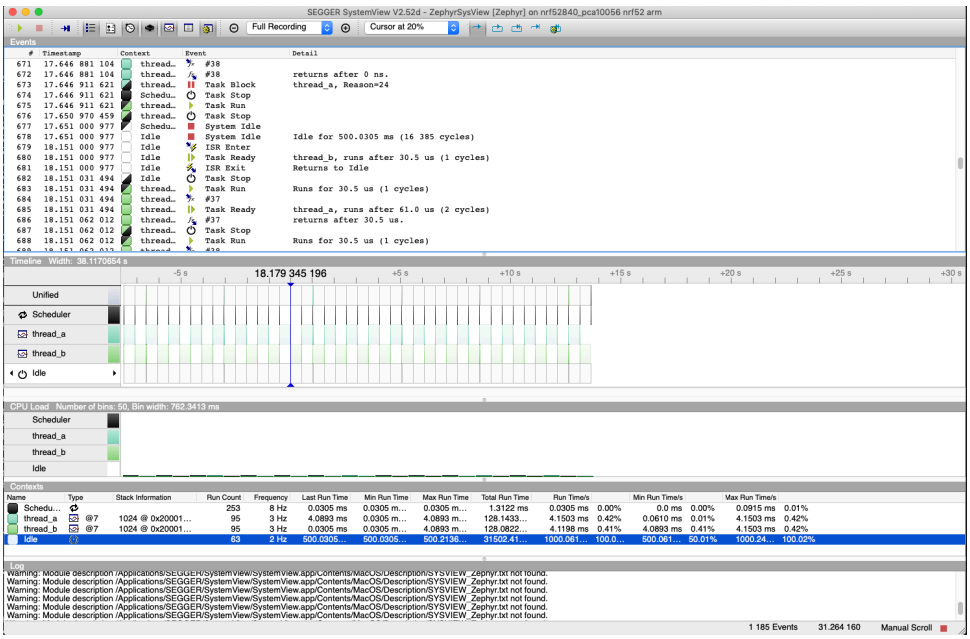
Zephyr provides built-in support for SEGGER SystemView that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with SEGGER SystemView add the *SystemView RTT Tracing Snippet (rtt-tracing)* to your build command:

```
west build -b <board> -S rtt-tracing samples/synchronization
```

SystemView can also be used for post-mortem tracing, which can be enabled with `CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE`. In this mode, a debugger can be attached after the system has crashed using `west attach` after which the latest data from the internal RAM buffer can be loaded into SystemView.



Recent versions of SEGGER SystemView come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```
# On Linux and MacOS
cp $ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

TraceCompass

TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems.

See also the presentation by Ericsson, Advanced Trouble-shooting Of Real-time Systems.

User-Defined Tracing

This tracing format allows the user to define functions to perform any work desired when a task is switched in or out, when an interrupt is entered or exited, and when the cpu is idle.

Examples include: - simple toggling of GPIO for external scope tracing while minimizing extra cpu load - generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The following functions can be defined by the user:

```
void sys_trace_thread_create_user(struct k_thread *thread);
void sys_trace_thread_abort_user(struct k_thread *thread);
void sys_trace_thread_suspend_user(struct k_thread *thread);
void sys_trace_thread_resume_user(struct k_thread *thread);
void sys_trace_thread_name_set_user(struct k_thread *thread);
void sys_trace_thread_switched_in_user(struct k_thread *thread);
void sys_trace_thread_switched_out_user(struct k_thread *thread);
void sys_trace_thread_info_user(struct k_thread *thread);
void sys_trace_thread_sched_ready_user(struct k_thread *thread);
void sys_trace_thread_pend_user(struct k_thread *thread);
void sys_trace_thread_priority_set_user(struct k_thread *thread, int prio);
void sys_trace_isr_enter_user(int nested_interrupts);
void sys_trace_isr_exit_user(int nested_interrupts);
void sys_trace_idle_user();
```

Enable this format with the `CONFIG_TRACING_USER` option.

4.17.5 Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using the native port with POSIX architecture based targets)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

4.17.6 Using Tracing

The sample samples/subsys/tracing demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the native_sim port, build the sample as follows:

Using west:

```
# From the root of the zephyr repository
west build -b native_sim samples/subsys/tracing -- -DCONF_FILE=prj_native_ctf.conf
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=native_sim -DCONF_FILE=prj_native_ctf.conf␣
↪samples/subsys/tracing

# Now run the build tool on the generated build system:
ninja -Cbuild
```

You can then run the resulting binary with the option `-trace-file` to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the `data` directory with the metadata and trace files.

Using RAM backend

For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace data, the ram backend can be enabled with configuration `CONFIG_TRACING_BACKEND_RAM`. Adjust `CONFIG_RAM_TRACING_BUFFER_SIZE` to be able to record enough traces for your needs. Then thanks to a runtime debugger such as gdb this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting channel0_0 file have to be placed in a directory with the `metadata` file like the other backend.

4.17.7 Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr's Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux's LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass' canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - **synchronous:**
    means data-transmission has completed with the return of the call.
  - **asynchronous:**
    means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:**
    means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

  Examples:

  - **sync unbuffered**
    E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (can't amortize the overhead of writing).
  - **sync buffered**
    E.g. `fwrite()` or enqueuing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.

  - **async unbuffered**
    E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
  - **async buffered**
    E.g. enqueuing into FIFO.

- Atomic Pull/Consume/Read/Dequeue:
  - **synchronous:**
    means data-reception has completed with the return of the call.
  - **asynchronous:**
    means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:**
    means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.

  Examples:
  - **sync unbuffered**
    E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.
  - **sync buffered**
    E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits spatial locality.
  - **async unbuffered**
    E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
  - **async buffered**
    E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if multiple independent channels are available.

- **The system has non-atomic write and one shared channel**
  E.g. UART. Locking required.

  ```
  lock(); emit(a); emit(b); emit(c); release();
  ```

- **The system has non-atomic write but many channels**
  E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own channel, thus alleviating races as each thread is sequentially consistent with itself.

  ```
  emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
  ```

- **The system has atomic write but one shared channel**
  E.g. `native_sim` or board with DMA. May or may not need locking.

  ```
  emit(a ## b ## c); /* Concat to buffer */

  lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
  ```

- **The system has atomic write and many channels**
  E.g. native_sim or board with multi-channel DMA. Lock-free.

  ```
  emit(a ## b ## c, thread_id);
  ```

4.17.8 Object tracking

The kernel can also maintain lists of objects that can be used to track their usage. Currently, the following lists can be enabled:

```
struct k_timer *_track_list_k_timer;
struct k_mem_slab *_track_list_k_mem_slab;
struct k_sem *_track_list_k_sem;
struct k_mutex *_track_list_k_mutex;
struct k_stack *_track_list_k_stack;
struct k_msgq *_track_list_k_msgq;
struct k_mbox *_track_list_k_mbox;
struct k_pipe *_track_list_k_pipe;
struct k_queue *_track_list_k_queue;
struct k_event *_track_list_k_event;
```

Those global variables are the head of each list - they can be traversed with the help of macro `SYS_PORT_TRACK_NEXT`. For instance, to traverse all initialized mutexes, one can write:

```
struct k_mutex *cur = _track_list_k_mutex;
while (cur != NULL) {
  /* Do something */

  cur = SYS_PORT_TRACK_NEXT(cur);
}
```

To enable object tracking, enable `CONFIG_TRACING_OBJECT_TRACKING`. Note that each list can be enabled or disabled via their tracing configuration. For example, to disable tracking of semaphores, one can disable `CONFIG_TRACING_SEMAPHORE`.

Object tracking is behind tracing configuration as it currently leverages tracing infrastructure to perform the tracking.

4.18 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multi-threaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.

- *On-Off Manager*

4.18.1 On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:

- The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.
- The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.
- The service transitions from off to on when first client request is received.
- The service transitions from on to off when last client release is received.
- Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invokable from both thread and interrupt context.
- The request and reset operations are asynchronous using *Asynchronous Notifications*. Both operations may be cancelled, but cancellation has no effect on the in-progress transition.
- Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through *Asynchronous Notifications*.

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by

registering a monitor with onoff_monitor_register(). Notification of changes are provided before issuing completion notifications associated with the new state.

Note

A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use `onoff_sync_service` and its supporting API rather than `onoff_manager`, with only a small reduction in functionality (primarily no support for the monitor API).

On-Off Service APIs

4.19 Memory Attributes

It is possible in the devicetree to mark the memory regions with attributes by using the `zephyr,memory-attr` property. This property and the related memory region can then be retrieved at run-time by leveraging a provided helper library.

The set of general attributes that can be specified in the property are defined and explained in include/zephyr/dt-bindings/memory-attr/memory-attr.h.

For example, to mark a memory region in the devicetree as non-volatile, cacheable, out-of-order:

```
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_NON_VOLATILE | DT_MEM_CACHEABLE | DT_MEM_OOO)>;
};
```

Note

The `zephyr,memory-attr` usage does not result in any memory region actually created. When it is needed to create an actual section out of the devicetree defined memory region, it is possible to use the compatible `zephyr,memory-region` that will result (only when supported by the architecture) in a new linker section and region.

The `zephyr,memory-attr` property can also be used to set architecture-specific and software-specific custom attributes that can be interpreted at run time. This is leveraged, among other things, to create MPU regions out of devicetree defined memory regions, for example:

```
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-region = "NOCACHE_REGION";
    zephyr,memory-attr = <DT_MEM_ARM_MPU_RAM_NOCACHE>;
};
```

See include/zephyr/dt-bindings/memory-attr/memory-attr-arm.h and *Memory map and MPU considerations* in the *Arm Cortex-M Developer Guide* for more details about MPU usage. Also see *Caching Basics* for details on how Zephyr handles caching.

The conventional and recommended way to deal and manage with memory regions marked with attributes is by using the provided `mem-attr` helper library by enabling `CONFIG_MEM_ATTR`. When this option is enabled the list of memory regions and their attributes are compiled in a user-accessible array and a set of functions is made available that can be used to query, probe and act on regions and attributes (see next section for more details).

Note

The `zephyr,memory-attr` property is only a descriptive property of the capabilities of the associated memory region, but it does not result in any actual setting for the memory to be set. The user, code or subsystem willing to use this information to do some work (for example creating an MPU region out of the property) must use either the provided `mem-attr` library or the usual devicetree helpers to perform the required work / setting. Note, however, that for some architectures (such as ARM and ARM64) the MPU driver uses this information to properly initialize caching at boot. See `CONFIG_ARM_MPU`, `CONFIG_RISCV_PMP`, etc.

A test for the `mem-attr` library and its usage is provided in `tests/subsys/mem_mgmt/mem_attr/`.

4.19.1 Migration guide from `zephyr,memory-region-mpu`

When the `zephyr,memory-attr` property was introduced, the `zephyr,memory-region-mpu` property was removed and deprecated.

The developers that are still using the deprecated property can move to the new one by renaming the property and changing its value according to the following list:

```
"RAM"          -> <DT_MEM_ARM_MPU_RAM>
"RAM_NOCACHE" -> <DT_MEM_ARM_MPU_RAM_NOCACHE>
"FLASH"        -> <DT_MEM_ARM_MPU_FLASH>
"PPB"          -> <DT_MEM_ARM_MPU_PPB>
"IO"           -> <DT_MEM_ARM_MPU_IO>
"EXTMEM"       -> <DT_MEM_ARM_MPU_EXTMEM>
```

4.19.2 Memory Attributes Heap Allocator

It is possible to leverage the memory attribute property `zephyr,memory-attr` to define and create a set of memory heaps from which the user can allocate memory from with certain attributes / capabilities.

When the `CONFIG_MEM_ATTR_HEAP` is set, every region marked with one of the memory attributes listed in include/zephyr/dt-bindings/memory-attr/memory-attr-sw.h is added to a pool of memory heaps used for dynamic allocation of memory buffers with certain attributes.

Here a non exhaustive list of possible attributes:

```
DT_MEM_SW_ALLOC_CACHE
DT_MEM_SW_ALLOC_NON_CACHE
DT_MEM_SW_ALLOC_DMA
```

For example we can define several memory regions with different attributes and use the appropriate attribute to indicate that it is possible to dynamically allocate memory from those regions:

```
mem_cacheable: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE | DT_MEM_SW_ALLOC_CACHE)>;
};

mem_non_cacheable: memory@20000000 {
    compatible = "mmio-sram";
    reg = <0x20000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_NON_CACHEABLE | ATTR_SW_ALLOC_NON_CACHE)>;
};
```

(continues on next page)

(continued from previous page)

```
mem_cacheable_big: memory@30000000 {
    compatible = "mmio-sram";
    reg = <0x30000000 0x10000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE | DT_MEM_OOO | DT_MEM_SW_ALLOC_CACHE)>;
};

mem_cacheable_dma: memory@40000000 {
    compatible = "mmio-sram";
    reg = <0x40000000 0x10000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE       | DT_MEM_DMA |
                           DT_MEM_SW_ALLOC_CACHE | DT_MEM_SW_ALLOC_DMA)>;
};
```

The user can then dynamically carve memory out of those regions using the provided functions, the library will take care of allocating memory from the correct heap depending on the provided attribute and size:

```
// Init the pool
mem_attr_heap_pool_init();

// Allocate 0x100 bytes of cacheable memory from `mem_cacheable`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE, 0x100);

// Allocate 0x200 bytes of non-cacheable memory aligned to 32 bytes
// from `mem_non_cacheable`
block = mem_attr_heap_aligned_alloc(ATTR_SW_ALLOC_NON_CACHE, 0x100, 32);

// Allocate 0x100 bytes of cacheable and dma-able memory from `mem_cacheable_dma`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE | DT_MEM_SW_ALLOC_DMA, 0x100);
```

When several regions are marked with the same attributes, the memory is allocated:

1. From the regions where the `zephyr,memory-attr` property has the requested property (or properties).
2. Among the regions as at point 1, from the smallest region if there is any unallocated space left for the requested size
3. If there is not enough space, from the next bigger region able to accommodate the requested size

The following example shows the point 3:

```
// This memory is allocated from `mem_non_cacheable`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_NON_CACHE, 0x100);

// This memory is allocated from `mem_cacheable_big`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE, 0x5000);
```

Note

The framework is assuming that the memory regions used to create the heaps are usable by the code and available at init time. The user must take of initializing and setting the memory area before calling `mem_attr_heap_pool_init()`.

That means that the region must be correctly configured in terms of MPU / MMU (if needed) and that an actual heap can be created out of it, for example by leveraging the `zephyr,`

`memory-region` property to create a proper linker section to accommodate the heap.

Memory heaps based on memory attributes

4.20 Network Buffers

- *Overview*
- *Creating buffers*
- *Common Operations*
- *Reference Counting*
- *API Reference*

4.20.1 Overview

Network buffers are a core concept of how the networking stack (as well as the Bluetooth stack) pass data around. The API for them is defined in include/zephyr/net_buf.h:.

4.20.2 Creating buffers

Network buffers are created by first defining a pool of them:

```
NET_BUF_POOL_DEFINE(pool_name, buf_count, buf_size, user_data_size, NULL);
```

The pool is a static variable, so if it's needed to be exported to another module a separate pointer is needed.

Once the pool has been defined, buffers can be allocated from it with:

```
buf = net_buf_alloc(&pool_name, timeout);
```

There is no explicit initialization function for the pool or its buffers, rather this is done implicitly as `net_buf_alloc()` gets called.

If there is a need to reserve space in the buffer for protocol headers to be prepended later, it's possible to reserve this headroom with:

```
net_buf_reserve(buf, headroom);
```

In addition to actual protocol data and generic parsing context, network buffers may also contain protocol-specific context, known as user data. Both the maximum data and user data capacity of the buffers is compile-time defined when declaring the buffer pool.

The buffers have native support for being passed through k_fifo kernel objects. Use `k_fifo_put()` and `k_fifo_get()` to pass buffer from one thread to another.

Special functions exist for dealing with buffers in single linked lists, where the `net_buf_slist_put()` and `net_buf_slist_get()` functions must be used instead of `sys_slist_append()` and `sys_slist_get()`.

4.20.3 Common Operations

The network buffer API provides some useful helpers for encoding and decoding data in the buffers. To fully understand these helpers it's good to understand the basic names of operations used with them:

Add
: Add data to the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Requires that there is enough tailroom in the buffer. Some examples of APIs for adding data:

```
void *net_buf_add(struct net_buf *buf, size_t len);
void *net_buf_add_mem(struct net_buf *buf, const void *mem, size_t len);
uint8_t *net_buf_add_u8(struct net_buf *buf, uint8_t value);
void net_buf_add_le16(struct net_buf *buf, uint16_t value);
void net_buf_add_le32(struct net_buf *buf, uint32_t value);
```

Remove
: Remove data from the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Some examples of APIs for removing data:

```
void *net_buf_remove_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_remove_u8(struct net_buf *buf);
uint16_t net_buf_remove_le16(struct net_buf *buf);
uint32_t net_buf_remove_le32(struct net_buf *buf);
```

Push
: Prepend data to the beginning of the buffer. Modifies both the data length value as well as the data pointer. Requires that there is enough headroom in the buffer. Some examples of APIs for pushing data:

```
void *net_buf_push(struct net_buf *buf, size_t len);
void *net_buf_push_mem(struct net_buf *buf, const void *mem, size_t len);
void net_buf_push_u8(struct net_buf *buf, uint8_t value);
void net_buf_push_le16(struct net_buf *buf, uint16_t value);
```

Pull
: Remove data from the beginning of the buffer. Modifies both the data length value as well as the data pointer. Some examples of APIs for pulling data:

```
void *net_buf_pull(struct net_buf *buf, size_t len);
void *net_buf_pull_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_pull_u8(struct net_buf *buf);
uint16_t net_buf_pull_le16(struct net_buf *buf);
uint32_t net_buf_pull_le32(struct net_buf *buf);
```

The Add and Push operations are used when encoding data into the buffer, whereas the Remove and Pull operations are used when decoding data from a buffer.

4.20.4 Reference Counting

Each network buffer is reference counted. The buffer is initially acquired from a free buffers pool by calling `net_buf_alloc()`, resulting in a buffer with reference count 1. The reference count can be incremented with `net_buf_ref()` or decremented with `net_buf_unref()`. When the count drops to zero the buffer is automatically placed back to the free buffers pool.

4.20.5 API Reference

Network Buffer Library

4.21 Modem modules

This service provides modules necessary to communicate with modems.

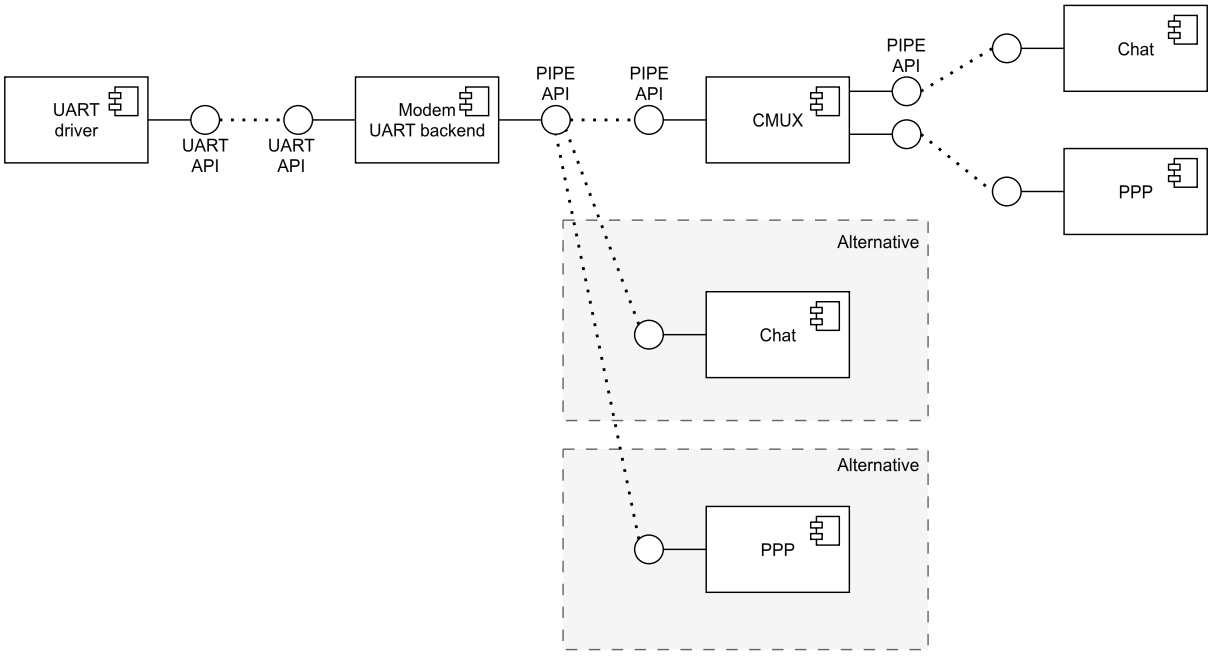
Modems are self-contained devices that implement the hardware and software necessary to perform RF (Radio-Frequency) communication, including GNSS, Cellular, WiFi etc.

The modem modules are inter-connected dynamically using data-in/data-out pipes making them independently testable and highly flexible, ensuring stability and scalability.

4.21.1 Modem pipe

This module is used to abstract data-in/data-out communication over a variety of mechanisms, like UART and CMUX DLCI channels, in a thread-safe manner.

A modem backend will internally contain an instance of a modem_pipe structure, alongside any buffers and additional structures required to abstract away its underlying mechanism.



The modem backend will return a pointer to its internal modem_pipe structure when initialized, which will be used to interact with the backend through the modem pipe API.

Modem Pipe

- AT Command ClientCreate a bidirectional UART bridge between console and modem for AT command communication.

4.21.2 Modem PPP

This module defines and binds a L2 PPP network interface, described in *L2 Layer Management*, to a modem backend. The L2 PPP interface sends and receives network packets. These network packets have to be wrapped in PPP frames before being transported via a modem backend. This module performs said wrapping.

Modem PPP

4.21.3 Modem CMUX

This module is an implementation of CMUX following the 3GPP 27.010 specification. CMUX is a multiplexing protocol, allowing for multiple bi-directional streams of data, called DLCI channels. The module attaches to a single modem backend, exposing multiple modem backends, each representing a DLCI channel.

Protocol defines simple framing for splitting each DLC into small chunks of data.

Flag	Address	Control	Length indicator	Information	FCS	Flag
1 octet	1 octet	1 octet	1 or 2 octet	Unspecified length	1 octet	1 octet

Zephyr implements the basic frame type, with build-time configurable MTU size.

The module also implements power-saving using CMUX Power Saving Command (PSC) for modems that support it. See the *CMUX Power Saving* section below for more details.

Modem CMUX

4.21.4 Modem pipelink

This module is used to share modem pipes globally. This module aims to decouple the creation and setup of modem pipes in device drivers from the users of said pipes. See drivers/modem/modem_at_shell.c and drivers/modem/modem_cellular.c for examples of how to use the modem pipelink between device driver and application.

Modem pipelink

4.21.5 Modem chat

This module implements scripted AT command communication with a modem. AT commands are organized into **scripts**, where each script is a sequence of command–response exchanges. The module sends a command string through a modem pipe and then waits for a response matching one of the expected patterns. When a match is found, an optional callback is invoked with parsed arguments.

Scripts are defined at build time using the `MODEM_CHAT_SCRIPT_DEFINE` and `MODEM_CHAT_SCRIPT_CMDS_DEFINE` macros. Each script entry pairs a request string with one or more `modem_chat_match` patterns. Match patterns support argument parsing by specifying a separator character (for example, `","`), making it easy to extract fields from responses such as `+CSQ: 20,99`.

In addition to scripted exchanges, the module continuously monitors the data stream for **unsolicited** responses — messages the modem sends without a preceding command (for example, `+CEREG:` network registration updates). These are handled by a separate set of match patterns registered when the chat instance is initialized.

The chat module attaches to any modem pipe, so it can communicate over a raw UART backend or over a CMUX DLCI channel interchangeably.

Modem Chat

4.21.6 Cellular Modem

The generic cellular modem driver, drivers/modem/modem_cellular.c, brings together all of the modules described above to implement a complete, hardware-agnostic cellular data connection. It exposes a standard Zephyr network interface so that applications can use the *BSD sockets API* without any modem-specific code.

Architecture overview

The driver assembles the modem modules into a layered pipe architecture:

1. **UART backend** — A `modem_backend_uart` instance provides the lowest-level modem pipe. It abstracts the physical UART peripheral into the modem pipe API, performing thread-safe, interrupt-driven transfers.
2. **CMUX** — The `modem_cmux` instance attaches to the UART pipe and multiplexes it into two DLCI channels, following the 3GPP 27.010 specification.
3. **DLCI channel 1 (data)** — This pipe carries either AT command traffic during initialization, or PPP-framed IP data once the connection is established.
4. **DLCI channel 2 (commands)** — This pipe is dedicated to AT command traffic while the data connection is active, allowing the driver to query signal quality, registration status, and other parameters without interrupting the data flow.
5. **Modem chat** — A `modem_chat` instance executes AT command scripts. Before CMUX is started it attaches directly to the UART pipe; afterwards it moves to DLCI 1 for initialization scripts and then to DLCI 2 for periodic monitoring.
6. **Modem PPP** — A `modem_ppp` instance wraps Zephyr IP packets in PPP frames and sends them through DLCI 1. In the receive direction it strips the PPP framing and delivers packets to the network stack.

The simultaneous use of two DLCI channels is the key enabler: the modem can transfer IP data at full speed on DLCI 1 while the driver continues to exchange AT commands on DLCI 2 in the background.

Connection lifecycle

The driver is built around an internal state machine that progresses through the following phases:

Power-on and hardware reset The driver pulses the modem reset and power GPIOs (if defined in the Device Tree) and waits for the modem to become responsive.

Initial AT configuration The modem chat module attaches directly to the UART pipe and runs the modem-specific `init_chat_script`. This script typically disables echo, queries the IMEI, model, firmware version, and configures unsolicited response reporting. All communication at this stage is plain AT over UART — CMUX is not yet active.

CMUX bring-up After the init script succeeds the driver sends the `AT+CMUX` command to switch the modem into multiplexed mode. The CMUX module attaches to the UART pipe and opens DLCI 1 and DLCI 2. From this point all communication is framed inside CMUX.

APN configuration and dialing The driver attaches the modem chat to DLCI 1 and runs a dynamically built APN script (`AT+CGDCONT`) followed by the dial script (`ATD*99#` or equivalent). On success the modem enters data mode on DLCI 1.

Data connection The modem PPP module attaches to the DLCI 1 pipe, and the modem chat moves to DLCI 2. The driver calls `net_if_carrier_on()` once a `+CEREG` (or `+CREG` / `+CGREG`) unsolicited response indicates that the modem has registered on the network.

At this point the Zephyr network stack negotiates a PPP session over DLCI 1 and the application can use sockets normally. Meanwhile, periodic chat scripts on DLCI 2 monitor signal quality and registration status.

Shutdown The driver runs a shutdown script and pulses the power-off GPIO to cleanly power down the modem. The state machine returns to the idle state.

Adding support for a new modem

The generic cellular driver uses per-modem configuration supplied through Device Tree compatible bindings and associated chat scripts. Adding a new modem requires three artifacts:

1. A **Device Tree binding** that includes the common cellular modem base binding.
2. **Chat scripts** defining the AT command sequences for initialization, dialing, periodic monitoring, and (optionally) shutdown.
3. A **device instantiation macro** that ties the chat scripts and hardware configuration together.

The driver handles all pipe plumbing, CMUX management, PPP framing, and state machine logic automatically.

Supported modems The following modems are already supported in drivers/modem/modem_cellular.c:

- Quectel BG95, BG96
- Quectel EG25-G, EG800Q
- SIMCom SIM7080, A76xx
- u-blox SARA-R4, SARA-R5, LARA-R6
- Sierra Wireless HL7800
- Telit ME910G1, ME310G1
- Nordic Semiconductor nRF91 SLM
- Sequans GM02S

Each supported modem is defined using the same set of macros (`MODEM_CHAT_SCRIPT_CMDS_DEFINE`, `MODEM_CHAT_SCRIPT_DEFINE`, `MODEM_CELLULAR_DEFINE_INSTANCE`, etc.). Refer to drivers/modem/modem_cellular.c for complete examples of init, dial, periodic, and shutdown chat scripts. The common base Device Tree properties shared by all modems are documented in dts/bindings/modem/zephyr,cellular-modem-device.yaml.

Out-of-tree modem The driver macros and data structures are exported through include/zephyr/drivers/modem/modem_cellular.h, so a completely new modem can be defined **outside** the Zephyr tree — for example in application source — without modifying any upstream files. This is useful for fine-tuning AT command sequences for a specific use case, or for developing support for a new modem before submitting it upstream.

Start by creating a Device Tree binding that includes the common base binding, then write a driver source file using the macros from `modem_cellular.h`. The following three files are all that is needed.

Device Tree binding — `app/dts/bindings/my,modem.yaml`:

```
compatible: "my,modem"

include: zephyr,cellular-modem-device.yaml
```

Device Tree overlay — `app.overlay` (partial):

```
&uart30 {
    modem: modem {
        compatible = "my,modem";
        status = "okay";
        mdm-power-gpios = <&gpio1 13 GPIO_ACTIVE_HIGH>;
    };
};
```

Driver source — app/src/my_modem.c:

```
#include <zephyr/drivers/modem/modem_cellular.h>
#include <zephyr/device.h>

MODEM_CHAT_MATCH_DEFINE(ok_match, "OK", "", NULL);
MODEM_CHAT_MATCH_DEFINE(connect_match, "CONNECT", "", NULL);
MODEM_CHAT_MATCHES_DEFINE(abort_matches,
    MODEM_CHAT_MATCH("ERROR", "", NULL),
    MODEM_CHAT_MATCH("NO CARRIER", "", NULL));

/* Init script - configure the modem, enable unsolicited LTE
 * registration notifications, then switch to CMUX.
 */
MODEM_CHAT_SCRIPT_CMDS_DEFINE(init_chat_script_cmds,
    MODEM_CHAT_SCRIPT_CMD_RESP("ATE0",              ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CEREG=1",        ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CMUX=0,0,5,127", ok_match));

MODEM_CHAT_SCRIPT_DEFINE(init_chat_script, init_chat_script_cmds,
    abort_matches, modem_cellular_chat_callback_handler, 1);

/* Dial script - enable the radio and open data mode */
MODEM_CHAT_SCRIPT_CMDS_DEFINE(dial_chat_script_cmds,
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CFUN=1", ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("ATD*99#",   connect_match));

MODEM_CHAT_SCRIPT_DEFINE(dial_chat_script, dial_chat_script_cmds,
    abort_matches, modem_cellular_chat_callback_handler, 60);

/* Macro for defining a DT instance */
#define MY_MODEM_DEVICE(inst)                                          \
    MODEM_DT_INST_PPP_DEFINE(inst,                                     \
        MODEM_CELLULAR_INST_NAME(ppp, inst), NULL, 98, 1500, 64);      \
                                                                       \
    static struct modem_cellular_data                                  \
        MODEM_CELLULAR_INST_NAME(data, inst) = {                       \
        .chat_delimiter = "\r",                                        \
        .chat_filter = "\n",                                           \
        .ppp = &MODEM_CELLULAR_INST_NAME(ppp, inst),                   \
    };                                                                 \
                                                                       \
    MODEM_CELLULAR_DEFINE_AND_INIT_USER_PIPES(inst,                    \
        (user_pipe_0, 3), (user_pipe_1, 4))                            \
                                                                       \
    MODEM_CELLULAR_DEFINE_INSTANCE(inst,                               \
        1000, 100, 5000, 5000, false, NULL,                            \
        &init_chat_script, &dial_chat_script, NULL, NULL)
```

(continues on next page)

(continued from previous page)

```
#define DT_DRV_COMPAT my_modem
DT_INST_FOREACH_STATUS_OKAY(MY_MODEM_DEVICE)
#undef DT_DRV_COMPAT
```

The example above is minimal but enough to start a PPP connection on a generic cellular modem. Refer to drivers/modem/modem_cellular.c for more complete examples.

4.21.7 CMUX Power Saving

The 3GPP TS 27.010 specifies a power saving mechanism for CMUX which can be used in Zephyr when the modem supports it.

The power saving mechanism is covered in the following sections on the specification:

- 5.2.5 Inter-frame Fill
- 5.4.6.3.2 Power Saving Control (PSC) message
- 5.4.7 Power Control and Wake-up Mechanisms

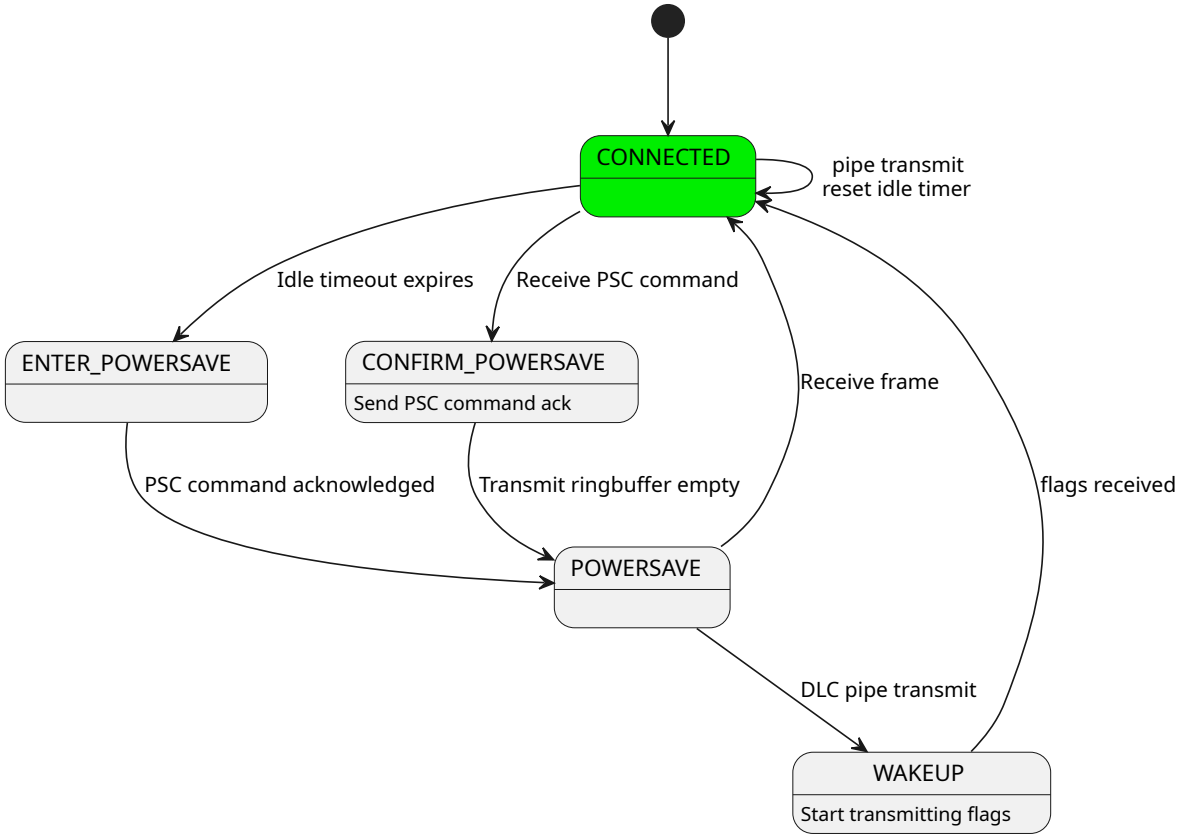
The power saving mechanism allows runtime power management for the UART device used by the CMUX module. When there is no data to be sent or received on any DLCI channel, the CMUX module will enter the idle state after a configurable timeout. In the idle state, the CMUX module will send a Power Saving Control message to the modem, requesting it to enter a low power state. The CMUX module may then close the pipe device, allowing the UART device to be powered down if runtime power management is enabled.

When data is to be sent or received on any DLCI channel, the CMUX module will exit the idle state and wakes the modem up by sending flag characters until it receives a flag character from the modem.

Some modems allow UART to be powered down only when the DTR (Data Terminal Ready) signal is de-asserted. In this case, a UART device with DTR support can be used with the CMUX module to control the DTR signal based on the power state of the UART.

Waking up on incoming data when UART is powered down requires a modem that supports RING signal to wake up the host. The RING signal is handled by the modem driver and it opens the pipe device when the RING signal is detected, allowing the CMUX module to wake up the modem and process incoming data.

The subsys/modem/modem_cmux.c module implements the power saving mechanism using the following state machine.



Within a connected state, `modem_cmux_process_received_byte()` is required to reply repeated flag characters as described in 5.2.5 Inter-frame Fill at the specification. Idle timer is kept running and cleared on every sent or received frame. Timer expiry will initiate transitioning to power saving modes.

Within the POWERSAVE state all DLC pipes remain open but the pipe towards UART is blocked or closed, so all data is buffered within CMUX ringbuffers to wait for waking up. Within this state, repeated flag characters are also replied to allow remote end proceed with wake-up procedure as described in 5.4.7. If pipe is closed, it allows UART device to be powered down if runtime power management is enabled.

When idle timer expires on CONNECTED state, CMUX state machine blocks all DLC pipes and sends PSC command for remote end to initiate transitioning to POWERSAVE state. When PSC command is replied, CMUX transitions to POWERSAVE mode.

When within the CONNECTED state, the remote end may send a PSC command to initiate the transitioning to power saving mode. CMUX blocks all DLC pipes and sends a PSC response. When TX buffers are emptied, CMUX enters the POWERSAVE state.

When any of DLC pipes try to transmit data during POWERSAVE state, CMUX buffers it and moves to WAKEUP state that initiates wake-up procedure as specified in 5.4.7 by sending repeated stream of flag characters. Remote end replies the flag characters to indicate it is ready to receive data. CMUX then stops sending flag characters and moves back to CONNECTED state, resuming normal operation.

The CMUX power saving mechanism can be configured using the following Device Tree properties:

```
cmux-enable-runtime-power-save:
  type: boolean
  description: Enable runtime power saving using CMUX PSC commands.
               This requires modem to support CMUX and PSC commands while keeping␣
↪the data
```

(continues on next page)

(continued from previous page)

```
              connection active.
cmux-close-pipe-on-power-save:
  type: boolean
  description: Close the modem pipe when entering power save mode.
               When runtime power management is enabled, this closes the UART.
               This requires modem to support waking up the UART using RING signal.
cmux-idle-timeout-ms:
  type: int
  description: Time in milliseconds after which CMUX will enter power save mode.
  default: 10000
```

Example Device Tree setup for CMUX with power saving:

```
&uart1 {
  status = "okay";
  zephyr,pm-device-runtime-auto;

  uart_dtr: uart-dtr {
    compatible = "zephyr,uart-dtr";
    dtr-gpios = <&interface_to_nrf9160 4 GPIO_ACTIVE_LOW>;
    status = "okay";
    zephyr,pm-device-runtime-auto;

    modem: modem {
      compatible = "nordic,nrf91-slm";
      status = "okay";
      mdm-ring-gpios = <&interface_to_nrf9160 5 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
      zephyr,pm-device-runtime-auto;
      cmux-enable-runtime-power-save;
      cmux-close-pipe-on-power-save;
      cmux-idle-timeout-ms = <5000>;
    };
  };
};
```

The above example shows a UART device with DTR support being used by a modem that supports CMUX and PSC commands. The DTR signal is used to control the power state of the UART. The RING signal from the modem is used to wake up the modem subsystem when it is powered down.

4.22 Asynchronous Notifications

Zephyr APIs often include *async* functions where an operation is initiated and the application needs to be informed when it completes, and whether it succeeded. Using `k_poll()` is often a good method, but some application architectures may be more suited to a callback notification, and operations like enabling clocks and power rails may need to be invoked before kernel functions are available so a busy-wait for completion may be needed.

This API is intended to be embedded within specific subsystems such as *On-Off Manager* and other APIs that support async transactions. The subsystem wrappers are responsible for extracting operation-specific data from requests that include a notification element, and for invoking callbacks with the parameters required by the API.

A limitation is that this API is not suitable for *System Calls* because:

- `sys_notify` is not a kernel object;
- copying the notification content from userspace will break use of `CONTAINER_OF` in the implementing function;

- neither the spin-wait nor callback notification methods can be accepted from userspace callers.

Where a notification is required for an asynchronous operation invoked from a user mode thread the subsystem or driver should provide a syscall API that uses `k_poll_signal` for notification.

4.22.1 API Reference

Asynchronous Notification APIs

4.23 Power Management

Zephyr RTOS power management subsystem provides several means for a system integrator to implement power management support that can take full advantage of the power saving features of SOCs.

4.23.1 Overview

The interfaces and APIs provided by the power management subsystem are designed to be architecture and SOC independent. This enables power management implementations to be easily adapted to different SOCs and architectures.

The architecture and SOC independence is achieved by separating the core PM infrastructure from implementations of the SOC specific components. Thus a coherent abstraction is presented to the rest of the OS and the application layer.

The power management features are classified into the following categories.

- System Power Management
- Device Power Management

4.23.2 System Power Management

Introduction

The kernel enters the idle state when it has nothing to schedule. Enabling `CONFIG_PM` allows the kernel to call upon the power management subsystem to put an idle system into one of the supported power states. The kernel requests an amount of time it would like to suspend, then the PM subsystem decides the appropriate power state to transition to based on the configured power management policy.

It is the application's responsibility to set up a wake-up event. A wake-up event will typically be an interrupt triggered by an SoC peripheral module. Examples include a SysTick, RTC, counter, or GPIO. Keep in mind that depending on the SoC and the power mode in question, not all peripherals may be active, and therefore some wake-up sources may not be usable in all power modes.

The following diagram describes system power management:

Power States The power management subsystem defines a set of states described by the power consumption and context retention associated with each of them.

The set of power states is defined by `pm_state`. In general, lower power states (higher index in the enum) will offer greater power savings and have higher wake latencies.

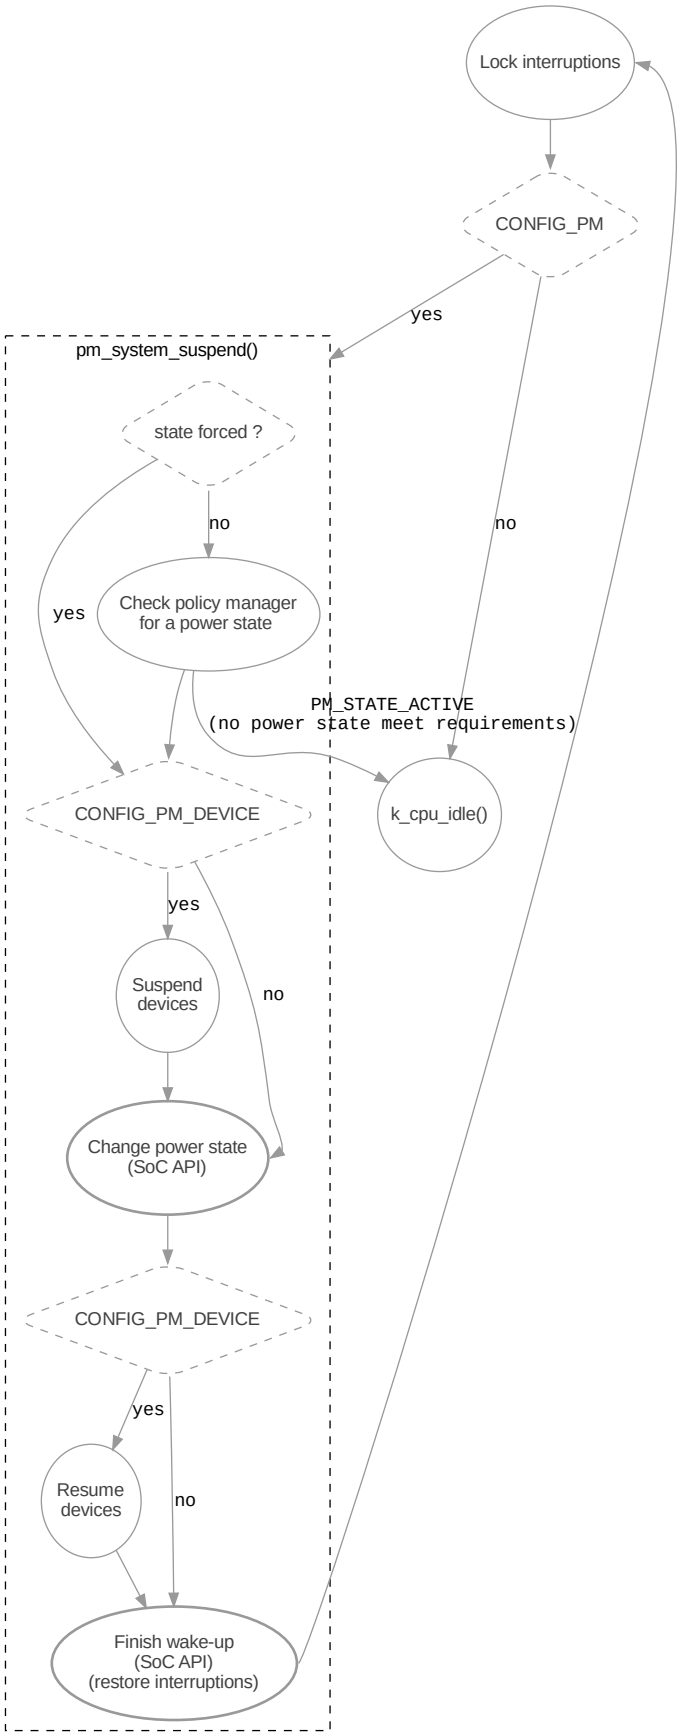


Fig. 7: System power management

Power Management Policies The power management subsystem supports the following power management policies:

- Residency based
- Application defined

The policy manager is the component of the power management subsystem responsible for deciding which power state the system should transition to. The policy manager can only choose between states that have been defined for the platform. Other constraints placed upon the decision may include locks disallowing certain power states, or various kinds of minimum and maximum latency values, depending on the policy.

More details on the states definition can be found in the `zephyr,power-state` binding documentation.

Residency Under the residency policy, the system will enter the power state which offers the highest power savings, with the constraint that the sum of the minimum residency value (see `zephyr,power-state`) and the latency to exit the mode must be less than or equal to the system idle time duration scheduled by the kernel.

Thus the core logic can be summarized with the following expression:

```
if (time_to_next_scheduled_event >= (state.min_residency_us + state.exit_latency))
↪{
   return state
}
```

Application The application defines the power management policy by implementing the `pm_policy_next_state()` function. In this policy, the application is free to decide which power state the system should transition to based on the remaining time until the next scheduled timeout.

An example of an application that defines its own policy can be found in tests/subsys/pm/power_mgmt/.

Custom ticks hook In addition to the kernel tick expiration and the PM policy event list, applications and SoC-specific code may need to derive the next wake-up time from proprietary or hardware-specific data sources. Examples include hardware registers, binary-only third-party modules, or complex/legacy data structures that are not practical to model as standard PM policy events.

When `CONFIG_PM_CUSTOM_TICKS_HOOK` is enabled, the PM core calls the optional function `pm_policy_next_custom_ticks()` during `pm_system_suspend()`. The hook returns the ticks to the next custom event, or `K_TICKS_FOREVER` if no custom event needs to be considered.

The PM core then selects the earliest expiration among:

- kernel tick expiration,
- PM policy event list ticks (from `pm_policy_next_event_ticks()`),
- the custom ticks value (from `pm_policy_next_custom_ticks()`).

This mechanism allows boards and applications to integrate additional timing sources into the system power management decisions without modifying the PM event list infrastructure.

Policy and Power States The power management subsystem allows different Zephyr components and applications to configure the policy manager to block the system from transitioning into certain power states. This can be used by devices when executing tasks in background to prevent the system from going to a specific state where it would lose context. See `pm_policy_state_lock_get()`.

Examples Some helpful examples showing different power management features:

- tests/subsys/pm/power_states_api/

4.23.3 Device Power Management

Introduction

Device Power Management in Zephyr is a feature which presents mechanisms to coherently affect the control of power management actions to be taken by device drivers. This control is based on unambiguous expectations which could be set by any component of the system, and on power-related dependencies that devices may have on each other.

Zephyr supports two methods of device power management:

- *Device Runtime Power Management*
- *System-Managed Device Power Management*

Device Runtime Power Management Device runtime power management involves coordinated interaction between device drivers, subsystems, and applications. While device drivers play a crucial role in directly controlling the power state of devices, the decision to suspend or resume a device can also be influenced by higher layers of the software stack.

Each layer—device drivers, subsystems, and applications—can operate independently without needing to know about the specifics of the other layers because the subsystem uses reference count to check when it needs to suspend or resume a device.

- **Device drivers** are responsible for managing the power state of devices. They interact directly with the hardware to put devices into low-power states (suspend) when they are not in use, and bring them back (resume) when needed. Drivers should use the *device runtime power management APIs* provided by Zephyr to control the power state of devices.
- **Subsystems**, such as sensors, file systems, and network, can also influence device power management. Subsystems may have better knowledge about the overall system state and workload, allowing them to make informed decisions about when to suspend or resume devices. For example, a networking subsystem may decide to keep a network interface powered on if it expects network activity in the near future.
- **Applications** running on Zephyr can impact device power management as well. An application may have specific requirements regarding device usage and power consumption. For example, an application that streams data over a network may need to keep the network interface powered on continuously.

Coordination between device drivers, subsystems, and applications is key to efficient device power management. For example, a device driver may not know that a subsystem will perform a series of sequential operations that require a device to remain powered on. In such cases, the subsystem can use device runtime power management to ensure that the device remains in an active state until the operations are complete.

When using this Device Runtime Power Management, the System Power Management subsystem is able to change power states quickly because it does not need to spend time suspending and resuming devices that are runtime enabled.

For more information, see *Device Runtime Power Management*.

System-Managed Device Power Management The system managed device power management (PM) framework is a method where devices are suspended along with the system entering a CPU (or SoC) power state. It can be enabled by setting `CONFIG_PM_DEVICE_SYSTEM_MANAGED`. When using this method, device power management is mostly done inside `pm_system_suspend()`.

If a decision to enter a CPU lower power state is made, the power management subsystem will check if the selected low power state triggers device power management and then suspend devices before changing state. The subsystem takes care of suspending devices following their initialization order, ensuring that possible dependencies between them are satisfied. As soon as the CPU wakes up from a sleep state, devices are resumed in the opposite order that they were suspended.

The decision about suspending devices when entering a low power state is done based on the state and if it has set the property `zephyr,pm-device-disabled`. Here is an example of a target with two low power states with only one triggering device power management:

```
/* Node in a DTS file */
cpus {
     power-states {
             state0: state0 {
                     compatible = "zephyr,power-state";
                     power-state-name = "standby";
                     min-residency-us = <5000>;
                     exit-latency-us = <240>;
                     zephyr,pm-device-disabled;
             };
             state1: state1 {
                     compatible = "zephyr,power-state";
                     power-state-name = "suspend-to-ram";
                     min-residency-us = <8000>;
                     exit-latency-us = <360>;
             };
     };
};
```

Note

When using *System Power Management*, device transitions can be run from the idle thread. As functions in this context cannot block, transitions that intend to use blocking APIs **must** check whether they can do so with `k_can_yield()`.

This method of device power management can be useful in the following scenarios:

- Systems with no device requiring any blocking operations when suspending and resuming. This implementation is reasonably simpler than device runtime power management.
- For devices that can not make any power management decision and have to be always active. For example a firmware using Zephyr that is controlled by an external entity (e.g Host CPU). In this scenario, some devices have to be always active and should be suspended together with the SoC when requested by this external entity.

It is important to emphasize that this method has drawbacks (see above) and *Device Runtime Power Management* is the **preferred** method for implementing device power management.

Note

When using this method of device power management, the CPU will not enter a low-power state if a device cannot be suspended. For example, if a device returns an error such as `-EBUSY`

in response to the PM_DEVICE_ACTION_SUSPEND action, indicating it is in the middle of a transaction that cannot be interrupted. Another condition that prevents the CPU from entering a low-power state is if the option CONFIG_PM_NEED_ALL_DEVICES_IDLE is set and a device is marked as busy.

Note

Devices are suspended only when the last active core is entering a low power state and devices are resumed by the first core that becomes active.

Device Power Management States

The power management subsystem defines device states in pm_device_state. This method is used to track power states of a particular device. It is important to emphasize that, although the state is tracked by the subsystem, it is the responsibility of each device driver to handle device actions(pm_device_action) which change device state.

Device drivers implement the pm_device_action_cb_t() hook internally which receives the pm_device_action for the device driver to handle. If the CONFIG_PM_DEVICE option is selected, the device drivers implementations of the hooks are exposed to the PM subsystem, enabling runtime power management of the devices.

pm_device_action actions have direct and unambiguous relationships with pm_device_state states:

As mentioned above, device drivers do not directly change between these states. This is entirely done by the power management subsystem. Instead, drivers are responsible for implementing any hardware-specific tasks needed to handle state changes.

Device Model with Device Power Management Support

Drivers initialize devices using macros. See *Device Driver Model* for details on how these macros are used. A driver which implements device power management support must provide these macros with arguments that describe its power management implementation.

Use PM_DEVICE_DEFINE or PM_DEVICE_DT_DEFINE to define the power management resources required by a driver. These macros allocate the driver-specific context which is required by the power management subsystem.

Drivers can use PM_DEVICE_GET or PM_DEVICE_DT_GET to get a pointer to this context. These pointers should be passed to DEVICE_DEFINE or DEVICE_DT_DEFINE to initialize the power management field in each device.

The following example code shows how to implement device power management support in a device driver. Note that return values are explicitly ignored for brevity, in real drivers they must be handled.

```
#include <zephyr/pm/device.h>
#include <zephyr/pm/device_runtime.h>

#define DT_DRV_COMPAT dummy_device

struct dummy_driver_data {
        struct gpio_callback int_pin_callback;
        const struct device *dev;
};
```

Device Model with Partial Device Power Management Support

If `CONFIG_PM_DEVICE` is not enabled, the device power state is tied to the devices initialization state.

Once a device is initialized, the device driver PM action hook is used to move the device to the expected initial state through calling `pm_device_driver_init()`. Following the De-

vice actions x states graph and the definition of the OFF state, this results in a call to PM_DEVICE_ACTION_TURN_ON followed by PM_DEVICE_ACTION_RESUME.

If the driver's PM hook returns an error, initialization fails and the device is left in its previous state (for devices that support PM this is typically SUSPENDED or OFF).

Given power domains and buses are "just devices", every power domain and bus will be resumed before its child devices as they are initialized according to the devicetree dependency ordinals. Every device is assumed to be powered, and the devices a device depends on are assumed to be ACTIVE, when device is initialized.

Once a device is deinitialized, the device driver PM action hook is used to move the device to the SUSPENDED state through calling pm_device_driver_deinit(). Following the Device actions x states, and assuming power domains are "always on" this results in a call to PM_DEVICE_ACTION_SUSPEND.

Shell Commands

Power management actions can be triggered from shell commands for testing purposes. To do that, enable the CONFIG_PM_DEVICE_SHELL option and issue a pm command on a device from the shell, for example:

```
uart:~$ device list
- buttons (active)
uart:~$ pm suspend buttons
uart:~$ device list
devices:
- buttons (suspended)
```

To print the power management state of a device, enable CONFIG_DEVICE_SHELL and use the device list command, for example:

```
uart:~$ device list
devices:
- i2c@40003000 (active)
- buttons (active, usage=1)
- leds (READY)
```

In this case, leds does not support PM, i2c supports PM with manual suspend and resume actions and it's currently active, buttons supports runtime PM and it's currently active with one user.

Busy Status Indication

When the system is idle and the SoC is going to sleep, the power management subsystem can suspend devices, as described in *System-Managed Device Power Management*. This can cause device hardware to lose some states. Suspending a device which is in the middle of a hardware transaction, such as writing to a flash memory, may lead to undefined behavior or inconsistent states. This API guards such transactions by indicating to the kernel that the device is in the middle of an operation and should not be suspended.

When pm_device_busy_set() is called, the device is marked as busy and the system will not do power management on it. After the device is no longer doing an operation and can be suspended, it should call pm_device_busy_clear().

Device Power Management X System Power Management

When managing power in embedded systems, it's crucial to understand the interplay between device power state and the overall system power state. Some devices may have dependencies on the system power state. For example, certain low-power states of the SoC might not supply

power to peripheral devices, leading to problems if the device is in the middle of an operation. Proper coordination is essential to maintain system stability and data integrity.

To avoid this sort of problem, devices must *get and release lock* power states that cause power loss during an operation.

Zephyr provides a mechanism for devices to declare which power states cause power loss and an API that automatically get and put lock on them. This feature is enabled setting `CONFIG_PM_POLICY_DEVICE_CONSTRAINTS` to `y`.

Once this feature is enabled, devices must declare in devicetree which states cause power loss. In the following example, device `test_dev` says that power states `state1` and `state2` cause power loss.

```
power-states {
        state0: state0 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-idle";
                min-residency-us = <10000>;
                exit-latency-us = <100>;
        };

        state1: state1 {
                compatible = "zephyr,power-state";
                power-state-name = "standby";
                min-residency-us = <20000>;
                exit-latency-us = <200>;
        };

        state2: state2 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-ram";
                min-residency-us = <50000>;
                exit-latency-us = <500>;
        };

        state3: state3 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-ram";
                status = "disabled";
        };
};

test_dev: test_dev {
        compatible = "test-device-pm";
        status = "okay";
        zephyr,disabling-power-states = <&state1 &state2>;
};
```

After that devices can lock these state calling `pm_policy_device_power_lock_get()` and release with `pm_policy_device_power_lock_put()`. For example:

```
static void timer_expire_cb(struct k_timer *timer)
{
       struct test_driver_data *data = k_timer_user_data_get(timer);

       data->ongoing = false;
       k_timer_stop(timer);
       pm_policy_device_power_lock_put(data->self);
```

(continues on next page)

(continued from previous page)

```
}

void test_driver_async_operation(const struct device *dev)
{
        struct test_driver_data *data = dev->data;

        data->ongoing = true;
        pm_policy_device_power_lock_get(dev);

        /** Lets set a timer big enough to ensure that any deep
         *  sleep state would be suitable but constraints will
         *  make only state0 (suspend-to-idle) will be used.
         */
        k_timer_start(&data->timer, K_MSEC(500), K_NO_WAIT);
}
```

Wakeup capability

Some devices are capable of waking the system up from a sleep state. When a device has such capability, applications can enable or disable this feature on a device dynamically using `pm_device_wakeup_enable()`.

This property can be set on device declaring the property `wakeup-source` in the device node in devicetree. For example, this devicetree fragment sets the `gpio0` device as a "wakeup" source:

```
gpio0: gpio@40022000 {
        compatible = "ti,cc13xx-cc26xx-gpio";
        reg = <0x40022000 0x400>;
        interrupts = <0 0>;
        status = "disabled";
        label = "GPIO_0";
        gpio-controller;
        wakeup-source;
        #gpio-cells = <2>;
};
```

By default, "wakeup" capable devices do not have this functionality enabled during the device initialization. Applications can enable this functionality later calling `pm_device_wakeup_enable()`.

Note

This property is **only** used by the system power management to identify devices that should not be suspended. It is responsibility of driver or the application to do any additional configuration required by the device to support it.

Examples

Some helpful examples showing device power management features:

4.23.4 Device Runtime Power Management

Introduction

The device runtime power management (PM) framework is an active power management mechanism which reduces the overall system power consumption by suspending the devices which are idle or not used independently of the system state. It can be enabled by setting `CONFIG_PM_DEVICE_RUNTIME`. In this model the device driver is responsible to indicate when it needs the device and when it does not. This information is used to determine when to suspend or resume a device based on usage count.

When device runtime power management is enabled on a device, its state will be initially set to a `PM_DEVICE_STATE_SUSPENDED` indicating it is not used. On the first device request, it will be resumed and so put into the `PM_DEVICE_STATE_ACTIVE` state. The device will remain in this state until it is no longer used. At this point, the device will be suspended until the next device request. If the suspension is performed synchronously the device will be immediately put into the `PM_DEVICE_STATE_SUSPENDED` state, whereas if it is performed asynchronously, it will be put into the `PM_DEVICE_STATE_SUSPENDING` state first and then into the `PM_DEVICE_STATE_SUSPENDED` state when the action is run.

For devices on a power domain (via the devicetree 'power-domains' property), device runtime power management automatically attempts to request and release the dependent domain in response to `pm_device_runtime_get()` and `pm_device_runtime_put()` calls on the child device.

For the previous to automatically control the power domain state, device runtime PM must be enabled on the power domain device. To enable device runtime PM globally, enable `CONFIG_PM_DEVICE_RUNTIME_DEFAULT_ENABLE`. To enable device runtime PM only for select devices, set the `zephyr,pm-device-runtime-auto` devicetree property, or use `pm_device_runtime_enable()` for the select devices.

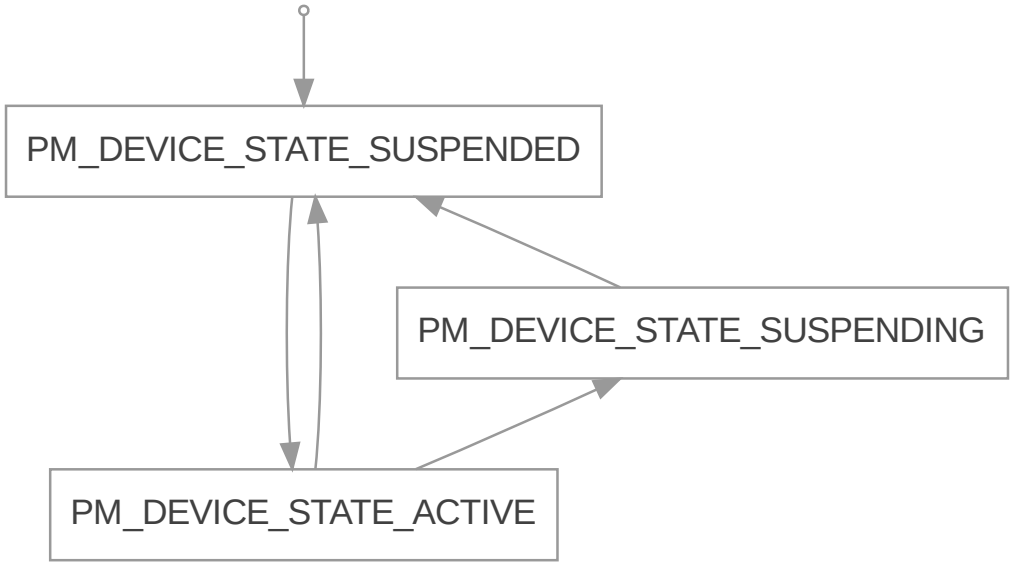

Fig. 9: Device states and transitions

The device runtime power management framework has been designed to minimize devices power consumption with minimal application work. Device drivers are responsible for indicating when they need the device to be operational and when they do not. Therefore, applications can not manually suspend or resume a device. An application can, however, decide when to

disable or enable runtime power management for a device. This can be useful, for example, if an application wants a particular device to be always active.

Design principles

When runtime PM is enabled on a device it will no longer be resumed or suspended during system power transitions. Instead, the device is fully responsible to indicate when it needs a device and when it does not. The device runtime PM API uses reference counting to keep track of device's usage. This allows the API to determine when a device needs to be resumed or suspended. The API uses the *get* and *put* terminology to indicate when a device is needed or not, respectively. This mechanism plays a key role when we account for device dependencies. For example, if a bus device is used by multiple sensors, we can keep the bus active until the last sensor has finished using it.

Note

As of today, the device runtime power management API does not manage device dependencies. This effectively means that, if a device depends on other devices to operate (e.g. a sensor may depend on a bus device), the bus will be resumed and suspended on every transaction. In general, it is more efficient to keep parent devices active when their children are used, since the children may perform multiple transactions in a short period of time. Until this feature is added, devices can manually *get* or *put* their dependencies.

The `pm_device_runtime_get()` function can be used by a device driver to indicate it *needs* the device to be active or operational. This function will increase device usage count and resume the device if necessary. Similarly, the `pm_device_runtime_put()` function can be used to indicate that the device is no longer needed. This function will decrease the device usage count and suspend the device if necessary. It is worth to note that in both cases, the operation is carried out synchronously. The sequence diagram shown below illustrates how a device can use this API and the expected sequence of events.

The synchronous model is as simple as it gets. However, it may introduce unnecessary delays since the application will not get the operation result until the device is suspended (in case device is no longer used). It will likely not be a problem if the operation is fast, e.g. a register toggle. However, the situation will not be the same if suspension involves sending packets through a slow bus. For this reason the device drivers can also make use of the `pm_device_runtime_put_async()` function. This function will schedule the suspend operation, again, if device is no longer used.

By default, runtime PM operations are offloaded to the system work queue. However, device drivers must not perform any blocking operations during suspend, as this can stall the system work queue and negatively impact system responsiveness.

To address this, applications can configure runtime PM to use a dedicated work queue by enabling `CONFIG_PM_DEVICE_RUNTIME_USE_DEDICATED_WQ`.

If blocking behavior is required—for example, when accessing a slow peripheral or waiting for a bus transaction—the PM subsystem work queue must be used instead. Drivers that require this behavior can explicitly request it by enabling `CONFIG_PM_DEVICE_DRIVER_NEEDS_DEDICATED_WQ`.

For targets with constrained resources that do not need asynchronous operations, this functionality can be disabled altogether by de-selecting `CONFIG_PM_DEVICE_RUNTIME_ASYNC`, reducing memory usage and system complexity.

Implementation guidelines

In a first place, a device driver needs to implement the PM action callback used by the PM subsystem to suspend or resume devices.

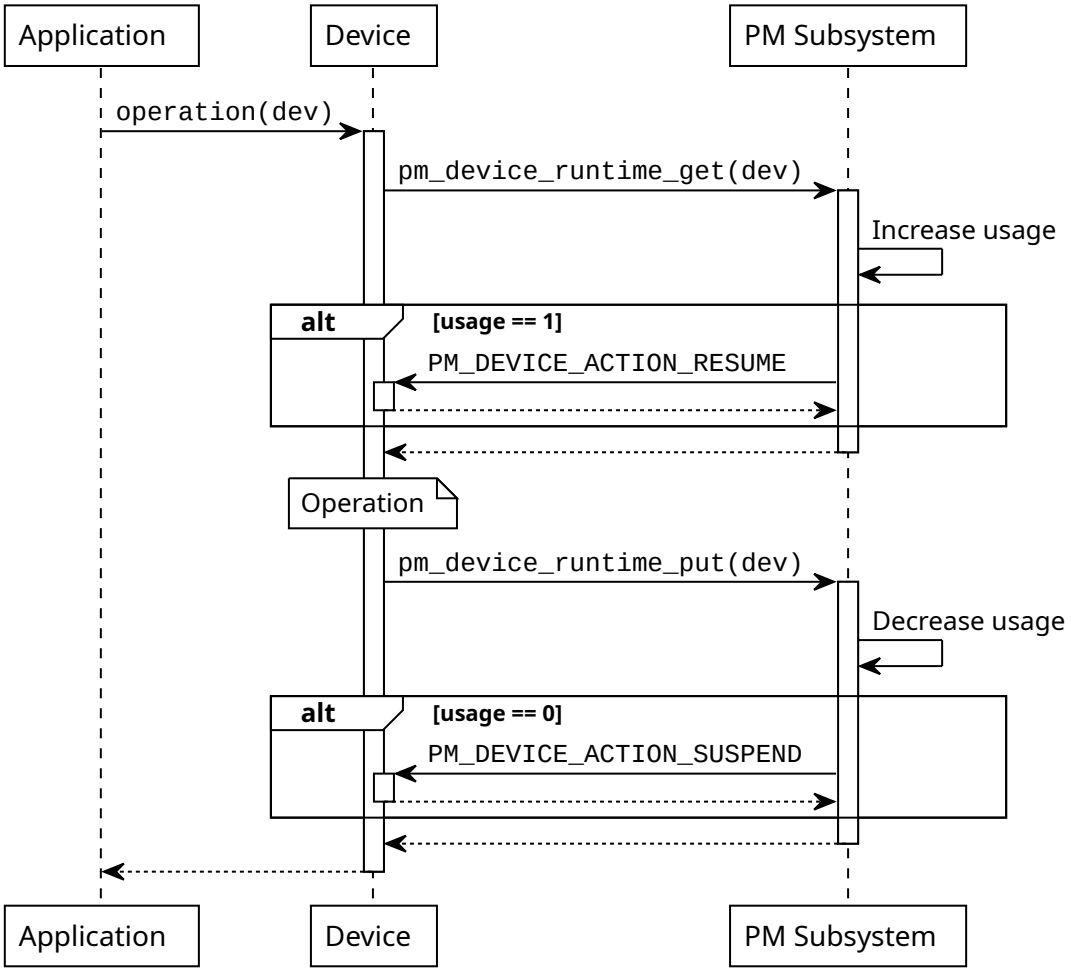

Fig. 10: Synchronous operation on a single device

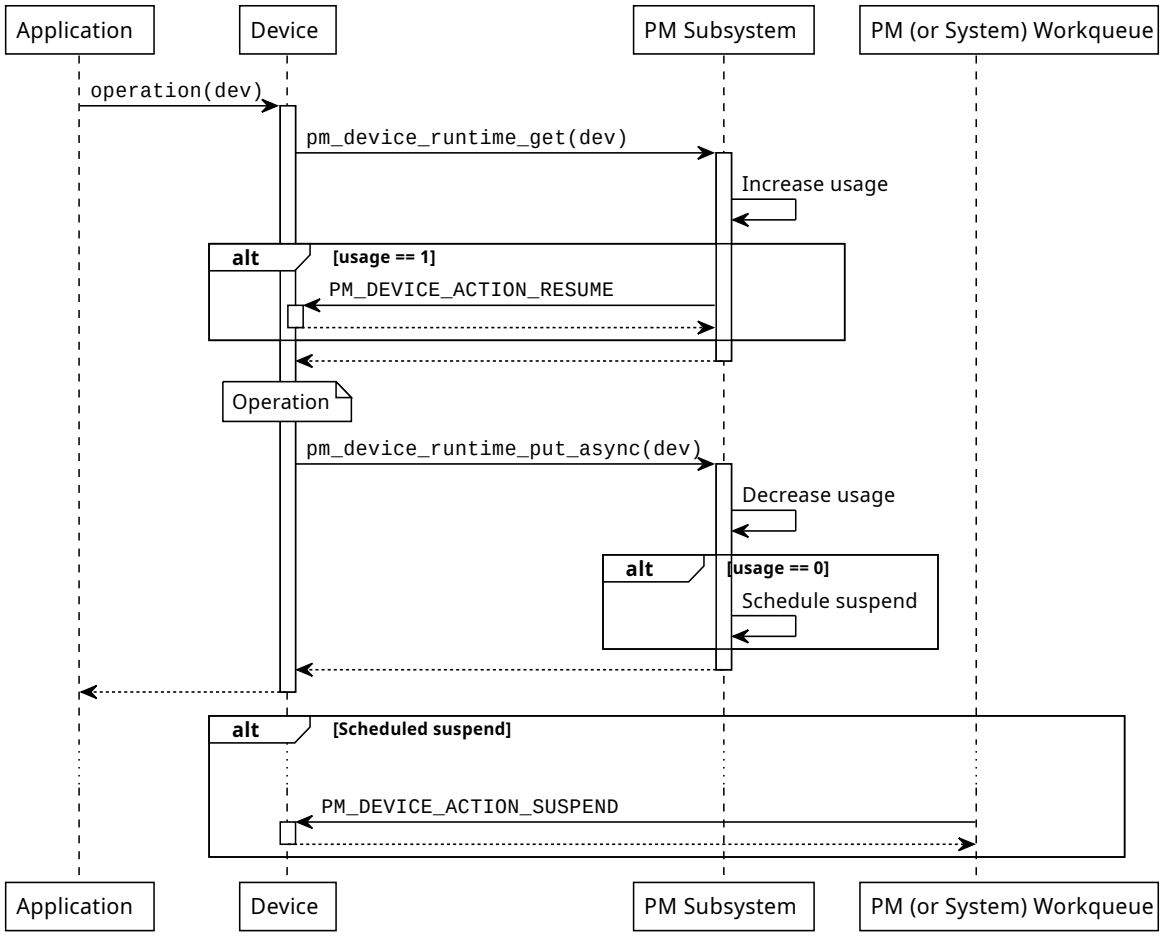

Fig. 11: Asynchronous operation on a single device

```
static int mydev_pm_action(const struct device *dev,
                           enum pm_device_action action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

The PM action callback calls are serialized by the PM subsystem, therefore, no special synchronization is required.

To enable device runtime power management on a device, the driver needs to call `pm_device_runtime_enable()` at initialization time. Note that this function will suspend the device if its state is `PM_DEVICE_STATE_ACTIVE`. In case the device is physically suspended, the init function should call `pm_device_init_suspended()` before calling `pm_device_runtime_enable()`.

```
/* device driver initialization function */
static int mydev_init(const struct device *dev)
{
    int ret;
    ...

    /* OPTIONAL: mark device as suspended if it is physically suspended */
    pm_device_init_suspended(dev);

    /* enable device runtime power management */
    ret = pm_device_runtime_enable(dev);
    if ((ret < 0) && (ret != -ENOSYS)) {
        return ret;
    }
}
```

Device runtime power management can also be automatically enabled on a device instance by adding the `zephyr,pm-device-runtime-auto` flag onto the corresponding devicetree node. If enabled, `pm_device_runtime_enable()` is called immediately after the `init` function of the device runs and returns successfully.

```
foo {
    /* ... */
    zephyr,pm-device-runtime-auto;
};
```

Assuming an example device driver that implements an `operation` API call, the *get* and *put* operations could be carried out as follows:

```
static int mydev_operation(const struct device *dev)
{
```

(continues on next page)

(continued from previous page)

```
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
    ...

    /* "put" device (decreases usage count, suspends device if no more users) */
    return pm_device_runtime_put(dev);
}
```

In case the suspend operation is *slow*, the device driver can use the asynchronous API:

```
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
    ...

    /* "put" device (decreases usage count, schedule suspend if no more users) */
    return pm_device_runtime_put_async(dev, K_NO_WAIT);
}
```

Examples

4.23.5 Power Domain

Introduction

The Zephyr power domain abstraction is designed to support groupings of devices powered by a common source to be notified of power source state changes in a generic fashion. Application code that is using device A does not need to know that device B is on the same power domain and should also be configured into a low power state.

Power domains are optional on Zephyr, to enable this feature the option `CONFIG_PM_DEVICE_POWER_DOMAIN` has to be set.

When a power domain turns itself on or off, it is the responsibility of the power domain to notify all devices using it through their power management callback called with

PM_DEVICE_ACTION_TURN_ON or PM_DEVICE_ACTION_TURN_OFF respectively. This work flow is illustrated in the diagram below.

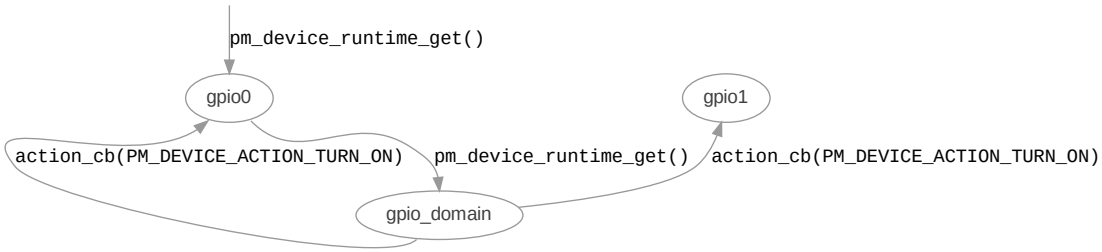

Fig. 12: Power domain work flow

Internal Power Domains Most of the devices in an SoC have independent power control that can be turned on or off to reduce power consumption. But there is a significant amount of static current leakage that can't be controlled only using device power management. To solve this problem, SoCs normally are divided into several regions grouping devices that are generally used together, so that an unused region can be completely powered off to eliminate this leakage. These regions are called "power domains", can be present in a hierarchy and can be nested.

External Power Domains Devices external to a SoC can be powered from sources other than the main power source of the SoC. These external sources are typically a switch, a regulator, or a dedicated power IC. Multiple devices can be powered from the same source, and this grouping of devices is typically called a "power domain".

Placing devices on power domains can be done for a variety of reasons, including to enable devices with high power consumption in low power mode to be completely turned off when not in use.

Implementation guidelines

In a first place, a device that acts as a power domain needs to declare compatible with `power-domain`. Taking *Power domain work flow* as example, the following code defines a domain called `gpio_domain`.

```
gpio_domain: gpio_domain@4 {
        compatible = "power-domain";
        ...
};
```

A power domain needs to implement the PM action callback used by the PM subsystem to turn devices on and off.

```
static int mydomain_pm_action(const struct device *dev,
                              enum pm_device_action action)
{
    switch (action) {
    case PM_DEVICE_ACTION_RESUME:
        /* resume the domain */
        ...
        /* notify children domain is now powered */
```

(continues on next page)

(continued from previous page)

```
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_ON, NULL);
        break;
    case PM_DEVICE_ACTION_SUSPEND:
        /* notify children domain is going down */
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_OFF, NULL);
        /* suspend the domain */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* turn on the domain (e.g. setup control pins to disabled) */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* turn off the domain (e.g. reset control pins to default state) */
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

Devices belonging to this device can be declared referring it in the `power-domain` node's property. The example below declares devices `gpio0` and `gpio1` belonging to domain `gpio_domain`.

```
&gpio0 {
        compatible = "zephyr,gpio-emul";
        gpio-controller;
        power-domains = <&gpio_domain>;
};

&gpio1 {
        compatible = "zephyr,gpio-emul";
        gpio-controller;
        power-domains = <&gpio_domain>;
};
```

All devices under a domain will be notified when the domain changes state. These notifications are sent as actions in the device PM action callback and can be used by them to do any additional work required. They can safely be ignored though.

```
static int mydev_pm_action(const struct device *dev,
                           enum pm_device_action *action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* configure the device into low power mode */
        ...
```

(continues on next page)

(continued from previous page)

```
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* prepare the device for power down */
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

Note

It is responsibility of driver or the application to set the domain as “wakeup” source if a device depending on it is used as “wakeup” source.

4.24 OS Abstraction

OS abstraction layers (OSAL) provide wrapper function APIs that encapsulate common system functions offered by any operating system. These APIs make it easier and quicker to develop for, and port code to multiple software and hardware platforms.

These sections describe the software and hardware abstraction layers supported by the Zephyr RTOS.

4.24.1 POSIX

Overview

The Portable Operating System Interface (POSIX) is a family of standards specified by the IEEE Computer Society for maintaining compatibility between operating systems. Zephyr implements a subset of the standard POSIX API specified by IEEE 1003.1-2017 (also known as POSIX-1.2017).

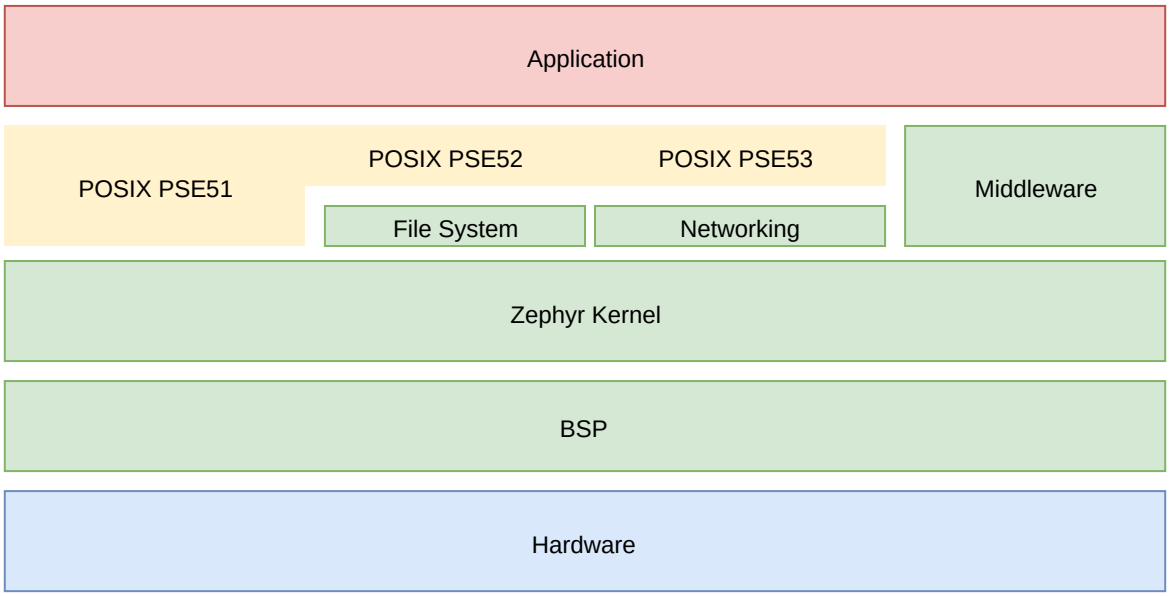

Fig. 13: POSIX support in Zephyr

Note

This page does not document Zephyr's POSIX architecture, which is used to run Zephyr as a native application under the host operating system for prototyping, test, and diagnostic purposes.

With the POSIX support available in Zephyr, an existing POSIX conformant application can be ported to run on the Zephyr kernel, and therefore leverage Zephyr features and functionality. Additionally, a library designed to be POSIX conformant can be ported to Zephyr kernel based applications with no changes.

The POSIX API is an increasingly popular OSAL (operating system abstraction layer) for IoT and embedded applications, as can be seen in Zephyr, AWS:FreeRTOS, TI-RTOS, and NuttX.

Benefits of POSIX support in Zephyr include:

- Offering a familiar API to non-embedded programmers, especially from Linux
- Enabling reuse (portability) of existing libraries based on POSIX APIs
- Providing an efficient API subset appropriate for small (MCU) embedded systems

POSIX Subprofiles While Zephyr supports running multiple *threads* (possibly in an *SMP* configuration), as well as *Virtual Memory and MMUs*, Zephyr code and data normally share a common address space that is partitioned into separate *Memory Domains*. The Zephyr kernel executable code and the application executable code are typically compiled into the same binary artifact. From that perspective, Zephyr apps can be seen as running in the context of a single process.

While multi-purpose operating systems (OS) offer full POSIX conformance, Real-Time Operating Systems (RTOS) such as Zephyr typically serve a fixed-purpose, have limited hardware resources, and experience limited user interaction. In such systems, full POSIX conformance can be impractical and unnecessary.

For that reason, POSIX defined the following *Application Environment Profiles (AEP)* as part of IEEE 1003.13-2003 (also known as POSIX.13-2003). Each AEP adds incrementally more features over the required *POSIX System Interfaces*.

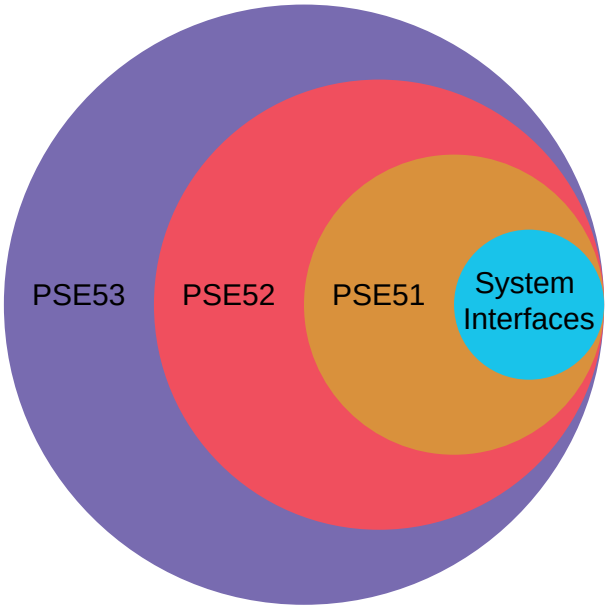

Fig. 14: POSIX Application Environment Profiles (AEP)

- Minimal Realtime System Profile (*PSE51*)
- Realtime Controller System Profile (*PSE52*)
- Dedicated Realtime System Profile (*PSE53*)
- Multi-Purpose Realtime System (PSE54)

POSIX.13-2003 AEP were formalized in 2003 via "Units of Functionality" but the specification is now inactive (for reference only). Nevertheless, the intent is still captured as part of POSIX-1.2017 via *Options* and *Option Groups*.

For more information, please see IEEE 1003.1-2017, Section E, Subprofiling Considerations.

POSIX Applications in Zephyr A POSIX app in Zephyr is *built like any other app* and therefore requires the usual `prj.conf`, `CMakeLists.txt`, and source code. For example, the app below leverages the `nanosleep()` and `perror()` POSIX functions.

Listing 13: *prj.conf* for a simple POSIX app in Zephyr

```
CONFIG_POSIX_API=y
```

Listing 14: A simple app that uses Zephyr's POSIX API

```
#include <stddef.h>
#include <stdio.h>
#include <time.h>

void megasleep(size_t megaseconds)
{
    struct timespec ts = {
        .tv_sec = megaseconds * 1000000,
        .tv_nsec = 0,
    };

    printf("See you in a while!\n");
    if (nanosleep(&ts, NULL) == -1) {
        perror("nanosleep");
    }
}

int main()
{
    megasleep(42);
    return 0;
}
```

For more examples of POSIX applications, please see the POSIX sample applications.

Configuration Like most features in Zephyr, POSIX features are *highly configurable* but disabled by default. Users must explicitly choose to enable POSIX options via *Kconfig* selection.

Subprofiles Enable one of the Kconfig options below to quickly configure a pre-defined *POSIX subprofile*.

- `CONFIG_POSIX_AEP_CHOICE_BASE` (*Base*)
- `CONFIG_POSIX_AEP_CHOICE_PSE51` (*PSE51*)
- `CONFIG_POSIX_AEP_CHOICE_PSE52` (*PSE52*)
- `CONFIG_POSIX_AEP_CHOICE_PSE53` (*PSE53*)

Additional POSIX *Options and Option Groups* may be enabled as needed via Kconfig (e.g. `CONFIG_POSIX_C_LIB_EXT=y`). Further fine-tuning may be accomplished via *additional POSIX-related Kconfig options*.

Subprofiles, Options, and Option Groups should be considered the preferred way to configure POSIX in Zephyr going forward.

Legacy Historically, Zephyr used `CONFIG_POSIX_API` to configure a set of POSIX features that was overloaded and always increasing in size.

- `CONFIG_POSIX_API`

The option is now frozen, and can be considered equivalent to the following:

- `CONFIG_POSIX_AEP_CHOICE_PSE51`
- `CONFIG_POSIX_FD_MGMT`
- `CONFIG_POSIX_MESSAGE_PASSING`
- `CONFIG_POSIX_NETWORKING`

However, `CONFIG_POSIX_API` should be considered legacy and should not be used for new Zephyr applications.

POSIX Conformance

As per IEEE 1003.1-2017, this section details Zephyr's POSIX conformance.

_POSIX_THREAD_ATTR_STACKADDR	200809L	CONFIG_POSIX_THREAD_ATTR_STACKADDR
_POSIX_THREAD_ATTR_STACKSIZE	200809L	CONFIG_POSIX_THREAD_ATTR_STACKSIZE
_POSIX_THREAD_PROCESS_SHARED	-1	

Note

Some features may exhibit undefined behaviour as they fall beyond the scope of Zephyr's current design and capabilities. For example, multi-processing, ad-hoc memory-mapping, multiple users, or regular expressions are features that are uncommon in low-footprint embedded systems. Such undefined behaviour is denoted with the † (obelus) symbol. Additional details *here*.

Note

Features listed in various POSIX Options or Option Groups may be provided in whole or in part by a conformant C library implementation. This includes (but is not limited to) POSIX Extensions to the ISO C Standard (CX).

POSIX Application Environment Profiles (AEP)

Although inactive, IEEE 1003.13-2003 defined a number of AEP that inspired the modern subprofiling options of IEEE 1003.1-2017. The single-purpose realtime system profiles are listed below, for reference, in terms that agree with the current POSIX-1 standard. PSE54 is not considered at this time.

System Interfaces The required POSIX *System Interfaces* are supported for each Application Environment Profile.

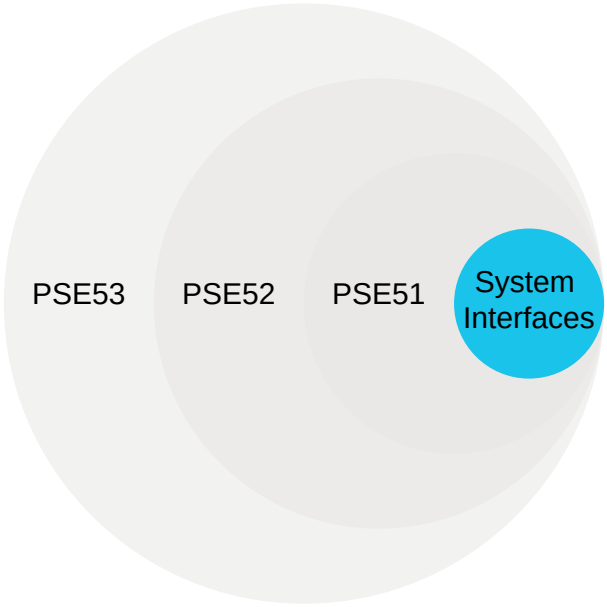

Fig. 15: System Interfaces

Minimal Realtime System Profile (PSE51) The *Minimal Realtime System Profile* (PSE51) includes all of the *System Interfaces* along with several additional features.

Table 15: PSE51 System Interfaces

_POSIX_SPAWN	-1	†
_POSIX_SPORADIC_SERVER	-1	†

Implementation Details

In many ways, Zephyr provides support like any POSIX OS; API bindings are provided in the C programming language, POSIX headers are available in the standard include path, when configured.

Unlike other multi-purpose POSIX operating systems

- Zephyr is not “a POSIX OS”. The Zephyr kernel was not designed around the POSIX standard, and POSIX support is an opt-in feature
- Zephyr apps are not linked separately, nor do they execute as subprocesses

- Zephyr, libraries, and application code are compiled and linked together, running similarly to a single-process application, in a single (possibly virtual) address space
- Zephyr does not provide a POSIX shell, compiler, utilities, and is not self-hosting.

Note

Unlike the Linux kernel or FreeBSD, Zephyr does not maintain a static table of system call numbers for each supported architecture, but instead generates system calls dynamically at build time. See *System Calls* for more information.

Design As a library, Zephyr's POSIX API implementation makes an effort to be a thin abstraction layer between the application, middleware, and the Zephyr kernel.

Some general design considerations:

- The POSIX interface and implementations should be part of Zephyr's POSIX library, and not elsewhere, unless required both by the POSIX API implementation and some other feature. An example where the implementation should remain part of the POSIX implementation is `getopt()`. Examples where the implementation should be part of separate libraries are multithreading and networking.
- When the POSIX API and another Zephyr subsystem both rely on a feature, the implementation of that feature should be as a separate Zephyr library that can be used by both the POSIX API and the other library or subsystem. This reduces the likelihood of dependency cycles in code. When practical, that rule should expand to include macros. In the example below, `libposix` depends on `libzfoo` for the implementation of some functionality "foo" in Zephyr. If `libzfoo` also depends on `libposix`, then there is a dependency cycle. The cycle can be removed via mutual dependency, `libcommon`.

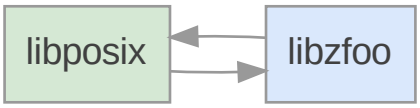

Fig. 19: Dependency cycle between POSIX and another Zephyr library

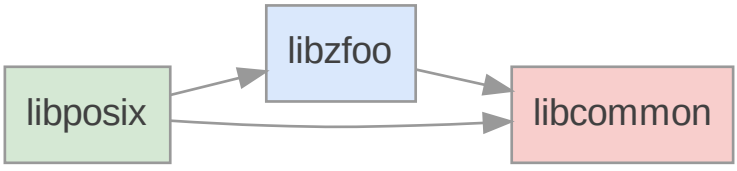

Fig. 20: Mutual dependencies between POSIX and other Zephyr libraries

- POSIX API calls should be provided as regular callable C functions; if a Zephyr *System Call* is needed as part of the implementation, the declaration and the implementation of that system call should be hidden behind the POSIX API.

POSIX Option and Option Group Details

POSIX Option Groups

POSIX_BARRIERS Enable this option group with `CONFIG_POSIX_BARRIERS`.

Table 24: POSIX_BARRIERS

API	Supported
pthread_barrier_destroy()	yes
pthread_barrier_init()	yes
pthread_barrier_wait()	yes
pthread_barrierattr_destroy()	yes
pthread_barrierattr_init()	yes

POSIX_C_LANG_JUMP The `POSIX_C_LANG_JUMP` Option Group is included in the ISO C standard.

> **Note**
>
> When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the `POSIX_C_LANG_JUMP` Option Group is considered supported.

Table 25: POSIX_C_LANG_JUMP

API	Supported
setjmp()	yes
longjmp()	yes

POSIX_C_LANG_MATH The `POSIX_C_LANG_MATH` Option Group is included in the ISO C standard.

> **Note**
>
> When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the `POSIX_C_LANG_MATH` Option Group is considered supported.

Please refer to Subprofiling Considerations for details on the `POSIX_C_LANG_MATH` Option Group.

POSIX_C_LANG_SUPPORT The POSIX_C_LANG_SUPPORT option group contains the general ISO C Library.

Note

When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the entire `POSIX_C_LANG_SUPPORT` Option Group is considered supported.

Please refer to Subprofiling Considerations for details on the `POSIX_C_LANG_SUPPORT` Option Group.

For more information on developing Zephyr applications in the C programming language, please refer to *details*.

POSIX_C_LANG_SUPPORT_R Enable this option group with `CONFIG_POSIX_C_LANG_SUPPORT_R`.

Table 26: POSIX_C_LANG_SUPPORT_R

API	Supported
asctime_r()	yes
ctime_r()	yes
gmtime_r()	yes
localtime_r()	yes
rand_r()	yes
strerror_r()	yes
strtok_r()	yes

POSIX_C_LIB_EXT Enable this option group with `CONFIG_POSIX_C_LIB_EXT`.

Table 27: POSIX_C_LIB_EXT

API	Supported
fnmatch()	yes
getopt()	yes
getsubopt()	
optarg	yes
opterr	yes
optind	yes
optopt	yes
stpcpy()	
stpncpy()	
strcasecmp()	
strdup()	
strfmon()	
strncasecmp()	yes
strndup()	
strnlen()	yes

POSIX_CLOCK_SELECTION Enable this option group with `CONFIG_POSIX_CLOCK_SELECTION`.

Table 28: POSIX_CLOCK_SELECTION

API	Supported
pthread_condattr_getclock()	yes
pthread_condattr_setclock()	yes
clock_nanosleep()	yes

POSIX_DEVICE_IO Enable this option group with `CONFIG_POSIX_DEVICE_IO`.

Note

When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the C89 components of the `POSIX_DEVICE_IO` Option Group are considered supported.

Table 29: POSIX_DEVICE_IO

API	Supported
FD_CLR()	yes
FD_ISSET()	yes
FD_SET()	yes
FD_ZERO()	yes
clearerr()	yes
close()	yes
fclose()	yes
fdopen()	yes
feof()	yes
ferror()	yes
fflush()	yes
fgetc()	yes
fgets()	yes
fileno()	yes
fopen()	yes
fprintf()	yes
fputc()	yes
fputs()	yes
fread()	yes
freopen()	yes
fscanf()	yes
fwrite()	yes
getc()	yes
getchar()	yes
gets()	yes
open()	yes
perror()	yes
poll()	yes
printf()	yes
pread()	yes
pselect()	yes
putc()	yes
putchar()	yes
puts()	yes
pwrite()	yes
read()	yes
scanf()	yes
select()	yes
setbuf()	yes
setvbuf()	yes
stderr	yes
stdin	yes
stdout	yes
ungetc()	yes
vfprintf()	yes

Table 29 – continued from previous page

API	Supported
vfscanf()	yes
vprintf()	yes
vscanf()	yes
write()	yes

POSIX_FD_MGMT Enable this option group with `CONFIG_POSIX_FD_MGMT`.

Table 30: POSIX_FD_MGMT

API	Supported
dup()	
dup2()	
fcntl()	
fgetpos()	
fseek()	
fseeko()	
fsetpos()	
ftell()	
ftello()	
ftruncate()	yes
lseek()	
rewind()	

POSIX_FILE_LOCKING

Table 31: POSIX_FILE_LOCKING

API	Supported
flockfile()	
ftrylockfile()	
funlockfile()	
getc_unlocked()	
getchar_unlocked()	
putc_unlocked()	
putchar_unlocked()	

POSIX_FILE_SYSTEM Enable this option group with `CONFIG_POSIX_FILE_SYSTEM`.

Table 32: POSIX_FILE_SYSTEM

API	Supported
access()	
chdir()	
closedir()	yes
creat()	
fchdir()	
fpathconf()	
fstat()	yes
fstatvfs()	
getcwd()	
link()	
mkdir()	yes
mkstemp()	
opendir()	yes
pathconf()	
readdir()	yes
remove()	yes
rename()	yes
rewinddir()	
rmdir()	yes
stat()	yes
statvfs()	
tmpfile()	
tmpnam()	
truncate()	
unlink()	yes
utime()	

POSIX_FILE_SYSTEM_R Enable this option with `CONFIG_POSIX_FILE_SYSTEM_R`.

Table 33: POSIX_FILE_SYSTEM_R

API	Supported
readdir_r()	yes

POSIX_MAPPED_FILES Enable this option group with `CONFIG_POSIX_MAPPED_FILES`.

Table 34: POSIX_MAPPED_FILES

API	Supported
mmap()	yes
msync()	yes
munmap()	yes

POSIX_MEMORY_PROTECTION Enable this option group with `CONFIG_POSIX_MEMORY_PROTECTION`.

Table 35: POSIX_MEMORY_PROTECTION

API	Supported
mprotect()	yes †

POSIX_MULTI_PROCESS Enable this option group with `CONFIG_POSIX_MULTI_PROCESS`.

Table 36: POSIX_MULTI_PROCESS

API	Supported
_Exit()	yes
_exit()	yes
assert()	yes
atexit()	†
clock()	
execl()	†
execle()	†
execlp()	†
execv()	†
execve()	†
execvp()	†
exit()	yes
fork()	†
getpgrp()	†
getpgid()	†
getpid()	yes †
getppid()	†
getsid()	†
setsid()	†
sleep()	yes
times()	
wait()	†
waitid()	†
waitpid()	†

POSIX_NETWORKING The function `sockatmark()` is not yet supported and is expected to fail setting `errno` to `ENOSYS` †.

Enable this option group with `CONFIG_POSIX_NETWORKING`.

Table 37: POSIX_NETWORKING

API	Supported
accept()	yes
bind()	yes
connect()	yes
endhostent()	yes
endnetent()	yes
endprotoent()	yes
endservent()	yes
freeaddrinfo()	yes
gai_strerror()	yes
getaddrinfo()	yes
gethostent()	yes
gethostname()	yes
getnameinfo()	yes
getnetbyaddr()	yes
getnetbyname()	yes
getnetent()	yes
getpeername()	yes
getprotobyname()	yes

continues on next page

Table 37 – continued from previous page

API	Supported

setnetent()	yes
setprotoent()	yes
setservent()	yes
setsockopt()	yes
shutdown()	yes
socket()	yes
sockatmark()	yes †
socketpair()	yes

POSIX_PIPE

Table 38: POSIX_PIPE

API	Supported
pipe()	

POSIX_REALTIME_SIGNALS Enable this option group with `CONFIG_POSIX_REALTIME_SIGNALS`.

Table 39: POSIX_REALTIME_SIGNALS

API	Supported
sigqueue()	
sigtimedwait()	
sigwaitinfo()	

POSIX_RW_LOCKS Enable this option with `CONFIG_POSIX_RW_LOCKS`.

Table 40: POSIX_RW_LOCKS

API	Supported
pthread_rwlock_destroy()	yes
pthread_rwlock_init()	yes
pthread_rwlock_rdlock()	yes
pthread_rwlock_tryrdlock()	yes
pthread_rwlock_trywrlock()	yes
pthread_rwlock_unlock()	yes
pthread_rwlock_wrlock()	yes
pthread_rwlockattr_destroy()	yes
pthread_rwlockattr_getpshared()	yes
pthread_rwlockattr_init()	yes
pthread_rwlockattr_setpshared()	yes

POSIX_SEMAPHORES Enable this option group with `CONFIG_POSIX_SEMAPHORES`.

Table 41: POSIX_SEMAPHORES

API	Supported
sem_close()	yes
sem_destroy()	yes
sem_getvalue()	yes
sem_init()	yes
sem_open()	yes
sem_post()	yes
sem_trywait()	yes
sem_unlink()	yes
sem_wait()	yes

POSIX_SIGNAL_JUMP

Table 42: POSIX_SIGNAL_JUMP

API	Supported
siglongjmp()	
sigsetjmp()	

POSIX_SIGNALS Enable this option group with `CONFIG_POSIX_SIGNALS`.

Note

As processes are not yet supported in Zephyr, the ISO C functions `abort()`, `signal()`, and `raise()`, as well as the other POSIX functions listed below, may exhibit undefined behaviour. The POSIX functions `kill()`, `pause()`, `sigaction()`, `sigpending()`, `sigsuspend()`, and `sigwait()` are implemented to ensure that conformant applications can link, but they are expected to fail, setting errno to `ENOSYS` †.

Table 43: POSIX_SIGNALS

API	Supported
abort()	yes †
alarm()	yes †
kill()	yes †
pause()	yes †
raise()	yes †
sigaction()	yes †
sigaddset()	yes
sigdelset()	yes
sigemptyset()	yes
sigfillset()	yes
sigismember()	yes
signal()	yes †
sigpending()	yes †
sigprocmask()	yes
sigsuspend()	yes †
sigwait()	yes †
strsignal()	yes

POSIX_SINGLE_PROCESS The POSIX_SINGLE_PROCESS option group contains services for single process applications.

Enable this option group with `CONFIG_POSIX_SINGLE_PROCESS`.

Table 44: POSIX_SINGLE_PROCESS

API	Supported
confstr()	yes
environ	yes
errno	yes
getenv()	yes
setenv()	yes
sysconf()	yes
uname()	yes
unsetenv()	yes

POSIX_SPIN_LOCKS Enable this option group with `CONFIG_POSIX_SPIN_LOCKS`.

Table 45: POSIX_SPIN_LOCKS

API	Supported
pthread_spin_destroy()	yes
pthread_spin_init()	yes
pthread_spin_lock()	yes
pthread_spin_trylock()	yes
pthread_spin_unlock()	yes

POSIX_THREADS_BASE The basic assumption in this profile is that the system consists of a single (implicit) process with multiple threads. Therefore, the standard requires all basic thread services, except those related to multiple processes.

Enable this option group with `CONFIG_POSIX_THREADS`.

Table 46: POSIX_THREADS_BASE

API	Supported
pthread_atfork()	yes
pthread_attr_destroy()	yes
pthread_attr_getdetachstate()	yes
pthread_attr_getschedparam()	yes
pthread_attr_init()	yes
pthread_attr_setdetachstate()	yes
pthread_attr_setschedparam()	yes
pthread_barrier_destroy()	yes
pthread_barrier_init()	yes
pthread_barrier_wait()	yes
pthread_barrierattr_destroy()	yes
pthread_barrierattr_getpshared()	yes
pthread_barrierattr_init()	yes
pthread_barrierattr_setpshared()	yes
pthread_cancel()	yes
pthread_cleanup_pop()	yes
pthread_cleanup_push()	yes
pthread_cond_broadcast()	yes
pthread_cond_destroy()	yes
pthread_cond_init()	yes
pthread_cond_signal()	yes
pthread_cond_timedwait()	yes
pthread_cond_wait()	yes
pthread_condattr_destroy()	yes
pthread_condattr_init()	yes
pthread_create()	yes
pthread_detach()	yes
pthread_equal()	yes
pthread_exit()	yes
pthread_getspecific()	yes
pthread_join()	yes
pthread_key_create()	yes
pthread_key_delete()	yes
pthread_kill()	
pthread_mutex_destroy()	yes
pthread_mutex_init()	yes
pthread_mutex_lock()	yes
pthread_mutex_trylock()	yes

continues on next page

Table 46 – continued from previous page

API	Supported
pthread_mutex_unlock()	yes
pthread_mutexattr_destroy()	yes
pthread_mutexattr_init()	yes
pthread_once()	yes
pthread_self()	yes
pthread_setcancelstate()	yes
pthread_setcanceltype()	yes
pthread_setspecific()	yes
pthread_sigmask()	yes
pthread_testcancel()	yes
sched_yield()	yes

POSIX_THREADS_EXT Enable this option group with `CONFIG_POSIX_THREADS_EXT`.

Table 47: POSIX_THREADS_EXT

API	Supported
pthread_attr_getguardsize()	yes
pthread_attr_setguardsize()	yes
pthread_mutexattr_gettype()	yes
pthread_mutexattr_settype()	yes

POSIX_TIMERS Enable this option group with `CONFIG_POSIX_TIMERS`.

Table 48: POSIX_TIMERS

API	Supported
clock_getres()	yes
clock_gettime()	yes
clock_settime()	yes
nanosleep()	yes
timer_create()	yes
timer_delete()	yes
timer_gettime()	yes
timer_getoverrun()	yes
timer_settime()	yes

XSI_REALTIME The `XSI_REALTIME` option group indicates that the *_POSIX_FSYNC*, *_POSIX_MEMLOCK*, *_POSIX_MEMLOCK_RANGE*, *_POSIX_MESSAGE_PASSING*, *_POSIX_PRIORITY_SCHEDULING*, *_POSIX_SHARED_MEMORY_OBJECTS*, and *_POSIX_SYNCHRONIZED_IO* options are enabled.

Enable this option group with `CONFIG_XSI_REALTIME`.

When this option group is enabled, the `_XOPEN_REALTIME` feature test macro will be defined to a value other than -1.

XSI_SINGLE_PROCESS Enable this option group with `CONFIG_XSI_SINGLE_PROCESS`.

Table 49: XSI_SINGLE_PROCESS

API	Supported
gethostid()	yes
gettimeofday()	yes
putenv()	yes

XSI_SYSTEM_LOGGING Enable this option group with `CONFIG_XSI_SYSTEM_LOGGING`.

Table 50: XSI_SYSTEM_LOGGING

API	Supported
closelog()	yes
openlog()	yes
setlogmask()	yes
syslog()	yes

XSI_THREADS_EXT The XSI_THREADS_EXT option group is required because it provides functions to control a thread's stack. This is considered useful for any real-time application.

Enable this option group with `CONFIG_XSI_THREADS_EXT`.

Table 51: XSI_THREADS_EXT

API	Supported
pthread_attr_getstack()	yes
pthread_attr_setstack()	yes
pthread_getconcurrency()	yes
pthread_setconcurrency()	yes

POSIX Options

_POSIX_ASYNCHRONOUS_IO Functions part of the `_POSIX_ASYNCHRONOUS_IO` Option are not implemented in Zephyr but are provided so that conformant applications can still link. These functions will fail, setting `errno` to `ENOSYS`†.

Enable this option with `CONFIG_POSIX_ASYNCHRONOUS_IO`.

Table 52: _POSIX_ASYNCHRONOUS_IO

API	Supported
aio_cancel()	yes †
aio_error()	yes †
aio_fsync()	yes †
aio_read()	yes †
aio_return()	yes †
aio_suspend()	yes †
aio_write()	yes †
lio_listio()	yes †

_POSIX_CPUTIME Enable this option with `CONFIG_POSIX_CPUTIME`.

Table 53: _POSIX_CPUTIME

API	Supported
CLOCK_PROCESS_CPUTIME_ID	yes

_POSIX_FSYNC Enable this option with `CONFIG_POSIX_FSYNC`.

Table 54: _POSIX_FSYNC

API	Supported
fsync()	yes

_POSIX_IPV6 Internet Protocol Version 6 is supported.

For more information, please refer to *Networking*.

Enable this option with `CONFIG_POSIX_IPV6`.

_POSIX_MEMLOCK Zephyr's *Demand Paging API* does not yet support pinning or unpinning all virtual memory regions. The functions below are expected to fail and set `errno` to `ENOSYS` †.

Enable this option with `CONFIG_POSIX_MEMLOCK`.

Table 55: _POSIX_MEMLOCK

API	Supported
mlockall()	yes
munlockall()	yes

_POSIX_MEMLOCK_RANGE Enable this option with `CONFIG_POSIX_MEMLOCK_RANGE`.

Table 56: _POSIX_MEMLOCK_RANGE

API	Supported
mlock()	yes
munlock()	yes

_POSIX_MESSAGE_PASSING Enable this option with `CONFIG_POSIX_MESSAGE_PASSING`.

Table 57: _POSIX_MESSAGE_PASSING

API	Supported
mq_close()	yes
mq_getattr()	yes
mq_notify()	yes
mq_open()	yes
mq_receive()	yes
mq_send()	yes
mq_setattr()	yes
mq_unlink()	yes

_POSIX_MONOTONIC_CLOCK Enable this option with `CONFIG_POSIX_MONOTONIC_CLOCK`.

Table 58: _POSIX_MONOTONIC_CLOCK

API	Supported
CLOCK_MONOTONIC	yes

_POSIX_PRIORITY_SCHEDULING As processes are not yet supported in Zephyr, the functions `sched_rr_get_interval()`, `sched_setparam()`, and `sched_setscheduler()` are expected to fail setting `errno` to `ENOSYS`†.

Enable this option with `CONFIG_POSIX_PRIORITY_SCHEDULING`.

Table 59: _POSIX_PRIORITY_SCHEDULING

API	Supported
sched_get_priority_max()	yes
sched_get_priority_min()	yes
sched_getparam()	yes
sched_getscheduler()	yes
sched_rr_get_interval()	yes †
sched_setparam()	yes †
sched_setscheduler()	yes †

_POSIX_RAW_SOCKETS Raw sockets are supported.

For more information, please refer to `CONFIG_NET_SOCKETS_PACKET`.

Enable this option with `CONFIG_POSIX_RAW_SOCKETS`.

_POSIX_SHARED_MEMORY_OBJECTS Enable this option with `CONFIG_POSIX_SHARED_MEMORY_OBJECTS`.

Table 60: _POSIX_SHARED_MEMORY_OBJECTS

API	Supported
mmap()	yes
munmap()	yes
shm_open()	yes
shm_unlink()	yes

_POSIX_SYNCHRONIZED_IO Enable this option with `CONFIG_POSIX_SYNCHRONIZED_IO`.

Table 61: _POSIX_SYNCHRONIZED_IO

API	Supported
fdatasync()	yes
fsync()	yes
msync()	yes

_POSIX_THREAD_ATTR_STACKADDR Enable this option with `CONFIG_POSIX_THREAD_ATTR_STACKADDR`.

Table 62: _POSIX_THREAD_ATTR_STACKADDR

API	Supported
pthread_attr_getstackaddr()	yes
pthread_attr_setstackaddr()	yes

_POSIX_THREAD_ATTR_STACKSIZE Enable this option with CONFIG_POSIX_THREAD_ATTR_STACKSIZE.

Table 63: _POSIX_THREAD_ATTR_STACKSIZE

API	Supported
pthread_attr_getstacksize()	yes
pthread_attr_setstacksize()	yes

_POSIX_THREAD_CPUTIME Enable this option with CONFIG_POSIX_THREAD_CPUTIME.

Table 64: _POSIX_THREAD_CPUTIME

API	Supported
CLOCK_THREAD_CPUTIME_ID	yes
pthread_getcpuclockid()	yes

_POSIX_THREAD_PRIO_INHERIT Enable this option with CONFIG_POSIX_THREAD_PRIO_INHERIT.

Table 65: _POSIX_THREAD_PRIO_INHERIT

API	Supported
pthread_mutexattr_getprotocol()	yes
pthread_mutexattr_setprotocol()	yes

_POSIX_THREAD_PRIO_PROTECT Enable this option with CONFIG_POSIX_THREAD_PRIO_PROTECT.

Table 66: _POSIX_THREAD_PRIO_PROTECT

API	Supported
pthread_mutex_getprioceiling()	yes
pthread_mutex_setprioceiling()	yes
pthread_mutexattr_getprioceiling()	yes
pthread_mutexattr_getprotocol()	yes
pthread_mutexattr_setprioceiling()	yes
pthread_mutexattr_setprotocol()	yes

_POSIX_THREAD_PRIORITY_SCHEDULING Enable this option with CONFIG_POSIX_THREAD_PRIORITY_SCHEDULING.

Table 67: _POSIX_THREAD_PRIORITY_SCHEDULING

API	Supported
pthread_attr_getinheritsched()	yes
pthread_attr_getschedpolicy()	yes
pthread_attr_getscope()	yes
pthread_attr_setinheritsched()	yes
pthread_attr_setschedpolicy()	yes
pthread_attr_setscope()	yes
pthread_getschedparam()	yes
pthread_setschedparam()	yes
pthread_setschedprio()	yes

_POSIX_THREAD_SAFE_FUNCTIONS Enable this option with `CONFIG_POSIX_THREAD_SAFE_FUNCTIONS`.

Table 68: _POSIX_THREAD_SAFE_FUNCTIONS

API	Supported
asctime_r()	yes
ctime_r()	yes (UTC timezone only)
flockfile()	
ftrylockfile()	
funlockfile()	
getc_unlocked()	
getchar_unlocked()	
getgrgid_r()	yes †
getgrnam_r()	yes †
getpwnam_r()	yes †
getpwuid_r()	yes †
gmtime_r()	yes
localtime_r()	yes (UTC timezone only)
putc_unlocked()	
putchar_unlocked()	
rand_r()	yes
readdir_r()	yes
strerror_r()	yes
strtok_r()	yes

_POSIX_TIMEOUTS Enable this option with `CONFIG_POSIX_TIMEOUTS`.

Table 69: _POSIX_TIMEOUTS

API	Supported
mq_timedreceive()	yes
mq_timedsend()	yes
pthread_mutex_timedlock()	yes
pthread_rwlock_timedrdlock()	yes
pthread_rwlock_timedwrlock()	yes
sem_timedwait()	yes
posix_trace_timedgetnext_event()	

_XOPEN_STREAMS With the exception of `ioctl()`, functions in the `_XOPEN_STREAMS` option group are not implemented in Zephyr but are provided so that conformant applications can still link. Unimplemented functions in this option group will fail, setting `errno` to `ENOSYS` †.

Enable this option with `CONFIG_XSI_STREAMS`.

Table 70: _XOPEN_STREAMS

API	Supported
fattach()	yes †
fdetach()	yes †
getmsg()	yes †
getpmsg()	yes †
ioctl()	yes
isastream()	yes †
putmsg()	yes †
putpmsg()	yes †

Additional Configuration Options

Below is a non-exhaustive list of additional *Configuration System (Kconfig)* options relating to Zephyr's implementation of the POSIX API.

- `CONFIG_DYNAMIC_THREAD`
- `CONFIG_DYNAMIC_THREAD_POOL_SIZE`
- `CONFIG_EVENTFD`
- `CONFIG_GETOPT_LONG`
- `CONFIG_MAX_PTHREAD_SPINLOCK_COUNT`
- `CONFIG_MQUEUE_NAMELEN_MAX`
- `CONFIG_POSIX_MQ_OPEN_MAX`
- `CONFIG_MSG_SIZE_MAX`
- `CONFIG_NET_SOCKETPAIR`
- `CONFIG_NET_SOCKETS`
- `CONFIG_ZVFS_POLL_MAX`
- `CONFIG_ZVFS_OPEN_MAX`
- `CONFIG_POSIX_API`
- `CONFIG_POSIX_OPEN_MAX`
- `CONFIG_POSIX_PTHREAD_ATTR_GUARDSIZE_BITS`
- `CONFIG_POSIX_PTHREAD_ATTR_GUARDSIZE_DEFAULT`
- `CONFIG_POSIX_PTHREAD_ATTR_STACKSIZE_BITS`
- `CONFIG_POSIX_RTSIG_MAX`
- `CONFIG_POSIX_SIGNAL_STRING_DESC`
- `CONFIG_POSIX_THREAD_KEYS_MAX`
- `CONFIG_POSIX_THREAD_THREADS_MAX`
- `CONFIG_POSIX_UNAME_NODENAME_LEN`
- `CONFIG_POSIX_UNAME_VERSION_LEN`
- `CONFIG_PTHREAD_CREATE_BARRIER`

- CONFIG_PTHREAD_RECYCLER_DELAY_MS
- CONFIG_POSIX_SEM_NAMELEN_MAX
- CONFIG_POSIX_SEM_NSEMS_MAX
- CONFIG_POSIX_SEM_VALUE_MAX
- CONFIG_TIMER_CREATE_WAIT
- CONFIG_THREAD_STACK_INFO
- CONFIG_ZVFS_EVENTFD_MAX
- CONFIG_ZVFS_FDTABLE

4.24.2 CMSIS RTOS v1

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v1, please refer to the CMSIS-RTOS1 Documentation.

4.24.3 CMSIS RTOS v2

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v2, please refer to the CMSIS-RTOS2 Documentation.

Features not supported in Zephyr implementation

Kernel
: `osKernelGetState`, `osKernelSuspend`, `osKernelResume`, `osKernelInitialize` and `osKernelStart` are not supported.

Mutex
: `osMutexPrioInherit` is supported by default and is not configurable, you cannot select/unselect this attribute.

  `osMutexRecursive` is also supported by default. If this attribute is not set, an error is thrown when the same thread tries to acquire it the second time.

  `osMutexRobust` is not supported in Zephyr.

Return values not supported in the Zephyr implementation

`osKernelUnlock`, `osKernelLock`, `osKernelRestoreLock`
: `osError` (Unspecified error) is not supported.

`osSemaphoreDelete`
: `osErrorResource` (the semaphore specified by parameter semaphore_id is in an invalid semaphore state) is not supported.

`osMutexDelete`
: `osErrorResource` (mutex specified by parameter mutex_id is in an invalid mutex state) is not supported.

`osTimerDelete`
: `osErrorResource` (the timer specified by parameter timer_id is in an invalid timer state) is not supported.

`osMessageQueueReset`
: `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.

`osMessageQueueDelete`
: `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.

`osMemoryPoolFree`
: `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.

`osMemoryPoolDelete`
: `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.

`osEventFlagsSet`, `osEventFlagsClear`
: `osFlagsErrorUnknown` (Unspecified error) and osFlagsErrorResource (Event flags object specified by parameter ef_id is not ready to be used) are not supported.

`osEventFlagsDelete`
: `osErrorParameter` (the value of the parameter ef_id is incorrect) is not supported.

`osThreadFlagsSet`
: `osFlagsErrorUnknown` (Unspecified error) and `osFlagsErrorResource` (Thread specified by parameter thread_id is not active to receive flags) are not supported.

`osThreadFlagsClear`
: `osFlagsErrorResource` (Running thread is not active to receive flags) is not supported.

`osDelayUntil`
: `osParameter` (the time cannot be handled) is not supported.

4.25 Power off

System power off

4.26 Profiling

Required Kconfig: `CONFIG_PROFILING`

4.26.1 Perf

Perf is a profiler tool based on stack tracing. It can be used for lightweight profiling with minimal code overhead.

Work Principle

The `perf record` shell command starts a timer with the perf tracer function. Timers are driven by interrupts, so the perf tracer function is called during an interruption. The Zephyr core saves the return address and frame pointer in the interrupt stack or `callee_saved` structure before calling the interrupt handler. Thus, the perf trace function makes stack traces by using the return address and frame pointer.

The scripts/profiling/stackcollapse.py script can be used to convert return addresses in the stack trace to function names using symbols from the ELF file, and to prints them in the format expected by FlameGraph.

Configuration

You can configure this module using the following options:

- `CONFIG_PROFILING_PERF`: Enables the module. This option adds the `perf` command to the shell.
- `CONFIG_PROFILING_PERF_BUFFER_SIZE`: Sets the size of the perf buffer where samples are saved before printing.

Usage

Refer to the profiling-perf sample for an example of how to use the perf tool.

4.27 Shell

- *Overview*
- *Backends*
  - *Telnet*
  - *USB CDC ACM*
  - *Bluetooth LE (NUS)*
  - *Segger RTT*
- *Commands*
  - *Commonly-used command groups*
  - *Creating commands*
  - *Dictionary commands*
  - *Commands execution*
  - *Built-in commands*
- *Tab Feature*
- *History Feature*
- *Wildcards Feature*
- *Meta Keys Feature*
- *sys_getopt Feature*
- *Obscured Input Feature*

- *Reading User Input*
- *Shell Logger Backend Feature*
- *RTT Backend Channel Selection*
- *Usage*
- *API Reference*

4.27.1 Overview

This module allows you to create and handle a shell with a user-defined command set. You can use it in examples where more than simple button or LED user interaction is required. This module is a Unix-like shell with these features:

- Support for multiple instances.
- Advanced cooperation with the *Logging*.
- Support for static and dynamic commands.
- Support for dictionary commands.
- Smart command completion with the `Tab` key.
- Built-in commands: **`clear`**, **`shell`**, **`colors`**, **`echo`**, **`history`** and **`resize`**.
- Viewing recently executed commands using keys: ↑ ↓ or meta keys.
- Text edition using keys: ←, →, `Backspace`, `Delete`, `End`, `Home`, `Insert`.
- Support for ANSI escape codes: `VT100` and `ESC[n~` for cursor control and color printing.
- Support for editing multiline commands.
- Built-in handler to display help for the commands.
- Support for wildcards: `*` and ?.
- Support for meta keys.
- Support for getopt and getopt_long.
- Kconfig configuration to optimize memory usage.

Note

Some of these features have a significant impact on RAM and flash usage, but many can be disabled when not needed. To default to options which favor reduced RAM and flash requirements instead of features, you should enable `CONFIG_SHELL_MINIMAL` and selectively enable just the features you want.

4.27.2 Backends

The module can be connected to any transport for command input and output. At this point, the following transport layers are implemented:

- MQTT
- Segger RTT
- SMP
- Telnet

- UART
- USB
- Bluetooth LE (NUS)
- RPMSG
- DUMMY - not a physical transport layer.

Telnet

Enabling `CONFIG_SHELL_BACKEND_TELNET` will allow users to use telnet as a shell backend. Connecting to it can be done using PuTTY or any `telnet` client. For example:

```
telnet <ip address> <port>
```

By default the telnet client won't handle telnet commands and configuration. Although command support can be enabled with `CONFIG_SHELL_TELNET_SUPPORT_COMMAND`. This will give the telnet client access to a very limited set of supported commands but still can be turned on if needed. One of the command options it supports is the `ECHO` option. This will allow the client to be in character mode (character at a time), similar to a UART backend in that regard. This will make the client send a character as soon as it is typed having the effect of increasing the network traffic considerably. For that cost, it will enable the line editing, *tab completion*, and *history* features of the shell.

USB CDC ACM

To configure Shell USB CDC ACM backend, simply add the snippet `cdc-acm-console` to your build:

```
west build -S cdc-acm-console [...]
```

Details on the configuration settings are captured in the following files:

- snippets/cdc-acm-console/cdc-acm-console.conf.
- snippets/cdc-acm-console/cdc-acm-console.overlay.

Bluetooth LE (NUS)

To configure Bluetooth LE (NUS) backend, simply add the snippet `nus-console` to your build:

```
west build -S nus-console [...]
```

Details on the configuration settings are captured in the following files:

- snippets/nus-console/nus-console.conf.
- snippets/nus-console/nus-console.overlay.

Segger RTT

To configure Segger RTT backend, add the following configurations to your build:

- `CONFIG_USE_SEGGER_RTT`
- `CONFIG_SHELL_BACKEND_RTT`
- `CONFIG_SHELL_BACKEND_SERIAL`

Details on additional configuration settings are captured in: samples/subsys/shell/shell_module/prj_minimal_rtt.conf.

Using west Attach to and configure RTT with:

```
$ west rtt
```

Note

If your default runner does not have support for RTT, check your board's documentation page for any other runners that support RTT. You may then use the `--runner` option to specify a different runner.

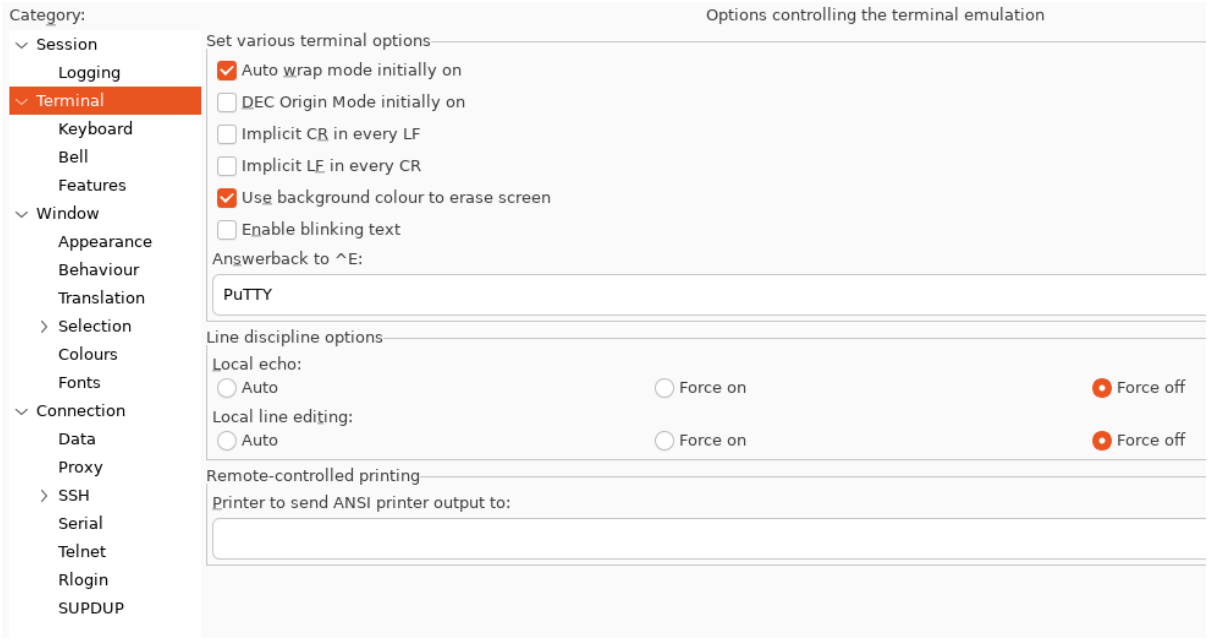
```
$ west rtt --runner <runner>
```

Using PuTTY Use following procedure:

- Open debug session and continue running the application.

  ```
  west attach
  ```

- Open PuTTY. Use telnet port 19021 and specific Terminal configuration. Set `Local echo` to `Force off` and `Local line editing` to `Force off` (see image below).



- Now you should have a network connection to RTT that will let you enter input to the shell.

Connecting to Segger RTT via TCP (on macOS, for example) On macOS JLinkRTTClient won't let you enter input. Instead, please use following procedure:

- Open up a first Terminal window and enter:

  ```
  JLinkRTTLogger -Device NRF52840_XXAA -RTTChannel 1 -if SWD -Speed 4000 ~/
  ↪rtt.log
  ```

  (change device if required)

- Open up a second Terminal window and enter:

  ```
  nc localhost 19021
  ```

- Now you should have a network connection to RTT that will let you enter input to the shell. However, contrary to *PuTTY* some features like Tab completion do not work.

4.27.3 Commands

Shell commands are organized in a tree structure and grouped into the following types:

- Root command (level 0): Gathered and alphabetically sorted in a dedicated memory section.
- Static subcommand (level > 0): Number and syntax must be known during compile time. Created in the software module.
- Dynamic subcommand (level > 0): Number and syntax does not need to be known during compile time. Created in the software module.

Commonly-used command groups

The following list is a set of useful command groups and how to enable them:

GPIO

- CONFIG_GPIO
- CONFIG_GPIO_SHELL

I2C

- CONFIG_I2C
- CONFIG_I2C_SHELL

Sensor

- CONFIG_SENSOR
- CONFIG_SENSOR_SHELL

Flash

- CONFIG_FLASH
- CONFIG_FLASH_SHELL

File-System

- CONFIG_FILE_SYSTEM
- CONFIG_FILE_SYSTEM_SHELL

ADC

- CONFIG_ADC
- CONFIG_ADC_SHELL
- CONFIG_ADC_EMUL_SHELL (requires CONFIG_ADC_EMUL)

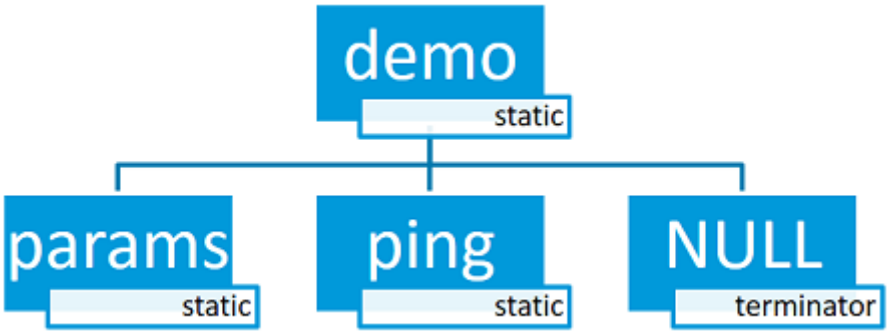
Creating commands

Use the following macros for adding shell commands:

- SHELL_CMD_REGISTER - Create root command. All root commands must have different name.
- SHELL_COND_CMD_REGISTER - Conditionally (if compile time flag is set) create root command. All root commands must have different name.
- SHELL_CMD_ARG_REGISTER - Create root command with arguments. All root commands must have different name.
- SHELL_COND_CMD_ARG_REGISTER - Conditionally (if compile time flag is set) create root command with arguments. All root commands must have different name.
- SHELL_CMD - Initialize a command.
- SHELL_COND_CMD - Initialize a command if compile time flag is set.
- SHELL_EXPR_CMD - Initialize a command if compile time expression is non-zero.
- SHELL_CMD_ARG - Initialize a command with arguments.
- SHELL_COND_CMD_ARG - Initialize a command with arguments if compile time flag is set.
- SHELL_EXPR_CMD_ARG - Initialize a command with arguments if compile time expression is non-zero.
- SHELL_STATIC_SUBCMD_SET_CREATE - Create a static subcommands array.
- SHELL_SUBCMD_DICT_SET_CREATE - Create a dictionary subcommands array.
- SHELL_DYNAMIC_CMD_CREATE - Create a dynamic subcommands array.

Commands can be created in any file in the system that includes include/zephyr/shell/shell.h. All created commands are available for all shell instances.

Static commands Example code demonstrating how to create a root command with static subcommands.



```
/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
        SHELL_CMD(params, NULL, "Print params command.",
                                                cmd_demo_params),
        SHELL_CMD(ping,   NULL, "Ping command.", cmd_demo_ping),
        SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);
```

Example implementation can be found under following location: samples/subsys/shell/shell_module/src/main.c.

Dictionary commands

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Let's use an example. Suppose you created a command to set an ADC gain. It is a perfect place where a dictionary can be used. The dictionary would be a set of pairs: (string: gain_value, int: value) where int value could be used with the ADC driver API.

Abstract code for this task would look like this:

```
static int gain_cmd_handler(const struct shell *sh,
                            size_t argc, char **argv, void *data)
{
        int gain;

        /* data is a value corresponding to called command syntax */
        gain = (int)data;
        adc_set_gain(gain);

        shell_print(sh, "ADC gain set to: %s\n"
                        "Value send to ADC driver: %d",
                        argv[0],
                        gain);

        return 0;
}

SHELL_SUBCMD_DICT_SET_CREATE(sub_gain, gain_cmd_handler,
        (gain_1, 1, "gain 1"), (gain_2, 2, "gain 2"),
        (gain_1_2, 3, "gain 1/2"), (gain_1_4, 4, "gain 1/4")
);
SHELL_CMD_REGISTER(gain, &sub_gain, "Set ADC gain", NULL);
```

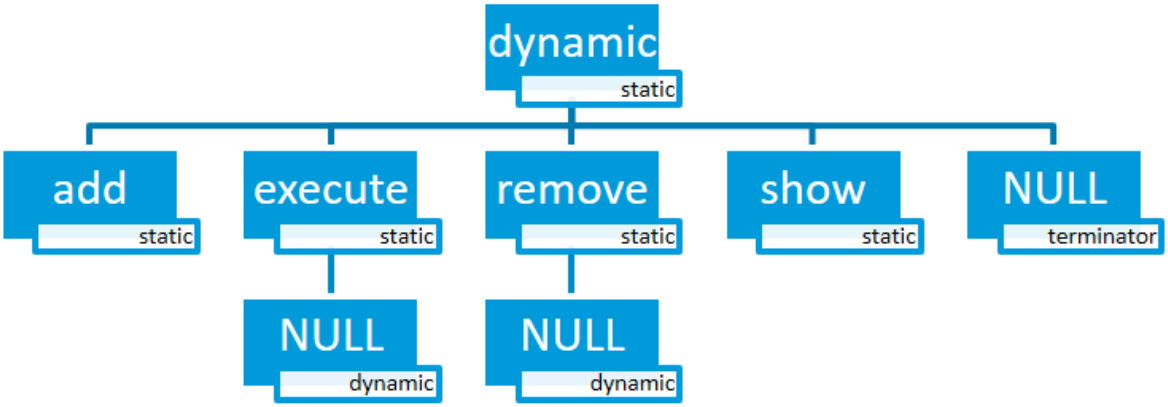
This is how it would look like in the shell:

```
uart:~$ gain ga
  gain_1    gain_2    gain_1_2  gain_1_4
uart:~$ gain gain_1
ADC gain set to: gain_1
Value send to ADC driver: 1
uart:~$ gain gain_2
ADC gain set to: gain_2
Value send to ADC driver: 2
uart:~$ gain gain_1_2
ADC gain set to: gain_1_2
Value send to ADC driver: 3
uart:~$ gain gain_1_4
ADC gain set to: gain_1_4
Value send to ADC driver: 4
uart:~$
```

Dynamic commands Example code demonstrating how to create a root command with static and dynamic subcommands. At the beginning dynamic command list is empty. New commands can be added by typing:

```
dynamic add <new_dynamic_command>
```

Newly added commands can be prompted or autocompleted with the Tab key.



```c
/* Buffer for 10 dynamic commands */
static char dynamic_cmd_buffer[10][50];

/* commands counter */
static uint8_t dynamic_cmd_cnt;

/* Function returning command dynamically created
 * in  dynamic_cmd_buffer.
 */
```

(continues on next page)

(continued from previous page)

```
static void dynamic_cmd_get(size_t idx,
                            struct shell_static_entry *entry)
{
        if (idx < dynamic_cmd_cnt) {
                entry->syntax = dynamic_cmd_buffer[idx];
                entry->handler  = NULL;
                entry->subcmd = NULL;
                entry->help = "Show dynamic command name.";
        } else {
                /* if there are no more dynamic commands available
                 * syntax must be set to NULL.
                 */
                entry->syntax = NULL;
        }
}

SHELL_DYNAMIC_CMD_CREATE(m_sub_dynamic_set, dynamic_cmd_get);
SHELL_STATIC_SUBCMD_SET_CREATE(m_sub_dynamic,
        SHELL_CMD(add, NULL,"Add new command to dynamic_cmd_buffer and"
                  " sort them alphabetically.",
                  cmd_dynamic_add),
        SHELL_CMD(execute, &m_sub_dynamic_set,
                  "Execute a command.", cmd_dynamic_execute),
        SHELL_CMD(remove, &m_sub_dynamic_set,
                  "Remove a command from dynamic_cmd_buffer.",
                  cmd_dynamic_remove),
        SHELL_CMD(show, NULL,
                  "Show all commands in dynamic_cmd_buffer.",
                  cmd_dynamic_show),
        SHELL_SUBCMD_SET_END
);
SHELL_CMD_REGISTER(dynamic, &m_sub_dynamic,
           "Demonstrate dynamic command usage.", cmd_dynamic);
```

Example implementation can be found under following location: samples/subsys/shell/shell_module/src/dynamic_cmd.c.

Commands execution

Each command or subcommand may have a handler. The shell executes the handler that is found deepest in the command tree and further subcommands (without a handler) are passed as arguments. Characters within parentheses are treated as one argument. If shell won't find a handler it will display an error message.

Commands can be also executed from a user application using any active backend and a function `shell_execute_cmd()`, as shown in this example:

```
int main(void)
{
        /* Below code will execute "clear" command on a DUMMY backend */
        shell_execute_cmd(NULL, "clear");

        /* Below code will execute "shell colors off" command on
         * an UART backend
         */
        shell_execute_cmd(shell_backend_uart_get_ptr(),
```

(continues on next page)

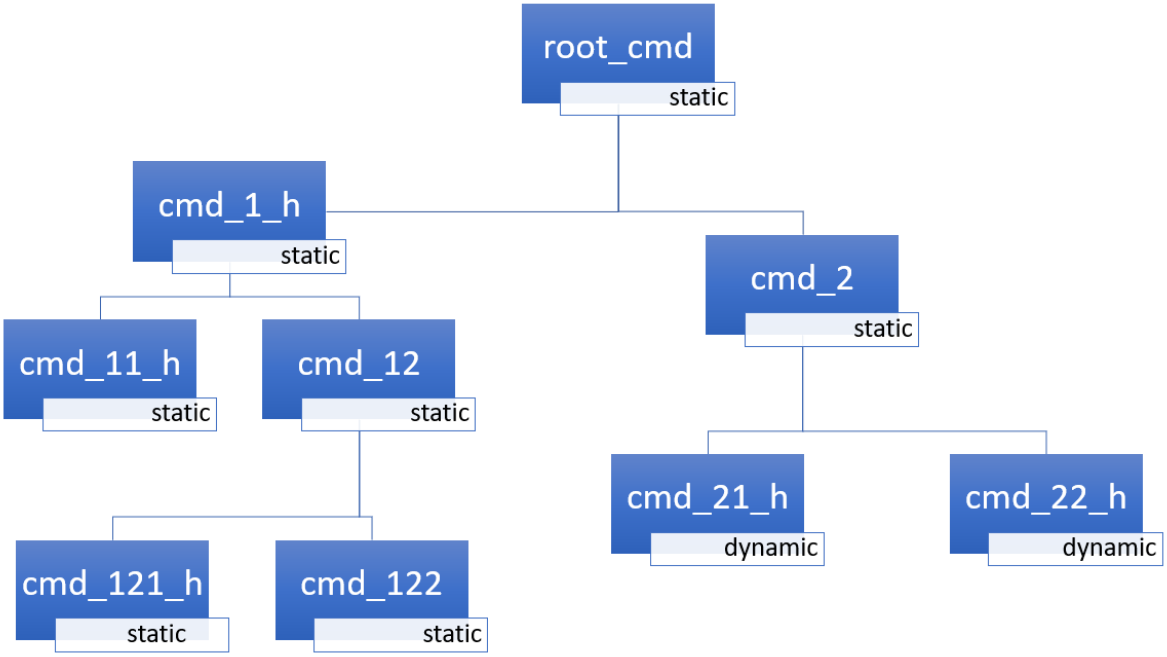
(continued from previous page)

```
                        "shell colors off");
}
```

Enable the DUMMY backend by setting the Kconfig `CONFIG_SHELL_BACKEND_DUMMY` option.

Commands execution example Let's assume a command structure as in the following figure, where:

- `root_cmd` - root command without a handler
- `cmd_xxx_h` - command has a handler
- `cmd_xxx` - command does not have a handler



Example 1 Sequence: `root_cmd cmd_1_h cmd_12_h cmd_121_h parameter` will execute command `cmd_121_h` and `parameter` will be passed as an argument.

Example 2 Sequence: `root_cmd cmd_2 cmd_22_h parameter1 parameter2` will execute command `cmd_22_h` and `parameter1 parameter2` will be passed as an arguments.

Example 3 Sequence: `root_cmd cmd_1_h parameter1 cmd_121_h parameter2` will execute command `cmd_1_h` and `parameter1`, `cmd_121_h` and `parameter2` will be passed as an arguments.

Example 4 Sequence: `root_cmd parameter cmd_121_h parameter2` will not execute any command.

Command handler Simple command handler implementation:

```
static int cmd_handler(const struct shell *sh, size_t argc,
                       char **argv)
{
        ARG_UNUSED(argc);
        ARG_UNUSED(argv);
```

(continues on next page)

(continued from previous page)

```
        shell_fprintf(shell, SHELL_INFO, "Print info message\n");

        shell_print(sh, "Print simple text.");

        shell_warn(sh, "Print warning text.");

        shell_error(sh, "Print error text.");

        return 0;
}
```

Function `shell_fprintf()` or the shell print macros: `shell_print`, `shell_info`, `shell_warn` and `shell_error` can be used from the command handler or from threads, but not from an interrupt context. Instead, interrupt handlers should use *Logging* for printing.

Command help Every user-defined command or subcommand can have its own help description. The help for commands and subcommands can be created with respective macros: `SHELL_CMD_REGISTER`, `SHELL_CMD_ARG_REGISTER`, `SHELL_CMD`, and `SHELL_CMD_ARG`.

Shell prints this help message when you call a command or subcommand with `-h` or `--help` parameter.

Parent commands In the subcommand handler, you can access both the parameters passed to commands or the parent commands, depending on how you index `argv`.

- When indexing `argv` with positive numbers, you can access the parameters.
- When indexing `argv` with negative numbers, you can access the parent commands.
- The subcommand to which the handler belongs has the `argv` index of 0.

```
static int cmd_handler(const struct shell *sh, size_t argc,
                       char **argv)
{
        ARG_UNUSED(argc);

        /* If it is a subcommand handler parent command syntax
         * can be found using argv[-1].
         */
        shell_print(sh, "This command has a parent command: %s",
                    argv[-1]);

        /* Print this command syntax */
        shell_print(sh, "This command syntax is: %s", argv[0]);

        /* Print first argument */
        shell_print(sh, "%s", argv[1]);

        return 0;
}
```

Built-in commands

These commands are activated by `CONFIG_SHELL_CMDS` set to `y`.

- **`clear`** - Clears the screen.
- **`history`** - Shows the recently entered commands.

- **resize** - Must be executed when terminal width is different than 80 characters or after each change of terminal width. It ensures proper multiline text display and ←, →, End, Home keys handling. Currently this command works only with UART flow control switched on. It can be also called with a subcommand:
  - **default** - Shell will send terminal width = 80 to the terminal and assume successful delivery.

  These command needs extra activation: CONFIG_SHELL_CMDS_RESIZE set to y.
- **select** - It can be used to set new root command. Exit to main command tree is with alt+r. This command needs extra activation: CONFIG_SHELL_CMDS_SELECT set to y.
- **shell** - Root command with useful shell-related subcommands like:
  - **echo** - Toggles shell echo.
  - **colors** - Toggles colored syntax. This might be helpful in case of Bluetooth shell to limit the amount of transferred bytes.
  - **stats** - Shows shell statistics.

4.27.4 Tab Feature

The Tab button can be used to suggest commands or subcommands. This feature is enabled by CONFIG_SHELL_TAB set to y. It can also be used for partial or complete auto-completion of commands. This feature is activated by CONFIG_SHELL_TAB_AUTOCOMPLETION set to y. When user starts writing a command and presses the Tab button then the shell will do one of 3 possible things:

- Autocomplete the command.
- Prompts available commands and if possible partly completes the command.
- Will not do anything if there are no available or matching commands.

```
uart:~$ log
  backend        disable        enable         go             halt
  list_backends  status
uart:~$ log enable
  dbg   err   inf   none  wrn
uart:~$ log enable err
  app               app_test         log              os
  shell.shell_uart  shell_uart
uart:~$ log enable err shell
  shell.shell_uart  shell_uart
uart:~$ log enable err shell
```

4.27.5 History Feature

This feature enables commands history in the shell. It is activated by: CONFIG_SHELL_HISTORY set to y. History can be accessed using keys: ↑ ↓ or Ctrl+n and Ctrl+p if meta keys are active. Number of commands that can be stored depends on size of CONFIG_SHELL_HISTORY_BUFFER parameter.

4.27.6 Wildcards Feature

The shell module can handle wildcards. Wildcards are interpreted correctly when expanded command and its subcommands do not have a handler. For example, if you want to set logging level to err for the app and app_test modules you can execute the following command:

```
log enable err a*
```

```
uart:~$ log status
module_name                                     | current | built-in
------------------------------------------------------------------
app                                             | inf     | inf
app_test                                        | inf     | inf
shell.uart_shell                                | inf     | inf
uart:~$ log enable err a*
uart:~$ log status
module_name                                     | current | built-in
------------------------------------------------------------------
app                                             | err     | inf
app_test                                        | err     | inf
shell.uart_shell                                | inf     | inf
uart:~$
```

This feature is activated by `CONFIG_SHELL_WILDCARD` set to y.

Note

When the wildcard feature is enabled, the characters * and ? cannot be used as normal characters in commands or arguments.

4.27.7 Meta Keys Feature

The shell module supports the following meta keys:

Table 71: Implemented meta keys

Meta keys	Action
Ctrl+a	Moves the cursor to the beginning of the line.
Ctrl+b	Moves the cursor backward one character.
Ctrl+c	Preserves the last command on the screen and starts a new command in a new line.
Ctrl+d	Deletes the character under the cursor.
Ctrl+e	Moves the cursor to the end of the line.
Ctrl+f	Moves the cursor forward one character.
Ctrl+k	Deletes from the cursor to the end of the line.
Ctrl+l	Clears the screen and leaves the currently typed command at the top of the screen.
Ctrl+n	Moves in history to next entry.
Ctrl+p	Moves in history to previous entry.
Ctrl+t	Toggles logs output on the shell when `CONFIG_SHELL_LOG_BACKEND` is set.
Ctrl+u	Clears the currently typed command.
Ctrl+w	Removes the word or part of the word to the left of the cursor. Words separated by period instead of space are treated as one word.
Alt+b	Moves the cursor backward one word.
Alt+f	Moves the cursor forward one word.

This feature is activated by `CONFIG_SHELL_METAKEYS` set to y.

4.27.8 sys_getopt Feature

Some shell users apart from subcommands might need to use options as well. the arguments string, looking for supported options. Typically, this task is accomplished by the `getopt` family functions.

For this purpose shell supports a variant of the getopt and getopt_long libraries from the FreeBSD project called sys_getopt and sys_getopt_long. This feature is activated by: `CONFIG_GETOPT` set to `y` and `CONFIG_GETOPT_LONG` set to `y`.

This feature can be used in thread safe as well as non thread safe manner. The former is full compatible with regular getopt usage while the latter a bit differs.

An example non-thread safe usage:

```
char *cvalue = NULL;
while ((char c = sys_getopt(argc, argv, "abhc:")) != -1) {
      switch (c) {
      case 'c':
              cvalue = sys_getopt_optarg;
              break;
      default:
              break;
      }
}
```

An example thread safe usage:

```
char *cvalue = NULL;
struct sys_getopt_state *state;
while ((char c = sys_getopt(argc, argv, "abhc:")) != -1) {
      state = sys_getopt_state_get();
      switch (c) {
      case 'c':
              cvalue = state->optarg;
              break;
      default:
              break;
      }
}
```

Thread safe sys_getopt functionality is activated by `CONFIG_SHELL_GETOPT` set to `y`.

4.27.9 Obscured Input Feature

With the obscured input feature, the shell can be used for implementing a login prompt or other user interaction whereby the characters the user types should not be revealed on screen, such as when entering a password.

Once the obscured input has been accepted, it is normally desired to return the shell to normal operation. Such runtime control is possible with the `shell_obscure_set` function.

An example of login and logout commands using this feature is located in samples/subsys/shell/shell_module/src/main.c and the config file samples/subsys/shell/shell_module/prj_login.conf.

This feature is activated upon startup by `CONFIG_SHELL_START_OBSCURED` set to `y`. With this set either way, the option can still be controlled later at runtime. `CONFIG_SHELL_CMDS_SELECT` is useful to prevent entry of any other command besides a login command, by means of the `shell_set_root_cmd` function. Likewise, `CONFIG_SHELL_PROMPT_UART` allows you to set the prompt upon startup, but it can be changed later with the `shell_prompt_change` function.

4.27.10 Reading User Input

The shell provides a `shell_readline()` function that allows command handlers to interactively read a line of input from the user. This is useful for implementing commands that need to prompt the user for additional information, such as confirmation dialogs, multi-step wizards, or interactive data entry.

The function reads from the shell transport until a newline character is received, storing the data in a provided buffer. The newline character itself is not included in the buffer. The buffer is automatically null-terminated on success.

Note

The `shell_readline()` function should be called from the shell thread in a shell command handler and blocks the thread until a result is returned.

Example usage:

```
static int cmd_read_secret(const struct shell *sh, size_t argc, char **argv)
{
        uint8_t input_buf[256];
        int ret;

        shell_fprintf_normal(sh, "Enter your secret: ");

        shell_obscure_set(sh, true);
        ret = shell_readline(sh, input_buf, sizeof(input_buf), K_SECONDS(10));
        shell_obscure_set(sh, false);

        if (ret < 0) {
                if (ret == -ETIMEDOUT) {
                        shell_error(sh, "Timeout waiting for input");
                } else if (ret == -ECANCELED) {
                        shell_error(sh, "Input canceled");
                } else if (ret == -ENOBUFS) {
                        shell_error(sh, "Input too long");
                }
                return ret;
        }

        shell_print(sh, "Secret input received (%d bytes)", ret);
        return 0;
}
```

4.27.11 Shell Logger Backend Feature

Shell instance can act as the *Logging* backend. Shell ensures that log messages are correctly multiplexed with shell output. Log messages from logger thread are enqueued and processed in the shell thread. Logger thread will block for configurable amount of time if queue is full, blocking logger thread context for that time. Oldest log message is removed from the queue after timeout and new message is enqueued. Use the `shell stats show` command to retrieve number of log messages dropped by the shell instance. Log queue size and timeout are `SHELL_DEFINE` arguments.

This feature is activated by: `CONFIG_SHELL_LOG_BACKEND` set to `y`.

Warning

Enqueuing timeout must be set carefully when multiple backends are used in the system. The shell instance could have a slow transport or could block, for example, by a UART with hardware flow control. If timeout is set too high, the logger thread could be blocked and impact other logger backends.

Warning

As the shell is a complex logger backend, it can not output logs if the application crashes before the shell thread is running. In this situation, you can enable one of the simple logging backends instead, such as UART (`CONFIG_LOG_BACKEND_UART`) or RTT (`CONFIG_LOG_BACKEND_RTT`), which are available earlier during system initialization.

4.27.12 RTT Backend Channel Selection

Instead of using the shell as a logger backend, RTT shell backend and RTT log backend can also be used simultaneously, but over different channels. By separating them, the log can be captured or monitored without shell output or the shell may be scripted without log interference. Enabling both the Shell RTT backend and the Log RTT backend does not work by default, because both default to channel `0`. There are two options:

1. The Shell buffer can use an alternate channel, for example using `CONFIG_SHELL_BACKEND_RTT_BUFFER` set to `1`. This allows monitoring the log using JLinkRTTViewer while a script interfaces over channel 1.

2. The Log buffer can use an alternate channel, for example using `CONFIG_LOG_BACKEND_RTT_BUFFER` set to `1`. This allows interactive use of the shell through JLinkRTTViewer, while the log is written to file.

See *shell backends* for details on how to enable RTT as a Shell backend.

4.27.13 Usage

The following code shows a simple use case of this library:

```
int main(void)
{

}

static int cmd_demo_ping(const struct shell *sh, size_t argc,
                         char **argv)
{
        ARG_UNUSED(argc);
        ARG_UNUSED(argv);

        shell_print(sh, "pong");
        return 0;
}

static int cmd_demo_params(const struct shell *sh, size_t argc,
                           char **argv)
{
        int cnt;
```

(continues on next page)

(continued from previous page)

```
        shell_print(sh, "argc = %d", argc);
        for (cnt = 0; cnt < argc; cnt++) {
                shell_print(sh, "  argv[%d] = %s", cnt, argv[cnt]);
        }
        return 0;
}

/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
        SHELL_CMD(params, NULL, "Print params command.",
                                                cmd_demo_params),
        SHELL_CMD(ping,   NULL, "Ping command.", cmd_demo_ping),
        SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" without a handler */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);

/* Creating root (level 0) command "version" */
SHELL_CMD_REGISTER(version, NULL, "Show kernel version", cmd_version);
```

Users may use the Tab key to complete a command/subcommand or to see the available subcommands for the currently entered command level. For example, when the cursor is positioned at the beginning of the command line and the Tab key is pressed, the user will see all root (level 0) commands:

```
clear  demo  shell  history  log  resize  version
```

Note

To view the subcommands that are available for a specific command, you must first type a space after this command and then hit Tab.

These commands are registered by various modules, for example:

- **clear**, **shell**, **history**, and **resize** are built-in commands which have been registered by subsys/shell/shell.c
- **demo** and **version** have been registered in example code above by main.c
- **log** has been registered by subsys/logging/log_cmds.c

Then, if a user types a **demo** command and presses the Tab key, the shell will only print the subcommands registered for this command:

```
params  ping
```

4.27.14 API Reference

Shell API

Related code samples

- Telnet consoleAccess Zephyr shell over telnet.

4.28 Serialization

Zephyr has support for several data serialization subsystems. These can be used to encode/decode structured data with a known format on-the-wire.

4.28.1 CBOR

CBOR (Concise Binary Object Representation) is a data format whose design goals include the possibility of extremely small code size, fairly small message size, and extensibility without the need for version negotiation.

Zephyr provides support for CBOR via the zcbor library, which is pulled in as a West module.

Configuration

To enable CBOR support, enable the `CONFIG_ZCBOR` Kconfig option.

API Reference

The zcbor library provides its own API documentation, please refer to it for more information.

4.28.2 JSON

Zephyr provides a JSON library that can be used to encode and decode JSON data.

Usage

Defining the Data Structure First, define the C structure that corresponds to the JSON object and the descriptor that maps the structure fields to JSON tokens.

```
#include <zephyr/data/json.h>

struct foo {
    int bar;
    const char *baz;
};

static const struct json_obj_descr foo_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct foo, bar, JSON_TOK_NUMBER),
    JSON_OBJ_DESCR_PRIM(struct foo, baz, JSON_TOK_STRING),
};
```

Encoding To encode a C structure into a JSON string, use `json_obj_encode_buf()`.

```
void encode_example(void)
{
    struct foo data = { .bar = 42, .baz = "hello" };
    char buffer[128];
    int ret;

    ret = json_obj_encode_buf(foo_descr, ARRAY_SIZE(foo_descr),
                              &data,
                              buffer, sizeof(buffer));
    if (ret < 0) {
        /* handle error */
    }
}
```

Decoding To decode a JSON string into a C structure, use `json_obj_parse()`.

```
void decode_example(void)
{
    struct foo data;
    const char *json_text = "{\"bar\": 42, \"baz\": \"hello\"}";
    int ret;

    ret = json_obj_parse(json_text, strlen(json_text),
                         foo_descr, ARRAY_SIZE(foo_descr),
                         &data);
    if (ret < 0) {
        /* handle error */
    }
}
```

Configuration

To enable JSON support, enable the `CONFIG_JSON_LIBRARY` Kconfig option.

API Reference

4.28.3 Nanopb

Nanopb is a C implementation of Google's Protocol Buffers.

Requirements

Nanopb uses the protocol buffer compiler to generate source and header files, make sure the `protoc` executable is installed and available.

Ubuntu

Use `apt` to install dependency:

```
sudo apt install protobuf-compiler
```

macOS

Use `brew` to install dependency:

```
brew install protobuf
```

Windows

Use `choco` to install dependency:

```
choco install protoc
```

Configuration

Make sure to include nanopb within your CMakeLists.txt file as follows:

```
list(APPEND CMAKE_MODULE_PATH ${ZEPHYR_BASE}/modules/nanopb)
include(nanopb)
```

Adding proto files can be done with the zephyr_nanopb_sources() CMake function which ensures the generated header and source files are created before building the specified target.

Nanopb has generator options that can be used to configure messages or fields. This allows to set fixed sizes or skip fields entirely.

The internal CMake generator has an extension to configure *.options.in files automatically with CMake variables.

See samples/modules/nanopb/src/simple.options.in and samples/modules/nanopb/CMakeLists.txt for usage example.

4.29 State Machine Framework

4.29.1 Overview

The State Machine Framework (SMF) is an application agnostic framework that provides an easy way for developers to integrate state machines into their application. The framework can be added to any project by enabling the CONFIG_SMF option.

4.29.2 State Creation

A state is represented by three functions, where one function implements the Entry actions, another function implements the Run actions, and the last function implements the Exit actions. The prototype for the entry and exit functions are as follows: `void funct(void *obj)`, and the prototype for the run action is `enum smf_state_result funct(void *obj)` where the obj parameter is a user defined structure that has the state machine context, smf_ctx, as its first member. For example:

```
struct user_object {
   struct smf_ctx ctx;
   /* All User Defined Data Follows */
};
```

The smf_ctx member must be first because the state machine framework's functions casts the user defined object to the smf_ctx type with the SMF_CTX macro.

For example instead of doing this `(struct smf_ctx *)&user_obj`, you could use `SMF_CTX(&user_obj)`.

By default, a state can have no ancestor states, resulting in a flat state machine. But to enable the creation of a hierarchical state machine, the CONFIG_SMF_ANCESTOR_SUPPORT option must be enabled.

The return value of the run action, smf_state_result determines if the state machine propagates the event to parent run actions (SMF_EVENT_PROPAGATE) or if the event was handled by the run action (SMF_EVENT_HANDLED). Flat state machines do not have parent actions, so the return code is ignored; returning SMF_EVENT_HANDLED is recommended.

Calling smf_set_state() prevents calling parent run actions, even if SMF_EVENT_PROPAGATE is returned.

By default, the hierarchical state machines do not support initial transitions to child states on entering a superstate. To enable them the CONFIG_SMF_INITIAL_TRANSITION option must be enabled.

The following macro can be used for easy state creation:

- SMF_CREATE_STATE Create a state

4.29.3 State Machine Creation

A state machine is created by defining a table of states that's indexed by an enum. For example, the following creates three flat states:

```
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, NULL),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, NULL, NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, NULL, NULL)
};
```

And this example creates three hierarchical states:

```
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, parent_s0, NULL),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, parent_s12, NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, parent_s12, NULL)
};
```

This example creates three hierarchical states with an initial transition from parent state S0 to child state S2:

```
enum demo_state { S0, S1, S2 };

/* Forward declaration of state table */
const struct smf_state demo_states[];

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, demo_states[S2]),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, demo_states[S0], NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, demo_states[S0], NULL)
};
```

To set the initial state, the smf_set_initial() function should be called.

To transition from one state to another, the smf_set_state() function is used.

Note

If CONFIG_SMF_INITIAL_TRANSITION is not set, smf_set_initial() and smf_set_state() function should not be passed a parent state as the parent state does not know which child state to transition to. Transitioning to a parent state is OK if an initial transition to a child state is defined. A well-formed HSM should have initial transitions defined for all parent states.

Note

While the state machine is running, `smf_set_state()` should only be called from the Entry or Run function. Calling `smf_set_state()` from Exit functions will generate a warning in the log and no transition will occur.

4.29.4 State Machine Execution

To run the state machine, the `smf_run_state()` function should be called in some application dependent way. An application should cease calling smf_run_state if it returns a non-zero value.

4.29.5 State Machine Termination

To terminate the state machine, the `smf_set_terminate()` function should be called. It can be called from the entry, run, or exit actions. The function takes a non-zero user defined value that will be returned by the `smf_run_state()` function.

4.29.6 Retrieving the Current State

Leaf State: In the context of a hierarchical state machine, a *leaf state* is a state that does not contain any child states. It represents the most granular level of state in the hierarchy, where no further decomposition is possible.

Executing State: The *executing state* refers to the state whose entry, run, or exit action is currently being executed by the state machine. This may be a parent or leaf state, depending on the current operation.

To retrieve the current leaf state, the `smf_get_current_leaf_state()` function should be called. For example:

```
const struct smf_state *leaf_state = smf_get_current_leaf_state(SMF_CTX(&s_obj));
```

Note

If `CONFIG_SMF_INITIAL_TRANSITION` is not enabled, or if the initial state of a parent state is not defined, always set the state to a leaf state. Otherwise, the state machine may enter a parent state directly, and `smf_get_current_leaf_state()` may return a parent state instead of a leaf state. Ensure initial transitions are properly configured for all parent states to avoid malformed hierarchical state machines.

To retrieve the state whose entry, run, or exit action is currently being executed, use the `smf_get_current_executing_state()` function.

4.29.7 UML State Machines

SMF follows UML hierarchical state machine rules for transitions i.e., the entry and exit actions of the least common ancestor are not executed on transition, unless said transition is a transition to self.

The UML Specification for StateMachines may be found in chapter 14 of the UML specification available here: https://www.omg.org/spec/UML/

SMF breaks from UML rules in:

1. Executing the actions associated with the transition within the context of the source state, rather than after the exit actions are performed.

2. Only allowing external transitions to self, not to sub-states. A transition from a superstate to a child state is treated as a local transition.
3. Prohibiting transitions using `smf_set_state()` in exit actions.

SMF also does not provide any pseudostates except the Initial Pseudostate. Terminate pseudostates can be modelled by calling `smf_set_terminate()` from the entry action of a 'terminate' state. Orthogonal regions are modelled by calling `smf_run_state()` for each region.

4.29.8 State Machine Examples

Flat State Machine Example

This example turns the following state diagram into code using the SMF, where the initial state is S0.

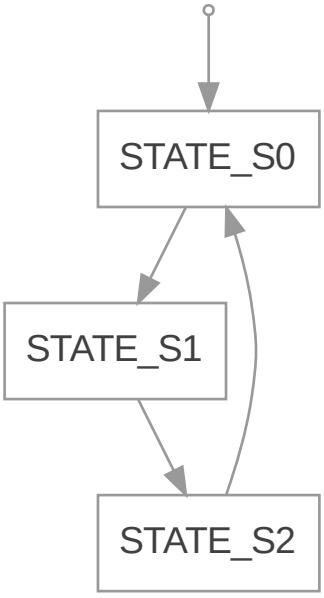

Fig. 21: Flat state machine diagram

Code:

```
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { S0, S1, S2 };

/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;
```

(continues on next page)

(continued from previous page)

```
        /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
        /* Do something */
}
static enum smf_state_result s0_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        return SMF_EVENT_HANDLED;
}
static void s0_exit(void *o)
{
        /* Do something */
}

/* State S1 */
static enum smf_state_result s1_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
        return SMF_EVENT_HANDLED;
}
static void s1_exit(void *o)
{
        /* Do something */
}

/* State S2 */
static void s2_entry(void *o)
{
        /* Do something */
}
static enum smf_state_result s2_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, NULL),
        /* State S1 does not have an entry action */
        [S1] = SMF_CREATE_STATE(NULL, s1_run, s1_exit, NULL, NULL),
        /* State S2 does not have an exit action */
        [S2] = SMF_CREATE_STATE(s2_entry, s2_run, NULL, NULL, NULL),
};

int main(void)
{
        int32_t ret;

        /* Set initial state */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);
```

(continues on next page)

(continued from previous page)

```
        /* Run the state machine */
        while(1) {
                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
                k_msleep(1000);
        }
}
```

Hierarchical State Machine Example

This example turns the following state diagram into code using the SMF, where S0 and S1 share a parent state and S0 is the initial state.

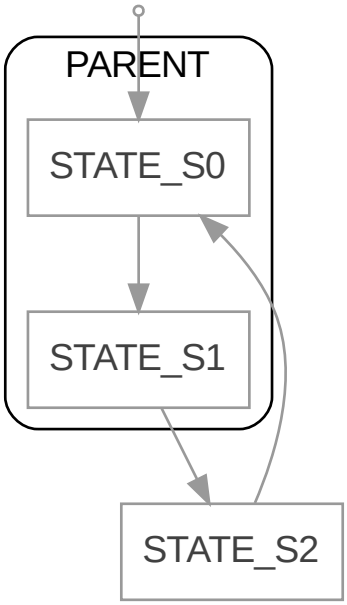

Fig. 22: Hierarchical state machine diagram

Code:

```
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { PARENT, S0, S1, S2 };
```

(continues on next page)

(continued from previous page)

```
/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;

        /* Other state specific data add here */
} s_obj;

/* Parent State */
static void parent_entry(void *o)
{
        /* Do something */
}
static void parent_exit(void *o)
{
        /* Do something */
}

/* State S0 */
static enum smf_state_result s0_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        return SMF_EVENT_HANDLED;
}

/* State S1 */
static enum smf_state_result s1_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
        return SMF_EVENT_HANDLED;
}

/* State S2 */
static enum smf_state_result s2_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        /* Parent state does not have a run action */
        [PARENT] = SMF_CREATE_STATE(parent_entry, NULL, parent_exit, NULL, NULL),
        /* Child states do not have entry or exit actions */
        [S0] = SMF_CREATE_STATE(NULL, s0_run, NULL, &demo_states[PARENT], NULL),
        [S1] = SMF_CREATE_STATE(NULL, s1_run, NULL, &demo_states[PARENT], NULL),
        /* State S2 do not have entry or exit actions and no parent */
        [S2] = SMF_CREATE_STATE(NULL, s2_run, NULL, NULL, NULL),
};

int main(void)
{
        int32_t ret;

        /* Set initial state */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);
```

(continues on next page)

(continued from previous page)

```
        /* Run the state machine */
        while(1) {
                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
                k_msleep(1000);
        }
}
```

When designing hierarchical state machines, the following should be considered:

- Ancestor entry actions are executed before the sibling entry actions. For example, the parent_entry function is called before the s0_entry function.
- Transitioning from one sibling to another with a shared ancestry does not re-execute the ancestor's entry action or execute the exit action. For example, the parent_entry function is not called when transitioning from S0 to S1, nor is the parent_exit function called.
- Ancestor exit actions are executed after the exit action of the current state. For example, the s1_exit function is called before the parent_exit function is called.
- The parent_run function only executes if the child_run function does not call either `smf_set_state()` or return `SMF_EVENT_HANDLED`.
- Avoid malformed hierarchical state machines by ensuring the state always transitions to a leaf state when `CONFIG_SMF_INITIAL_TRANSITION` is not enabled, or when a parent state's initial state is undefined.

Event Driven State Machine Example

Events are not explicitly part of the State Machine Framework but an event driven state machine can be implemented using Zephyr *Events*.

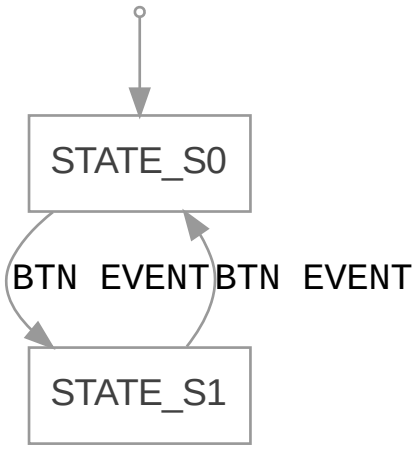

Fig. 23: Event driven state machine diagram

Code:

```
#include <zephyr/kernel.h>
#include <zephyr/drivers/gpio.h>
#include <zephyr/smf.h>

#define SW0_NODE        DT_ALIAS(sw0)

/* List of events */
#define EVENT_BTN_PRESS BIT(0)

static const struct gpio_dt_spec button =
        GPIO_DT_SPEC_GET_OR(SW0_NODE, gpios, {0});

static struct gpio_callback button_cb_data;

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { S0, S1 };

/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;

        /* Events */
        struct k_event smf_event;
        int32_t events;

        /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
        printk("STATE0\n");
}

static enum smf_state_result s0_run(void *o)
{
        struct s_object *s = (struct s_object *)o;

        /* Change states on Button Press Event */
        if (s->events & EVENT_BTN_PRESS) {
                smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        }
        return SMF_EVENT_HANDLED;
}

/* State S1 */
static void s1_entry(void *o)
{
        printk("STATE1\n");
}
```

(continues on next page)

(continued from previous page)

```
static enum smf_state_result s1_run(void *o)
{
        struct s_object *s = (struct s_object *)o;

        /* Change states on Button Press Event */
        if (s->events & EVENT_BTN_PRESS) {
                smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        }
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        [S0] = SMF_CREATE_STATE(s0_entry, s0_run, NULL, NULL, NULL),
        [S1] = SMF_CREATE_STATE(s1_entry, s1_run, NULL, NULL, NULL),
};

void button_pressed(const struct device *dev,
                struct gpio_callback *cb, uint32_t pins)
{
        /* Generate Button Press Event */
        k_event_post(&s_obj.smf_event, EVENT_BTN_PRESS);
}

int main(void)
{
        int ret;

        if (!gpio_is_ready_dt(&button)) {
                printk("Error: button device %s is not ready\n",
                        button.port->name);
                return;
        }

        ret = gpio_pin_configure_dt(&button, GPIO_INPUT);
        if (ret != 0) {
                printk("Error %d: failed to configure %s pin %d\n",
                        ret, button.port->name, button.pin);
                return;
        }

        ret = gpio_pin_interrupt_configure_dt(&button,
                GPIO_INT_EDGE_TO_ACTIVE);
        if (ret != 0) {
                printk("Error %d: failed to configure interrupt on %s pin %d\n",
                        ret, button.port->name, button.pin);
                return;
        }

        gpio_init_callback(&button_cb_data, button_pressed, BIT(button.pin));
        gpio_add_callback(button.port, &button_cb_data);

        /* Initialize the event */
        k_event_init(&s_obj.smf_event);

        /* Set initial state */
```

(continues on next page)

(continued from previous page)

```
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Run the state machine */
        while(1) {
                /* Block until an event is detected */
                s_obj.events = k_event_wait(&s_obj.smf_event,
                                EVENT_BTN_PRESS, true, K_FOREVER);

                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
        }
}
```

State Machine Example With Initial Transitions And Transition To Self

tests/lib/smf/src/test_lib_self_transition_smf.c defines a state machine for testing the initial transitions and transitions to self in a parent state. The statechart for this test is below.

4.29.9 Test Instrumentation

The SMF provides optional instrumentation hooks for observing state machine behavior during testing. To enable them, set `CONFIG_SMF_INSTRUMENTATION`.

When enabled, three hook callbacks can be registered on a state machine context via `smf_set_hooks()`:

- **on_action** — called before each entry, run, or exit action executes.
- **on_transition** — called after the current state pointer is updated but before the new state's entry actions execute.
- **on_error** — called when an invalid operation is detected (e.g. a NULL transition target or a transition attempted from an exit action).

Important

`smf_set_hooks()` must be called **after** `smf_set_initial()`, because `smf_set_initial()` resets the hooks pointer to `NULL`. As a consequence, entry actions executed during `smf_set_initial()` (i.e. the initial state's entry actions and those of its ancestors) will **not** be captured by the hooks.

Example:

```
#include <zephyr/smf.h>

static void on_action(struct smf_ctx *ctx,
                      const struct smf_state *state,
                      smf_action_type action_type)
{
        /* Log or record the action */
}
```

(continues on next page)

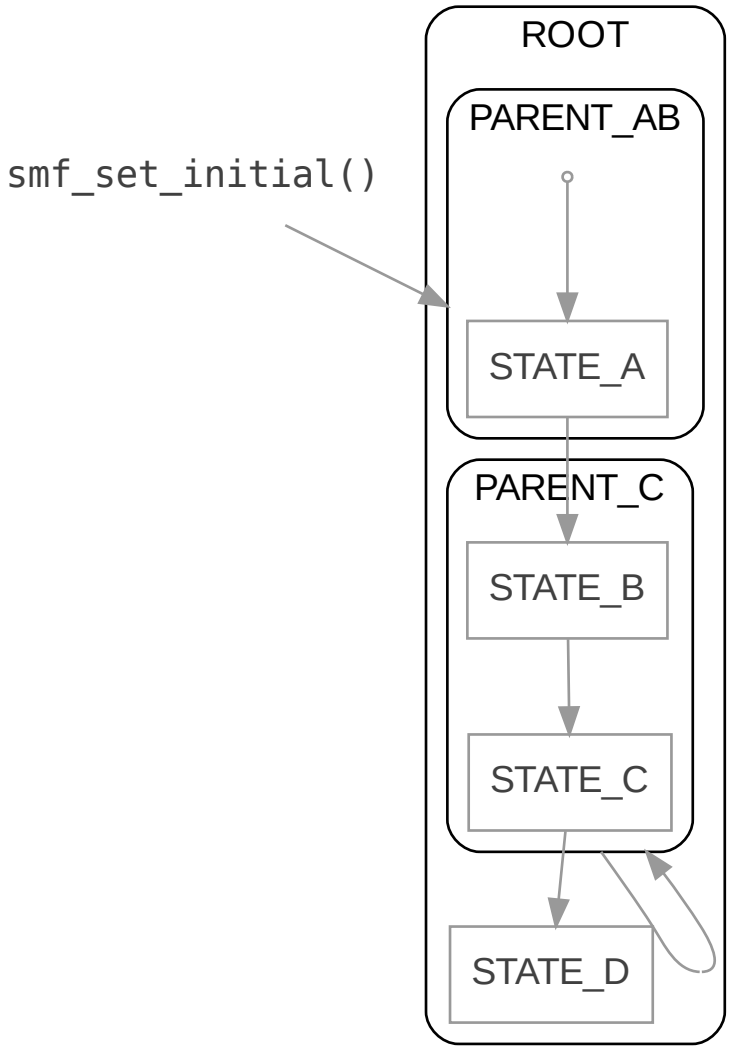

Fig. 24: Test state machine for UML State Transitions

(continued from previous page)

```
static void on_transition(struct smf_ctx *ctx,
                          const struct smf_state *source,
                          const struct smf_state *dest)
{
        /* Log or record the transition */
}

static const struct smf_hooks hooks = {
        .on_action = on_action,
        .on_transition = on_transition,
        /* .on_error = NULL - any member may be NULL */
};

void test_example(void)
{
        struct s_object s_obj;

        /* Set the initial state first */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Install hooks after init - initial entry actions are not captured */
        smf_set_hooks(SMF_CTX(&s_obj), &hooks);

        /* Run the state machine - hooks fire on every action and transition */
        while (!smf_run_state(SMF_CTX(&s_obj))) {
                /* ... */
        }
}
```

When `CONFIG_SMF_INSTRUMENTATION` is not set, all instrumentation code is compiled out and there is zero runtime overhead.

4.30 Storage

4.30.1 Disk Access

Overview

The disk access API provides access to storage devices.

Initializing Disks

Since many disk devices (such as SD cards) are hotpluggable, the disk access API provides IOCTLs to initialize and de-initialize the disk. They are as follows:

- `DISK_IOCTL_CTRL_INIT`: Initialize the disk. Must be called before additional I/O operations can be run on the disk device. Equivalent to calling the legacy function `disk_access_init()`.
- `DISK_IOCTL_CTRL_DEINIT`: De-initialize the disk. Once this IOCTL is issued, the `DISK_IOCTL_CTRL_INIT` must be issued before the disk can be used for addition I/O operations.

Init/deinit IOCTL calls are balanced, so a disk will not de-initialize until an equal number of deinit IOCTLs have been issued as init IOCTLs.

It is also possible to force a disk de-initialization by passing a pointer to a boolean set to `true` as a parameter to the `DISK_IOCTL_CTRL_DEINIT` IOCTL. This is an unsafe operation which each disk driver may handle differently, but it will always return a value indicating success.

Note that de-initializing a disk is a low level operation- typically the de-initialization and initialization calls should be left to the filesystem implementation, and the user application should not need to manually de-initialize the disk and can instead call `fs_unmount()`

SD Card support

Zephyr has support for some SD card controllers and support for interfacing SD cards via SPI. These drivers use disk driver interface and a file system can access the SD cards via disk access API. Both standard and high-capacity SD cards are supported.

> **Note**
>
> FAT filesystems are not power safe so the filesystem may become corrupted if power is lost or if the card is removed without unmounting the filesystem

SD Memory Card subsystem Zephyr supports SD memory cards via the disk driver API, or via the SDMMC subsystem. This subsystem can be used transparently via the disk driver API, but also supports direct block level access to cards. The SDMMC subsystem interacts with the *sd host controller api* to communicate with attached SD cards.

SD Card support via SPI Example devicetree fragment below shows how to add SD card node to `spi1` interface. Example uses pin `PA27` for chip select, and runs the SPI bus at 24 MHz once the SD card has been initialized:

```
&spi1 {
        status = "okay";
        cs-gpios = <&porta 27 GPIO_ACTIVE_LOW>;

        sdhc0: sdhc@0 {
                compatible = "zephyr,sdhc-spi-slot";
                reg = <0>;
                status = "okay";
                mmc {
                    compatible = "zephyr,sdmmc-disk";
                    disk-name = "SD";
                    status = "okay";
                };
                spi-max-frequency = <24000000>;
        };
};
```

The SD card will be automatically detected and initialized by the filesystem driver when the board boots.

To read and write files and directories, see the *File Systems* in include/zephyr/fs/fs.h such as `fs_open()`, `fs_read()`, and `fs_write()`.

eMMC Device Support

Zephyr also has support for eMMC devices using the Disk Access API. MMC in zephyr is implemented using the SD subsystem because the MMC bus shares a lot of similarity with the SD bus. MMC controllers also use the SDHC device driver API.

Emulated block device on flash partition support

Zephyr flashdisk driver makes it possible to use flash memory partition as a block device. The flashdisk instances are defined in devicetree:

```
/ {
    msc_disk0 {
        compatible = "zephyr,flash-disk";
        partition = <&storage_partition>;
        disk-name = "NAND";
        cache-size = <4096>;
    };
};
```

The cache size specified in `zephyr,flash-disk` node should be equal to backing partition minimum erasable block size.

NVMe disk support NVMe disks are also supported

NVMe NVMe is a standardized logical device interface on PCIe bus exposing storage devices.

NVMe controllers and disks are supported. Disks can be accessed via the *Disk Access API* they expose and thus be used through the *File System API*.

Driver design The driver is sliced up in 3 main parts:

- NVMe controller: drivers/disk/nvme/nvme_controller.c
- NVMe commands: drivers/disk/nvme/nvme_cmd.c
- NVMe namespace: drivers/disk/nvme/nvme_namespace.c

Where the NVMe controller is the root of the device driver. This is the one that will get device driver instances. Note that this is only what DTS describes: the NVMe controller, and none of its namespaces (disks). The NVMe command is the generic logic used to communicate with the controller and the namespaces it exposes. Finally the NVMe namespace is the dedicated part to deal with an actual namespace which, in turn, enables applications accessing each ones through the Disk Access API drivers/disk/nvme/nvme_disk.c.

If a controller exposes more than 1 namespace (disk), it will be possible to raise the amount of built-in namespace support by tweaking the configuration option CONFIG_NVME_MAX_NAMESPACES (see below).

Each exposed disk, via it's related disk_info structure, will be distinguished by its name which is inherited from it's related namespace. As such, the disk name follows NVMe naming which is nvme<k>n<n> where k is the controller number and n the namespame number. Most of the time, if only one NVMe disk is plugged into the system, one will see 'nvme0n0' as an exposed disk.

NVMe configuration

DTS Any board exposing an NVMe disk should provide a DTS overlay to enable its use within Zephyr

```
#include <zephyr/dt-bindings/pcie/pcie.h>
/ {
    pcie0 {
        nvme0: nvme0 {
            compatible = "nvme-controller";
            vendor-id = <VENDOR_ID>;
            device-id = <DEVICE_ID>;
            status = "okay";
        };
    };
};
```

Where VENDOR_ID and DEVICE_ID are the ones from the exposed NVMe controller.

Options

- CONFIG_NVME

Note that NVME requires the target to support PCIe multi-vector MSI-X in order to function.

- CONFIG_NVME_MAX_NAMESPACES

Important note for users NVMe specifications mandate the data buffer to be placed in a dword (4 bytes) aligned address. While this is not a problem for advanced OS managing virtual memory and dynamic allocations below the user processes, this can become an issue in Zephyr as soon as buffer addresses map directly to physical memory.

At this stage then, it is up to the user to make sure the buffer address being provided to `disk_access_read()` and `disk_access_write()` are dword aligned.

4.30.2 Flash Circular Buffer (FCB)

Flash circular buffer provides an abstraction through which you can treat flash like a FIFO. You append entries to the end, and read data from the beginning.

Description

Entries in the flash contain the length of the entry, the data within the entry, and checksum over the entry contents.

Storage of entries in flash is done in a FIFO fashion. When you request space for the next entry, space is located at the end of the used area. When you start reading, the first entry served is the oldest entry in flash.

Entries can be appended to the end of the area until storage space is exhausted. You have control over what happens next; either erase oldest block of data, thereby freeing up some space, or stop writing new data until existing data has been collected. FCB treats underlying storage as an array of flash sectors; when it erases old data, it does this a sector at a time.

Entries in the flash are checksummed. That is how FCB detects whether writing entry to flash completed ok. It will skip over entries which don't have a valid checksum.

Usage

To add an entry to circular buffer:

- Call `fcb_append()` to get the location where data can be written. If this fails due to lack of space, you can call `fcb_rotate()` to erase the oldest sector which will make the space. And then call `fcb_append()` again.
- Use `flash_area_write()` to write entry contents.
- Call `fcb_append_finish()` when done. This completes the writing of the entry by calculating the checksum.

To read contents of the circular buffer:

- Call `fcb_walk()` with a pointer to your callback function.
- Within callback function copy in data from the entry using `flash_area_read()`. You can tell when all data from within a sector has been read by monitoring the returned entry's area pointer. Then you can call `fcb_rotate()`, if you're done with that data.

Alternatively:

- Call `fcb_getnext()` with 0 in entry offset to get the pointer to the oldest entry.
- Use `flash_area_read()` to read entry contents.
- Call `fcb_getnext()` with pointer to current entry to get the next one. And so on.

API Reference

The FCB subsystem APIs are provided by `fcb.h`:

Data structures
Flash Circular Buffer Data Structures

API functions
fcb API

4.30.3 File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at different mount points (e.g., `/fatfs` and `/lfs`). The mount point data structure contains all the necessary information required to instantiate, mount, and operate on a file system. The File system Switch decouples the applications from directly accessing an individual file system's specific API or internal functions by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file system registration API. Each file system implementation must have a globally unique integer identifier; use `FS_TYPE_EXTERNAL_BASE` to avoid clashes with in-tree identifiers.

```
int fs_register(int type, const struct fs_file_system_t *fs);

int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```
static struct fs_mount_t mp = {
.type = FS_FATFS,
.mnt_point = FATFS_MNTP,
.fs_data = &fat_fs,
};
```

where

- `FS_FATFS` is the file system type like FATFS or LittleFS.
- `FATFS_MNTP` is the mount point where the file system will be mounted.
- `fat_fs` is the file system data which will be used by fs_mount() API.

Samples

Samples for the VFS are mainly supplied in `samples/subsys/fs`, although various examples of the VFS usage are provided as important functionalities in samples for different subsystems. Here is the list of samples worth looking at:

- fs is an example of FAT file system usage with SDHC media;
- shell-fs is an example of Shell fs subsystem, using internal flash partition formatted to LittleFS;
- usb-mass example of USB Mass Storage device that uses FAT FS driver with RAM or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

4.30.4 Flash map

The <zephyr/storage/flash_map.h> API allows accessing information about device flash partitions via flash_area structures.

Each flash_area describes a flash partition. The API provides access to a "flash map", which contains predefined flash areas accessible via globally unique ID numbers. The map is created from "fixed-partition" compatible entries in DTS file. Users may also create flash_area objects at runtime for application-specific purposes.

This documentation uses "flash area" when referencing single "fixed-partition" entities.

The flash_area contains a pointer to a device, which can be used to access the flash device an area is placed on directly with the *flash API*. Each flash area is characterized by a device it is placed on, offset from the beginning of the device and size on the device. An additional identifier parameter is used by the flash_area_open() function to find flash area in flash map.

The flash_map.h API provides functions for operating on a flash_area. The main examples are flash_area_read() and flash_area_write(). These functions are basically wrappers around the flash API with additional offset and size checks, to limit flash operations to a predefined area.

Most <zephyr/storage/flash_map.h> API functions require a flash_area object pointer characterizing the flash area they will be working on. There are two possible methods to obtain such a pointer:

- obtain it using flash_area_open();
- defining a flash_area type object, which requires providing a valid device object pointer with offset and size of the area within the flash device.

flash_area_open() uses numeric identifiers to search flash map for flash_area objects and returns, if found, a pointer to an object representing area with given ID. The ID number for a flash area can be obtained from a fixed-partition DTS node label using FIXED_PARTITION_ID(); these labels are obtained from the devicetree as described below.

Relationship with Devicetree

The flash_map.h API uses data generated from the *Devicetree API*, in particular its *Fixed flash partitions*. Zephyr additionally has some partitioning conventions used for *Device Firmware Upgrade* via the MCUboot bootloader, as well as defining partitions usable by *file systems* or other nonvolatile *storage*.

Here is an example devicetree fragment which uses fixed flash partitions for both MCUboot and a storage partition. Some details were left out for clarity.

```
/ {
        soc {
                flashctrl: flash-controller@deadbeef {
                        flash0: flash@0 {
                                compatible = "soc-nv-flash";
```

(continues on next page)

(continued from previous page)

```
                                reg = <0x0 0x100000>;

                                partitions {
                                        compatible = "fixed-partitions";
                                        #address-cells = <0x1>;
                                        #size-cells = <0x1>;

                                        boot_partition: partition@0 {
                                                reg = <0x0 0x10000>;
                                                read-only;
                                        };

                                        storage_partition: partition@1e000 {
                                                reg = <0x1e000 0x2000>;
                                        };

                                        slot0_partition: partition@20000 {
                                                reg = <0x20000 0x60000>;
                                        };

                                        slot1_partition: partition@80000 {
                                                reg = <0x80000 0x60000>;
                                        };

                                        scratch_partition: partition@e0000 {
                                                reg = <0xe0000 0x20000>;
                                        };
                                };
                        };
                };
        };
};
```

Partition offset shall be expressed in relation to the flash memory beginning address, to which the partition belongs to.

The `boot_partition`, `slot0_partition`, `slot1_partition`, and `scratch_partition` node labels are defined for MCUboot, though not all MCUboot configurations require all of them to be defined. See the MCUboot documentation for more details.

The `storage_partition` node is defined for use by a file system or other nonvolatile storage API.

Numeric flash area ID is obtained by passing DTS node label to `FIXED_PARTITION_ID()`; for example to obtain ID number for `slot0_partition`, user would invoke `FIXED_PARTITION_ID(slot0_partition)`.

All `FIXED_PARTITION_*` macros take DTS node labels as partition identifiers.

Users do not have to obtain a `flash_area` object pointer using `flash_map_open()` to get information on flash area size, offset or device, if such area is defined in DTS file. Knowing the DTS node label of an area, users may use `FIXED_PARTITION_OFFSET()`, `FIXED_PARTITION_SIZE()` or `FIXED_PARTITION_DEVICE()` respectively to obtain such information directly from DTS node definition. For example to obtain offset of `storage_partition` it is enough to invoke `FIXED_PARTITION_OFFSET(storage_partition)`.

Below example shows how to obtain a `flash_area` object pointer using `flash_area_open()` and DTS node label:

```
const struct flash_area *my_area;
int err = flash_area_open(FIXED_PARTITION_ID(slot0_partition), &my_area);

if (err != 0) {
     handle_the_error(err);
} else {
     flash_area_read(my_area, ...);
}
```

4.30.5 Non-Volatile Memory (NVMEM)

The NVMEM subsystem provides a generic interface for accessing non-volatile memory devices. It abstracts the underlying hardware and provides a unified API for reading and writing data.

Key Concepts

NVMEM Provider An NVMEM provider is a driver that exposes NVMEM cells. For example, an EEPROM driver can be an NVMEM provider. The NVMEM provider is responsible for reading and writing data to the underlying hardware.

NVMEM Cell An NVMEM cell is a region of non-volatile memory. It is defined in the devicetree and has properties like offset, size, and read-only status.

NVMEM Consumer An NVMEM consumer is a driver or application that uses NVMEM cells to store or retrieve data.

Configuration

- `CONFIG_NVMEM`: Enables the NVMEM subsystem.
- `CONFIG_NVMEM_BBRAM`: Enables NVMEM support for Battery Backed RAM.
- `CONFIG_NVMEM_EEPROM`: Enables NVMEM support for EEPROM devices.
- `CONFIG_NVMEM_FLASH.*`: Configure NVMEM support for flash devices.
- `CONFIG_NVMEM_OTP.*`: Configure NVMEM support for OTP devices.

Devicetree Bindings

The NVMEM subsystem relies on devicetree bindings to define NVMEM cells. The following is an example of how to define an NVMEM provider and cells in the devicetree:

```
&eeprom0 {
        nvmem-layout {
                compatible = "fixed-layout";
                #address-cells = <1>;
                #size-cells = <1>;

                mac_address: mac_address@0 {
                        reg = <0x0 6>;
                        #nvmem-cell-cells = <0>;
                        read-only;
                };

                calibration_data: calibration_data@6 {
                        reg = <0x6 100>;
                        #nvmem-cell-cells = <0>;
                };
        };
};
```

A consumer can then reference the NVMEM cells like this:

```
my_consumer: my-consumer {
        compatible = "my,consumer";
        nvmem-cells = <&mac_address>, <&calibration_data>;
        nvmem-cell-names = "mac-address", "calibration-data";
};
```

Usage Example

The following is an example of how to use the NVMEM API to read data from an NVMEM cell:

```
#include <zephyr/nvmem.h>

static const struct nvmem_cell mac_address =
        NVMEM_CELL_GET_BY_NAME(DT_NODELABEL(my_consumer), mac_address);

int main(void)
{
        uint8_t mac[6];
        int ret;

        if (!nvmem_cell_is_ready(&mac_address)) {
                printk("NVMEM cell is not ready\n");
                return -ENODEV;
        }

        ret = nvmem_cell_read(&mac_address, mac, 0, sizeof(mac));
        if (ret < 0) {
                printk("Failed to read MAC address: %d\n", ret);
                return ret;
        }

        /* ... */
}
```

NVMEM

4.30.6 Non-Volatile Storage (NVS)

Elements, represented as id-data pairs, are stored in flash using a FIFO-managed circular buffer. The flash area is divided into sectors. Elements are appended to a sector until storage space in the sector is exhausted. Then a new sector in the flash area is prepared for use (erased). Before erasing the sector it is checked that identifier - data pairs exist in the sectors in use, if not the id-data pair is copied.

The id is a 16-bit unsigned number. NVS ensures that for each used id there is at least one id-data pair stored in flash at all time.

NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Each element is stored in flash as metadata (8 byte) and data. The metadata is written in a table starting from the end of a nvs sector, the data is written one after the other from the start of the sector. The metadata consists of: id, data offset in sector, data length, part (unused), and a CRC. This CRC is only calculated over the metadata and only ensures that a write has been completed. The actual data of the element can be protected by a different (and optional) CRC-32. Use the `CONFIG_NVS_DATA_CRC` configuration item to enable the data part CRC.

Note

The data CRC is checked only when the whole data of the element is read. The data CRC is not checked for a partial read, as it is stored at the end of the element data area.

Note

Enabling the data CRC feature on a previously existing NVS content without data CRC will make all existing data invalid.

A write of data to nvs always starts with writing the data, followed by a write of the metadata. Data that is written in flash without metadata is ignored during initialization.

During initialization NVS will verify the data stored in flash, if it encounters an error it will ignore any data with missing/incorrect metadata.

NVS checks the id-data pair before writing data to flash. If the id-data pair is unchanged no write to flash is performed.

To protect the flash area against frequent erases it is important that there is sufficient free space. NVS has a protection mechanism to avoid getting in a endless loop of flash page erases when there is limited free space. When such a loop is detected NVS returns that there is no more space available.

For NVS the file system is declared as:

```
static struct nvs_fs fs = {
.flash_device = NVS_FLASH_DEVICE,
.sector_size = NVS_SECTOR_SIZE,
.sector_count = NVS_SECTOR_COUNT,
.offset = NVS_STORAGE_OFFSET,
};
```

where

- `NVS_FLASH_DEVICE` is a reference to the flash device that will be used. The device needs to be operational.

- NVS_SECTOR_SIZE is the sector size, it has to be a multiple of the flash erase page size and a power of 2.
- NVS_SECTOR_COUNT is the number of sectors, it is at least 2, one sector is always kept empty to allow copying of existing data.
- NVS_STORAGE_OFFSET is the offset of the storage area in flash.

Flash wear

When writing data to flash a study of the flash wear is important. Flash has a limited life which is determined by the number of times flash can be erased. Flash is erased one page at a time and the pagesize is determined by the hardware. As an example a nRF51822 device has a pagesize of 1024 bytes and each page can be erased about 20,000 times.

Calculating expected device lifetime Suppose we use a 4 bytes state variable that is changed every minute and needs to be restored after reboot. NVS has been defined with a sector_size equal to the pagesize (1024 bytes) and 2 sectors have been defined.

Each write of the state variable requires 12 bytes of flash storage: 8 bytes for the metadata and 4 bytes for the data. When storing the data the first sector will be full after 1024/12 = 85.33 minutes. After another 85.33 minutes, the second sector is full. When this happens, because we're using only two sectors, the first sector will be used for storage and will be erased after 171 minutes of system time. With the expected device life of 20,000 writes, with two sectors writing every 171 minutes, the device should last about 171 * 20,000 minutes, or about 6.5 years.

More generally then, with

- NS as the number of storage requests per minute,
- DS as the data size in bytes,
- SECTOR_SIZE in bytes, and
- PAGE_ERASES as the number of times the page can be erased,

the expected device life (in minutes) can be calculated as:

```
SECTOR_COUNT * SECTOR_SIZE * PAGE_ERASES / (NS * (DS+8)) minutes
```

From this formula it is also clear what to do in case the expected life is too short: increase SECTOR_COUNT or SECTOR_SIZE.

Flash write block size migration

It is possible that during a DFU process, the flash driver used by the NVS changes the supported minimal write block size. The NVS in-flash image will stay compatible unless the physical ATE size changes. Especially, migration between 1,2,4,8-bytes write block sizes is allowed.

Sample

A sample of how NVS can be used is supplied in samples/subsys/kvss/nvs.

Troubleshooting

MPU fault while using NVS, or -ETIMEDOUT error returned
NVS can use the internal flash of the SoC. While the MPU is enabled, the flash driver requires MPU RWX access to flash memory, configured using CONFIG_MPU_ALLOW_FLASH_WRITE. If this option is disabled, the NVS application will get an MPU fault if it references the internal SoC flash and it's the only thread running. In a multi-threaded application, another thread might intercept the fault and the NVS API will return an -ETIMEDOUT error.

4.30.7 Retention System

The retention system provides an API which allows applications to read and write data from and to memory areas or devices that retain the data while the device is powered. This allows for sharing information between different applications or within a single application without losing state information when a device reboots. The stored data should not persist in the event of a power failure (or during some low-power modes on some devices) nor should it be stored to a non-volatile storage like *Flash*, *EEPROM API*, or battery-backed RAM.

The retention system builds on top of the retained data driver, and adds additional software-level features to it for ensuring the validity of data. Optionally, a magic header can be used to check if the front of the retained data memory section contains this specific value, and an optional checksum (1, 2, or 4-bytes in size) of the stored data can be appended to the end of the data. Additionally, the retention system API allows partitioning of the retained data sections into multiple distinct areas. For example, a 64-byte retained data area could be split up into 4 bytes for a boot mode, 16 bytes for a timestamp, 44 bytes for a last log message. All of these sections can be accessed or updated independently. The prefix and checksum can be set per-instance using devicetree.

Devicetree setup

To use the retention system, a retained data driver must be setup for the board you are using, there is a zephyr driver which can be used which will use some RAM as non-init for this purpose. The retention system is then initialised as a child node of this device 1 or more times - note that the memory region will need to be decremented to account for this reserved portion of RAM. See the following example (examples in this guide are based on the nrf52840dk board and memory layout):

```
/ {
        sram@2003FC00 {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FC00 DT_SIZE_K(1)>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
                        #address-cells = <1>;
                        #size-cells = <1>;

                        /* This creates a 256-byte partition */
                        retention0: retention@0 {
                                compatible = "zephyr,retention";
                                status = "okay";
```

(continues on next page)

(continued from previous page)

```
                        /* The total size of this area is 256
                         * bytes which includes the prefix and
                         * checksum, this means that the usable
                         * data storage area is 256 - 3 = 253
                         * bytes
                         */
                        reg = <0x0 0x100>;

                        /* This is the prefix which must appear
                         * at the front of the data
                         */
                        prefix = [08 04];

                        /* This uses a 1-byte checksum */
                        checksum = <1>;
                };

                /* This creates a 768-byte partition */
                retention1: retention@100 {
                        compatible = "zephyr,retention";
                        status = "okay";

                        /* Start position must be after the end
                         * of the previous partition. The total
                         * size of this area is 768 bytes which
                         * includes the prefix and checksum,
                         * this means that the usable data
                         * storage area is 768 - 6 = 762 bytes
                         */
                        reg = <0x100 0x300>;

                        /* This is the prefix which must appear
                         * at the front of the data
                         */
                        prefix = [00 11 55 88 fa bc];

                        /* If omitted, there will be no
                         * checksum
                         */
                };
        };
};

/* Reduce SRAM0 usage by 1KB to account for non-init area */
&sram0 {
        reg = <0x20000000 DT_SIZE_K(255)>;
};
```

The retention areas can then be accessed using the data retention API (once enabled with `CONFIG_RETENTION`, which requires that `CONFIG_RETAINED_MEM` be enabled) by getting the device by using:

```
#include <zephyr/device.h>
#include <zephyr/retention/retention.h>
```

(continues on next page)

(continued from previous page)

```
const struct device *retention0 = DEVICE_DT_GET(DT_NODELABEL(retention0));
const struct device *retention1 = DEVICE_DT_GET(DT_NODELABEL(retention1));
```

When the write function is called, the magic header and checksum (if enabled) will be set on the area, and it will be marked as valid from that point onwards.

Mutex protection

Mutex protection of retention areas is enabled by default when applications are compiled with multithreading support. This means that different threads can safely call the retention functions without clashing with other concurrent thread function usage, but means that retention functions cannot be used from ISRs. It is possible to disable mutex protection globally on all retention areas by enabling `CONFIG_RETENTION_MUTEX_FORCE_DISABLE` - users are then responsible for ensuring that the function calls do not conflict with each other. Note that to use this, retention driver mutex support must also be disabled by enabling `CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE`.

Boot mode

An addition to the retention subsystem is a boot mode interface, this can be used to dynamically change the state of an application or run a different application with a minimal set of functions when a device is rebooted (an example is to have a buttonless way of entering mcuboot's serial recovery feature from the main application).

To use the boot mode feature, a data retention entry must exist in the device tree, which is dedicated for use as the boot mode selection (the user area data size only needs to be a single byte), and this area be assigned to the chosen node of `zephyr,boot-mode`. See the following example:

```
/ {
        sram@2003FFFF {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FFFF 0x1>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
                        #address-cells = <1>;
                        #size-cells = <1>;

                        retention0: retention@0 {
                                compatible = "zephyr,retention";
                                status = "okay";
                                reg = <0x0 0x1>;
                        };
                };
        };

        chosen {
                zephyr,boot-mode = &retention0;
        };
};

/* Reduce SRAM0 usage by 1 byte to account for non-init area */
&sram0 {
```

(continues on next page)

(continued from previous page)

```
        reg = <0x20000000 0x3FFFF>;
};
```

The boot mode interface can be enabled with `CONFIG_RETENTION_BOOT_MODE` and then accessed by using the boot mode functions. If using mcuboot with serial recovery, it can be built with `CONFIG_MCUBOOT_SERIAL` and `CONFIG_BOOT_SERIAL_BOOT_MODE` enabled which will allow rebooting directly into the serial recovery mode by using:

```
#include <zephyr/retention/bootmode.h>
#include <zephyr/sys/reboot.h>

bootmode_set(BOOT_MODE_TYPE_BOOTLOADER);
sys_reboot(0);
```

Retention system modules

Modules can expand the functionality of the retention system by using it as a transport (e.g. between a bootloader and application).

Bootloader Information The bootloader information (abbreviated to blinfo) subsystem is an extension of the *Retention System* which allows for reading shared data from a bootloader and allowing applications to query it. It has an optional feature of organising the information retrieved from the bootloader and storing it in the *Settings* with the `blinfo/` prefix.

Devicetree setup To use the bootloader information subsystem, a retention area needs to be created which has a retained data section as its parent, generally non-init RAM is used for this purpose. See the following example (examples in this guide are based on the nrf52840dk board and memory layout):

```
/ {
        sram@2003FC00 {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FC00 DT_SIZE_K(1)>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
                        #address-cells = <1>;
                        #size-cells = <1>;

                        boot_info0: boot_info@0 {
                                compatible = "zephyr,retention";
                                status = "okay";
                                reg = <0x0 0x100>;
                        };
                };
        };

        chosen {
                zephyr,bootloader-info = &boot_info0;
        };
};
```

(continues on next page)

(continued from previous page)

```
/* Reduce SRAM0 usage by 1KB to account for non-init area */
&sram0 {
        reg = <0x20000000 DT_SIZE_K(255)>;
};
```

Note that this configuration needs to be applied on both the bootloader (MCUboot) and application to be usable. It can be combined with other retention system APIs such as the *Boot mode*

MCUboot setup Once the above devicetree configuration is applied, MCUboot needs to be configured to store the shared data in this area, the following Kconfigs need to be set for this:

- `CONFIG_RETAINED_MEM` - Enables retained memory driver
- `CONFIG_RETENTION` - Enables retention system
- `CONFIG_BOOT_SHARE_DATA` - Enables shared data
- `CONFIG_BOOT_SHARE_DATA_BOOTINFO` - Enables boot information shared data type
- `CONFIG_BOOT_SHARE_BACKEND_RETENTION` - Stores shared data using retention/blinfo subsystem

Application setup The application must enable the following base Kconfig options for the bootloader information subsystem to function:

- `CONFIG_RETAINED_MEM`
- `CONFIG_RETENTION`
- `CONFIG_RETENTION_BOOTLOADER_INFO`
- `CONFIG_RETENTION_BOOTLOADER_INFO_TYPE_MCUBOOT`

The following include is needed to use the bootloader information subsystem:

```
#include <zephyr/retention/blinfo.h>
```

By default, only the lookup function is provided: `blinfo_lookup()`, the application can call this to query the information from the bootloader. This function is enabled by default with `CONFIG_RETENTION_BOOTLOADER_INFO_OUTPUT_FUNCTION`, however, applications can optionally choose to use the settings storage feature instead. In this mode, the bootloader information can be queries by using settings keys, the following Kconfig options need to be enabled for this mode:

- `CONFIG_SETTINGS`
- `CONFIG_SETTINGS_RUNTIME`
- `CONFIG_RETENTION_BOOTLOADER_INFO_OUTPUT_SETTINGS`

This allows the information to be queried via the `settings_runtime_get()` function with the following keys:

- `blinfo/mode` The mode that MCUboot is configured for (`enum mcuboot_mode` value)
- `blinfo/signature_type` The signature type MCUboot is configured for (`enum mcuboot_signature_type` value)
- `blinfo/recovery` The recovery type enabled in MCUboot (`enum mcuboot_recovery_mode` value)
- `blinfo/running_slot` The running slot, useful for direct-XIP mode to know which slot to use for an update
- `blinfo/bootloader_version` Version of the bootloader (`struct image_version` object)

- `blinfo/max_application_size` Maximum size of an application (in bytes) that can be loaded

In addition to the previous include, the following includes are required for this mode:

```
#include <bootutil/boot_status.h>
#include <bootutil/image.h>
#include <zephyr/mcuboot_version.h>
#include <zephyr/settings/settings.h>
```

4.30.8 Secure Storage

The secure storage subsystem provides an implementation of the functions defined in the Platform Security Architecture (PSA) Secure Storage API.
It can be enabled on *board targets* that don't already have an implementation of the API.

Overview

The secure storage subsystem makes the PSA Secure Storage API available on all board targets with non-volatile memory support. As such, it provides an implementation of the API on those that don't already have one, ensuring functional support for the API. Board targets with *Trusted Firmware-M (TF-M)* enabled (ending in `/ns`), for instance, cannot enable the subsystem because TF-M already provides an implementation of the API.

In addition to providing functional support for the API, depending on device-specific security features and the configuration, the subsystem may secure the data stored via the PSA Secure Storage API at rest.
Keep in mind, however, that it's preferable to use a secure processing environment like TF-M when possible because it's able to provide more security due to isolation guarantees.

Limitations

The secure storage subsystem's implementation of the PSA Secure Storage API:

- does not aim at full compliance with the specification.

  Its foremost goal is functional support for the API on all board targets.
  See below for important ways the implementation deviates from the specification.

- does not guarantee that the data it stores will be secure at rest in all cases.

  This depends on device-specific security features and the configuration.

- does not yet provide an implementation of the Protected Storage (PS) API as of this writing.

  Instead, the PS API directly calls into the Internal Trusted Storage (ITS) API (unless a *custom implementation* of the PS API is provided).

Below are some ways the implementation purposefully deviates from the specification and an explanation why. This is not an exhaustive list.

- The UID type is only 30 bits by default. (Against 2.5 UIDs.)

  This is an optimization done to make it more convenient to directly use the UIDs as storage entry IDs (e.g., with *ZMS* when `CONFIG_SECURE_STORAGE_ITS_STORE_IMPLEMENTATION_ZMS` is enabled).
  Zephyr defines numerical ranges to be used by different users of the API which guarantees that there are no collisions and that they all fit within 30 bits. See the header files in include/zephyr/psa for more information.

- The data stored in the ITS is by default encrypted and authenticated (Against `1.` in 3.2. Internal Trusted Storage requirements.)

  The specification considers the storage underlying the ITS to be `implicitly confidential and protected from replay` (2.4. The Internal Trusted Storage API) because `most embedded microprocessors (MCU) have on-chip flash storage that can be made inaccessible except to software running on the MCU` (2.2. Technical Background).
  This is not the case on all MCUs. Thus, additional protection is provided to the stored data.

  However, this does not guarantee that the data stored will be secure at rest in all cases, because this depends on device-specific security features and the configuration. It requires a random entropy source and especially a secure encryption key provider (`CONFIG_SECURE_STORAGE_ITS_TRANSFORM_AEAD_KEY_PROVIDER`).

  In addition, the data stored in the ITS is not protected against replay attacks, because this requires storage that is protected by hardware.

- The data stored via the PSA Secure Storage API is not protected from direct read/write by software or debugging. (Against `2.` and `10.` in 3.2. Internal Trusted Storage requirements.)

  It is only secured at rest. Protecting it at runtime as well requires specific hardware mechanisms to support this.

Configuration

To configure the implementation of the PSA Secure Storage API provided by Zephyr, have a look at the available Kconfig options. They are defined in the various Kconfig files found under subsys/secure_storage/.

Customization

Custom implementations can also replace those of Zephyr at different levels if the functionality provided by the existing implementations isn't enough.

Whole API If you already have an implementation of the whole ITS or PS API and want to make use of it, you can do so by enabling the following Kconfig option and implementing the relevant functions:

- `CONFIG_SECURE_STORAGE_ITS_IMPLEMENTATION_CUSTOM`, for the ITS API.
- `CONFIG_SECURE_STORAGE_PS_IMPLEMENTATION_CUSTOM`, for the PS API.

ITS API Zephyr's implementation of the ITS API (`CONFIG_SECURE_STORAGE_ITS_IMPLEMENTATION_ZEPHYR`) makes use of the ITS transform and store modules, which can be configured and customized separately. Have a look at the ITS transform and store Kconfig options to see the different customization possibilities.

It's especially recommended to implement a custom encryption key provider (`CONFIG_SECURE_STORAGE_ITS_TRANSFORM_AEAD_KEY_PROVIDER_CUSTOM`) that is more secure than the available options, if possible.

4.30.9 Settings

The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. A variety of storage implementations are provided behind a common API using FCB, NVS, ZMS or a file system. These different implementations give the application developer flexibility to select an appropriate storage medium, and even change it later as needs change. This subsystem is used by various Zephyr components and can be used simultaneously by user applications.

Settings items are stored as key-value pair strings. By convention, the keys can be organized by the package and subtree defining the key, for example the key `id/serial` would define the `serial` configuration element for the package `id`.

Convenience routines are provided for converting a key value to and from a string type.

For an example of the settings subsystem refer to settings sample.

Note

As of Zephyr release 4.1 the recommended backends for non-filesystem storage are *NVS* and *ZMS*.

Handlers

Settings handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register()` for dynamic handlers or defined using a call to `SETTINGS_STATIC_HANDLER_DEFINE()` for static handlers.

h_get
: This gets called when asking for a settings element value by its name using `settings_runtime_get()` from the runtime backend.

h_set
: This gets called when the value is loaded from persistent storage with `settings_load()`, or when using `settings_runtime_set()` from the runtime backend.

h_commit
: This gets called after the settings have been loaded in full. Sometimes you don't want an individual setting value to take effect right away, for example if there are multiple settings which are interdependent.

h_export
: This gets called to write all current settings. This happens when `settings_save()` tries to save the settings or transfer to any user-implemented back-end.

Settings handlers also have a commit priority `cprio` that allows to prioritize the `h_commit` calls. This can be advantageous when e.g. a subsystem initializes a service that other `h_commit` calls depend on.

Settings handlers `h_commit` routines are by default initialized with `cprio = 0`, initializing a settings handler with a different priority is done using a call to `settings_register_with_cprio()` for dynamic handlers or using a call to `SETTINGS_STATIC_HANDLER_DEFINE_WITH_CPRIO()` for static handlers. The specified `cprio` value is an integer where lower values mean higher priority.

Backends

Backends are meant to load and save data to/from setting handlers, and implement a set of handler functions. These are registered using a call to `settings_src_register()` for backends that can load data, and/or `settings_dst_register()` for backends that can save data. The current implementation allows for multiple source backends but only a single destination backend.

csi_load
: This gets called when loading values from persistent storage using `settings_load()`.

csi_load_one
: This gets called when loading only one item from persistent storage using `settings_load_one()`.

csi_get_val_len
: This gets called when getting a value's length from persistent storage using `settings_get_val_len()`.

csi_save
: This gets called when saving a single setting to persistent storage using `settings_save_one()`.

csi_save_start
: This gets called when starting a save of all current settings using `settings_save()` or `settings_save_subtree()`.

csi_save_end
: This gets called after having saved of all current settings using `settings_save()` or `settings_save_subtree()`.

Zephyr Storage Backends

Zephyr offers the following storage backends:

- Flash Circular Buffer (`CONFIG_SETTINGS_FCB`).
- A file in the filesystem (`CONFIG_SETTINGS_FILE`).

- Non-Volatile Storage (CONFIG_SETTINGS_NVS).
- Zephyr Memory Storage (CONFIG_SETTINGS_ZMS).

You can declare multiple sources for settings; settings from all of these are restored when settings_load() is called.

There can be only one target for writing settings; this is where data is stored when you call settings_save(), or settings_save_one().

FCB read target is registered using settings_fcb_src(), and write target using settings_fcb_dst(). As a side-effect, settings_fcb_src() initializes the FCB area, so it must be called before calling settings_fcb_dst(). File read target is registered using settings_file_src(), and write target by using settings_file_dst().

Non-volatile storage read target is registered using settings_nvs_src(), and write target by using settings_nvs_dst().

Zephyr Memory Storage (ZMS) read target is registered using settings_zms_src(), and write target is registered using settings_zms_dst().

ZMS backend has the particularity of using hash functions to hash the settings key before storing it to the persistent storage. This implementation implies that some collisions between key's hashes could occur if a big number of different keys are stored. This number depends on the selected hash function.

ZMS backend can handle 2^n maximum collisions where n is defined by (CONFIG_SETTINGS_ZMS_MAX_COLLISIONS_BITS).

Storage Location

The FCB, non-volatile storage (NVS) and ZMS backends look for a fixed partition with label "storage" by default. A different partition can be selected by setting the zephyr,settings-partition property of the chosen node in the devicetree.

The file path used by the file backend to store settings is selected via the option CONFIG_SETTINGS_FILE_PATH.

Loading data from persistent storage

A call to settings_load() uses an h_set implementation to load settings data from storage to volatile memory. After all data is loaded, the h_commit handler is issued, signalling the application that the settings were successfully retrieved.

Alternatively, a call to settings_load_one() will load only one Settings entry and store it in the provided buffer.

Optionally, to get only the value's length associated with the Settings entry, a call to settings_get_val_len() can be performed. This is used for example by applications that allocates dynamically the data buffer and needs to get the data size before reading it by settings_load_one().

Technically FCB and file backends may store some history of the entities. This means that the newest data entity is stored after any older existing data entities. Starting with Zephyr 2.1, the back-end must filter out all old entities and call the callback with only the newest entity.

Storing data to persistent storage

A call to settings_save_one() uses a backend implementation to store settings data to the storage medium. A call to settings_save() uses an h_export implementation to store different data in one operation using settings_save_one(). A key needs to be covered by a h_export only if it is supposed to be stored by settings_save() call.

For both FCB and file back-end only storage requests with data which changes most actual key's value are stored, therefore there is no need to check whether a value changed by the application. Such a storage mechanism implies that storage can contain multiple value assignments for a key , while only the last is the current value for the key.

Garbage collection When storage becomes full (FCB) or consumes too much space (file), the backend removes non-recent key-value pairs records and unnecessary key-delete records.

Secure domain settings

Currently settings doesn't provide scheme of being secure, and non-secure configuration storage simultaneously for the same instance. It is recommended that secure domain uses its own settings instance and it might provide data for non-secure domain using dedicated interface if needed (case dependent).

Example: Device Configuration

This is a simple example, where the settings handler only implements `h_set` and `h_export`. `h_set` is called when the value is restored from storage (or when set initially), and `h_export` is used to write the value to storage thanks to `storage_func()`. The user can also implement some other export functionality, for example, writing to the shell console).

```
#define DEFAULT_FOO_VAL_VALUE 1

static int8 foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            /* key-value pair was properly read.
             * rc contains value length.
             */
            return 0;
        }
        /* read-out error */
        return rc;
    }

    return -ENOENT;
}

static int foo_settings_export(int (*storage_func)(const char *name,
                                                   const void *value,
                                                   size_t val_len))
{
    return storage_func("foo/bar", &foo_val, sizeof(foo_val));
}
```

(continues on next page)

(continued from previous page)

```
struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set,
    .h_export = foo_settings_export
};
```

Example: Persist Runtime State

This is a simple example showing how to persist runtime state. In this example, only `h_set` is defined, which is used when restoring value from persistent storage.

In this example, the `main` function increments `foo_val`, and then persists the latest number. When the system restarts, the application calls `settings_load()` while initializing, and `foo_val` will continue counting up from where it was before restart.

```
#include <zephyr/kernel.h>
#include <zephyr/sys/reboot.h>
#include <zephyr/settings/settings.h>
#include <zephyr/sys/printk.h>
#include <inttypes.h>

#define DEFAULT_FOO_VAL_VALUE 0

static uint8_t foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            return 0;
        }

        return rc;
    }

    return -ENOENT;
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set
};

int main(void)
{
```

(continues on next page)

(continued from previous page)

```
    settings_subsys_init();
    settings_register(&my_conf);
    settings_load();

    foo_val++;
    settings_save_one("foo/bar", &foo_val, sizeof(foo_val));

    printk("foo: %d\n", foo_val);

    k_msleep(1000);
    sys_reboot(SYS_REBOOT_COLD);
}
```

Example: Custom Backend Implementation

This is a simple example showing how to register a simple custom backend handler (CONFIG_SETTINGS_CUSTOM).

```
static int settings_custom_load(struct settings_store *cs,
                                const struct settings_load_arg *arg)
{
    //...
}

static int settings_custom_save(struct settings_store *cs, const char *name,
                                const char *value, size_t val_len)
{
    //...
}

/* custom backend interface */
static struct settings_store_itf settings_custom_itf = {
    .csi_load = settings_custom_load,
    .csi_save = settings_custom_save,
};

/* custom backend node */
static struct settings_store settings_custom_store = {
    .cs_itf = &settings_custom_itf
};

int settings_backend_init(void)
{
    /* register custom backend */
    settings_dst_register(&settings_custom_store);
    settings_src_register(&settings_custom_store);
    return 0;
}
```

Settings backend interface

4.30.10 Stream Flash

The Stream Flash module takes contiguous fragments of a stream of data (e.g. from radio packets), aggregates them into a user-provided buffer, then when the buffer fills (or stream ends) writes it to a raw flash partition. It supports providing the read-back buffer to the client to use in validating the persisted stream content.

One typical use of a stream write operation is when receiving a new firmware image to be used in a DFU operation.

There are several reasons why one might want to use buffered writes instead of writing the data directly as it is made available. Some devices have hardware limitations which does not allow flash writes to be performed in parallel with other operations, such as radio RX and TX. Also, fewer write operations result in faster response times seen from the application.

Persistent stream write progress

Some stream write operations, such as DFU operations, may run for a long time. When performing such long running operations it can be useful to be able to save the stream write progress to persistent storage so that the operation can resume at the same point after an unexpected interruption.

The Stream Flash module offers an API for loading, saving and clearing stream write progress to persistent storage using the *Settings* module. The API can be enabled using `CONFIG_STREAM_FLASH_PROGRESS`.

API Reference

Stream to flash interface

4.30.11 Zephyr Memory Storage (ZMS)

Zephyr Memory Storage is a new key-value storage system that is designed to work with all types of non-volatile storage technologies. It supports classical on-chip NOR flash as well as new technologies like RRAM and MRAM that do not require a separate erase operation at all, that is, data on these types of devices can be overwritten directly at any time.

General behavior

ZMS divides the memory space into sectors (minimum 2), and each sector is filled with key-value pairs until it is full.

The key-value pair is divided into two parts:

- The key part is written in an ATE (Allocation Table Entry) called "ID-ATE" which is stored starting from the bottom of the sector.
- The value part is defined as "data" and is stored raw starting from the top of the sector.

Additionally, for each sector we store at the last positions header ATEs which are ATEs that are needed for the sector to describe its status (closed, open) and the current version of ZMS.

When the current sector is full we verify first that the following sector is empty, we garbage collect the sector N+2 (where N is the current sector number) by moving the valid ATEs to the N+1 empty sector, we erase the garbage-collected sector and then we close the current sector by writing a garbage_collect_done ATE and the close ATE (one of the header entries). Afterwards we move forward to the next sector and start writing entries again.

This behavior is repeated until it reaches the end of the partition. Then it starts again from the first sector after garbage collecting it and erasing its content.

Composition of a sector A sector is organized in this form (example with 3 sectors):

Sector 0 (closed)	Sector 1 (open)	Sector 2 (empty)
Data_a0	Data_b0	Data_c0
Data_a1	Data_b1	Data_c1
Data_a2	Data_b2	Data_c2
GC_done	.	.
.	.	.
.	.	.
.	ID ATE_b2	ID ATE_c2
ID ATE_a2	ID ATE_b1	ID ATE_c1
ID ATE_a1	ID ATE_b0	ID ATE_c0
ID ATE_a0	GC_done ATE	GC_done ATE
Close ATE (cyc=1)	Close ATE (cyc=1)	Close ATE (cyc=1)
Empty ATE (cyc=1)	Empty ATE (cyc=2)	Empty ATE (cyc=2)

Definition of each element in the sector `Empty ATE` is written when erasing a sector (last position of the sector).

`Close ATE` is written when closing a sector (second to last position of the sector).

`GC_done ATE` is written to indicate that the next sector has already been garbage-collected. This ATE could be at any position of the sector.

`ID ATE` contains a key of type `zms_id_t` and describes where the data is stored, its size and its CRC32.

`Data` is the actual value associated to the ID-ATE.

How does ZMS work?

Mounting the storage system Mounting the storage system starts by getting the flash parameters, checking that the file system properties are correct (sector_size, sector_count ...) then calling the zms_init function to make the storage ready.

By default, `zms_mount()` returns an error if the partition cannot be mounted. For recovery-oriented use cases, `zms_mount_force()` can be used to automatically wipe and reinitialize the partition when the first mount attempt fails.

To mount the filesystem the following elements in the `zms_fs` structure must be initialized:

```
struct zms_fs {
        /** File system offset in flash **/
        off_t offset;

        /** Storage system is split into sectors, each sector size must be␣
↪multiple of
         * erase-blocks if the device has erase capabilities
         */
        uint32_t sector_size;
        /** Number of sectors in the file system */
        uint32_t sector_count;

        /** Flash device runtime structure */
        const struct device *flash_device;
};
```

Initialization As ZMS has a fast-forward write mechanism, it must find the last sector and the last pointer of the entry where it stopped the last time. It must look for a closed sector followed by an open one, then within the open sector, it finds (recovers) the last written ATE. After that, it checks that the sector after this one is empty, or it will erase it.

ZMS ID/data write To avoid rewriting the same data with the same ID again, ZMS must look in all the sectors if the same ID exists and then compares its data. If the data is identical, no write is performed. If it must perform a write, then an ATE and the data (if the operation is not a delete) are written in the sector. If the sector is full (cannot hold the current data + ATE), ZMS has to move to the next sector, garbage collect the sector after the newly opened one then erase it.

ZMS ID/data read (with history) By default ZMS looks for the last data with the same ID by browsing through all stored ATEs from the most recent ones to the oldest ones. If it finds a valid ATE with a matching ID it retrieves its data and returns the number of bytes that were read. If a history count is provided and different than 0, older data with same ID is retrieved.

ZMS free space calculation ZMS can also return the free space remaining in the partition. However, this operation is very time-consuming as it needs to browse through all valid ATEs in all sectors of the partition and for each valid ATE try to find if an older one exists. It is not recommended for applications to use this function often, as it is time-consuming and could slow down the calling thread.

The cycle counter Each sector has a lead cycle counter which is a `uint8_t` that is used to validate all the other ATEs. The lead cycle counter is stored in the empty ATE. To become valid, an ATE must have the same cycle counter as the one stored in the empty ATE. Each time an ATE is moved from a sector to another it must get the cycle counter of the destination sector. To erase a sector, the cycle counter of the empty ATE is incremented and a single write of the empty ATE is done. All the ATEs in that sector become invalid.

Closing sectors To close a sector a close ATE is added at the end of the sector and it must have the same cycle counter as the empty ATE. When closing a sector, all the remaining space that has not been used is filled with garbage data to avoid having old ATEs with a valid cycle counter.

Triggering garbage collection Some applications need to make sure that storage writes have a maximum defined latency. When calling ZMS to make a write, the current sector could be almost full such that ZMS needs to trigger the GC to switch to the next sector. This operation is time-consuming and will cause some applications to not meet their real time constraints. ZMS adds an API for the application to get the current remaining free space in a sector. The application could then decide when to switch to the next sector if the current one is almost full. This will of course trigger the garbage collection operation on the next sector. This will guarantee the application that the next write won't trigger the garbage collection.

ATE (Allocation Table Entry) structure An entry uses 16 bytes to encode its information. The exact structure is determined by ATE format which can be selected for a given application.

ZMS defines multiple ATE formats tailored for different feature sets. At runtime, it recognizes the format using the metadata field in empty ATEs, which has the same byte position in all formats.

Table 72: Entry format for 32-bit IDs

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
crc8	cycle_cnt	len		id				data (if len <= 8)							
								offset				data_crc			
												metadata			

This is the default format which is captured in the API documentation for `zms_ate`. The `data_crc` is optionally included to integrity-check data stored at the top of the sector.

Note

The CRC of the data is checked only when a full read of the data is made. The CRC of the data is not checked for a partial read, as it is computed for the whole element.

Warning

Enabling the CRC feature on previously existing ZMS content that did not have it enabled will make all existing data invalid.

Table 73: Entry format for 64-bit IDs

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
crc8	cycle_cnt	len		id								data (if len <= 4)			
												offset			
												metadata			

This format is selected when `CONFIG_ZMS_ID_64BIT` is enabled.

Warning

Selecting a different ATE format than the one used by previously existing ZMS content will make all existing data invalid.

Note

The ZMS backend for *Settings* does not support this format.

Available space for user data (key-value pairs)

ZMS always needs an empty sector to be able to perform the garbage collection (GC). So, if we suppose that 4 sectors exist in a partition, ZMS will only use 3 sectors to store key-value pairs and keep one sector empty to be able to perform GC. The empty sector will rotate between the 4 sectors in the partition.

Note

The maximum single data length that can be written at once in a sector is 64K (this could change in future versions of ZMS).

Small data values Values which are sufficiently small will be stored within the entry (ATE) itself, without writing data at the top of the sector. The amount of data that can fit inside the entry depends on its selected format. See the *ATE structure* section.

ZMS has an entry size of 16 bytes which means that the maximum available space in a partition to store data is computed in this scenario as:

$$\frac{(NUM_SECTORS - 1) \times (SECTOR_SIZE - (5 \times ATE_SIZE)) \times (DATA_SIZE)}{ATE_SIZE}$$

Where:

`NUM_SECTOR`: Total number of sectors

`SECTOR_SIZE`: Size of the sector

`ATE_SIZE`: 16 bytes

`(5 * ATE_SIZE)`: Reserved ATEs for header and delete items

`DATA_SIZE`: 8 bytes or 4 bytes depending on the ATE format

For example for 4 sectors of 1024 bytes, with the default ATE format, free space for 8-byte length data is $\frac{3 \times 944 \times 8}{16} = 1416$ bytes.

Large data values Values exceeding `DATA_SIZE` are stored outside of the ATE at the top of the sector. In this case, it is hard to estimate the free available space, as this depends on the size of the data. But we can take into account that for N bytes of data added at the top of the sector, an additional 16 bytes of ATE must be added at the bottom of the sector, which adds up to $N + 16$ bytes for the key-value pair.

Let's take an example:

For a partition that has 4 sectors of 1024 bytes and for data size of 64 bytes. Only 3 sectors are available for writes with a capacity of 944 bytes each, which makes it possible to store 11 key-value pairs in each sector ($\frac{944}{64+16}$). Total data that could be stored in this partition for this case is $11 \times 3 \times 64 = 2112$ bytes.

Wear leveling

This storage system is optimized for devices that do not require an erase. Storage systems that rely on an erase value (NVS as an example) need to emulate the erase with write operations. This causes a significant decrease in the life expectancy of these devices as well as more delays for write operations and initialization of the device when it is empty. ZMS uses a cycle count

mechanism that avoids emulating erase operations for these devices. It also guarantees that every memory location is written only once for each cycle of sector write.

As an example, to erase a 4096-byte sector on devices that do not require an erase operation using NVS, 256 flash writes must be performed (supposing that `write-block-size` = 16 bytes), while using ZMS, only 1 write of 16 bytes is needed. This operation is 256 times faster in this case.

The garbage collection operation also reduces the memory cell life expectancy as it performs write operations when moving blocks from one sector to another. To make the garbage collector not affect the life expectancy of the device it is recommended to dimension the partition appropriately. Its size should be the double of the maximum size of data (including headers) that could be written in the storage.

See *Available space for user data*.

Device lifetime calculation Storage devices, whether they are classical flash or new technologies like RRAM/MRAM, have a limited life expectancy which is determined by the number of times memory cells can be erased/written. Flash devices are erased one page at a time as part of their functional behavior (otherwise memory cells cannot be overwritten), and for storage devices that do not require an erase operation, memory cells can be overwritten directly.

A typical scenario is shown here to calculate the life expectancy of a device: Let's suppose that we store a 4-byte variable using the same ID but its content changes every minute. The partition has 4 sectors with 1024 bytes each. Each write of the variable requires 16 bytes of storage. As we have 944 bytes available for ATEs for each sector, and because ZMS is a fast-forward storage system, we are going to rewrite the first location of the first sector after $\frac{(944 \times 4)}{16} = 236$ minutes.

In addition to the normal writes, the garbage collector will move the data that is still valid from old sectors to new ones. As we are using the same ID and a big partition size, no data will be moved by the garbage collector in this case. For storage devices that can be written 20 000 times, the storage will last about 4 720 000 minutes (~9 years).

To make a more general formula we must first compute the effective used size in ZMS by our typical set of data. For ID/data pairs with *small data*, `effective_size` is `16` bytes, while for *large data*, `effective_size` is `16 + sizeof(data)` bytes. Let's suppose that `total_effective_size` is the total size of the data that is written in the storage and that the partition is sized appropriately (double of the effective size) to avoid having the garbage collector moving blocks all the time.

The expected lifetime of the device in minutes is computed as:

$$\frac{(SECTOR_EFFECTIVE_SIZE \times SECTOR_NUMBER \times MAX_NUM_WRITES)}{(TOTAL_EFFECTIVE_SIZE \times WR_MIN)}$$

Where:

`SECTOR_EFFECTIVE_SIZE`: The sector size - header size (80 bytes)

`SECTOR_NUMBER`: The number of sectors

`MAX_NUM_WRITES`: The life expectancy of the storage device in number of writes

`TOTAL_EFFECTIVE_SIZE`: Total effective size of the set of written data

`WR_MIN`: Number of writes of the set of data per minute

Features

ZMS has introduced many features compared to existing storage system like NVS and will evolve from its initial version to include more features that satisfies new technologies requirements such as low latency and bigger storage space.

Existing features

Version 1

- Supports storage devices that do not require an erase operation (only one write operation to invalidate a sector)
- Supports large partition and sector sizes (64-bit address space)
- Supports 32-bit IDs and 64-bit IDs
- Small data values are stored in the ATE itself
- Built-in data CRC32 (included in the ATE)
- Versioning of ZMS (to handle future evolutions)
- Supports large `write-block-size` (only for platforms that need it)
- Supports multiple ATE formats to satisfy the requirements of different applications
- Supports forced mount recovery via `zms_mount_force()` (automatic partition wipe and reinitialization on mount failure)

Future features

- Add the possibility to mount multiple filesystems with different ATE formats (currently, all filesystems in the same application must use the same format)
- Add the possibility to skip garbage collector for some application usage where ID/value pairs are written periodically and do not exceed half of the partition size (there is always an old entry with the same ID).
- Divide IDs into namespaces and allocate IDs on demand from application to handle collisions between IDs used by different subsystems or samples.
- Add the possibility to retrieve the wear out value of the device based on the cycle count value
- Add a recovery function that can recover a storage partition if something went wrong
- Add a library/application to allow migration from NVS entries to ZMS entries

ZMS and other storage systems in Zephyr This section describes ZMS in the wider context of storage systems in Zephyr (not full filesystems, but simpler, non-hierarchical ones). Today Zephyr includes at least two other systems that are somewhat comparable in scope and functionality: *NVS* and *FCB*. Which one to use in your application will depend on your needs and the hardware you are using, and this section provides information to help make a choice.

- If you are using devices that do not require an erase operation like RRAM or MRAM, *ZMS* is definitely the best fit for your storage subsystem as it is designed to avoid emulating erase operation using large block writes for these devices and replaces it with a single write call.
- For devices that have a large `write_block_size` and/or need a sector size that is different than the classical flash page size (equal to erase_block_size), *ZMS* is also the best fit as there is the possibility to customize these parameters and add the support of these devices in ZMS.
- For classical flash technology devices, *NVS* is recommended as it has low footprint (smaller ATEs and smaller header ATEs). Erasing flash in NVS is also very fast and do not require an additional write operation compared to ZMS. For these devices, NVS reads/writes will be faster as well than ZMS as it has smaller ATE size.
- If your application needs more than 64K IDs for storage, *ZMS* is recommended here because the ID field is up to 64-bit.
- If your application is working in a FIFO mode (First-in First-out) then *FCB* is the best storage solution for this use case.

More generally to make the right choice between NVS and ZMS, all the blockers should be first verified to make sure that the application could work with one subsystem or the other, then if both solutions could be implemented, the best choice should be based on the calculations of the life expectancy of the device described in this section: *Wear leveling*.

Recommendations to increase performance

Sector size and count

- The total size of the storage partition should be set appropriately to achieve the best performance with ZMS. All the information regarding the effectively available free space in ZMS can be found in the documentation. See *Available space for user data*. It's recommended to choose a storage partition size that is double the size of the key-value pairs that will be written in the storage.
- The sector size needs to be set such that a sector can fit the maximum data size that will be stored. Increasing the sector size will slow down the garbage collection operation and make it occur less frequently. Decreasing its size, on the opposite, will make the garbage collection operation faster but also occur more frequently.
- For some subsystems like *Settings*, all path-value pairs are split into two ZMS entries (ATEs). The headers needed by the two entries should be accounted for when computing the needed storage space.
- Using *small data values* can increase the performance, as this data is written within the entry. For example, for the *Settings* subsystem, choosing a path name that is less than or equal to 8 bytes can make reads and writes faster.

Cache size

- When using the ZMS API directly, the recommendation for the cache size is to make it at least equal to the number of different entries that will be written in the storage.
- Each additional cache entry will add 8 bytes to your RAM usage. Cache size should be carefully chosen.
- If you use ZMS through *Settings*, you have to take into account that each Settings entry is divided into two ZMS entries. The recommendation for the cache size is to make it at least twice the number of Settings entries.

ID size

- The 64-bit ID space is expected to be larger than necessary for most applications. Unless you have a particular need for this, it's recommended to stick with 32-bit IDs. This is expected to have a slight impact on code size and performance, even on 64-bit systems, because the byte position of IDs in storage is not aligned to an 8-byte boundary.

API Reference

The ZMS API is provided by `zms.h`:

4.31 Sensing Subsystem

- *Overview*
- *Configurability*
- *Main Features*
- *Major Flows*
- *Sensor Types And Instance*
- *Sensor Instance Handler*
- *Sensor Sample Value*
- *Device Tree Configuration*
- *API Reference*

4.31.1 Overview

Sensing Subsystem is a high level sensor framework inside the OS user space service layer. It is a framework focused on sensor fusion, client arbitration, sampling, timing, scheduling and sensor based power management.

Key concepts in Sensing Subsystem include physical sensor and virtual sensor objects, and a scheduling framework over sensor object relationships. Physical sensors do not depend on any other sensor objects for input, and will directly interact with existing zephyr sensor device drivers. Virtual sensors rely on other sensor objects (physical or virtual) as report inputs.

The sensing subsystem relies on Zephyr sensor device APIs (existing version or update in future) to leverage Zephyr's large library of sensor device drivers (100+).

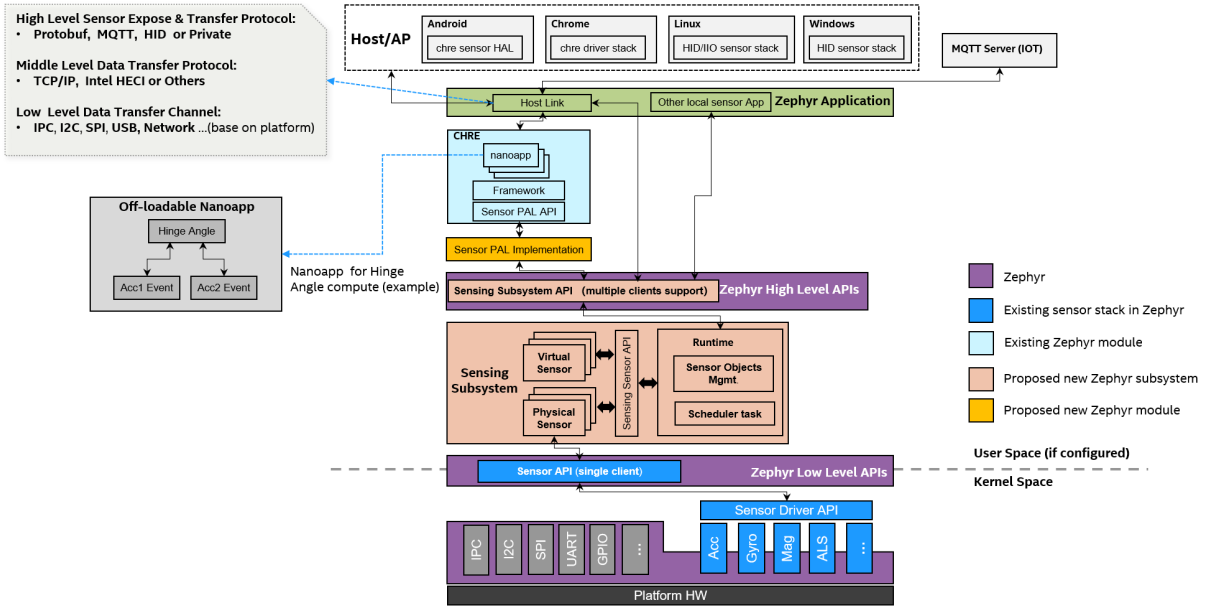
Use of the sensing subsystem is optional. Applications that only need to access simple sensors devices can use the Zephyr *Sensors* API directly.

Since the sensing subsystem is separated from device driver layer or kernel space and could support various customizations and sensor algorithms in user space with virtual sensor concepts. The existing sensor device driver can focus on low layer device side works, can keep simple as much as possible, just provide device HW abstraction and operations etc. This is very good for system stability.

The sensing subsystem is decoupled with any sensor expose/transfer protocols, the target is to support various up-layer frameworks and Applications with different sensor expose/transfer protocols, such as CHRE, HID sensors Applications, MQTT sensor Applications according different products requirements. Or even support multiple Applications with different up-layer sensor protocols at the same time with it's multiple clients support design.

Sensing subsystem can help build a unified Zephyr sensing architecture for cross host OSes support and as well as IoT sensor solutions.

The diagram below illustrates how the Sensing Subsystem integrates with up-layer frameworks.



4.31.2 Configurability

- Reusable and configurable standalone subsystem.
- Based on Zephyr existing low-level Sensor API (reuse 100+ existing sensor device drivers)
- Provide Zephyr high-level Sensing Subsystem API for Applications.
- Separate option CHRE Sensor PAL Implementation module to support CHRE.
- Decoupled with any host link protocols, it's Zephyr Application's role to handle different protocols (MQTT, HID or Private, all configurable)

4.31.3 Main Features

Scope
Focus on framework for sensor fusion, multiple clients, arbitration, data sampling, timing management and scheduling.

Sensor Abstraction

- **Physical sensor**: interacts with Zephyr sensor device drivers, focus on data collecting.
- **Virtual sensor**: relies on other sensor(s), **physical** or **virtual**, focus on data fusion.

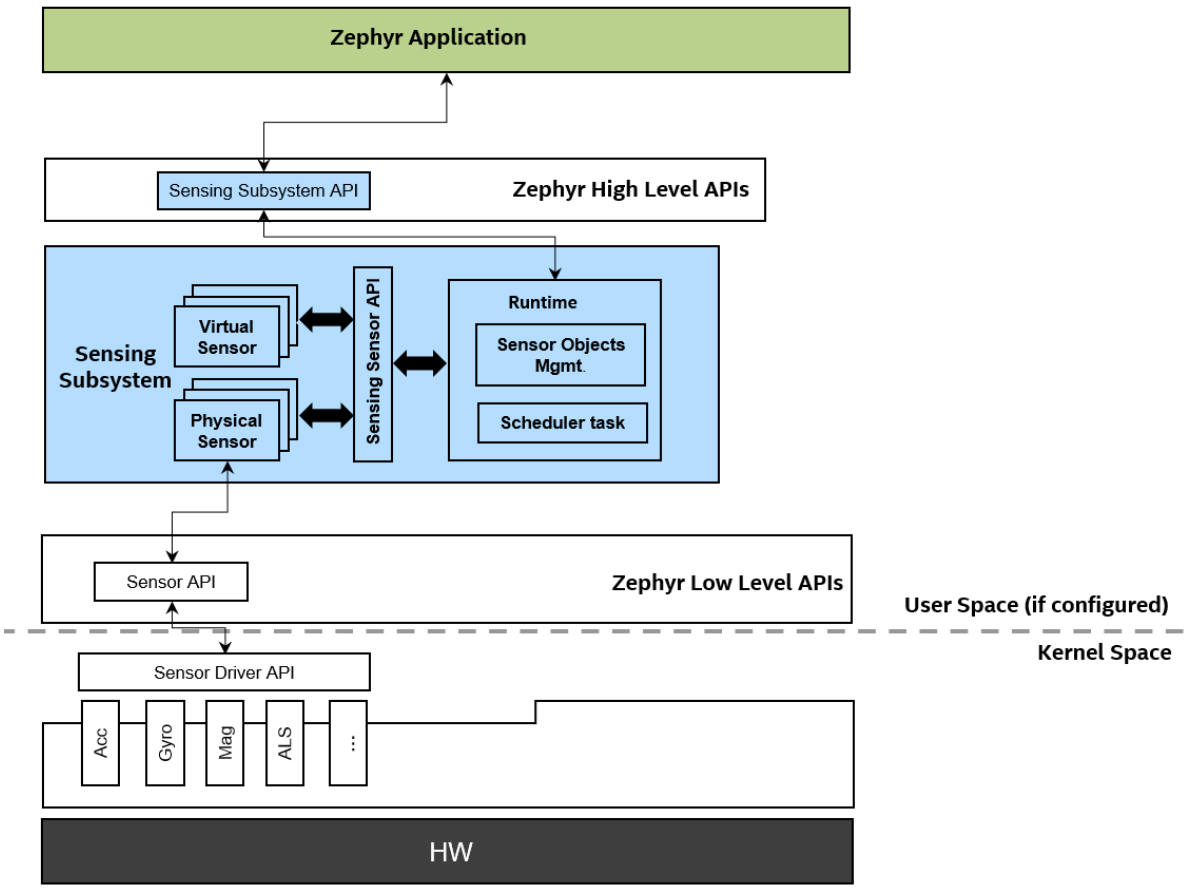
Data Driven Model

- **Polling mode**: periodical sampling rate
- **Interrupt mode**: data ready, threshold interrupt etc.

Scheduling
Single thread main loop for all sensor objects sampling and process.

Buffer Mode for Batching
Configurable Via Devicetree

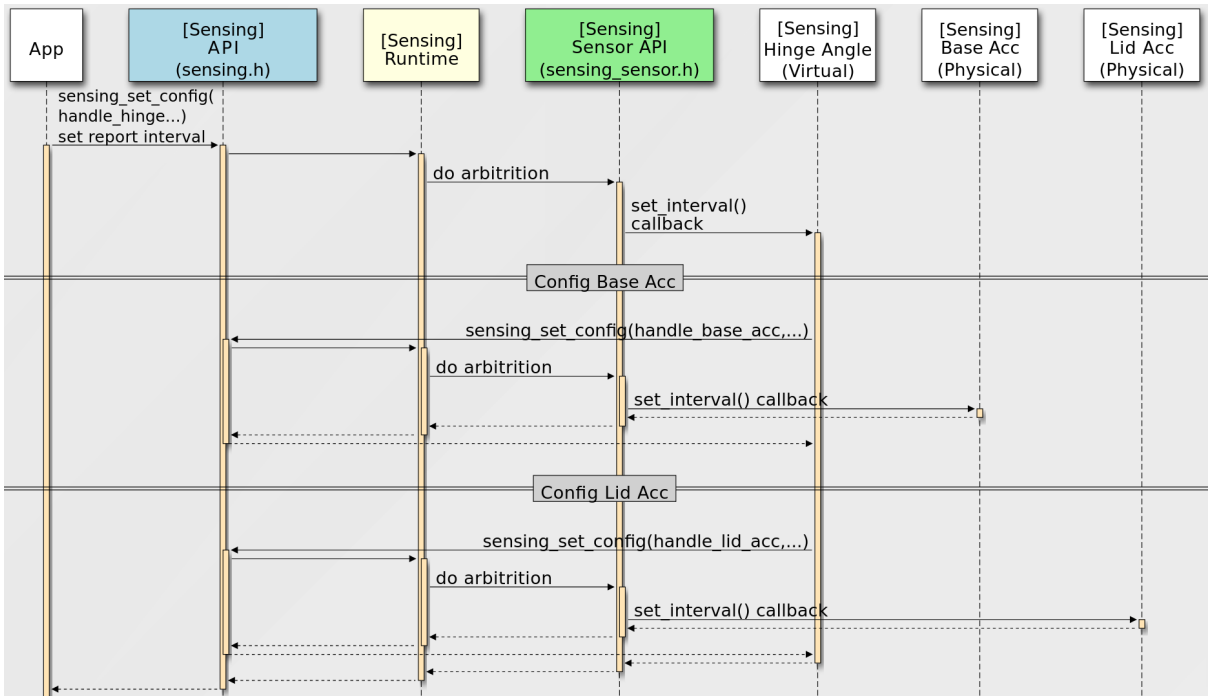
Below diagram shows the API position and scope:



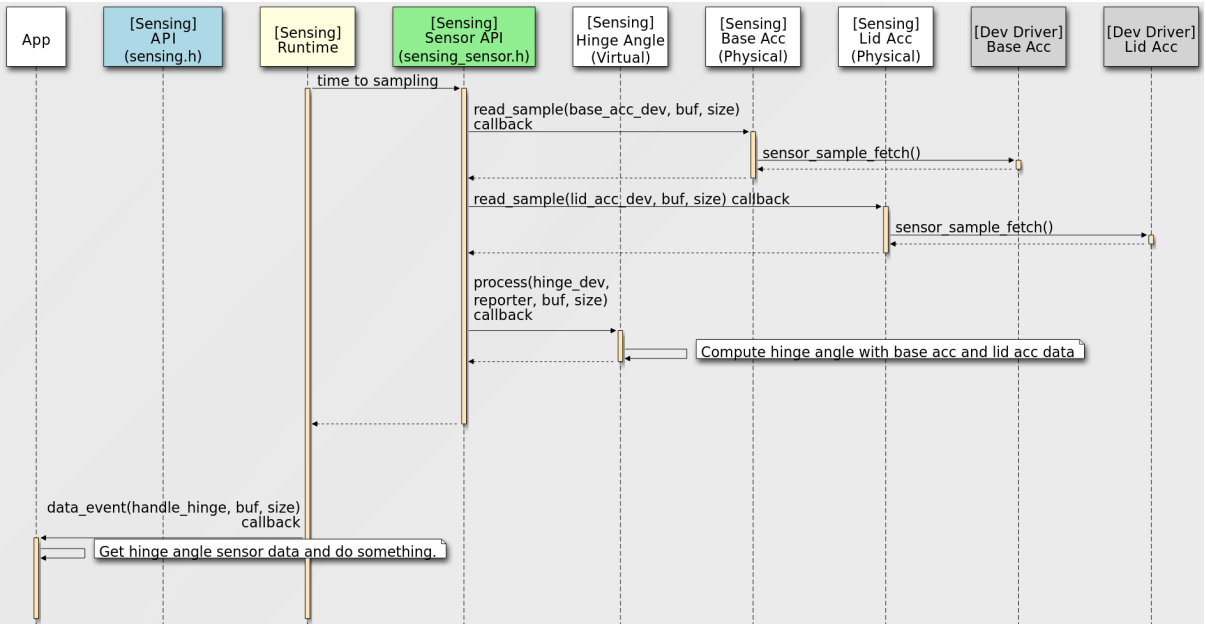
`Sensing Subsystem API` is for Applications. `Sensing Sensor API` is for development sensors.

4.31.4 Major Flows

- Sensor Configuration Flow



- Sensor Data Flow



4.31.5 Sensor Types And Instance

The `Sensing Subsystem` supports multiple instances of the same sensor type, there're two methods for Applications to identify and open an unique sensor instance:

- Enumerate all sensor instances

  `sensing_get_sensors()` returns all current board configuration supported sensor instances' information in a `sensing_sensor_info` pointer array .

  Then Applications can use `sensing_open_sensor()` to open specific sensor instance for future accessing, configuration and receive sensor data etc.

  This method is suitable for supporting some up-layer frameworks like `CHRE`, `HID` which need to dynamically enumerate the underlying platform's sensor instances.

- Open the sensor instance by devicetree node directly

  Applications can use `sensing_open_sensor_by_dt()` to open a sensor instance directly with sensor devicetree node identifier.

  For example:

```
sensing_open_sensor_by_dt(DEVICE_DT_GET(DT_NODELABEL(base_accel)), cb_list,␣
↪handle);
sensing_open_sensor_by_dt(DEVICE_DT_GET(DT_CHOSEN(zephyr_sensing_base_accel)),␣
↪cb_list, handle);
```

This method is useful and easy use for some simple Application which just want to access specific sensor(s).

`Sensor type` follows the HID standard sensor types definition.

See include/zephyr/sensing/sensing_sensor_types.h

4.31.6 Sensor Instance Handler

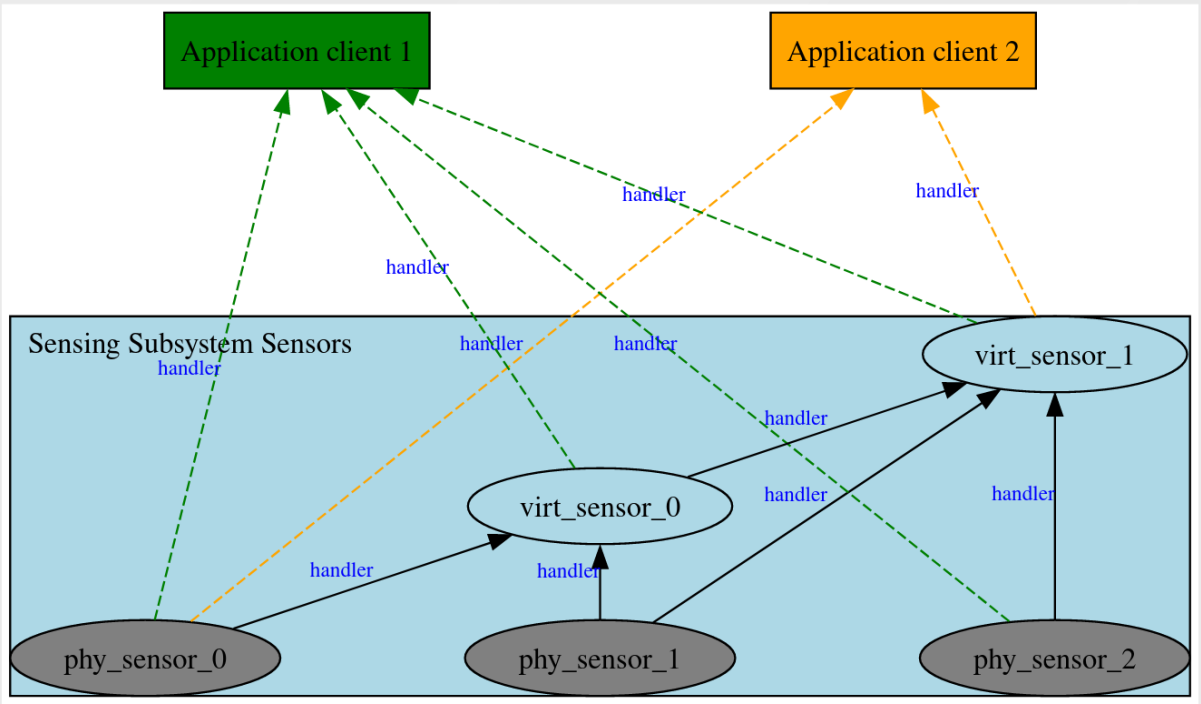
Clients using a `sensing_sensor_handle_t` type handler to handle a opened sensor instance, and all subsequent operations on this sensor instance need use this handler, such as set configurations, read sensor sample data, etc.

For a sensor instance, could have two kinds of clients: `Application clients` and `Sensor clients`.

`Application clients` can use `sensing_open_sensor()` to open a sensor instance and get it's handler.

For `Sensor clients`, there is no open API for opening a reporter, because the client-report relationship is built at the sensor's registration stage with devicetree.

The `Sensing Subsystem` will auto open and create `handlers` for client sensor to it's reporter sensors. `Sensor clients` can get it's reporters' handlers via `sensing_sensor_get_reporters()`.



Note

Sensors inside the Sensing Subsystem, the reporting relationship between them are all auto generated by Sensing Subsystem according devicetree definitions, handlers between client sensor and reporter sensors are auto created. Application(s) need to call `sensing_open_sensor()` to explicitly open the sensor instance.

4.31.7 Sensor Sample Value

- Data Structure

  Each sensor sample value defines as a common `header + readings[]` data structure, like `sensing_sensor_value_3d_q31`, `sensing_sensor_value_q31`, and `sensing_sensor_value_uint32`.

  The `header` definition `sensing_sensor_value_header()`.

- Time Stamp

  Time stamp unit in sensing subsystem is `micro seconds`.

  The `header` defines a **base_timestamp**, and each element in the **readings[]** array defines **timestamp_delta**.

  The **timestamp_delta** is in relation to the previous **readings** (or the **base_timestamp**)

  For example:

  - timestamp of `readings[0]` is `header.base_timestamp + readings[0].timestamp_delta`.
  - timestamp of `readings[1]` is `timestamp of readings[0] + readings[1].timestamp_delta`.

  Since timestamp unit is micro seconds, the max **timestamp_delta** (`uint32_t`) is `4295` seconds.

  If a sensor has batched data where two consecutive readings differ by more than `4295` seconds, the sensing subsystem runtime will split them across multiple instances of the readings structure, and send multiple events.

  This concept is referred from CHRE Sensor API.

- Data Format

  `Sensing Subsystem` uses per sensor type defined data format structure, and support `Q Format` defined in include/zephyr/dsp/types.h for zdsp lib support.

  For example `sensing_sensor_value_3d_q31` can be used by 3D IMU sensors like `SENSING_SENSOR_TYPE_MOTION_ACCELEROMETER_3D`, `SENSING_SENSOR_TYPE_MOTION_UNCALIB_ACCELEROMETER_3D`, and `SENSING_SENSOR_TYPE_MOTION_GYROMETER_3D`.

  `sensing_sensor_value_uint32` can be used by `SENSING_SENSOR_TYPE_LIGHT_AMBIENTLIGHT` sensor,

  and `sensing_sensor_value_q31` can be used by `SENSING_SENSOR_TYPE_MOTION_HINGE_ANGLE` sensor

  See include/zephyr/sensing/sensing_datatypes.h

4.31.8 Device Tree Configuration

Sensing subsystem using device tree to configuration all sensor instances and their properties, reporting relationships.

See the example samples/subsys/sensing/simple/boards/native_sim.overlay

4.32 Task Watchdog

4.32.1 Overview

Many microcontrollers feature a hardware watchdog timer peripheral. Its purpose is to trigger an action (usually a system reset) in case of severe software malfunctions. Once initialized, the watchdog timer has to be restarted (“fed”) in regular intervals to prevent it from timing out. If the software got stuck and does not manage to feed the watchdog anymore, the corrective action is triggered to bring the system back to normal operation.

In real-time operating systems with multiple tasks running in parallel, a single watchdog instance may not be sufficient anymore, as it can be used for only one task. This software watch-

dog based on kernel timers provides a method to supervise multiple threads or tasks (called watchdog channels).

An existing hardware watchdog can be used as an optional fallback if the task watchdog itself or the scheduler has a malfunction.

The task watchdog uses a kernel timer as its backend. If configured properly, the timer ISR is never actually called during normal operation, as the timer is continuously updated in the feed calls.

It's currently not possible to have multiple instances of task watchdogs. Instead, the task watchdog API can be accessed globally to add or delete new channels without passing around a context or device pointer in the firmware.

The maximum number of channels is predefined via Kconfig and should be adjusted to match exactly the number of channels required by the application.

4.32.2 Configuration Options

Related configuration options can be found under subsys/task_wdt/Kconfig.

- CONFIG_TASK_WDT
- CONFIG_TASK_WDT_CHANNELS
- CONFIG_TASK_WDT_HW_FALLBACK
- CONFIG_TASK_WDT_MIN_TIMEOUT
- CONFIG_TASK_WDT_HW_FALLBACK_DELAY

4.33 Trusted Firmware-M (TF-M)

4.33.1 Trusted Firmware-M Overview

Trusted Firmware-M (TF-M) is a reference implementation of the Platform Security Architecture (PSA) IoT Security Framework. It defines and implements an architecture and a set of software components that aim to address some of the main security concerns in IoT products.

Zephyr RTOS has been PSA Certified since Zephyr 2.0.0 with TF-M 1.0, and is currently integrated with TF-M 2.1.0.

What Does TF-M Offer?

Through a set of secure services and by design, TF-M provides:

- Isolation of secure and non-secure resources
- Embedded-appropriate crypto
- Management of device secrets (keys, etc.)
- Firmware verification (and encryption)
- Protected off-chip data storage and retrieval

- Proof of device identity (device attestation)
- Audit logging

Build System Integration

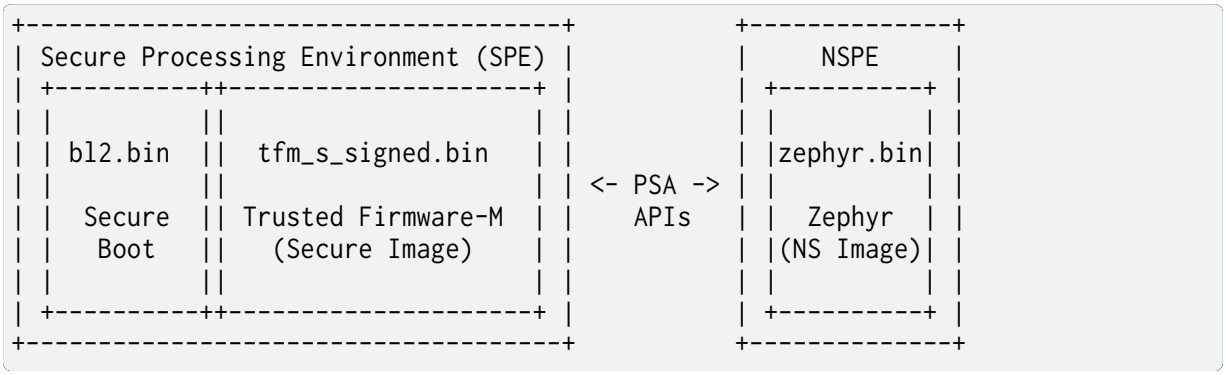
When using TF-M with a supported platform, TF-M will be automatically built and link in the background as part of the standard Zephyr build process. This build process makes a number of assumptions about how TF-M is being used, and has certain implications about what the Zephyr application image can and can not do:

- The secure processing environment (secure boot and TF-M) starts first
- Resource allocation for Zephyr relies on choices made in the secure image.

Architecture Overview

A TF-M application will, generally, have the following three parts, from most to least trusted, left-to-right, with code execution happening in the same order (secure boot > secure image > ns image).

While the secure bootloader is optional, it is enabled by default, and secure boot is an important part of providing a secure solution:



Communication between the (Zephyr) Non-Secure Processing Environment (NSPE) and the (TF-M) Secure Processing Environment image happens based on a set of PSA APIs, and normally makes use of an IPC mechanism that is included as part of the TF-M build, and implemented in Zephyr (see modules/trusted-firmware-m/interface).

Root of Trust (RoT) Architecture TF-M is based upon a **Root of Trust (RoT)** architecture. This allows for hierarchies of trust from most, to less, to least trusted, providing a sound foundation upon which to build or access trusted services and resources.

The benefit of this approach is that less trusted components are prevented from accessing or compromising more critical parts of the system, and error conditions in less trusted environments won't corrupt more trusted, isolated resources.

The following RoT hierarchy is defined for TF-M, from most to least trusted:

- PSA Root of Trust (**PRoT**), which consists of:
  - PSA Immutable Root of Trust: secure boot
  - PSA Updateable Root of Trust: most trusted secure services
- Application Root of Trust (**ARoT**): isolated secure services

The **PSA Immutable Root of Trust** is the most trusted piece of code in the system, to which subsequent Roots of Trust are anchored. In TF-M, this is the secure boot image, which verifies that

the secure and non-secure images are valid, have not been tampered with, and come from a reliable source. The secure bootloader also verifies new images during the firmware update process, thanks to the public signing key(s) built into it. As the name implies, this image is **immutable**.

The **PSA Updateable Root of Trust** implements the most trusted secure services and components in TF-M, such as the Secure Partition Manager (SPM), and shared secure services like PSA Crypto, Internal Trusted Storage (ITS), etc. Services in the PSA Updateable Root of Trust have access to other resources in the same Root of Trust.

The **Application Root of Trust** is a reduced-privilege area in the secure processing environment which, depending on the isolation level chosen when building TF-M, has limited access to the PRoT, or even other ARoT services at the highest isolation levels. Some standard services exist in the ARoT, such as Protected Storage (PS), and generally custom secure services that you implement should be placed in the ARoT, unless a compelling reason is present to place them in the PRoT.

These divisions are distinct from the **untrusted code**, which runs in the non-secure environment, and has the least privilege in the system. This is the Zephyr application image in this case.

Isolation Levels At present, there are three distinct **isolation levels** defined in TF-M, with increasingly rigid boundaries between regions. The isolation level used will depend on your security requirements, and the system resources available to you.

- **Isolation Level 1** is the lowest isolation level, and the only major boundary is between the secure and non-secure processing environment, usually by means of Arm TrustZone on Armv8-M processors. There is no distinction here between the PSA Updateable Root of Trust (PRoT) and the Application Root of Trust (ARoT). They execute at the same privilege level. This isolation level will lead to the smallest combined application images.
- **Isolation Level 2** builds upon level one by introducing a distinction between the PSA Updateable Root of Trust and the Application Root of Trust, where ARoT services have limited access to PRoT services, and can only communicate with them through public APIs exposed by the PRoT services. ARoT services, however, are not strictly isolated from one another.
- **Isolation Level 3** is the highest isolation level, and builds upon level 2 by isolating ARoT services from each other, so that each ARoT is essentially silo'ed from other services. This provides the highest level of isolation, but also comes at the cost of additional overhead and code duplication between services.

The current isolation level can be checked via `CONFIG_TFM_ISOLATION_LEVEL`.

Secure Boot The default secure bootloader in TF-M is based on MCUBoot, and is referred to as `BL2` in TF-M (for the second-stage bootloader, potentially after a HW-based bootloader on the secure MCU, etc.).

All images in TF-M are hashed and signed, with the hash and signature verified by MCUBoot during the firmware update process.

Some key features of MCUBoot as used in TF-M are:

- Public signing key(s) are baked into the bootloader
- S and NS images can be signed using different keys
- Firmware images can optionally be encrypted
- Client software is responsible for writing a new image to the secondary slot
- By default, uses static flash layout of two identically-sized memory regions
- Optional security counter for rollback protection

When dealing with (optionally) encrypted images:

- Only the payload is encrypted (header, TLVs are plain text)

- Hashing and signing are applied over the un-encrypted data
- Uses `AES-CTR-128` or `AES-CTR-256` for encryption
- Encryption key randomized every encryption cycle (via `imgtool`)
- The `AES-CTR` key is included in the image and can be encrypted using:
  - `RSA-OAEP`
  - `AES-KW` (128 or 256 bits depending on the `AES-CTR` key length)
  - `ECIES-P256`
  - `ECIES-X25519`

Key config properties to control secure boot in Zephyr are:

- `CONFIG_TFM_BL2` toggles the bootloader (default = `y`).
- `CONFIG_TFM_KEY_FILE_S` overrides the secure signing key.
- `CONFIG_TFM_KEY_FILE_NS` overrides the non-secure signing key.

Secure Processing Environment Once the secure bootloader has finished executing, a TF-M based secure image will begin execution in the **secure processing environment**. This is where our device will be initially configured, and any secure services will be initialised.

Note that the starting state of our device is controlled by the secure firmware, meaning that when the non-secure Zephyr application starts, peripherals may not be in the HW-default reset state. In case of doubts, be sure to consult the board support packages in TF-M, available in the `platform/ext/target/` folder of the TF-M module (which is in `modules/tee/tf-m/trusted-firmware-m/` within a default Zephyr west workspace.)

Secure Services As of TF-M 1.8.0, the following secure services are generally available (although vendor support may vary):

- Crypto
- Firmware Update (FWU)
- Initial Attestation
- Platform
- Secure Storage, which has two parts:
  - Internal Trusted Storage (ITS)
  - Protected Storage (PS)

A template also exists for creating your own custom services.

For full details on these services, and their exposed APIs, please consult the TF-M Documentation.

Key Management and Derivation Key and secret management is a critical part of any secure device. You need to ensure that key material is available to regions that require it, but not to anything else, and that it is stored securely in a way that makes it difficult to tamper with or maliciously access.

The **Internal Trusted Storage** service in TF-M is used by the **PSA Crypto** service (which itself makes use of mbedtls) to store keys, and ensure that private keys are only ever accessible to the secure processing environment. Crypto operations that make use of key material, such as when signing payloads or when decrypting sensitive data, all take place via key handles. At no point should the key material ever be exposed to the NS environment.

One exception is that private keys can be provisioned into the secure processing environment as a one-way operation, such as during a factory provisioning process, but even this should be

avoided where possible, and a request should be made to the SPE (via the PSA Crypto service) to generate a new private key itself, and the public key for that can be requested during provisioning and logged in the factory. This ensures the private key material is never exposed, or even known during the provisioning phase.

TF-M also makes extensive use of the **Hardware Unique Key (HUK)**, which every TF-M device must provide. This device-unique key is used by the **Protected Storage** service, for example, to encrypt information stored in external memory. For example, this ensures that the contents of flash memory can't be decrypted if they are removed and placed on a new device, since each device has its own unique HUK used while encrypting the memory contents the first time.

HUKs provide an additional advantage for developers, in that they can be used to derive new keys, and the **derived keys** don't need to be stored since they can be regenerated from the HUK at startup, using an additional salt/seed value (depending on the key derivation algorithm used). This removes the storage issue and a frequent attack vector. The HUK itself it usually highly protected in secure devices, and inaccessible directly by users.

`TFM_CRYPTO_ALG_HUK_DERIVATION` identifies the default key derivation algorithm used if a software implementation is used. The current default algorithm is `HKDF` (**RFC 5869**) with a SHA-256 hash. Other hardware implementations may be available on some platforms.

Non-Secure Processing Environment Zephyr is used for the NSPE, using a board that is supported by TF-M where the `CONFIG_BUILD_WITH_TFM` flag has been enabled.

Generally, you simply need to select the `*/ns` board target of a valid board (for example `mps2/an521/cpu0/ns`), which will configure your Zephyr application to run in the NSPE, correctly build and link it with the TF-M secure images, sign the secure and non-secure images, and merge the three binaries into a single `tfm_merged.hex` file. The *west flash* command will flash `tfm_merged.hex` by default in this configuration.

At present, Zephyr can not be configured to be used as the secure processing environment.

4.33.2 TF-M Requirements

The following are some of the boards that can be used with TF-M:

Board	NSPE board name
mps2_an521_board	`mps2/an521/cpu0/ns` (qemu supported)
mps3	• `mps3/corstone300/fvp/ns` (armfvp supported) • `mps3/corstone310/fvp/ns` (armfvp supported)
mps4	• `mps4/corstone315/fvp/ns` (armfvp supported) • `mps4/corstone320/fvp/ns` (armfvp supported)
bl5340_dvk	`bl5340_dvk/nrf5340/cpuapp/ns`
lpcxpresso55s69	`lpcxpresso55s69_ns`
nrf9160dk_nrf9160	`nrf9160dk/nrf9160/ns`
nrf5340dk	`nrf5340dk/nrf5340/cpuapp/ns`
b_u585i_iot02a	`b_u585i_iot02a/stm32u585xx/ns`
nucleo_l552ze_q	`nucleo_l552ze_q/stm32l552xx/ns`
stm32l562e_dk	`stm32l562e_dk/stm32l562xx/ns`
v2m_musca_b1	`v2m_musca_b1/musca_b1/ns`
v2m_musca_s1	`v2m_musca_s1/musca_s1/ns`

To make sure TF-M is supported for a board in its output, check that `CONFIG_TRUSTED_EXECUTION_NONSECURE` is set to y in that board's default configuration.

Software Requirements

The Python modules required when building TF-M binaries are listed in the TF-M repository under `tools/requirements.txt`.

You can install them via:

```
$ pip3 install -r "$(west list trusted-firmware-m -f '{abspath}')/
↪tools/requirements.txt"
```

They are used by TF-M's signing utility to prepare firmware images for validation by the bootloader.

Part of the process of generating binaries for QEMU and merging signed secure and non-secure binaries on certain platforms also requires the use of the `srec_cat` utility.

This can be installed on Linux via:

```
$ sudo apt-get install srecord
```

And on OS X via:

```
$ brew install srecord
```

For Windows-based systems, please make sure you have a copy of the utility available on your system path. See, for example: SRecord for Windows

4.33.3 TF-M Build System

When building a valid `_ns` board target, TF-M will be built in the background, and linked with the Zephyr non-secure application. No knowledge of TF-M's build system is required in most cases, and the following will build a TF-M and Zephyr image pair, and run it in qemu with no additional steps required:

```
$ west build -p auto -b mps2/an521/cpu0/ns␣
↪samples/tfm_integration/psa_protected_storage/ -t run
```

The outputs and certain key steps in this build process are described here, however, since you will need to understand and interact with the outputs, and deal with signing the secure and non-secure images before deploying them.

Images Created by the TF-M Build

The TF-M build system creates the following executable files:

- tfm_s - TF-M secure firmware
- tfm_ns - TF-M non-secure app (only used by regression tests).
- bl2 - TF-M MCUboot, if enabled

For each of these, it creates .bin, .hex, .elf, and .axf files.

The TF-M build system also creates signed variants of tfm_s and tfm_ns, and a file which combines them:

- tfm_s_signed
- tfm_ns_signed
- tfm_s_ns_signed

For each of these, only .bin files are created.

The TF-M non-secure app is discarded in favor of Zephyr non-secure app except when running the TF-M regression test suite.

The Zephyr build system usually signs both tfm_s and the Zephyr non-secure app itself. See below for details.

The 'tfm' target contains properties for all these paths. For example, the following will resolve to <path>/tfm_s.hex:

```
$<TARGET_PROPERTY:tfm,TFM_S_HEX_FILE>
```

See the top level CMakeLists.txt file in the tfm module for an overview of all the properties.

Signing Images

When CONFIG_TFM_BL2 is set to y, TF-M uses a secure bootloader (BL2) and firmware images must be signed with a private key. The firmware image is validated by the bootloader during updates using the corresponding public key, which is stored inside the secure bootloader firmware image.

By default, <tfm-dir>/bl2/ext/mcuboot/root-rsa-3072.pem is used to sign secure images, and <tfm-dir>/bl2/ext/mcuboot/root-rsa-3072_1.pem is used to sign non-secure images. These default .pem keys can (and **should**) be overridden using the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

To satisfy PSA Certified Level 1 requirements, **You MUST replace the default .pem file with a new key pair!**

To generate a new public/private key pair, run the following commands:

```
$ imgtool keygen -k root-rsa-3072_s.pem -t rsa-3072
$ imgtool keygen -k root-rsa-3072_ns.pem -t rsa-3072
```

You can then place the new .pem files in an alternate location, such as your Zephyr application folder, and reference them in the prj.conf file via the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

> **Warning**
>
> Be sure to keep your private key file in a safe, reliable location! If you lose this key file, you will be unable to sign any future firmware images, and it will no longer be possible to update your devices in the field!

After the built-in signing script has run, it creates a tfm_merged.hex (and tfm_merged.bin) file that contains all three binaries: bl2, tfm_s, and the zephyr app. These files can then be flashed to your development board or run in QEMU.

Output Files

Upon completion of the Zephyr TF-M build, the following output files exist:

Table 74: TF-M Output Files

Filename	Created From	Boot-loader Flags	Usage
tfm_s_signed.{hex/bin}	TF-M Secure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 2)
zephyr_ns_signed.{hex/bin}	Zephyr Nonsecure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 2)
tfm_s_zephyr_ns_sig{hex/bin}	TF-M Secure, Zephyr Nonsecure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 1)
tfm_merged.{hex/bin}	Bootloader, TF-M Secure, Zephyr Nonsecure	Signed, Confirmed	Production Programming, flashed by west flash

Custom CMake arguments When building a Zephyr application with TF-M it might be necessary to control the CMake arguments passed to the TF-M build.

Zephyr TF-M build offers several Kconfig options for controlling the build, but doesn't cover every CMake argument supported by the TF-M build system.

The TFM_CMAKE_OPTIONS property on the zephyr_property_target can be used to pass custom CMake arguments to the TF-M build system.

To pass the CMake argument -DFOO=bar to the TF-M build system, place the following CMake snippet in your CMakeLists.txt file.

```
set_property(TARGET zephyr_property_target
             APPEND PROPERTY TFM_CMAKE_OPTIONS
             -DFOO=bar
)
```

Note

The TFM_CMAKE_OPTIONS is a list so it is possible to append multiple options. Also CMake generator expressions are supported, such as $<1:-DFOO=bar>

Since TFM_CMAKE_OPTIONS is a list argument it will be expanded before it is passed to the TF-M build system. Options that have list arguments must therefore be properly escaped to avoid being expanded as a list.

```
set_property(TARGET zephyr_property_target
             APPEND PROPERTY TFM_CMAKE_OPTIONS
             -DFOO="bar\\\;baz"
)
```

Footprint and Memory Usage

The build system offers targets to view and analyse RAM and ROM usage in generated images. The tools run on the final images and give information about size of symbols and code being used in both RAM and ROM. For more information on these tools look here: *Footprint and Memory Usage*

Use the tfm_ram_report to get the RAM report for TF-M secure firmware (tfm_s).

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t tfm_ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild tfm_ram_report
```

Use the `tfm_rom_report` to get the ROM report for TF-M secure firmware (tfm_s).

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t tfm_rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild tfm_rom_report
```

Use the `bl2_ram_report` to get the RAM report for TF-M MCUboot, if enabled.

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t bl2_ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild bl2_ram_report
```

Use the `bl2_rom_report` to get the ROM report for TF-M MCUboot, if enabled.

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t bl2_rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
```

(continues on next page)

(continued from previous page)

```
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild bl2_rom_report
```

4.33.4 Trusted Firmware-M Integration

The Trusted Firmware-M (TF-M) section contains information about the integration between TF-M and Zephyr RTOS. Use this information to help understand how to integrate TF-M with Zephyr for Cortex-M platforms and make use of its secure run-time services in Zephyr applications.

Board Definitions

TF-M will be built for the secure processing environment along with Zephyr if the `CONFIG_BUILD_WITH_TFM` flag is set to `y`.

Generally, this value should never be set at the application level, however, and all config flags required for TF-M should be set in a board variant with the `_ns` suffix.

This board variant must define an appropriate flash, SRAM and peripheral configuration that takes into account the initialisation process in the secure processing environment. `CONFIG_TFM_BOARD` must also be set via modules/trusted-firmware-m/Kconfig.tfm to the board name that TF-M expects for this target, so that it knows which target to build for the secure processing environment.

Example: `mps2/an521/cpu0/ns` The `mps2/an521/cpu0` board target is a dual-core Arm Cortex-M33 evaluation board that generates a secure Zephyr binary.

The optional `mps2/an521/cpu0/ns` board target, however, sets these additional kconfig flags that indicate that Zephyr should be built as a non-secure image, linked with TF-M as an external project, and optionally the secure bootloader:

- `CONFIG_TRUSTED_EXECUTION_NONSECURE y`
- `CONFIG_ARM_TRUSTZONE_M y`

Comparing the boards/arm/mps2/mps2_an521_cpu0.dts and boards/arm/mps2/mps2_an521_cpu0_ns.dts files, we can see that the `ns` version defines offsets in flash and SRAM memory, which leave the required space for TF-M and the secure bootloader:

```
reserved-memory {
            #address-cells = <1>;
            #size-cells = <1>;
            ranges;

            /* The memory regions defined below must match what the TF-M
             * project has defined for that board - a single image boot is
             * assumed. Please see the memory layout in:
             *␣
↪https://git.trustedfirmware.org/TF-M/trusted-firmware-m.git/tree/platform/ext/target/mps2/an521
             */

            code: memory@100000 {
                    reg = <0x00100000 DT_SIZE_K(512)>;
            };

            ram: memory@28100000 {
                    reg = <0x28100000 DT_SIZE_M(1)>;
```

(continues on next page)

(continued from previous page)

```
            };
    };
```

This reserves 1 MB of code memory and 1 MB of RAM for secure boot and TF-M, such that our non-secure Zephyr application code will start at 0x10000, with RAM at 0x28100000. 512 KB code memory is available for the NS zephyr image, along with 1 MB of RAM.

This matches the flash memory layout we see in `flash_layout.h` in TF-M:

```
* 0x0000_0000 BL2 - MCUBoot (0.5 MB)
* 0x0008_0000 Secure image     primary slot (0.5 MB)
* 0x0010_0000 Non-secure image primary slot (0.5 MB)
* 0x0018_0000 Secure image     secondary slot (0.5 MB)
* 0x0020_0000 Non-secure image secondary slot (0.5 MB)
* 0x0028_0000 Scratch area (0.5 MB)
* 0x0030_0000 Protected Storage Area (20 KB)
* 0x0030_5000 Internal Trusted Storage Area (16 KB)
* 0x0030_9000 NV counters area (4 KB)
* 0x0030_A000 Unused (984 KB)
```

`mps2/an521` will be passed in to Tf-M as the board target, specified via `CONFIG_TFM_BOARD`.

4.33.5 Test Suites

TF-M includes two sets of test suites:

- tf-m-tests - Standard TF-M specific regression tests
- psa-arch-tests - Test suites for specific PSA APIs (secure storage, etc.)

These test suites can be run from Zephyr via an appropriate sample application in the samples/tfm_integration folder.

TF-M Regression Tests

The regression test suite can be run via the tfm_regression_test sample.

This sample tests various services and communication mechanisms across the NS/S boundary via the PSA APIs. They provide a useful sanity check for proper integration between the NS RTOS (Zephyr in this case) and the secure application (TF-M).

PSA Arch Tests

The PSA Arch Test suite, available via tfm_psa_test, contains a number of test suites that can be used to validate that PSA API specifications are being followed by the secure application, TF-M being an implementation of the Platform Security Architecture (PSA).

Only one of these suites can be run at a time, with the available test suites described via `CONFIG_TFM_PSA_TEST_*` KConfig flags:

Purpose

The output of these test suites is required to obtain PSA Certification for your specific board, RTOS (Zephyr here), and PSA implementation (TF-M in this case).

They also provide a useful test case to validate any PRs that make meaningful changes to TF-M, such as enabling a new TF-M board target, or making changes to the core TF-M module(s). They should generally be run as a coherence check before publishing a new PR for new board support, etc.

4.34 UUID

4.34.1 Overview

Universally Unique Identifiers (UUID), also known as Globally Unique IDentifiers (GUIDs), are 128-bit identifiers intended to guarantee uniqueness across space and time. They are defined by **RFC 9562**.

The UUID subsystem provides utility functions for the generation, parsing, and manipulation of UUIDs. It supports generating version 4 (random) and version 5 (name-based) UUIDs.

Usage

To use the UUID API, include the header file:

```
#include <zephyr/sys/uuid.h>
```

Generating a UUIDv4 UUIDv4 is based on random numbers (hence requires an entropy generator), and can be generated using the `uuid_generate_v4()` function. `CONFIG_UUID_V4` must also be enabled.

```
struct uuid my_uuid;
char uuid_str[UUID_STR_LEN];

int ret = uuid_generate_v4(&my_uuid);

if (ret != 0) {
    printk("Failed to generate UUID v4 (err %d)\n", ret);
    return ret;
}

ret = uuid_to_string(&my_uuid, uuid_str);
if (ret != 0) {
    printk("Failed to convert UUID to string (err %d)\n", ret);
    return ret;
}

 printk("UUID: %s\n", uuid_str);
```

Generating a UUIDv5 UUIDv5 is generated from a namespace UUID and a name (binary data), and can be generated using the `uuid_generate_v5()` function. `CONFIG_UUID_V5` must also be enabled.

UUIDv5 is deterministic: the same namespace and name will always result in the same UUID.

```
struct uuid ns_uuid;
struct uuid my_uuid;
char uuid_str[UUID_STR_LEN];

/* Well-known namespace ID for URLs (RFC 9562) */
uuid_from_string("6ba7b811-9dad-11d1-80b4-00c04fd430c8", &ns_uuid);

const char *name = "https://zephyrproject.org/";
int ret = uuid_generate_v5(&ns_uuid, name, strlen(name), &my_uuid);

if (ret != 0) {
    printk("Failed to generate UUID v5 (err %d)\n", ret);
```

(continues on next page)

(continued from previous page)

```
    return ret;
}

ret = uuid_to_string(&my_uuid, uuid_str);
if (ret != 0) {
    printk("Failed to convert UUID to string (err %d)\n", ret);
    return ret;
}

/* outputs: "UUID: abdb72b5-b342-5882-925b-4ce0e3cb4790" */
printk("UUID: %s\n", uuid_str);
```

UUID

4.35 Virtualization

4.35.1 Inter-VM Shared Memory

- *Overview*
- *Support*
- *ivshmem-v2*
- *API Reference*

Overview

As Zephyr is enabled to run as a guest OS on Qemu and ACRN it might be necessary to make VMs aware of each other, or aware of the host. This is made possible by exposing a shared memory among parties via a feature called ivshmem, which stands for inter-VM Shared Memory.

The two types are supported: a plain shared memory (ivshmem-plain) or a shared memory with the ability for a VM to generate an interruption on another, and thus to be interrupted as well itself (ivshmem-doorbell).

Please refer to the official Qemu ivshmem documentation for more information.

Support

Zephyr supports both versions: plain and doorbell. Ivshmem driver can be built by enabling `CONFIG_IVSHMEM`. By default, this will expose the plain version. `CONFIG_IVSHMEM_DOORBELL` needs to be enabled to get the doorbell version.

Because the doorbell version uses MSI-X vectors to support notification vectors, the `CONFIG_IVSHMEM_MSI_X_VECTORS` has to be tweaked to the number of vectors that will be needed.

Note that a tiny shell module can be exposed to test the ivshmem feature by enabling `CONFIG_IVSHMEM_SHELL`.

ivshmem-v2

Zephyr also supports ivshmem-v2:

https://github.com/siemens/jailhouse/blob/master/Documentation/ivshmem-v2-specification.md

This is primarily used for IPC in the Jailhouse hypervisor (e.g. eth-ivshmem). It is also possible to use ivshmem-v2 without Jailhouse by building the Siemens fork of QEMU, and modifying the QEMU launch flags:

https://github.com/siemens/qemu/tree/wip/ivshmem2

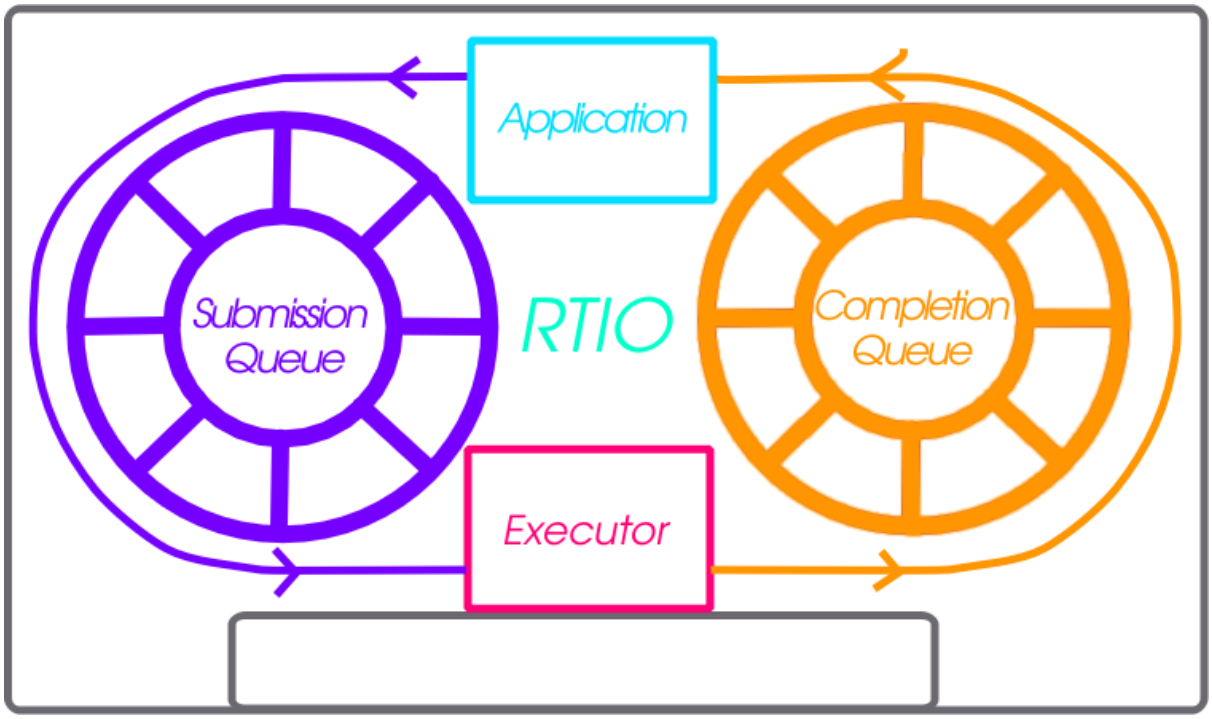
4.36 Real Time I/O (RTIO)

- *Problem*
- *Inspiration, introducing io_uring*
- *Submission Queue*
- *Completion Queue*
- *Executor*
- *IO Device*
- *Cancellation*
- *Memory pools*
- *When to Use*
- *Supported Buses*
- *API Reference*



RTIO provides a framework for doing asynchronous operation chains with event driven I/O. This section covers the RTIO API, queues, executor, iodev, and common usage patterns with peripheral devices.

RTIO takes a lot of inspiration from Linux's io_uring in its operations and API as that API matches up well with hardware transfer queues and descriptions such as DMA transfer lists.

4.36.1 Problem

An application wishing to do complex DMA or interrupt driven operations today in Zephyr requires direct knowledge of the hardware and how it works. There is no understanding in the DMA API of other Zephyr devices and how they relate.

This means doing complex audio, video, or sensor streaming requires direct hardware knowledge or leaky abstractions over DMA controllers. Neither is ideal.

To enable asynchronous operations, especially with DMA, a description of what to do rather than direct operations through C and callbacks is needed. Enabling DMA features such as channels with priority, and sequences of transfers requires more than a simple list of descriptions.

Using DMA and/or interrupt driven I/O shouldn't dictate whether or not the call is blocking or not.

4.36.2 Inspiration, introducing io_uring

It's better not to reinvent the wheel (or ring in this case) and io_uring as an API from the Linux kernel provides a winning model. In io_uring there are two lock-free ring buffers acting as queues shared between the kernel and a userland application. One queue for submission entries which may be chained and flushed to create concurrent sequential requests. A second queue for completion queue events. Only a single syscall is actually required to execute many operations, the io_uring_submit call. This call may block the caller when a number of operations to wait on is given.

This model maps well to DMA and interrupt driven transfers. A request to do a sequence of operations in an asynchronous way directly relates to the way hardware typically works with interrupt driven state machines potentially involving multiple peripheral IPs like bus and DMA controllers.

4.36.3 Submission Queue

The submission queue (sq), is the description of the operations to perform in concurrent chains.

For example imagine a typical SPI transfer where you wish to write a register address to then read from. So the sequence of operations might be...

1. Chip Select
2. Clock Enable
3. Write register address into SPI transmit register
4. Read from the SPI receive register into a buffer
5. Disable clock
6. Disable Chip Select

If anything in this chain of operations fails give up. Some of those operations can be embodied in a device abstraction that understands a read or write implicitly means setup the clock and chip select. The transactional nature of the request also needs to be embodied in some manner. Of the operations above perhaps the read could be done using DMA as its large enough make sense. That requires an understanding of how to setup the device's particular DMA to do so.

The above sequence of operations is embodied in RTIO as chain of submission queue entries (sqe). Chaining is done by setting a bitflag in an sqe to signify the next sqe must wait on the current one.

Because the chip select and clocking is common to a particular SPI controller and device on the bus it is embodied in what RTIO calls an iodev.

Multiple operations against the same iodev are done in the order provided as soon as possible. If two operation chains have varying points using the same device its possible one chain will have to wait for another to complete.

4.36.4 Completion Queue

In order to know when a sqe has completed there is a completion queue (cq) with completion queue events (cqe). A sqe once completed results in a cqe being pushed into the cq. The ordering of cqe may not be the same order of sqe. A chain of sqe will however ensure ordering and failure cascading.

Other potential schemes are possible but a completion queue is a well trod idea with io_uring and other similar operating system APIs.

4.36.5 Executor

The RTIO executor is a low overhead concurrent I/O task scheduler. It ensures certain request flags provide the expected behavior. It takes a list of submissions working through them in order. Various flags allow for changing the behavior of how submissions are worked through. Flags to form in order chains of submissions, transactional sets of submissions, or create multi-shot (continuously producing) requests are all possible!

4.36.6 IO Device

Turning submission queue entries (sqe) into completion queue events (cqe) is the job of objects implementing the iodev (IO device) API. This API accepts requests in the form of the iodev submit API call. It is the io devices job to work through its internal queue of submissions and convert them into completions. In effect every io device can be viewed as an independent, event driven actor like object, that accepts a never ending queue of I/O like requests. How the iodev does this work is up to the author of the iodev, perhaps the entire queue of operations can be converted to a set of DMA transfer descriptors, meaning the hardware does almost all of the real work.

4.36.7 Cancellation

Canceling an already queued operation is possible but not guaranteed. If the SQE has not yet started, it's likely that a call to `rtio_sqe_cancel()` will remove the SQE and never run it. If, however, the SQE already started running, the cancel request will be ignored.

4.36.8 Memory pools

In some cases requests to read may not know how much data will be produced. Alternatively, a reader might be handling data from multiple io devices where the frequency of the data is unpredictable. In these cases it may be wasteful to bind memory to in flight read requests. Instead with memory pools the memory to read into is left to the iodev to allocate from a memory pool associated with the RTIO context that the read was associated with. To create such an RTIO context the `RTIO_DEFINE_WITH_MEMPOOL` can be used. It allows creating an RTIO context with a dedicated pool of "memory blocks" which can be consumed by the iodev. Below is a snippet setting up the RTIO context with a memory pool. The memory pool has 128 blocks, each block has the size of 16 bytes, and the data is 4 byte aligned.

```
#include <zephyr/rtio/rtio.h>

#define SQ_SIZE       4
#define CQ_SIZE       4
#define MEM_BLK_COUNT 128
#define MEM_BLK_SIZE  16
#define MEM_BLK_ALIGN 4

RTIO_DEFINE_WITH_MEMPOOL(rtio_context,
    SQ_SIZE, CQ_SIZE, MEM_BLK_COUNT, MEM_BLK_SIZE, MEM_BLK_ALIGN);
```

When a read is needed, the caller simply needs to replace the call `rtio_sqe_prep_read()` (which takes a pointer to a buffer and a length) with a call to `rtio_sqe_prep_read_with_pool()`. The iodev requires only a small change which works with both pre-allocated data buffers as well as the mempool. When the read is ready, instead of getting the buffers directly from the `rtio_iodev_sqe`, the iodev should get the buffer and count by calling `rtio_sqe_rx_buf()` like so:

```
uint8_t *buf;
uint32_t buf_len;
int rc = rtio_sqe_rx_buff(iodev_sqe, MIN_BUF_LEN, DESIRED_BUF_LEN, &buf, &buf_len);

if (rc != 0) {
  LOG_ERR("Failed to get buffer of at least %u bytes", MIN_BUF_LEN);
  return;
}
```

Finally, the consumer will be able to access the allocated buffer via `rtio_cqe_get_mempool_buffer()`.

```
uint8_t *buf;
uint32_t buf_len;
int rc = rtio_cqe_get_mempool_buffer(&rtio_context, &cqe, &buf, &buf_len);

if (rc != 0) {
  LOG_ERR("Failed to get mempool buffer");
  return rc;
}

/* Release the cqe events (note that the buffer is not released yet */
```

(continues on next page)

(continued from previous page)

```
rtio_cqe_release_all(&rtio_context);

/* Do something with the memory */

/* Release the mempool buffer */
rtio_release_buffer(&rtio_context, buf);
```

4.36.9 When to Use

RTIO is useful in cases where concurrent or batch like I/O flows are useful.

From the driver/hardware perspective the API enables batching of I/O requests, potentially in an optimal way. Many requests to the same SPI peripheral for example might be translated to hardware command queues or DMA transfer descriptors entirely. Meaning the hardware can potentially do more than ever.

There is a small cost to each RTIO context and iodev. This cost could be weighed against using a thread for each concurrent I/O operation or custom queues and threads per peripheral. RTIO is much lower cost than that.

4.36.10 Supported Buses

To check if your bus supports RTIO natively, you can check the driver API implementation, if the driver implements the `iodev_submit` function of the bus API, then RTIO is supported. If the driver doesn't support the RTIO APIs, it will set the submit function to `i2c_iodev_submit_fallback`.

I2C buses have a default implementation which allows apps to leverage the RTIO work queue while vendors implement the submit function. With this queue, any I2C bus driver that does not implement the `iodev_submit` function will defer to a work item which will perform a blocking I2C transaction. To change the pool size, set a different value to `CONFIG_RTIO_WORKQ_POOL_ITEMS`.

- *API Reference*

4.37.1 Concepts

Threads can send messages to one or more observers using zbus. It makes the many-to-many communication possible. The bus implements message-passing and publish/subscribe communication paradigms that enable threads to communicate synchronously or asynchronously through shared memory.

The communication through zbus is channel-based. Threads (or callbacks) use channels to exchange messages. Additionally, besides other actions, threads can publish and observe channels. When a thread publishes a message on a channel, the bus will make the message available to all the published channel's observers. Based on the observer's type, it can access the message directly, receive a copy of it, or even receive only a reference of the published channel.

The figure below shows an example of a typical application using zbus in which the application logic (hardware independent) talks to other threads via software bus. Note that the threads are decoupled from each other because they only use zbus channels and do not need to know each other to talk.

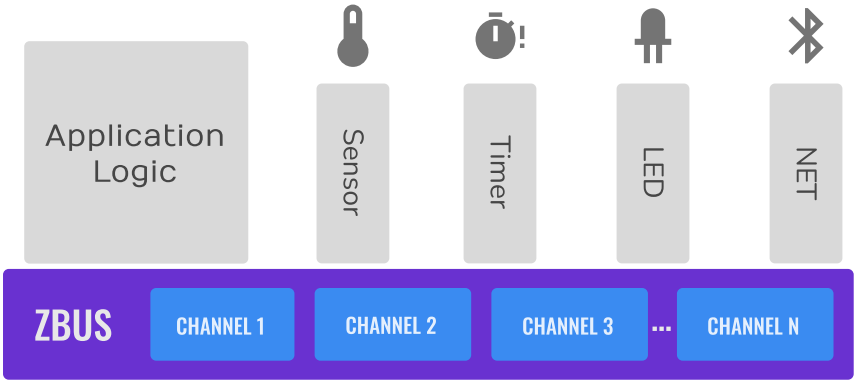

Fig. 25: A typical zbus application architecture.

The bus comprises:

- Set of channels that consists of the control metadata information, and the message itself;
- *Virtual Distributed Event Dispatcher* (VDED), the bus logic responsible for sending notifications/messages to the observers. The VDED logic runs inside the publishing action in the

same thread context, giving the bus an idea of a distributed execution. When a thread publishes to a channel, it also propagates the notifications to the observers;

- Threads (subscribers and message subscribers) and callbacks (listeners) publishing, reading, and receiving notifications from the bus.

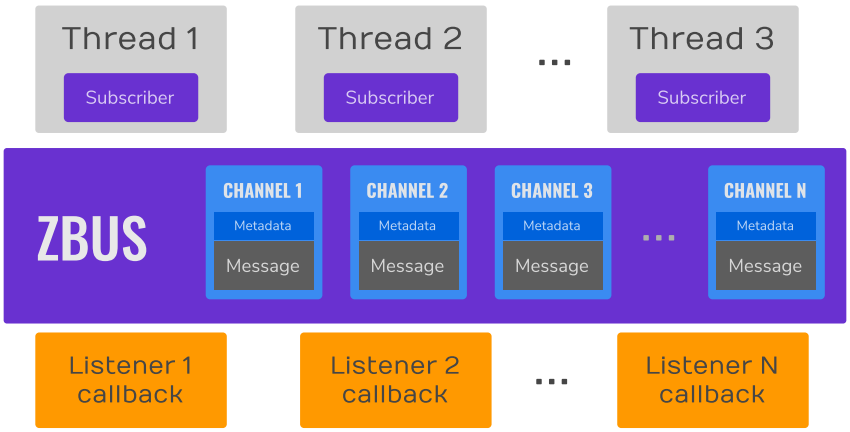

Fig. 26: ZBus anatomy.

The bus makes the publish, read, claim, finish, notify, and subscribe actions available over channels. Publishing, reading, claiming, and finishing are available in all RTOS thread contexts, including ISRs. The publish and read operations are simple and fast; the procedure is channel locking followed by a memory copy to and from a shared memory region and then a channel unlocking. Another essential aspect of zbus is the observers. There are three types of observers:

Fig. 27: ZBus observers.

- Listeners, a callback that the event dispatcher executes every time an observed channel is published or notified;
- Async Listeners, a callback that the event dispatcher schedules to execute in a work queue (system work queue by default) every time an observed channel is published or notified;
- Subscriber, a thread-based observer that relies internally on a message queue where the event dispatcher puts a changed channel's reference every time an observed channel is published or notified. Note this kind of observer does not receive the message itself. It should read the message from the channel after receiving the notification;
- Message subscribers, a thread-based observer that relies internally on a FIFO where the event dispatcher puts a copy of the message every time an observed channel is published or notified.

Channel observation structures define the relationship between a channel and its observers. For every observation, a pair channel/observer. Developers can statically allocate observation using the `ZBUS_CHAN_DEFINE` or `ZBUS_CHAN_ADD_OBS`. There are also runtime observers, enabling developers to create runtime observations. It is possible to disable an observer entirely or observations individually. The event dispatcher will ignore disabled observers and observations.

The above figure illustrates some states, from (a) to (d), for channels from `C1` to `C5`, `Subscriber 1`, and the observations. The last two are in orange to indicate they are dynamically allocated (runtime observation). (a) shows that the observer and all observations are enabled. (b) shows the observer is disabled, so the event dispatcher will ignore it. (c) shows the observer enabled. However, there is one static observation disabled. The event dispatcher will only stop sending notifications from channel `C3`. In (d), the event dispatcher will stop sending notifications from channels `C3` and `C5` to `Subscriber 1`.

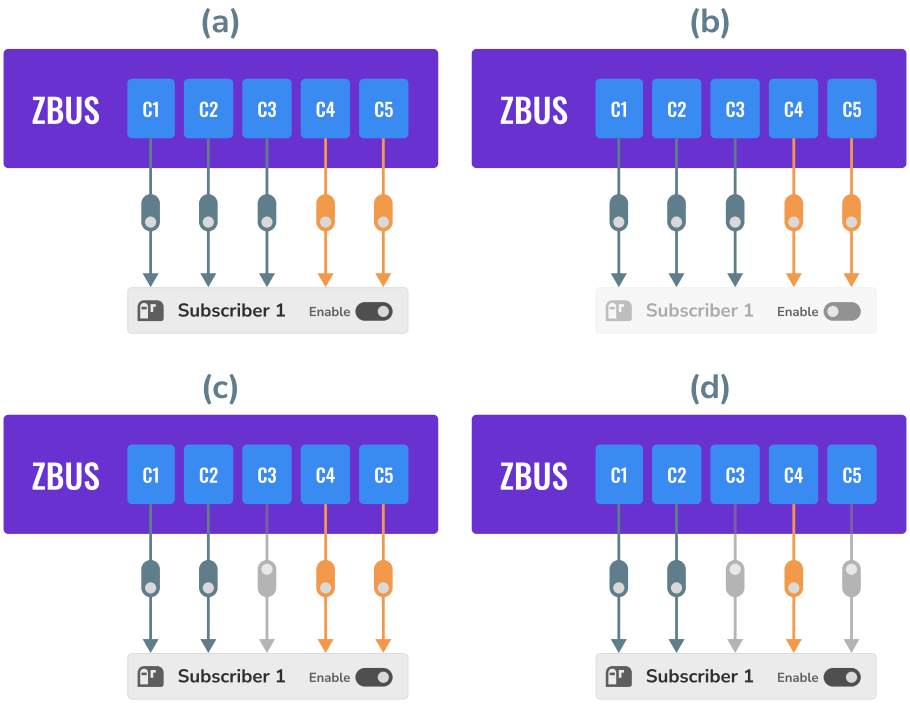

Fig. 28: ZBus observation mask.

Suppose a usual sensor-based solution is in the figure below for illustration purposes. When triggered, the timer publishes to the `Trigger` channel. As the sensor thread subscribed to the `Trigger` channel, it receives the sensor data. Notice the VDED executes the `Blink` because it also listens to the `Trigger` channel. When the sensor data is ready, the sensor thread publishes it to the `Sensor data` channel. The core thread receives the message as a `Sensor data` channel message subscriber, processes the sensor data, and stores it in an internal sample buffer. It repeats until the sample buffer is full; when it happens, the core thread aggregates the sample buffer information, prepares a package, and publishes that to the `Payload` channel. The Lora thread receives that because it is a `Payload` channel message subscriber and sends the payload to the cloud. When it completes the transmission, the Lora thread publishes to the `Transmission done` channel. The VDED executes the `Blink` again since it listens to the `Transmission done` channel.

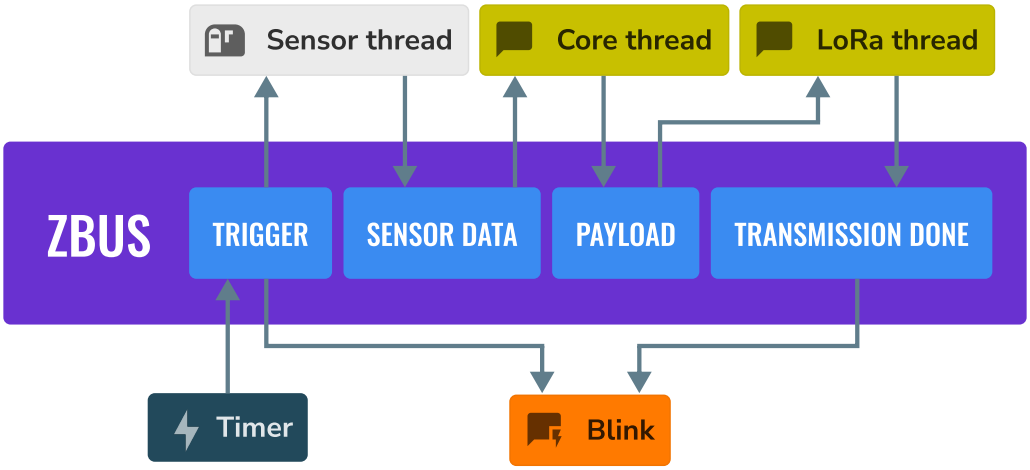

Fig. 29: ZBus sensor-based application.

This way of implementing the solution makes the application more flexible, enabling us to change things independently. For example, we want to change the trigger from a timer to a button press. We can do that, and the change does not affect other parts of the system. Likewise,

we would like to change the communication interface from LoRa to Bluetooth; we only need to change the LoRa thread. No other change is required in order to make that work. Thus, the developer would do that for every block of the image. Based on that, there is a sign zbus promotes decoupling in the system architecture.

Another important aspect of using zbus is the reuse of system modules. If a code portion with well-defined behaviors (we call that module) only uses zbus channels and not hardware interfaces, it can easily be reused in other solutions. The new solution must implement the interfaces (set of channels) the module needs to work. That indicates zbus could improve the module reuse.

The last important note is the zbus solution reach. We can count on many ways of using zbus to enable the developer to be as free as possible to create what they need. For example, messages can be dynamic or static allocated; notifications can be synchronous or asynchronous; the developer can control the channel in so many different ways claiming the channel, developers can add their metadata information to a channel by using the user-data field, the discretionary use of a validator enables the systems to be accurate over message format, and so on. Those characteristics increase the solutions that can be done with zbus and make it a good fit as an open-source community tool.

Virtual Distributed Event Dispatcher

The VDED execution always happens in the publisher's context. It can be a thread or an ISR. Be careful with publications inside ISR because the scheduler won't preempt the VDED. Use that wisely. The basic description of the execution is as follows:

- The channel lock is acquired;
- The channel receives the new message via direct copy (by a raw `memcpy()`);
- The event dispatcher logic executes the listeners, sends a copy of the message to the message subscribers, and pushes the channel's reference to the subscribers' notification message queue in the same sequence they appear on the channel observers' list. The listeners can perform non-copy quick access to the constant message reference directly (via the `zbus_chan_const_msg()` function) since the channel is still locked;
- At last, the publishing function unlocks the channel.

To illustrate the VDED execution, consider the example illustrated below. We have four threads in ascending priority `S1`, `MS2`, `MS1`, and `T1` (the highest priority); two listeners, `L1` and `L2`; and channel A. Supposing `L1`, `L2`, `MS1`, `MS2`, and `S1` observer channel A.

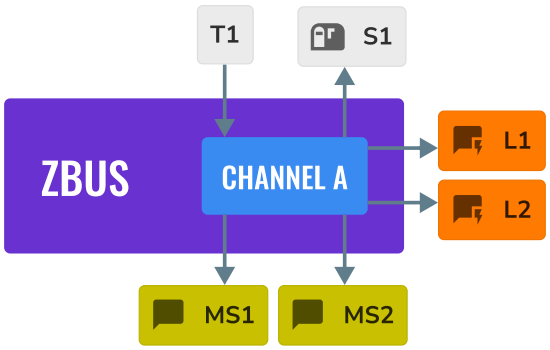

Fig. 30: ZBus VDED execution example scenario.

The following code implements channel A. Note the `struct a_msg` is illustrative only.

```
ZBUS_CHAN_DEFINE(a_chan,                        /* Name */
         struct a_msg,                          /* Message type */

         NULL,                                  /* Validator */
```

(continues on next page)

(continued from previous page)

```
        NULL,                                   /* User Data */
        ZBUS_OBSERVERS(L1, L2, MS1, MS2, S1), /* observers */
        ZBUS_MSG_INIT(0)                        /* Initial value {0} */
);
```

In the figure below, the letters indicate some action related to the VDED execution. The X-axis represents the time, and the Y-axis represents the priority of threads. Channel A's message, represented by a voice balloon, is only one memory portion (shared memory). It appears several times only as an illustration of the message at that point in time.

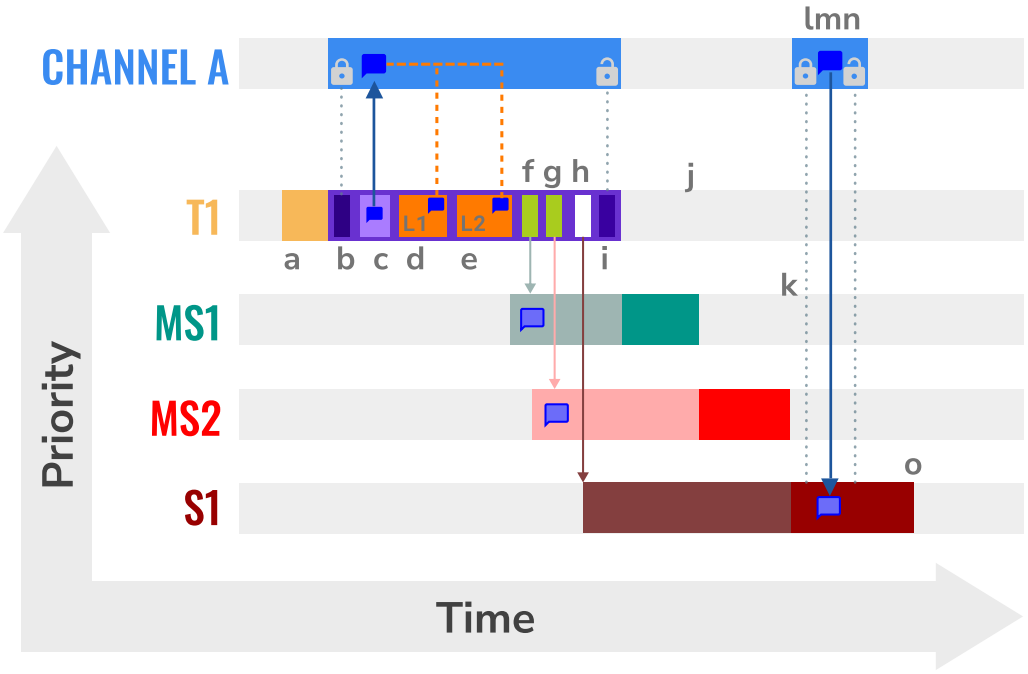

Fig. 31: ZBus VDED execution detail for priority T1 > MS1 > MS2 > S1.

The figure above illustrates the actions performed during the VDED execution when T1 publishes to channel A. Thus, the table below describes the activities (represented by a letter) of the VDED execution. The scenario considers the following priorities: T1 > MS1 > MS2 > S1. T1 has the highest priority.

Table 75: VDED execution steps in detail for priority T1 > MS1 > MS2 > S1.

Actions	Description
a	T1 starts and, at some point, publishes to channel A.
b	The publishing (VDED) process starts. The VDED locks the channel A.
c	The VDED copies the T1 message to the channel A message.
d, e	The VDED executes L1 and L2 in the respective sequence. Inside the listeners, usually, there is a call to the `zbus_chan_const_msg()` function, which provides a direct constant reference to channel A's message. It is quick, and no copy is needed here.
f, g	The VDED copies the message and sends that to MS1 and MS2 sequentially. Notice the threads get ready to execute right after receiving the notification. However, they go to a pending state because they have less priority than T1.
h	The VDED pushes the notification message to the queue of S1. Notice the thread gets ready to execute right after receiving the notification. However, it goes to a pending state because it cannot access the channel since it is still locked.
i	VDED finishes the publishing by unlocking channel A. The MS1 leaves the pending state and starts executing.
j	MS1 finishes execution. The MS2 leaves the pending state and starts executing.
k	MS2 finishes execution. The S1 leaves the pending state and starts executing.
l, m, n	The S1 leaves the pending state since channel A is not locked. It gets in the CPU again and starts executing. As it did receive a notification from channel A, it performed a channel read (as simple as lock, memory copy, unlock), continues its execution and goes out of the CPU.
o	S1 finishes its workload.

The figure below illustrates the actions performed during the VDED execution when T1 publishes to channel A. The scenario considers the following priorities: T1 < MS1 < MS2 < S1.

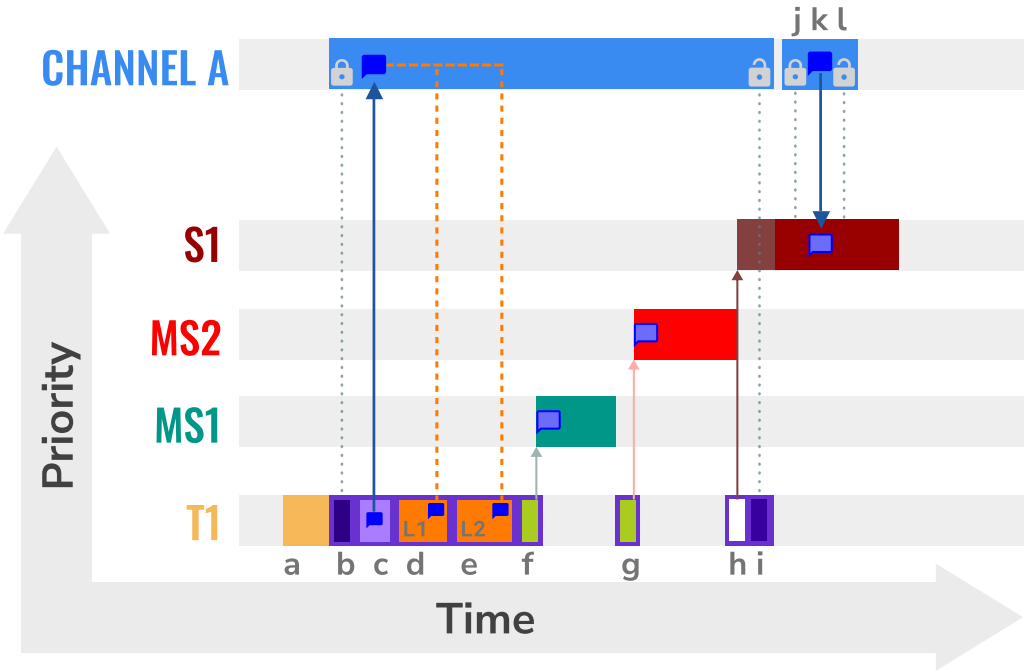

Fig. 32: ZBus VDED execution detail for priority T1 < MS1 < MS2 < S1.

Thus, the table below describes the activities (represented by a letter) of the VDED execution.

Table 76: VDED execution steps in detail for priority T1 < MS1 < MS2 < S1.

Actions	Description
a	T1 starts and, at some point, publishes to channel A.
b	The publishing (VDED) process starts. The VDED locks the channel A.
c	The VDED copies the T1 message to the channel A message.
d, e	The VDED executes L1 and L2 in the respective sequence. Inside the listeners, usually, there is a call to the `zbus_chan_const_msg()` function, which provides a direct constant reference to channel A's message. It is quick, and no copy is needed here.
f	The VDED copies the message and sends that to MS1. MS1 preempts T1 and starts working. After that, the T1 regain MCU.
g	The VDED copies the message and sends that to MS2. MS2 preempts T1 and starts working. After that, the T1 regain MCU.
h	The VDED pushes the notification message to the queue of S1.
i	VDED finishes the publishing by unlocking channel A.
j, k, l	The S1 leaves the pending state since channel A is not locked. It gets in the CPU again and starts executing. As it did receive a notification from channel A, it performs a channel read (as simple as lock, memory copy, unlock), continues its execution, and goes out the CPU.

HLP priority boost ZBus implements the Highest Locker Protocol that relies on the observers' thread priority to determine a temporary publisher priority. The protocol considers the channel's Highest Observer Priority (HOP); even if the observer is not waiting for a message on the channel, it is considered in the calculation. The VDED will elevate the publisher's priority based on the HOP to ensure small latency and as few preemptions as possible.

Note

The priority boost is enabled by default. To deactivate it, you must set the `CONFIG_ZBUS_PRIORITY_BOOST` configuration.

Warning

ZBus priority boost does not consider runtime observers on the HOP calculations.

The figure below illustrates the actions performed during the VDED execution when T1 publishes to channel A. The scenario considers the priority boost feature and the following priorities: T1 < MS1 < MS2 < S1.

To properly use the priority boost, attaching the observer to a thread is necessary. When the subscriber is attached to a thread, it assumes its priority, and the priority boost algorithm will consider the observer's priority. The following code illustrates the thread-attaching function.

```
ZBUS_SUBSCRIBER_DEFINE(s1, 4);
void s1_thread(void *ptr1, void *ptr2, void *ptr3)
{
        ARG_UNUSED(ptr1);
        ARG_UNUSED(ptr2);
        ARG_UNUSED(ptr3);

        const struct zbus_channel *chan;
```

(continues on next page)

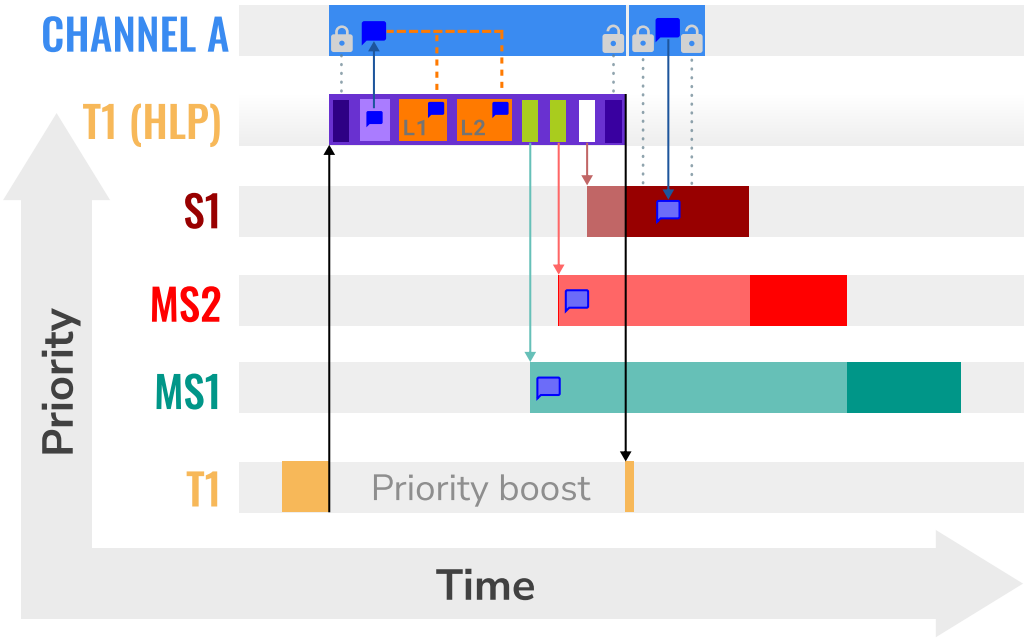

Fig. 33: ZBus VDED execution detail with priority boost enabled and for priority T1 < MS1 < MS2 < S1.

(continued from previous page)

```
        zbus_obs_attach_to_thread(&s1);

        while (1) {
                zbus_sub_wait(&s1, &chan, K_FOREVER);

                /* Subscriber implementation */

        }
}
K_THREAD_DEFINE(s1_id, CONFIG_MAIN_STACK_SIZE, s1_thread, NULL, NULL, NULL, 2, 0,␣
↪0);
```

On the above code, the `zbus_obs_attach_to_thread()` will set the s1 observer with priority two as the thread has that priority. It is possible to reverse that by detaching the observer using the `zbus_obs_detach_from_thread()`. Only enabled observers and observations will be considered on the channel HOP calculation. Masking a specific observation of a channel will affect the channel HOP.

In summary, the benefits of the feature are:

- The HLP is more effective for zbus than the mutexes priority inheritance;
- No bounded priority inversion will happen among the publisher and the observers;
- No other threads (that are not involved in the communication) with priority between T1 and S1 can preempt T1, avoiding unbounded priority inversion;
- Message subscribers will wait for the VDED to finish the message delivery process. So the VDED execution will be faster and more consistent;
- The HLP priority is dynamic and can change in execution;
- ZBus operations can be used inside ISRs;
- The priority boosting feature can be turned off, and plain semaphores can be used as the

channel lock mechanism;

- The Highest Locker Protocol's major disadvantage, the Inheritance-related Priority Inversion, is acceptable in the zbus scenario since it will ensure a small bus latency.

Limitations

Based on the fact that developers can use zbus to solve many different problems, some challenges arise. ZBus will not solve every problem, so it is necessary to analyze the situation to be sure zbus is applicable. For instance, based on the zbus benchmark, it would not be well suited to a high-speed stream of bytes between threads. The *Pipe* kernel object solves this kind of need.

Delivery guarantees ZBus always delivers the messages to the listeners, message subscribers, and async listeners. However, there are no message delivery guarantees for subscribers because zbus only sends the notification, but the message reading depends on the subscriber's implementation. It is possible to increase the delivery rate by following design tips:

- Keep the listeners as quick as possible (deal with them as ISRs). If time-consuming processing is required, consider offloading some or all of it to a work queue using async listeners.
- Try to give consumers a high priority to avoid losses.
- Leave spare CPU for observers to consume data produced.
- Consider using message queues or pipes for intensive byte transfers.

Warning

ZBus uses include/zephyr/net_buf.h (network buffers) to exchange data with message subscribers. Thus, choose carefully the configurations `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_SIZE` and `CONFIG_HEAP_MEM_POOL_ADD_SIZE_ZBUS` are crucial to a proper VDED execution (delivery guarantee) considering message subscribers and async listeners. If you want to keep an isolated pool for a specific set of channels, you can use `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_ISOLATION` with a dedicated pool. Look at the zbus-msg-subscriber and zbus-async-listeners to see the isolation in action.

Warning

Subscribers will receive only the reference of the changing channel. A data loss may be perceived if the channel is published twice before the subscriber reads it. The second publication overwrites the value from the first. Thus, the subscriber will receive two notifications, but only the last data is there.

Message delivery sequence The message delivery will follow the precedence:

1. Observers defined in a channel using the `ZBUS_CHAN_DEFINE` (following the definition sequence);
2. Observers defined using the `ZBUS_CHAN_ADD_OBS` based on the sequence priority (parameter of the macro);
3. The latest is the runtime observers in the addition sequence using the `zbus_chan_add_obs()`.

Note

The VDED will ignore all disabled observers or observations.

4.37.2 Usage

ZBus operation depends on channels and observers. Therefore, it is necessary to determine the channel's message during the channel definition and its list of observers, which can be either statically (in the channel definition), using the ZBUS_CHAN_ADD_OBS or at runtime (see *runtime observers*). A message is a regular C struct; the observer can be a listener (synchronous), an async listener (asynchronous), a subscriber (asynchronous), or a message subscriber (asynchronous).

The following code defines and initializes a regular channel and its dependencies. This channel exchanges accelerometer data, for example.

```
struct acc_msg {
        int x;
        int y;
        int z;
};

ZBUS_CHAN_DEFINE(acc_chan,                              /* Name */
         struct acc_msg,                                /* Message type */

         NULL,                                          /* Validator */
         NULL,                                          /* User Data */
         ZBUS_OBSERVERS(my_listener, my_subscriber,
                        my_msg_subscriber),             /* observers */
         ZBUS_MSG_INIT(.x = 0, .y = 0, .z = 0)          /* Initial value */
);

void listener_callback_example(const struct zbus_channel *chan)
{
        const struct acc_msg *acc;
        if (&acc_chan == chan) {
                acc = zbus_chan_const_msg(chan); // Direct message access
                LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y,␣
↪acc->z);
        }
}

ZBUS_LISTENER_DEFINE(my_listener, listener_callback_example);

ZBUS_LISTENER_DEFINE(my_listener2, listener_callback_example);

ZBUS_CHAN_ADD_OBS(acc_chan, my_listener2, 3);

ZBUS_SUBSCRIBER_DEFINE(my_subscriber, 4);
void subscriber_task(void)
{
        const struct zbus_channel *chan;

        while (!zbus_sub_wait(&my_subscriber, &chan, K_FOREVER)) {
                struct acc_msg acc = {0};

                if (&acc_chan == chan) {
                        // Indirect message access
                        zbus_chan_read(&acc_chan, &acc, K_NO_WAIT);
                        LOG_DBG("From subscriber -> Acc x=%d, y=%d, z=%d", acc.x,␣
↪acc.y, acc.z);
                }
        }
```

(continues on next page)

(continued from previous page)

```
}
K_THREAD_DEFINE(subscriber_task_id, 512, subscriber_task, NULL, NULL, NULL, 3, 0,␣
↪0);

ZBUS_MSG_SUBSCRIBER_DEFINE(my_msg_subscriber);
static void msg_subscriber_task(void *ptr1, void *ptr2, void *ptr3)
{
        ARG_UNUSED(ptr1);
        ARG_UNUSED(ptr2);
        ARG_UNUSED(ptr3);
        const struct zbus_channel *chan;

        struct acc_msg acc = {0};

        while (!zbus_sub_wait_msg(&my_msg_subscriber, &chan, &acc, K_FOREVER)) {
                if (&acc_chan == chan) {
                        LOG_INF("From msg subscriber -> Acc x=%d, y=%d, z=%d",␣
↪acc.x, acc.y, acc.z);
                }
        }
}
K_THREAD_DEFINE(msg_subscriber_task_id, 1024, msg_subscriber_task, NULL, NULL,␣
↪NULL, 3, 0, 0);
```

It is possible to add static observers to a channel using the `ZBUS_CHAN_ADD_OBS`. We call that a post-definition static observer. The command enables us to indicate an initialization priority that affects the observers' initialization order. The sequence priority param only affects the post-definition static observers. There is no possibility to overwrite the message delivery sequence of the static observers.

Note

It is unnecessary to claim/lock a channel before accessing the message inside the listener since the event dispatcher calls listeners with the notifying channel already locked. Subscribers, however, must claim/lock that or use regular read operations to access the message after being notified.

Channels can have a *validator function* that enables a channel to accept only valid messages. Publish attempts invalidated by hard channels will return immediately with an error code. This allows original creators of a channel to exert some authority over other developers/publishers who may want to piggy-back on their channels. The following code defines and initializes a *hard channel* and its dependencies. Only valid messages can be published to a *hard channel*. It is possible because a *validator function* was passed to the channel's definition. In this example, only messages with `move` equal to 0, -1, and 1 are valid. Publish function will discard all other values to `move`.

```
struct control_msg {
        int move;
};

bool control_validator(const void* msg, size_t msg_size) {
        const struct control_msg* cm = msg;
        bool is_valid = (cm->move == -1) || (cm->move == 0) || (cm->move == 1);
        return is_valid;
}
```

(continues on next page)

(continued from previous page)

```
static int message_count = 0;

ZBUS_CHAN_DEFINE(control_chan,    /* Name */
         struct control_msg,      /* Message type */

         control_validator,       /* Validator */
         &message_count,          /* User data */
         ZBUS_OBSERVERS_EMPTY,    /* observers */
         ZBUS_MSG_INIT(.move = 0) /* Initial value */
);
```

The following sections describe in detail how to use zbus features.

Publishing to a channel

Messages are published to a channel in zbus by calling `zbus_chan_pub()`. For example, the following code builds on the examples above and publishes to channel `acc_chan`. The code is trying to publish the message `acc1` to channel `acc_chan`, and it will wait up to one second for the message to be published. Otherwise, the operation fails. As can be inferred from the code sample, it's OK to use stack allocated messages since VDED copies the data internally.

```
struct acc_msg acc1 = {.x = 1, .y = 1, .z = 1};
zbus_chan_pub(&acc_chan, &acc1, K_SECONDS(1));
```

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

Reading from a channel

Messages are read from a channel in zbus by calling `zbus_chan_read()`. So, for example, the following code tries to read the channel `acc_chan`, which will wait up to 500 milliseconds to read the message. Otherwise, the operation fails.

```
struct acc_msg acc = {0};
zbus_chan_read(&acc_chan, &acc, K_MSEC(500));
```

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

Warning

Choose the timeout of `zbus_chan_read()` after receiving a notification from `zbus_sub_wait()` carefully because the channel will always be unavailable during the VDED execution. Using `K_NO_WAIT` for reading is highly likely to return a timeout error if there are more than one subscriber. For example, consider the VDED illustration again and notice how `S1` read attempts would definitely fail with K_NO_WAIT. For more details, check the *Virtual Distributed Event Dispatcher* section.

Notifying a channel

It is possible to force zbus to notify a channel's observers by calling `zbus_chan_notify()`. For example, the following code builds on the examples above and forces a notification for the channel `acc_chan`. Note this can send events with no message, which does not require any data exchange. See the code example under *Claim and finish a channel* where this may become useful.

```
zbus_chan_notify(&acc_chan, K_NO_WAIT);
```

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

Declaring channels and observers

For accessing channels or observers from files other than its defining files, it is necessary to declare them by calling `ZBUS_CHAN_DECLARE` and `ZBUS_OBS_DECLARE`. In other words, zbus channel definitions and declarations with the same channel names in different files would point to the same (global) channel. Thus, developers should be careful about existing channels, and naming new channels or linking will fail. It is possible to declare more than one channel or observer on the same call. The following code builds on the examples above and displays the defined channels and observers.

```
ZBUS_OBS_DECLARE(my_listener, my_subscriber);
ZBUS_CHAN_DECLARE(acc_chan, version_chan);
```

Unique channel identifiers To simplify integrations with external entities, it is possible to assign a unique numeric identifier to a channel. Users can then retrieve the channel reference by using the identifier with `zbus_chan_from_id()`, rather than needing to obtain the reference at compile time with `ZBUS_CHAN_DECLARE`. Channels using this feature are declared with `ZBUS_CHAN_DEFINE_WITH_ID()`.

```
ZBUS_CHAN_DEFINE_WITH_ID(control_chan,    /* Name */
    0x12345678,              /* Unique channel identifier */
    struct control_msg,      /* Message type */
    control_validator,       /* Validator */
    &message_count,          /* User data */
    ZBUS_OBSERVERS_EMPTY,    /* observers */
    ZBUS_MSG_INIT(.move = 0) /* Initial value */
);

static void channel_retrieve(void)
{
    const struct zbus_channel *chan = zbus_chan_from_id(0x12345678);

    ...
}
```

Iterating over channels and observers

ZBus subsystem also implements *Iterable Sections* for channels and observers, for which there are supporting APIs like `zbus_iterate_over_channels()`, `zbus_iterate_over_channels_with_user_data()`, `zbus_iterate_over_observers()` and `zbus_iterate_over_observers_with_user_data()`. This feature enables developers to call a procedure over all declared channels, where the procedure parameter is a `zbus_channel`.

The execution sequence is in the alphabetical name order of the channels (see *Iterable Sections* documentation for details). ZBus also implements this feature for `zbus_observer`.

```
static bool print_channel_data_iterator(const struct zbus_channel *chan, void␣
↪*user_data)
{
	int *count = user_data;

	LOG_INF("%d - Channel %s:", *count, zbus_chan_name(chan));
	LOG_INF("	Message size: %d", zbus_chan_msg_size(chan));
	LOG_INF("	Observers:");

	++(*count);

	struct zbus_channel_observation *observation;

	for (int16_t i = *chan->observers_start_idx, limit = *chan->
↪observers_end_idx; i < limit;
		++i) {
		STRUCT_SECTION_GET(zbus_channel_observation, i, &observation);

		LOG_INF("	- %s", observation->obs->name);
	}

	struct zbus_observer_node *obs_nd, *tmp;

	SYS_SLIST_FOR_EACH_CONTAINER_SAFE(chan->observers, obs_nd, tmp, node) {
		LOG_INF("	- %s", obs_nd->obs->name);
	}

	return true;
}

static bool print_observer_data_iterator(const struct zbus_observer *obs, void␣
↪*user_data)
{
	int *count = user_data;

	LOG_INF("%d - %s %s", *count, obs->queue ? "Subscriber" : "Listener",␣
↪zbus_obs_name(obs));

	++(*count);

	return true;
}

int main(void)
{
	int count = 0;

	LOG_INF("Channel list:");

	zbus_iterate_over_channels_with_user_data(print_channel_data_iterator, &
↪count);

	count = 0;
```

(continues on next page)

(continued from previous page)

```
	LOG_INF("Observers list:");

	zbus_iterate_over_observers_with_user_data(print_observer_data_iterator, &
↪count);

	return 0;
}
```

The code will log the following output:

```
D: Channel list:
D: 0 - Channel acc_chan:
D:       Message size: 12
D:       Observers:
D:       - my_listener
D:       - my_subscriber
D: 1 - Channel version_chan:
D:       Message size: 4
D:       Observers:
D: Observers list:
D: 0 - Listener my_listener
D: 1 - Subscriber my_subscriber
```

Advanced channel control

ZBus was designed to be as flexible and extensible as possible. Thus, there are some features designed to provide some control and extensibility to the bus.

Listeners message access For performance purposes, listeners can access the receiving channel message directly since they already have the channel locked for it. To access the channel's message, the listener should use the `zbus_chan_const_msg()` because the channel passed as an argument to the listener function is a constant pointer to the channel. The const pointer return type tells developers not to modify the message.

```
void listener_callback_example(const struct zbus_channel *chan)
{
        const struct acc_msg *acc;
        if (&acc_chan == chan) {
                acc = zbus_chan_const_msg(chan); // Use this
                // instead of zbus_chan_read(chan, &acc, K_MSEC(200))
                // or zbus_chan_msg(chan)

                LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y,␣
↪acc->z);
        }
}
```

Async listeners message access Async listeners are implemented by utilizing the established message subscriber infrastructure. They are executed in a work queue context rather than in the publisher's context. When using the system work queue, the user will experience similar behavior to the regular listeners. Since the system work queue is, by default, a cooperative thread with a priority of -1, async listeners would run before all other application threads (usually preemptive) after the VDED execution.

Async listeners can access the receiving channel's message directly via the message copy reference passed to the callback. Be aware that the message copy is freed just after the async listener

execution. To access the channel's message, the async listener should only cast to the proper constant message format. The following example demonstrates how to access the message from an async listener.

```
static void async_listener_callback(const struct zbus_channel *chan, const void␣
↪*message)
{
        if (chan != &chan_event) {
                LOG_ERR("Unexpected channel");
                return;
        }

        const struct msg_event *msg = message;

        LOG_INF("From async listener -> Evt=%d | %s", msg->type,
                k_thread_name_get(k_current_get()));
}
```

User Data It is possible to pass custom data into the channel's `user_data` for various purposes, such as writing channel metadata. That can be achieved by passing a pointer to the channel definition macro's `user_data` field, which will then be accessible by others. Note that `user_data` is individual for each channel. Also, note that `user_data` access is not thread-safe. For thread-safe access to `user_data`, see the next section.

Claim and finish a channel To take more control over channels, two functions were added `zbus_chan_claim()` and `zbus_chan_finish()`. With these functions, it is possible to access the channel's metadata safely. When a channel is claimed, no actions are available to that channel. After finishing the channel, all the actions are available again.

Warning

Never change the fields of the channel struct directly. It may cause zbus behavior inconsistencies and scheduling issues.

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

The following code builds on the examples above and claims the `acc_chan` to set the `user_data` to the channel. Suppose we would like to count how many times the channels exchange messages. We defined the `user_data` to have the 32 bits integer. This code could be added to the listener code described above.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        int *message_counting = (int *) zbus_chan_user_data(&acc_chan);
        *message_counting += 1;
        zbus_chan_finish(&acc_chan);
}
```

The following code has the exact behavior of the code in *Publishing to a channel*.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        struct acc_msg *acc1 = (struct acc_msg *) zbus_chan_msg(&acc_chan);
        acc1.x = 1;
```

(continues on next page)

(continued from previous page)

```
        acc1.y = 1;
        acc1.z = 1;
        zbus_chan_finish(&acc_chan);
        zbus_chan_notify(&acc_chan, K_SECONDS(1));
}
```

The following code has the exact behavior of the code in *Reading from a channel*.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        const struct acc_msg *acc1 = (const struct acc_msg *) zbus_chan_const_msg(&
↪acc_chan);
        // access the acc_msg fields directly.
        zbus_chan_finish(&acc_chan);
}
```

Runtime observer registration It is possible to add observers to channels in runtime. Set the `CONFIG_ZBUS_RUNTIME_OBSERVERS` to enable the feature. This feature uses the heap to allocate the nodes dynamically, a memory slab to allocate the nodes statically, or user-provided nodes. It depends on the `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC`, which can be `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_DYNAMIC`, `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC`, and `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_NONE`. The dynamic is the default. When `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC` is enabled, you need to set the number of runtime observers you are going to use by setting the `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_POOL_SIZE` configuration. The following example illustrates the runtime registration usage.

```
ZBUS_LISTENER_DEFINE(my_listener, callback);
// ...
void thread_entry(void) {
        // ...
        /* Adding the observer to channel chan1 */
        zbus_chan_add_obs(&chan1, &my_listener, K_NO_WAIT);
        /* Removing the observer from channel chan1 */
        zbus_chan_rm_obs(&chan1, &my_listener, K_NO_WAIT);
```

Warning

The `zbus_observer_node` can only be reused in `zbus_chan_add_obs_with_node()` after removing the channel observer it was first associated with through `zbus_chan_rm_obs()`.

4.37.3 Samples

For a complete overview of zbus usage, take a look at the samples. There are the following samples available:

- zbus-hello-world illustrates the code used above in action;
- zbus-work-queue shows how to define and use different kinds of observers. Note there is an example of using a work queue instead of executing the listener as an execution option;
- zbus-msg-subscriber illustrates how to use message subscribers;
- zbus-async-listeners illustrates how to use async listeners;
- zbus-dyn-channel demonstrates how to use dynamically allocated exchanging data in zbus;
- zbus-uart-bridge shows an example of sending the operation of the channel to a host via serial;

- zbus-remote-mock illustrates how to implement an external mock (on the host) to send and receive messages to and from the bus;
- zbus-priority-boost illustrates zbus priority boost feature with a priority inversion scenario;
- zbus-runtime-obs-registration illustrates a way of using the runtime observer registration feature;
- zbus-confirmed-channel implements a way of implement confirmed channel only with subscribers;
- zbus-benchmark implements a benchmark with different combinations of inputs.

4.37.4 Suggested Uses

Use zbus to transfer data (messages) between threads in one-to-one, one-to-many, and many-to-many synchronously or asynchronously. Choosing the proper observer type is crucial. Use subscribers for scenarios that can tolerate message losses and duplications; when they cannot, use message subscribers (if you need a thread) or listeners (if you need to be lean and fast). In addition to the listener, another asynchronous message processing mechanism (like *message queues*) may be necessary to retain the pending message until it gets processed.

Note

ZBus can be used to transfer streams from the producer to the consumer. However, this can increase zbus' communication latency. So maybe consider a Pipe a good alternative for this communication topology.

4.37.5 Configuration Options

For enabling zbus, it is necessary to enable the `CONFIG_ZBUS` option.

Related configuration options:

- `CONFIG_ZBUS_PRIORITY_BOOST` zbus Highest Locker Protocol implementation;
- `CONFIG_ZBUS_CHANNELS_SYS_INIT_PRIORITY` determine the `SYS_INIT` priority used by zbus to organize the channels observations by channel;
- `CONFIG_ZBUS_CHANNEL_NAME` enables the name of channels to be available inside the channels metadata. The log uses this information to show the channels' names;
- `CONFIG_ZBUS_OBSERVER_NAME` enables the name of observers to be available inside the channels metadata;
- `CONFIG_ZBUS_PREFER_DYNAMIC_ALLOCATION` instructs zbus to use dynamic allocation for its internals. That can be disabled by the user and tuned later;
- `CONFIG_ZBUS_MSG_SUBSCRIBER` enables the message subscriber observer type;
- `CONFIG_ZBUS_MSG_SUBSCRIBER_BUF_ALLOC_DYNAMIC` uses the heap to allocate message buffers;
- `CONFIG_ZBUS_MSG_SUBSCRIBER_BUF_ALLOC_STATIC` uses the stack to allocate message buffers;
- `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_SIZE` the available number of message buffers to be used simultaneously;
- `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_ISOLATION` enables the developer to isolate a pool for the message subscriber for a set of channels;
- `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_STATIC_DATA_SIZE` the biggest message of zbus channels to be transported into a message buffer;

- CONFIG_HEAP_MEM_POOL_ADD_SIZE_ZBUS the reserved heap size for ZBus in a whole including message buffer allocation;
- CONFIG_ZBUS_ASYNC_LISTENER enables the async listener observer type;
- CONFIG_ZBUS_RUNTIME_OBSERVERS enables the runtime observer registration;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_DYNAMIC allocate the runtime observers dynamically using the heap;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC allocate the runtime observers statically using a memory slab;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_POOL_SIZE the amount of enabled runtime observers to statically allocate.
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_NONE use user-provided runtime observers nodes;

Chapter 5

Build and Configuration Systems

5.1 Build System (CMake)

CMake is used to build your application together with the Zephyr kernel. A CMake build is done in two stages. The first stage is called **configuration**. During configuration, the CMakeLists.txt build scripts are executed. After configuration is finished, CMake has an internal model of the Zephyr build, and can generate build scripts that are native to the host platform.

CMake supports generating scripts for several build systems, but only Ninja and Make are tested and supported by Zephyr. After configuration, you begin the **build** stage by executing the generated build scripts. These build scripts can recompile the application without involving CMake following most code changes. However, after certain changes, the configuration step must be executed again before building. The build scripts can detect some of these situations and reconfigure automatically, but there are cases when this must be done manually.

Zephyr uses CMake's concept of a 'target' to organize the build. A target can be an executable, a library, or a generated file. For application developers, the library target is the most important to understand. All source code that goes into a Zephyr build does so by being included in a library target, even application code.

Library targets have source code, that is added through CMakeLists.txt build scripts like this:

```
target_sources(app PRIVATE src/main.c)
```

In the above `CMakeLists.txt`, an existing library target named `app` is configured to include the source file `src/main.c`. The `PRIVATE` keyword indicates that we are modifying the internals of how the library is being built. Using the keyword `PUBLIC` would modify how other libraries that link with app are built. In this case, using `PUBLIC` would cause libraries that link with `app` to also include the source file `src/main.c`, behavior that we surely do not want. The `PUBLIC` keyword could however be useful when modifying the include paths of a target library.

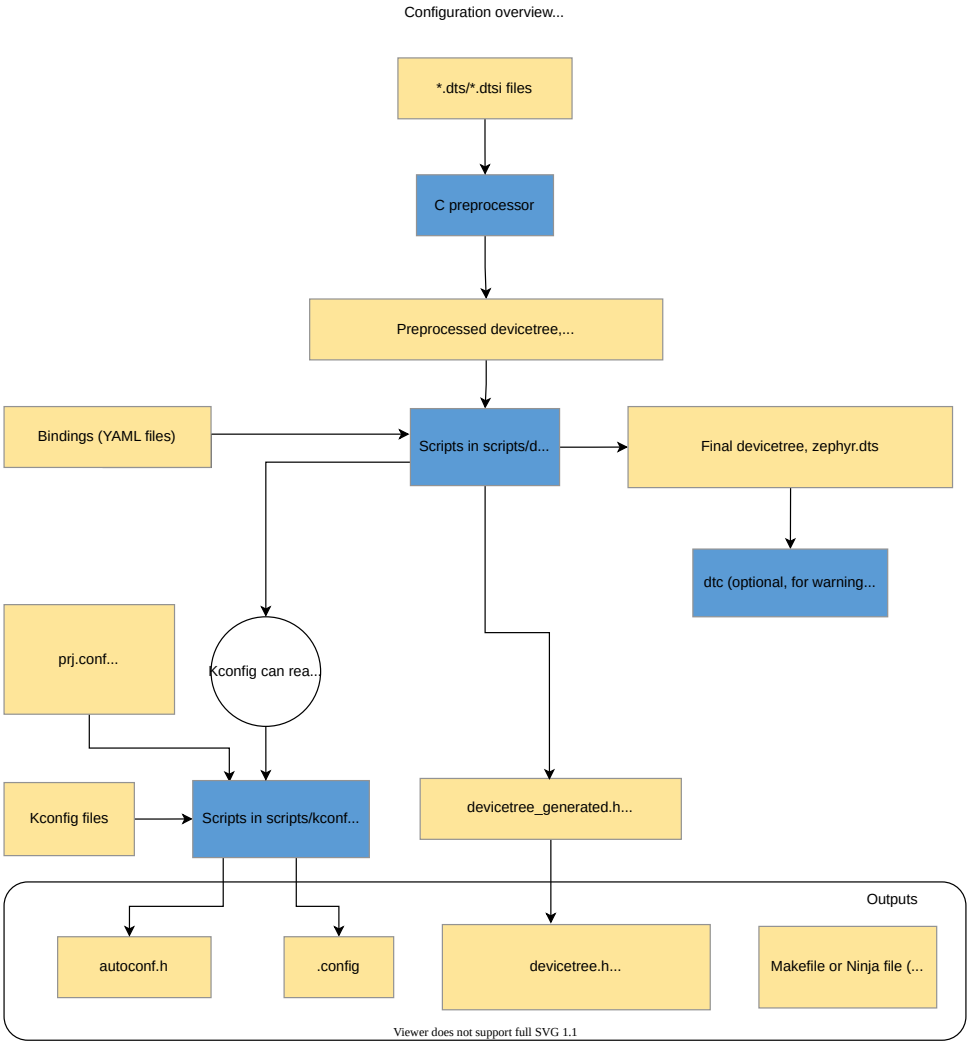
When introducing build system code using CMake or adding new CMake files, please follow the style guidelines outlined *here*.

5.1.1 Build and Configuration Phases

The Zephyr build process can be divided into two main phases: a configuration phase (driven by CMake) and a build phase (driven by Make or Ninja).

Configuration Phase

The configuration phase begins when the user invokes *CMake* to generate a build system, specifying a source application directory and a board target.



Configuration overview...
.dts/.dtsi files
C preprocessor
Preprocessed devicetree,...
Bindings (YAML files)
Scripts in scripts/d...
Final devicetree, zephyr.dts
dtc (optional, for warning...
prj.conf...

Kconfig files
Scripts in scripts/kconf...
devicetree_generated.h...
Outputs
autoconf.h
.config
devicetree.h...
Makefile or Ninja file (...
Viewer does not support full SVG 1.1

CMake begins by processing the `CMakeLists.txt` file in the application directory, which refers to the `CMakeLists.txt` file in the Zephyr top-level directory, which in turn refers to `CMakeLists.txt` files throughout the build tree (directly and indirectly). Its primary output is a set of Makefiles or Ninja files to drive the build process, but the CMake scripts also do some processing of their own, which is explained here.

Note that paths beginning with `build/` below refer to the build directory you create when running CMake.

Devicetree
: `*.dts` (*devicetree source*) and `*.dtsi` (*devicetree source include*) files are collected from the target's architecture, SoC, board, and application directories.

  `*.dtsi` files are included by `*.dts` files via the C preprocessor (often abbreviated *cpp*, which should not be confused with C++). The C preprocessor is also used to merge in any devicetree `*.overlay` files, and to expand macros in `*.dts`, `*.dtsi`, and `*.overlay` files. The preprocessor output is placed in `build/zephyr/zephyr.dts.pre`.

  The preprocessed devicetree sources are parsed by gen_defines.py to generate a `build/zephyr/include/generated/zephyr/devicetree_generated.h` header with preprocessor macros.

  Source code should access preprocessor macros generated from devicetree by including the devicetree.h header, which includes `devicetree_generated.h`.

  `gen_defines.py` also writes the final devicetree to `build/zephyr/zephyr.dts` in the build directory. This file's contents may be useful for debugging.

  If the devicetree compiler `dtc` is installed, it is run on `build/zephyr/zephyr.dts` to catch any extra warnings and errors generated by this tool. The output from `dtc` is unused otherwise, and this step is skipped if `dtc` is not installed.

  The above is just a brief overview. For more information on devicetree, see *Devicetree Guide*.

Kconfig
: `Kconfig` files define available configuration options for the target architecture, SoC, board, and application, as well as dependencies between options.

  Kconfig configurations are stored in *configuration files*. The initial configuration is generated by merging configuration fragments from the board and application (e.g. `prj.conf`).

  The output from Kconfig is an `autoconf.h` header with preprocessor assignments, and a `.config` file that acts both as a saved configuration and as configuration output (used by CMake). The definitions in `autoconf.h` are automatically exposed at compile time, so there is no need to include this header.

  Information from devicetree is available to Kconfig, through the functions defined in kconfigfunctions.py.

  See *the Kconfig section of the manual* for more information.

Build Phase

The build phase begins when the user invokes `make` or `ninja`. Its ultimate output is a complete Zephyr application in a format suitable for loading/flashing on the desired target board (`zephyr.elf`, `zephyr.hex`, etc.) The build phase can be broken down, conceptually, into four stages: the pre-build, first-pass binary, final binary, and post-processing.

Pre-build Pre-build occurs before any source files are compiled, because during this phase header files used by the source files are generated.

Build-time constants generation
: Some constants must be derived from C struct layouts at build time rather than hard-coded. The CMake function `zephyr_constants_library()` automates this: it compiles a C

source file containing `GEN_ABSOLUTE_SYM()` declarations into an OBJECT library, then runs `gen_offset_header.py` to extract symbols ending in `_OFFSET` or `_SIZEOF` and emit them as `#define` lines in a generated header under `include/generated/zephyr/`.

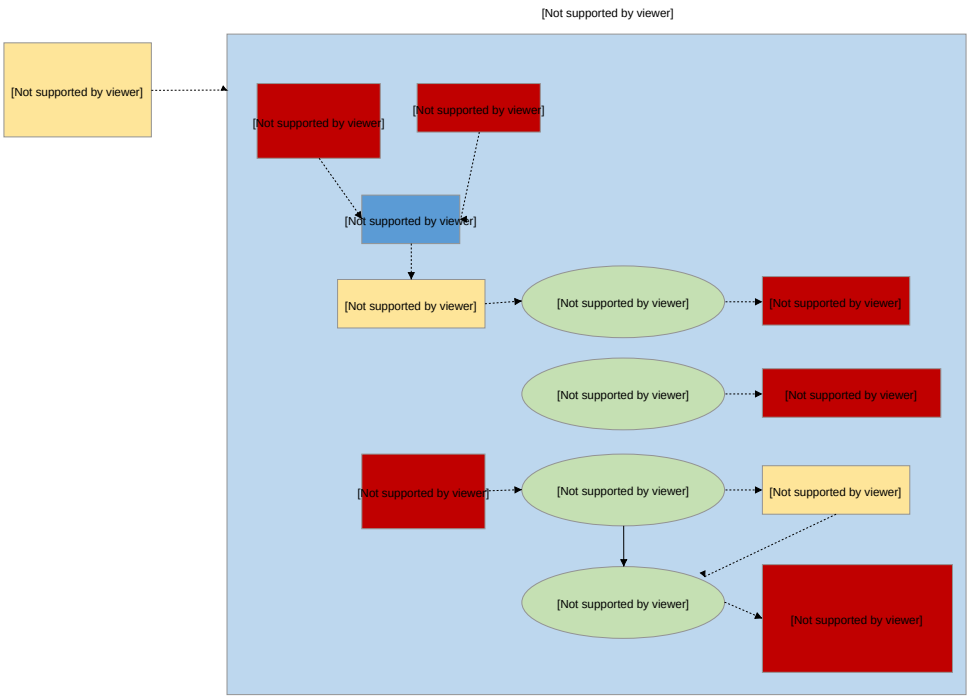
This mechanism is used in two places:

- **offsets.h**: Architecture-specific offsets for assembly code that needs access to high-level data structures when the definitions of those structures are not immediately accessible. The source file is `arch/<arch>/core/offsets/offsets.c`.
- **heap_constants.h**: Heap sizing constants (`Z_HEAP_MIN_SIZE`, `Z_HEAP_MIN_SIZE_FOR`) computed from actual heap struct layouts, replacing previously hardcoded values in `kernel.h`. The source file is `lib/heap/heap_constants.c`.

To add new build-time constants, create a C source file that includes `<gen_offset.h>` and uses `GEN_ABSOLUTE_SYM()` to declare each constant, then call `zephyr_constants_library()` from your `CMakeLists.txt`. If the new library's source includes a header generated by another constants library, use the `DEPENDS` parameter to declare that ordering (e.g., `DEPENDS heap_constants`). The resulting OBJECT library can also be linked into the final binary (as offsets.h does via `$<TARGET_OBJECTS:offsets>` in linker scripts).

System call boilerplate

The *gen_syscall.py* and *parse_syscalls.py* scripts work together to bind potential system call functions with their implementations.



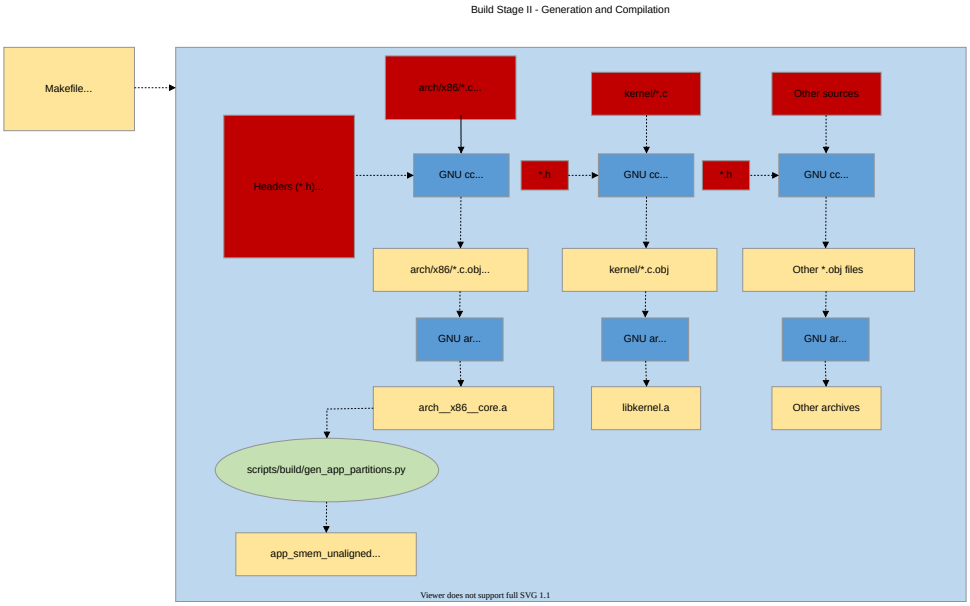
Intermediate binaries Compilation proper begins with the first intermediate binary. Source files (C and assembly) are collected from various subsystems (which ones is decided during the configuration phase), and compiled into archives (with reference to header files in the tree, as well as those generated during the configuration phase and the pre-build stage(s)).

The exact number of intermediate binaries is decided during the configuration phase.

If memory protection is enabled, then:

Partition grouping

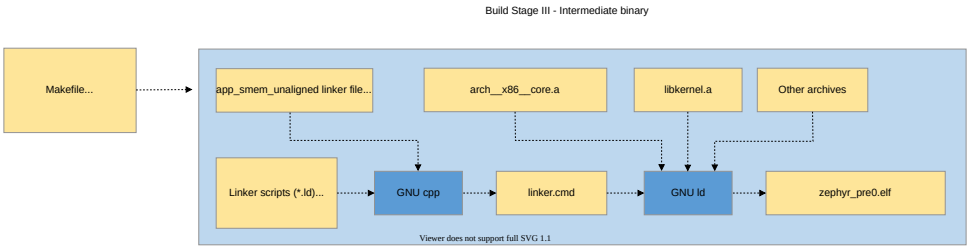
The *gen_app_partitions.py* script scans all the generated archives and outputs linker scripts to ensure that application partitions are properly grouped and aligned for the target's memory protection hardware.



Then *cpp* is used to combine linker script fragments from the target's architecture/SoC, the kernel tree, optionally the partition output if memory protection is enabled, and any other fragments selected during the configuration process, into a *linker.cmd* file. The compiled archives are then linked with *ld* as specified in the *linker.cmd*.

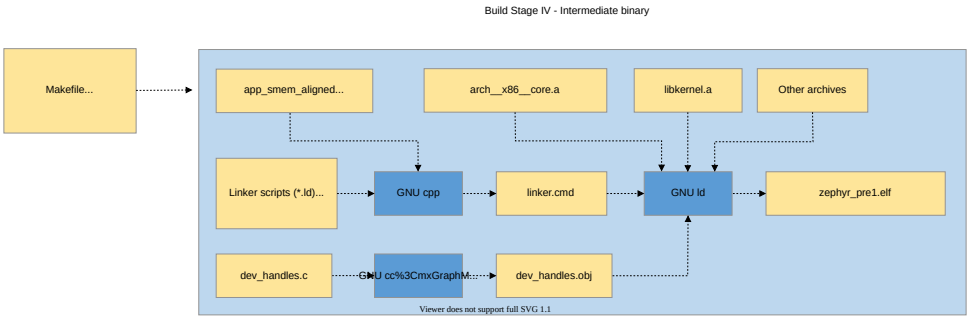
Unfixed size binary

The unfixed size intermediate binary is produced when *User Mode* is enabled or *Devicetree* is in use. It produces a binary where sizes are not fixed and thus it may be used by post-process steps that will impact the size of the final binary.



Fixed size binary

The fixed size intermediate binary is produced when *User Mode* is enabled or when generated IRQ tables are used, `CONFIG_GEN_ISR_TABLES` It produces a binary where sizes are fixed and thus the size must not change between the intermediate binary and the final binary.

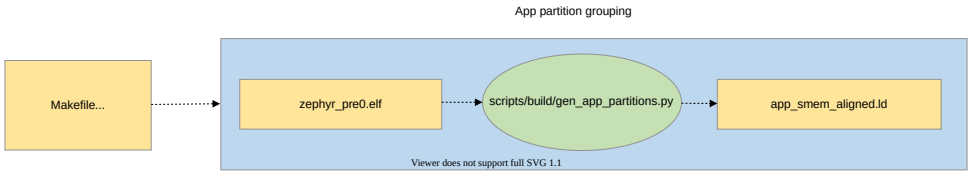


Intermediate binaries post-processing The binaries from the previous stage are incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

To complete the build procedure the following scripts are executed on the intermediate binaries to produce the missing pieces needed for the final binary.

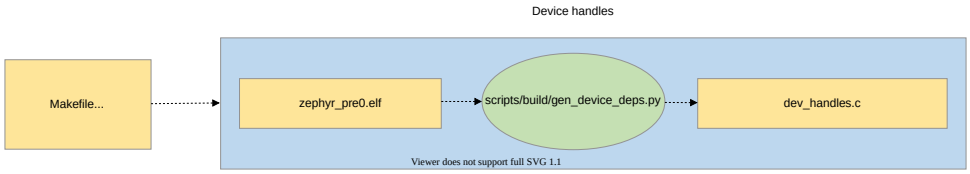
When *User Mode* is enabled:

Partition alignment
: The *gen_app_partitions.py* script scans the unfixed size binary and generates an app shared memory aligned linker script snippet where the partitions are sorted in descending order.

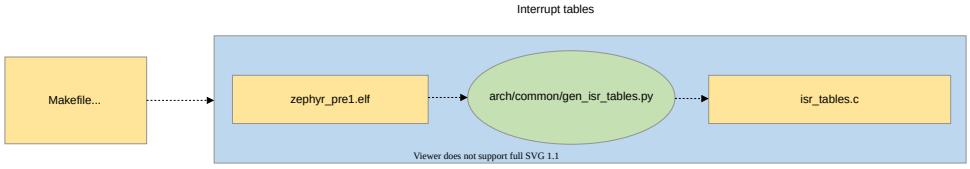


When *Devicetree* is used:

Device dependencies
: The *gen_device_deps.py* script scans the unfixed size binary to determine relationships between devices that were recorded from devicetree data, and replaces the encoded relationships with values that are optimized to locate the devices actually present in the application.



When `CONFIG_GEN_ISR_TABLES` is enabled:
: The *gen_isr_tables.py* script scans the fixed size binary and creates an isr_tables.c source file with a hardware vector table and/or software IRQ table.



When *User Mode* is enabled:

Kernel object hashing
: The *gen_kobject_list.py* scans the *ELF DWARF* debug data to find the address of the all kernel objects. This list is passed to *gperf*, which generates a perfect hash function and table of those addresses, then that output is optimized by *process_gperf.py*, using known properties of our special case.

When no intermediate binary post-processing is required then the first intermediate binary will be directly used as the final binary.

Final binary The binary from the previous stage is incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

The link from the previous stage is repeated, this time with the missing pieces populated.

Post processing Finally, if necessary, the completed kernel is converted from *ELF* to the format expected by the loader and/or flash tool required by the target. This is accomplished in a straightforward manner with *objdump*.

5.1.2 Supporting Scripts and Tools

The following is a detailed description of the scripts used during the build process.

scripts/build/gen_syscalls.py

Script to generate system call invocation macros

This script parses the system call metadata JSON file emitted by parse_syscalls.py to create several files:

- A file containing weak aliases of any potentially unimplemented system calls, as well as the system call dispatch table, which maps system call type IDs to their handler functions.
- A header file defining the system call type IDs, as well as function prototypes for all system call handler functions.
- A directory containing header files. Each header corresponds to a header that was identified as containing system call declarations. These generated headers contain the inline invocation functions for each system call in that header.

scripts/build/gen_device_deps.py

Translate generic handles into ones optimized for the application.

Immutable device data includes information about dependencies, e.g. that a particular sensor is controlled through a specific I2C bus and that it signals event on a pin on a specific GPIO controller. This information is encoded in the first-pass binary using identifiers derived from the devicetree. This script extracts those identifiers and replaces them with ones optimized for use with the devices actually present.

For example the sensor might have a first-pass handle defined by its devicetree ordinal 52, with the I2C driver having ordinal 24 and the GPIO controller ordinal 14. The runtime ordinal is the index of the corresponding device in the static devicetree array, which might be 6, 5, and 3, respectively.

The output is a C source file that provides alternative definitions for the array contents referenced from the immutable device objects. In the final link these definitions supersede the ones in the driver-specific object file.

scripts/build/gen_kobject_list.py

Script to generate gperf tables of kernel object metadata

User mode threads making system calls reference kernel objects by memory address, as the kernel/driver APIs in Zephyr are the same for both user and supervisor contexts. It is necessary for the kernel to be able to validate accesses to kernel objects to make the following assertions:

- That the memory address points to a kernel object
- The kernel object is of the expected type for the API being invoked
- The kernel object is of the expected initialization state
- The calling thread has sufficient permissions on the object

For more details see the *Kernel Objects* section in the documentation.

The zephyr build generates an intermediate ELF binary, zephyr_prebuilt.elf, which this script scans looking for kernel objects by examining the DWARF debug information to look for instances of data structures that are considered kernel objects. For device drivers, the API struct pointer populated at build time is also examined to disambiguate between various device driver instances since they are all 'struct device'.

This script can generate five different output files:

- A gperf script to generate the hash table mapping kernel object memory addresses to kernel object metadata, used to track permissions, object type, initialization state, and any object-specific data.
- A header file containing generated macros for validating driver instances inside the system call handlers for the driver subsystem APIs.
- A code fragment included by kernel.h with one enum constant for each kernel object type and each driver instance.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping the kernel object types and driver instances to their human-readable representation in the otype_to_str() function.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping kernel object types to their sizes. This is used for allocating instances of them at runtime (CONFIG_DYNAMIC_OBJECTS) in the obj_size_get() function.

scripts/build/gen_offset_header.py

This script scans a specified object file and generates a header file that defined macros for the offsets of various found structure members (particularly symbols ending with `_OFFSET` or `_SIZEOF`), primarily intended for use in assembly code.

scripts/build/parse_syscalls.py

Script to scan Zephyr include directories and emit system call and subsystem metadata

System calls require a great deal of boilerplate code in order to implement completely. This script is the first step in the build system's process of auto-generating this code by doing a text scan of directories containing C or header files, and building up a database of system calls and their function call prototypes. This information is emitted to a generated JSON file for further processing.

This script also scans for struct definitions such as __subsystem and __net_socket, emitting a JSON dictionary mapping tags to all the struct declarations found that were tagged with them.

If the output JSON file already exists, its contents are checked against what information this script would have outputted; if the result is that the file would be unchanged, it is not modified to prevent unnecessary incremental builds.

arch/x86/gen_idt.py

Generate Interrupt Descriptor Table for x86 CPUs.

This script generates the interrupt descriptor table (IDT) for x86. Please consult the IA Architecture SW Developer Manual, volume 3, for more details on this data structure.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the IDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols. From the kernel binary we read a special section "intList" which contains the desired interrupt routing configuration for the kernel, populated by instances of the IRQ_CONNECT() macro.

This script outputs three binary tables:

1. The interrupt descriptor table itself.
2. A bitfield indicating which vectors in the IDT are free for installation of dynamic interrupts at runtime.
3. An array which maps configured IRQ lines to their associated vector entries in the IDT, used to program the APIC at runtime.

arch/x86/gen_gdt.py

Generate a Global Descriptor Table (GDT) for x86 CPUs.

For additional detail on GDT and x86 memory management, please consult the IA Architecture SW Developer Manual, vol. 3.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the GDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols.

The input kernel ELF binary is used to obtain the following information:

- Memory addresses of the Main and Double Fault TSS structures so GDT descriptors can be created for them
- Memory addresses of where the GDT lives in memory, so that this address can be populated in the GDT pseudo descriptor
- whether userspace or HW stack protection are enabled in Kconfig

The output is a GDT whose contents depend on the kernel configuration. With no memory protection features enabled, we generate flat 32-bit code and data segments. If hardware- based stack overflow protection or userspace is enabled, we additionally create descriptors for the main and double- fault IA tasks, needed for userspace privilege elevation and double-fault handling. If userspace is enabled, we also create flat code/data segments for ring 3 execution.

scripts/build/gen_relocate_app.py

This script will relocate .text, .rodata, .data and .bss sections from required files and places it in the required memory region. This memory region and file are given to this python script in the form of a file. A regular expression filter can be applied to select only the required sections from the file.

Example of content in such an input file would be:

```
SRAM2:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,.*foo|.*bar
SRAM1:COPY:/home/xyz/zephyr/samples/hello_world/src/main2.c,.*bar
FLASH2:NOCOPY:/home/xyz/zephyr/samples/hello_world/src/main3.c,
```

One can also specify the program header for a given memory region:

SRAM2\ :phdr0:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,

To invoke this script:

```
python3 gen_relocate_app.py -i input_file -o generated_linker -c generated_code
```

Configuration that needs to be sent to the python script.

- If the memory is like SRAM1/SRAM2/CCD/AON then place full object in the sections
- If the memory type is appended with _DATA / _TEXT/ _RODATA/ _BSS only the selected memory is placed in the required memory region. Others are ignored.
- COPY/NOCOPY defines whether the script should generate the relocation code in code_relocation.c or not
- NOKEEP will suppress the default behavior of marking every relocated symbol with KEEP() in the generated linker script.

Multiple regions can be appended together like SRAM2_DATA_BSS this will place data and bss inside SRAM2.

scripts/build/process_gperf.py

gperf C file post-processor

We use gperf to build up a perfect hashtable of pointer values. The way gperf does this is to create a table 'wordlist' indexed by a string representation of a pointer address, and then doing memcmp() on a string passed in for comparison

We are exclusively working with 4-byte pointer values. This script adjusts the generated code so that we work with pointers directly and not strings. This saves a considerable amount of space.

scripts/build/gen_app_partitions.py

Script to generate a linker script organizing application memory partitions

Applications may declare build-time memory domain partitions with K_APPMEM_PARTITION_DEFINE, and assign globals to them using K_APP_DMEM or K_APP_BMEM macros. For each of these partitions, we need to route all their data into appropriately-sized memory areas which meet the size/alignment constraints of the memory protection hardware.

This linker script is created very early in the build process, before the build attempts to link the kernel binary, as the linker script this tool generates is a necessary pre-condition for kernel linking. We extract the set of memory partitions to generate by looking for variables which have been assigned to input sections that follow a defined naming convention. We also allow entire libraries to be pulled in to assign their globals to a particular memory partition via command line directives.

This script takes as inputs:

- The base directory to look for compiled objects
- key/value pairs mapping static library files to what partitions their globals should end up in.

The output is either a linker script fragment or linker-script generator fragments containing the definition of the app shared memory section, which is further divided, for each partition found, into data and BSS for each partition.

scripts/build/check_init_priorities.py

Checks the initialization priorities

This script parses a Zephyr executable file, creates a list of known devices and their effective initialization priorities and compares that with the device dependencies inferred from the devicetree hierarchy.

This can be used to detect devices that are initialized in the incorrect order, but also devices that are initialized at the same priority but depends on each other, which can potentially break if the linking order is changed.

Optionally, it can also produce a human readable list of the initialization calls for the various init levels.

5.2 Devicetree

A *devicetree* is a hierarchical data structure primarily used to describe hardware. Zephyr uses devicetree in two main ways:

- to describe hardware to the *Device Driver Model*
- to provide that hardware's initial configuration

This page links to a high level guide on devicetree as well as reference material.

5.2.1 Devicetree Guide

The pages in this section are a high-level guide to using devicetree for Zephyr development.

Introduction to devicetree

> **Tip**
>
> This is a conceptual overview of devicetree and how Zephyr uses it. For step-by-step guides and examples, see *Devicetree HOWTOs*.

The following pages introduce general devicetree concepts and how they apply to Zephyr.

Scope and purpose A *devicetree* is primarily a hierarchical data structure that describes hardware. The Devicetree specification defines its source and binary representations.

Zephyr uses devicetree to describe:

- the hardware available on its boards
- that hardware's initial configuration

As such, devicetree is both a hardware description language and a configuration language for Zephyr. See *Devicetree versus Kconfig* for some comparisons between devicetree and Zephyr's other main configuration language, Kconfig.

There are two types of devicetree input files: *devicetree sources* and *devicetree bindings*. The sources contain the devicetree itself. The bindings describe its contents, including data types. The *build system* uses devicetree sources and bindings to produce a generated C header. The generated header's contents are abstracted by the `devicetree.h` API, which you can use to get information from your devicetree.

Here is a simplified view of the process:

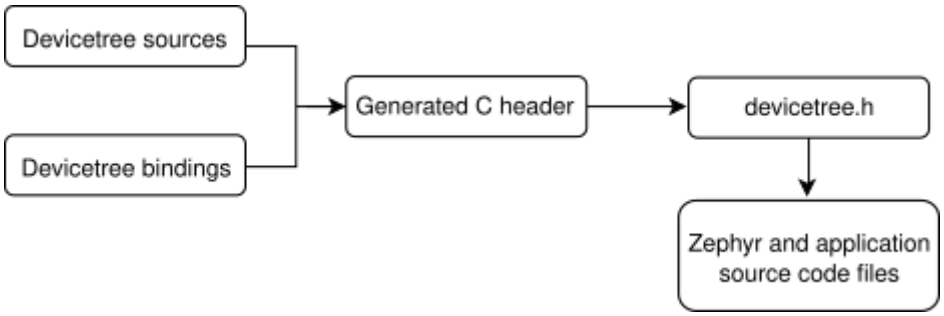

Fig. 1: Devicetree build flow

All Zephyr and application source code files can include and use `devicetree.h`. This includes *device drivers*, *applications*, *tests*, the kernel, etc.

The API itself is based on C macros. The macro names all start with `DT_`. In general, if you see a macro that starts with `DT_` in a Zephyr source file, it's probably a `devicetree.h` macro. The generated C header contains macros that start with `DT_` as well; you might see those in compiler error messages. You always can tell a generated- from a non-generated macro: generated macros have some lowercased letters, while the `devicetree.h` macro names have all capital letters.

Syntax and structure As the name indicates, a devicetree is a tree. The human-readable text format for this tree is called DTS (for devicetree source), and is defined in the Devicetree specification.

This page's purpose is to introduce devicetree in a more gradual way than the specification. However, you may still need to refer to the specification to understand some detailed cases.

Contents

- *Example*
- *Nodes*
- *Properties*
- *Devicetrees reflect hardware*
- *Properties in practice*
- *Unit addresses*
- *Important properties*
- *Writing property values*
- *Aliases and chosen nodes*

Example Here is an example DTS file:

```
/dts-v1/;

/ {
        a-node {
                subnode_nodelabel: a-sub-node {
                        foo = <3>;
                };
        };
};
```

The `/dts-v1/;` line means the file's contents are in version 1 of the DTS syntax, which has replaced a now-obsolete "version 0".

Nodes Like any tree data structure, a devicetree has a hierarchy of *nodes*. The above tree has three nodes:

1. A root node: `/`
2. A node named `a-node`, which is a child of the root node
3. A node named `a-sub-node`, which is a child of `a-node`

Nodes can be assigned *node labels*, which are unique shorthands that refer to the labeled node. Above, `a-sub-node` has the node label `subnode_nodelabel`. A node can have zero, one, or multiple node labels. You can use node labels to refer to the node elsewhere in the devicetree.

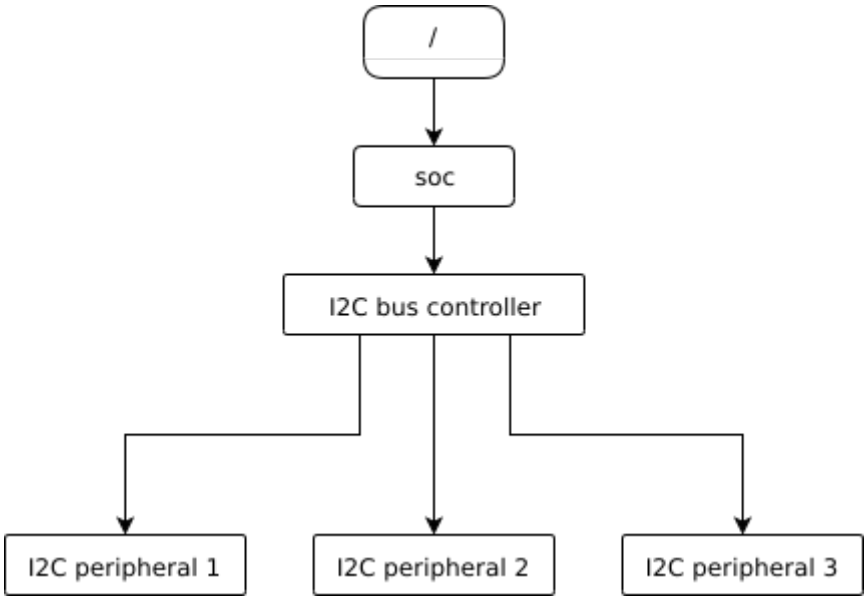
Devicetree nodes have *paths* identifying their locations in the tree. Like Unix file system paths, devicetree paths are strings separated by slashes (`/`), and the root node's path is a single slash: `/`. Otherwise, each node's path is formed by concatenating the node's ancestors' names with the node's own name, separated by slashes. For example, the full path to `a-sub-node` is `/a-node/a-sub-node`.

Properties Devicetree nodes can also have *properties*. Properties are name/value pairs. Property values can be any sequence of bytes. In some cases, the values are an array of what are called *cells*. A cell is just a 32-bit unsigned integer.

Node `a-sub-node` has a property named `foo`, whose value is a cell with value 3. The size and type of `foo`'s value are implied by the enclosing angle brackets (< and >) in the DTS.

See *Writing property values* below for more example property values.

Devicetrees reflect hardware In practice, devicetree nodes usually correspond to some hardware, and the node hierarchy reflects the hardware's physical layout. For example, let's consider a board with three I2C peripherals connected to an I2C bus controller on an SoC, like this:



Nodes corresponding to the I2C bus controller and each I2C peripheral would be present in the devicetree. Reflecting the hardware layout, the I2C peripheral nodes would be children of the bus controller node. Similar conventions exist for representing other types of hardware.

The DTS would look something like this:

```
/dts-v1/;

/ {
        soc {
                i2c-bus-controller {
                        i2c-peripheral-1 {
                        };
                        i2c-peripheral-2 {
                        };
                        i2c-peripheral-3 {
                        };
                };
        };
};
```

Properties in practice In practice, properties usually describe or configure the hardware the node represents. For example, an I2C peripheral's node has a property whose value is the peripheral's address on the bus.

Here's a tree representing the same example, but with real-world node names and properties you might see when working with I2C devices.

This is the corresponding DTS:

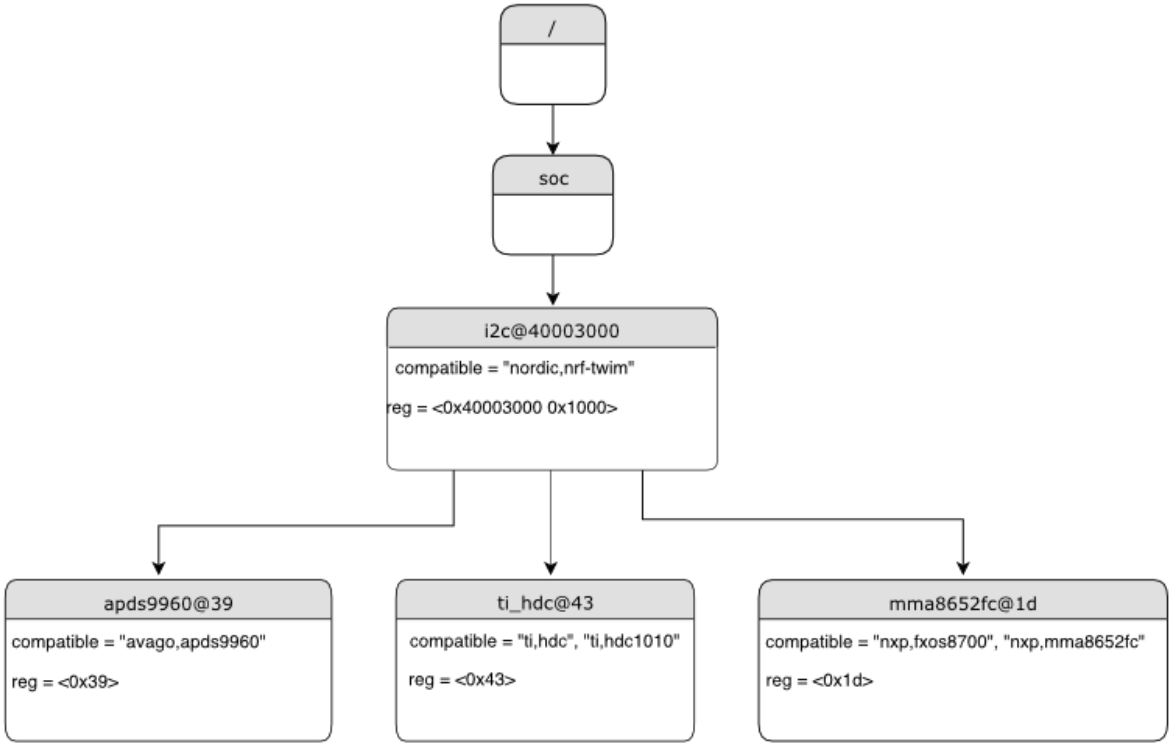


Fig. 2: I2C devicetree example with real-world names and properties. Node names are at the top of each node with a gray background. Properties are shown as "name=value" lines.

```
/dts-v1/;

/ {
        soc {
                i2c@40003000 {
                        compatible = "nordic,nrf-twim";
                        reg = <0x40003000 0x1000>;

                        apds9960@39 {
                                compatible = "avago,apds9960";
                                reg = <0x39>;
                        };
                        ti_hdc@43 {
                                compatible = "ti,hdc", "ti,hdc1010";
                                reg = <0x43>;
                        };
                        mma8652fc@1d {
                                compatible = "nxp,fxos8700", "nxp,mma8652fc";
                                reg = <0x1d>;
                        };
                };
        };
};
```

Unit addresses In addition to showing more real-world names and properties, the above example introduces a new devicetree concept: unit addresses. Unit addresses are the parts of node names after an "at" sign (`@`), like `40003000` in `i2c@40003000`, or `39` in `apds9960@39`. Unit addresses are optional: the `soc` node does not have one.

In devicetree, unit addresses give a node's address in the address space of its parent node. Here are some example unit addresses for different types of hardware.

Memory-mapped peripherals
: The peripheral's register map base address. For example, the node named `i2c@40003000` represents an I2C controller whose register map base address is 0x40003000.

I2C peripherals
: The peripheral's address on the I2C bus. For example, the child node `apds9960@39` of the I2C controller in the previous section has I2C address 0x39.

SPI peripherals
: An index representing the peripheral's chip select line number. (If there is no chip select line, 0 is used.)

Memory
: The physical start address. For example, a node named `memory@2000000` represents RAM starting at physical address 0x2000000.

Memory-mapped flash
: Like RAM, the physical start address. For example, a node named `flash@8000000` represents a flash device whose physical start address is 0x8000000.

Fixed flash partitions
: This applies when the devicetree is used to store a flash partition table. The unit address is the partition's start offset within the flash memory. For example, take this flash device and its partitions:

```
flash@8000000 {
    /* ... */
    partitions {
            partition@0 { /* ... */ };
            partition@20000 {  /* ... */ };
            /* ... */
    };
};
```

The node named `partition@0` has offset 0 from the start of its flash device, so its base address is 0x8000000. Similarly, the base address of the node named `partition@20000` is 0x8020000.

Important properties The devicetree specification defines several standard properties. Some of the most important ones are:

compatible
: The name of the hardware device the node represents.

The recommended format is `"vendor,device"`, like `"avago,apds9960"`, or a sequence of these, like `"ti,hdc", "ti,hdc1010"`. The `vendor` part is an abbreviated name of the vendor. The file dts/bindings/vendor-prefixes.txt contains a list of commonly accepted `vendor` names. The `device` part is usually taken from the datasheet.

It is also sometimes a value like `gpio-keys`, `mmio-sram`, or `fixed-clock` when the hardware's behavior is generic.

The build system uses the compatible property to find the right *bindings* for the node. Device drivers use `devicetree.h` to find nodes with relevant compatibles, in order to determine the available hardware to manage.

The `compatible` property can have multiple values. Additional values are useful when the device is a specific instance of a more general family, to allow the system to match from most- to least-specific device drivers.

Within Zephyr's bindings syntax, this property has type `string-array`.

reg
: Information used to address the device. The value is specific to the device (i.e. is different depending on the compatible property).

  The `reg` property is a sequence of `(address, length)` pairs. Each pair is called a "register block". Values are conventionally written in hex.

  Here are some common patterns:

  - Devices accessed via memory-mapped I/O registers (like `i2c@40003000`): `address` is usually the base address of the I/O register space, and `length` is the number of bytes occupied by the registers.
  - I2C devices (like `apds9960@39` and its siblings): `address` is a slave address on the I2C bus. There is no `length` value.
  - SPI devices: `address` is a chip select line number; there is no `length`.

  You may notice some similarities between the `reg` property and common unit addresses described above. This is not a coincidence. The `reg` property can be seen as a more detailed view of the addressable resources within a device than its unit address.

status
: A string which describes whether the node is enabled.

  The devicetree specification allows this property to have values `"okay"`, `"disabled"`, `"reserved"`, `"fail"`, and `"fail-sss"`. Only the values `"okay"` and `"disabled"` are currently relevant to Zephyr; use of other values currently results in undefined behavior.

  A node is considered enabled if its status property is either `"okay"` or not defined (i.e. does not exist in the devicetree source). Nodes with status `"disabled"` are explicitly disabled. Devicetree nodes which correspond to physical devices must be enabled for the corresponding `struct device` in the Zephyr driver model to be allocated and initialized.

  Note that a child node is not implicitly disabled when its parent node is disabled, i.e. child nodes should be disabled explicitly if desired.

interrupts
: Information about interrupts generated by the device, encoded as an array of one or more *interrupt specifiers*. Each interrupt specifier has some number of cells. See section 2.4, *Interrupts and Interrupt Mapping*, in the Devicetree Specification release v0.3 for more details.

  Zephyr's devicetree bindings language lets you give a name to each cell in an interrupt specifier.

> **Note**
>
> Earlier versions of Zephyr made frequent use of the `label` property, which is distinct from the standard *node label*. Use of the label *property* in new devicetree bindings, as well as use of the `DT_LABEL` macro in new code, are actively discouraged. Label properties continue to persist for historical reasons in some existing bindings and overlays, but should not be used in new bindings or device implementations.

Writing property values This section describes how to write property values in DTS format. The property types in the table below are described in detail in *Devicetree bindings*.

Some specifics are skipped in the interest of keeping things simple; if you're curious about details, see the devicetree specification.

Property type	How to write	Example
string	Double quoted	`a-string = "hello, world!";`
int	between angle brackets (< and >)	`an-int = <1>;`
boolean	for `true`, with no value (for `false`, use `/delete-property/`)	`my-true-boolean;`
array	between angle brackets (< and >), separated by spaces	`foo = <0xdeadbeef 1234 0>;`
uint8-array	in hexadecimal *without* leading `0x`, between square brackets (`[` and `]`).	`a-byte-array = [00 01 ab];`
string-array	separated by commas	`a-string-array = "string one", "string two", "string three";`
phandle	between angle brackets (< and >)	`a-phandle = <&mynode>;`
phandles	between angle brackets (< and >), separated by spaces	`some-phandles = <&mynode0 &mynode1 &mynode2>;`
phandle-array	between angle brackets (< and >), separated by spaces	`a-phandle-array = <&mynode0 1 2>, <&mynode1 3 4>;`

Additional notes on the above:

- The values in the `phandle`, `phandles`, and `phandle-array` types are described further in *Phandles*
- Boolean properties are true if present. They should not have a value. A boolean property is only false if it is completely missing in the DTS.
- The `foo` property value above has three *cells* with values 0xdeadbeef, 1234, and 0, in that order. Note that hexadecimal and decimal numbers are allowed and can be intermixed. Since Zephyr transforms DTS to C sources, it is not necessary to specify the endianness of an individual cell here.
- 64-bit integers are written as two 32-bit cells in big-endian order. The value 0xaaaa0000bbbb1111 would be written `<0xaaaa0000 0xbbbb1111>`.
- The `a-byte-array` property value is the three bytes 0x00, 0x01, and 0xab, in that order.
- Parentheses, arithmetic operators, and bitwise operators are allowed. The `bar` property contains a single cell with value 64:

  ```
  bar = <(2 * (1 << 5))>;
  ```

  Note that the entire expression must be parenthesized.
- Property values refer to other nodes in the devicetree by their *phandles*. You can write a phandle using `&foo`, where `foo` is a *node label*. Here is an example devicetree fragment:

  ```
  foo: device@0 { };
  device@1 {
          sibling = <&foo 1 2>;
  };
  ```

  The `sibling` property of node `device@1` contains three cells, in this order:

  1. The `device@0` node's phandle, which is written here as `&foo` since the `device@0` node has a node label `foo`
  2. The value 1
  3. The value 2

In the devicetree, a phandle value is a cell – which again is just a 32-bit unsigned int. However, the Zephyr devicetree API generally exposes these values as *node identifiers*. Node identifiers are covered in more detail in *Devicetree access from C/C++*.

- Array and similar type property values can be split into several <> blocks, like this:

```
foo = <1 2>, <3 4>;                          // Okay for 'type: array'
foo = <&label1 &label2>, <&label3 &label4>; // Okay for 'type: phandles'
foo = <&label1 1 2>, <&label2 3 4>;          // Okay for 'type: phandle-array'
```

This is recommended for readability when possible if the value can be logically grouped into blocks of sub-values.

Aliases and chosen nodes There are two additional ways beyond *node labels* to refer to a particular node without specifying its entire path: by alias, or by chosen node.

Here is an example devicetree which uses both:

```
/dts-v1/;

/ {
     chosen {
             zephyr,console = &uart0;
     };

     aliases {
             my-uart = &uart0;
     };

     soc {
             uart0: serial@12340000 {
                     ...
             };
     };
};
```

The `/aliases` and `/chosen` nodes do not refer to an actual hardware device. Their purpose is to specify other nodes in the devicetree.

Above, `my-uart` is an alias for the node with path `/soc/serial@12340000`. Using its node label `uart0`, the same node is set as the value of the chosen `zephyr,console` node.

Zephyr sample applications sometimes use aliases to allow overriding the particular hardware device used by the application in a generic way. For example, blinky uses this to abstract the LED to blink via the `led0` alias.

The `/chosen` node's properties are used to configure system- or subsystem-wide values. See *Chosen nodes* for more information.

Input and output files This section describes the input and output files shown in the figure in *Scope and purpose* in more detail.

Input files There are four types of devicetree input files:

- sources (`.dts`)
- includes (`.dtsi`)
- overlays (`.overlay`)
- bindings (`.yaml`)

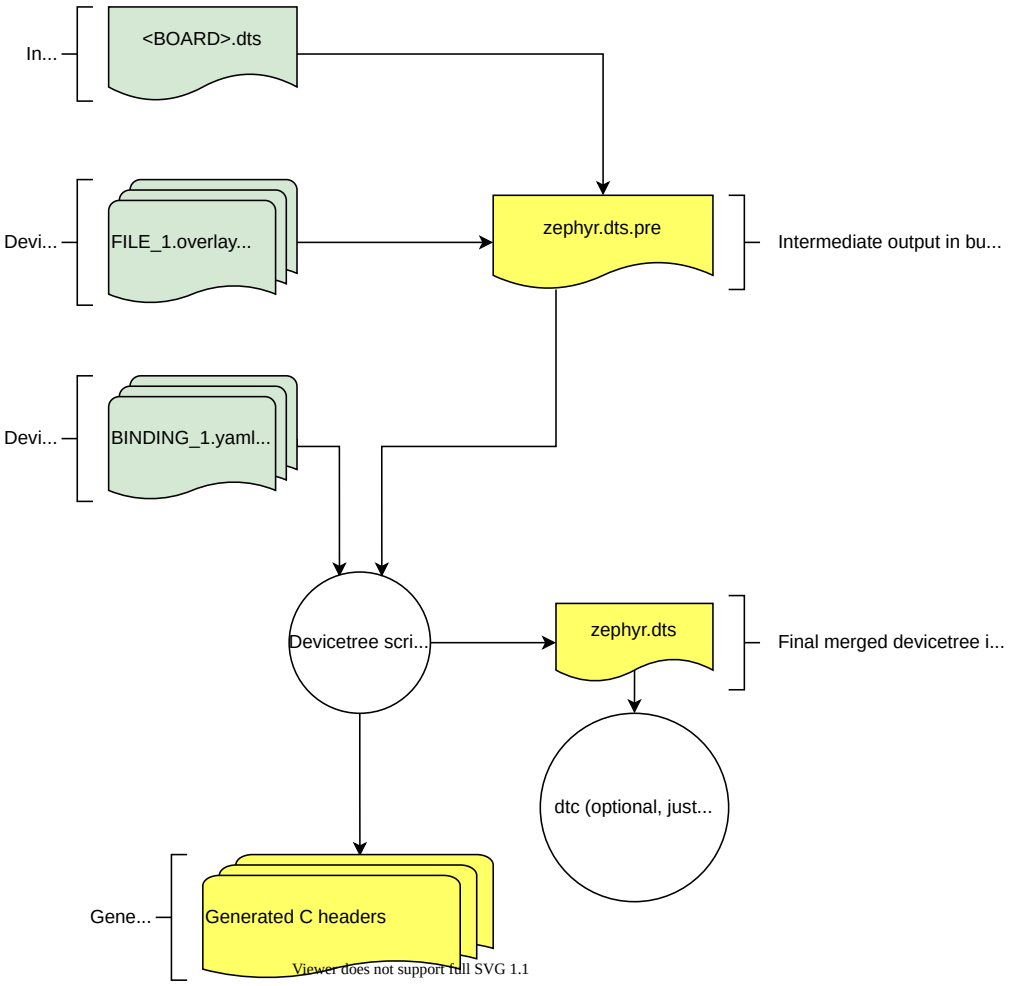

Fig. 3: Devicetree input (green) and output (yellow) files

The devicetree files inside the zephyr directory look like this:

```
boards/<ARCH>/<BOARD>/<BOARD>.dts
dts/common/skeleton.dtsi
dts/<ARCH>/.../<SOC>.dtsi
dts/bindings/.../binding.yaml
```

Generally speaking, every supported board has a BOARD.dts file describing its hardware. For example, the reel_board has boards/phytec/reel_board/reel_board.dts.

BOARD.dts includes one or more .dtsi files. These .dtsi files describe the CPU or system-on-chip Zephyr runs on, perhaps by including other .dtsi files. They can also describe other common hardware features shared by multiple boards. In addition to these includes, BOARD.dts also describes the board's specific hardware.

The dts/common directory contains skeleton.dtsi, a minimal include file for defining a complete devicetree. Architecture-specific subdirectories (dts/<ARCH>) contain .dtsi files for CPUs or SoCs which extend skeleton.dtsi.

The C preprocessor is run on all devicetree files to expand macro references, and includes are generally done with #include <filename> directives, even though DTS has a /include/ "<filename>" syntax.

BOARD.dts can be extended or modified using *overlays*. Overlays are also DTS files; the .overlay extension is just a convention which makes their purpose clear. Overlays adapt the base devicetree for different purposes:

- Zephyr applications can use overlays to enable a peripheral that is disabled by default, select a sensor on the board for an application specific purpose, etc. Along with *Configuration System (Kconfig)*, this makes it possible to reconfigure the kernel and device drivers without modifying source code.
- Overlays are also used when defining *Shields*.

The build system automatically picks up .overlay files stored in certain locations. It is also possible to explicitly list the overlays to include, via the DTC_OVERLAY_FILE CMake variable. See *Set devicetree overlays* for details.

The build system combines BOARD.dts and any .overlay files by concatenating them, with the overlays put last. This relies on DTS syntax which allows merging overlapping definitions of nodes in the devicetree. See *Example: FRDM-K64F and Hexiwear K64* for an example of how this works (in the context of .dtsi files, but the principle is the same for overlays). Putting the contents of the .overlay files last allows them to override BOARD.dts.

Devicetree bindings (which are YAML files) are essentially glue. They describe the contents of devicetree sources, includes, and overlays in a way that allows the build system to generate C macros usable by device drivers and applications. The dts/bindings directory contains bindings.

Scripts and tools The following libraries and scripts, located in scripts/dts/, create output files from input files. Their sources have extensive documentation.

dtlib.py
: A low-level DTS parsing library.

edtlib.py
: A library layered on top of dtlib that uses bindings to interpret properties and give a higher-level view of the devicetree. Uses dtlib to do the DTS parsing.

gen_defines.py
: A script that uses edtlib to generate C preprocessor macros from the devicetree and bindings.

In addition to these, the standard `dtc` (devicetree compiler) tool is run on the final devicetree if it is installed on your system. This is just to catch errors or warnings. The output is unused. Boards may need to pass `dtc` additional flags, e.g. for warning suppression. Board directories can contain a file named `pre_dt_board.cmake` which configures these extra flags, like this:

```
list(APPEND EXTRA_DTC_FLAGS "-Wno-simple_bus_reg")
```

Shield directories can contain a file named `pre_dt_shield.cmake` which has the same functionality as the aforementioned `pre_dt_board.cmake`.

Output files These are created in your application's build directory.

Warning

Don't include the header files directly. *Devicetree access from C/C++* explains what to do instead.

<build>/zephyr/zephyr.dts.pre
: The preprocessed DTS source. This is an intermediate output file, which is input to `gen_defines.py` and used to create `zephyr.dts` and `devicetree_generated.h`.

<build>/zephyr/include/generated/zephyr/devicetree_generated.h
: The generated macros and additional comments describing the devicetree. Included by `devicetree.h`.

<build>/zephyr/zephyr.dts
: The final merged devicetree. This file is output by `gen_defines.py`. It is useful for debugging any issues. If the devicetree compiler `dtc` is installed, it is also run on this file, to catch any additional warnings or errors.

Design goals

Zephyr's use of devicetree has evolved significantly over time, and further changes are expected. The following are the general design goals, along with specific examples about how they impact Zephyr's source code, and areas where more work remains to be done.

Single source for hardware information Zephyr's built-in device drivers and sample applications shall obtain configurable hardware descriptions from devicetree.

Examples

- New device drivers shall use devicetree APIs to determine which *devices to create*.
- In-tree sample applications shall use *aliases* to determine which of multiple possible generic devices of a given type will be used in the current build. For example, the blinky sample uses this to determine the LED to blink.
