- Boot-time pin muxing and pin control for new SoCs shall be accomplished via a devicetree-based pinctrl driver

Example remaining work

- Zephyr's *Test Runner (Twister)* currently use `board.yaml` files to determine the hardware supported by a board. This should be obtained from devicetree instead.
- Legacy device drivers currently use Kconfig to determine which instances of a particular compatible are enabled. This can and should be done with devicetree overlays instead.

- Board-level documentation still contains tables of hardware support which are generated and maintained by hand. This can and should be obtained from the board level devicetree instead.
- Runtime determination of `struct device` relationships should be done using information obtained from devicetree, e.g. for device power management.

Source compatibility with other operating systems Zephyr's devicetree tooling is based on a generic layer which is interoperable with other devicetree users, such as the Linux kernel.

Zephyr's binding language *semantics* can support Zephyr-specific attributes, but shall not express Zephyr-specific relationships.

Examples

- Zephyr's devicetree source parser, *dtlib.py*, is source-compatible with other tools like dtc in both directions: `dtlib.py` can parse `dtc` output, and `dtc` can parse `dtlib.py` output.
- Zephyr's "extended dtlib" library, `edtlib.py`, shall not include Zephyr-specific features. Its purpose is to provide a higher-level view of the devicetree for common elements like interrupts and buses.

  Only the high-level `gen_defines.py` script, which is built on top of `edtlib.py`, contains Zephyr-specific knowledge and features.

Example remaining work

- Zephyr has a custom *Devicetree bindings* language *syntax*. While Linux's dtschema does not yet meet Zephyr's needs, we should try to follow what it is capable of representing in Zephyr's own bindings.
- Due to inflexibility in the bindings language, Zephyr cannot support the full set of bindings supported by Linux.
- Devicetree source sharing between Zephyr and Linux is not done.

Devicetree bindings

A devicetree on its own is only half the story for describing hardware, as it is a relatively unstructured format. *Devicetree bindings* provide the other half.

A devicetree binding declares requirements on the contents of nodes, and provides semantic information about the contents of valid nodes. Zephyr devicetree bindings are YAML files in a custom format (Zephyr does not use the dt-schema tools used by the Linux kernel).

These pages introduce bindings, describe what they do, note where they are found, and explain their data format.

> **Note**
>
> See the *Bindings index* for reference information on bindings built in to Zephyr.

Note

For a detailed syntax reference, see *Devicetree bindings syntax*.

Introduction to Devicetree Bindings Devicetree nodes are matched to bindings using their *compatible properties*.

During the *Configuration Phase*, the build system tries to match each node in the devicetree to a binding file. When this succeeds, the build system uses the information in the binding file both when validating the node's contents and when generating macros for the node.

A simple example Here is an example devicetree node:

```
/* Node in a DTS file */
bar-device {
     compatible = "foo-company,bar-device";
     num-foos = <3>;
};
```

Here is a minimal binding file which matches the node:

```
# A YAML binding matching the node

compatible: "foo-company,bar-device"

properties:
  num-foos:
    type: int
    required: true
```

The build system matches the `bar-device` node to its YAML binding because the node's `compatible` property matches the binding's `compatible:` line.

What the build system does with bindings The build system uses bindings both to validate devicetree nodes and to convert the devicetree's contents into the generated *devicetree_generated.h* header file.

For example, the build system would use the above binding to check that the required `num-foos` property is present in the `bar-device` node, and that its value, `<3>`, has the correct type.

The build system will then generate a macro for the `bar-device` node's `num-foos` property, which will expand to the integer literal `3`. This macro lets you get the value of the property in C code using the API which is discussed later in this guide in *Devicetree access from C/C++*.

For another example, the following node would cause a build error, because it has no `num-foos` property, and this property is marked required in the binding:

```
bad-node {
     compatible = "foo-company,bar-device";
};
```

Other ways nodes are matched to bindings If a node has more than one string in its `compatible` property, the build system looks for compatible bindings in the listed order and uses the first match.

Take this node as an example:

```
baz-device {
     compatible = "foo-company,baz-device", "generic-baz-device";
};
```

The `baz-device` node would get matched to a binding with a `compatible: "generic-baz-device"` line if the build system can't find a binding with a `compatible: "foo-company,baz-device"` line.

Nodes without compatible properties can be matched to bindings associated with their parent nodes. These are called "child bindings". If a node describes hardware on a bus, like I2C or SPI, then the bus type is also taken into account when matching nodes to bindings. (See *On-bus* for details).

See *The /zephyr,user node* for information about a special node that doesn't require any binding.

Where bindings are located Binding file names usually match their `compatible:` lines. For example, the above example binding would be named `foo-company,bar-device.yaml` by convention.

The build system looks for bindings in `dts/bindings` subdirectories of the following places:

- the zephyr repository
- your *application source directory*
- your *board directory*
- any *shield directories*
- any directories manually included in the *DTS_ROOT* CMake variable
- any *module* that defines a `dts_root` in its *Build settings*

The build system will consider any YAML file in any of these, including in any subdirectories, when matching nodes to bindings. A file is considered YAML if its name ends with `.yaml` or `.yml`.

Warning

The binding files must be located somewhere inside the `dts/bindings` subdirectory of the above places.

For example, if `my-app` is your application directory, then you must place application-specific bindings inside `my-app/dts/bindings`. So `my-app/dts/bindings/serial/my-company,my-serial-port.yaml` would be found, but `my-app/my-company,my-serial-port.yaml` would be ignored.

Devicetree bindings syntax This page documents the syntax of Zephyr's bindings format. Zephyr bindings files are YAML files. A *simple example* was given in the introduction page.

Top level keys The top level of a bindings file maps keys to values. The top-level keys look like this:

```
# When the description text is too long, this field can
# be used to improve readability, e.g.:
#
# title: Binding the device's hardware model.
#
# description |
#   A piece of content with 20 lines.
#   ...
title: Concise title for the long description [optional]

# A high level description of the device the binding applies to:
description: |
   This is the Vendomatic company's foo-device.

   Descriptions which span multiple lines (like this) are OK,
   and are encouraged for complex bindings.

   See https://yaml-multiline.info/ for formatting help.

# You can include definitions from other bindings using this syntax:
include: other.yaml

# Used to match nodes to this binding:
compatible: "manufacturer,foo-device"

properties:
  # Requirements for and descriptions of the properties that this
```

(continues on next page)

(continued from previous page)

```
  # binding's nodes need to satisfy go here.

child-binding:
  # You can constrain the children of the nodes matching this binding
  # using this key.

# If the node describes bus hardware, like an SPI bus controller
# on an SoC, use 'bus:' to say which one, like this:
bus: spi

# If the node instead appears as a device on a bus, like an external
# SPI memory chip, use 'on-bus:' to say what type of bus, like this.
# Like 'compatible', this key also influences the way nodes match
# bindings.
on-bus: spi

examples:
  # You can put a sample node here showing how to use the binding.
  # - |
  #  ...
  # or
  # - ...

foo-cells:
  # "Specifier" cell names for the 'foo' domain go here; example 'foo'
  # values are 'gpio', 'pwm', and 'dma'. See below for more information.
```

These keys are explained in the following sections.

Title An *optional*, short description of the bound device, typically the hardware model. It should typically be of the format “Vendor Family Model”. If acronyms are used, they should be spelled out in parentheses. The naming should stay as close to the vendor datasheet as possible.

Titles should not exceed 100 characters. The description field should be used for longer descriptions. The words “binding”, “schema” or “driver” should not be used in the title, everything is a binding.

```
title: Acme Foo UART (Universal Asynchronous Receiver/Transmitter)
```

Description A free-form description of node hardware goes here. You can put links to datasheets or example nodes or properties as well.

Compatible This key is used to match nodes to this binding as described in *Introduction to Devicetree Bindings*. It should look like this in a binding file:

```
# Note the comma-separated vendor prefix and device name
compatible: "manufacturer,device"
```

This devicetree node would match the above binding:

```
device {
     compatible = "manufacturer,device";
};
```

Assuming no binding has `compatible: "manufacturer,device-v2"`, it would also match this node:

```
device-2 {
    compatible = "manufacturer,device-v2", "manufacturer,device";
};
```

Each node's `compatible` property is tried in order. The *bindings* are uniquely identified by a pair of (*compatible*, *on-bus*), where the *on-bus* may be unspecified. A specified *on-bus* takes precedence over unspecified. The first matching binding is used.

For the following device:

```
spi-bus {
        device-3 {
                compatible = "manufacturer,device";
        };
};
```

The following two bindings can coexist and would match in the following order:

`manufacturer,device-spi.yaml`

```
compatible: "manufacturer,device"
on-bus: spi
```

`manufacturer,device.yaml`

```
compatible: "manufacturer,device"
```

The following binding can coexist but would not match.

`manufacturer,device-i2c.yaml`

```
compatible: "manufacturer,device"
on-bus: i2c
```

If more than one matching binding for a compatible is found, an error is raised.

The `manufacturer` prefix identifies the device vendor. See dts/bindings/vendor-prefixes.txt for a list of accepted vendor prefixes. The `device` part is usually from the datasheet.

Some bindings apply to a generic class of devices which do not have a specific vendor. In these cases, there is no vendor prefix. One example is the `gpio-leds` compatible which is commonly used to describe board LEDs connected to GPIOs.

Properties The `properties:` key describes properties that nodes which match the binding contain. For example, a binding for a UART peripheral might look something like this:

```
compatible: "manufacturer,serial"

properties:
  reg:
    type: array
    description: UART peripheral MMIO register space
    required: true
  current-speed:
    type: int
    description: current baud rate
    required: true
```

In this example, a node with compatible `"manufacturer,serial"` must contain a property named `current-speed`. The property's value must be a single integer. Similarly, the node must contain a `reg` property.

The build system uses bindings to generate C macros for devicetree properties that appear in DTS files. You can read more about how to get property values in source code from these macros in *Devicetree access from C/C++*. Generally speaking, the build system only generates macros for properties listed in the `properties:` key for the matching binding. Properties not mentioned in the binding are generally ignored by the build system.

The one exception is that the build system will always generate macros for standard properties, like *reg*, whose meaning is defined by the devicetree specification. This happens regardless of whether the node has a matching binding or not.

Property entry syntax Property entries in `properties:` are written in this syntax:

```
<property name>:
  required: <true | false>
  type: <string | int | boolean | array | uint8-array | string-array |
         phandle | phandles | phandle-array | path | compound>
  deprecated: <true | false>
  default: <default>
  description: <description of the property>
  enum:
    - <item1>
    - <item2>
    ...
    - <itemN>
  const: <string | int | array | uint8-array | string-array>
  specifier-space: <space-name>
```

Example property definitions Here are some more examples.

```
properties:
    # Describes a property like 'current-speed = <115200>;'. We pretend that
    # it's obligatory for the example node and set 'required: true'.
    current-speed:
        type: int
        required: true
        description: Initial baud rate for bar-device

    # Describes an optional property like 'keys = "foo", "bar";'
    keys:
        type: string-array
        description: Keys for bar-device

    # Describes an optional property like 'maximum-speed = "full-speed";'
    # the enum specifies known values that the string property may take
    maximum-speed:
        type: string
        description: Configures USB controllers to work up to a specific speed.
        enum:
            - "low-speed"
            - "full-speed"
            - "high-speed"
            - "super-speed"

    # Describes an optional property like 'resolution = <16>;'
    # the enum specifies known values that the int property may take
    resolution:
      type: int
```

(continues on next page)

(continued from previous page)

```
      enum:
        - 8
        - 16
        - 24
        - 32

    # Describes a required property '#address-cells = <1>';  the const
    # specifies that the value for the property is expected to be the value 1
    "#address-cells":
        type: int
        required: true
        const: 1

    int-with-default:
        type: int
        default: 123
        description: Value for int register, default is power-up configuration.

    array-with-default:
        type: array
        default: [1, 2, 3] # Same as 'array-with-default = <1 2 3>'

    string-with-default:
        type: string
        default: "foo"

    string-array-with-default:
        type: string-array
        default: ["foo", "bar"] # Same as 'string-array-with-default = "foo",
↪"bar"'

    uint8-array-with-default:
        type: uint8-array
        default: [0x12, 0x34] # Same as 'uint8-array-with-default = [12 34]'
```

required Adding `required: true` to a property definition will fail the build if a node matches the binding, but does not contain the property.

The default setting is `required: false`; that is, properties are optional by default. Using `required: false` is therefore redundant and strongly discouraged.

type The type of a property constrains its values. The following types are available. See *Writing property values* for more details about writing values of each type in a DTS file. See *Phandles* for more information about the `phandle*` type properties.

Type	Description	Example in DTS
`string`	exactly one string	`status = "disabled";`
`int`	exactly one 32-bit value (cell)	`current-speed = <115200>;`
`boolean`	flags that don't take a value when true, and are absent if false	`hw-flow-control;`
`array`	zero or more 32-bit values (cells)	`offsets = <0x100 0x200 0x300>;`
`uint8-array`	zero or more bytes, in hex ('bytestring' in the Devicetree specification)	`local-mac-address = [de ad be ef 12 34];`
`string-array`	zero or more strings	`dma-names = "tx", "rx";`
`phandle`	exactly one phandle	`interrupt-parent = <&gic>;`
`phandles`	zero or more phandles	`pinctrl-0 = <&usart2_tx_pd5 &usart2_rx_pd6>;`
`phandle-array`	a list of phandles and 32-bit cells (usually specifiers)	`dmas = <&dma0 2>, <&dma0 3>;`
`path`	a path to a node as a phandle path reference or path string	`zephyr,bt-c2h-uart = &uart0;` or `foo = "/path/to/some/node";`
`compound`	a catch-all for more complex types (no macros will be generated)	`foo = <&label>, [01 02];`

deprecated A property with `deprecated: true` indicates to both the user and the tooling that the property is meant to be phased out.

The tooling will report a warning if the devicetree includes the property that is flagged as deprecated. (This warning is upgraded to an error in the *Test Runner (Twister)* for upstream pull requests.)

The default setting is `deprecated: false`. Using `deprecated: false` is therefore redundant and strongly discouraged.

default The optional `default:` setting gives a value that will be used if the property is missing from the devicetree node.

For example, with this binding fragment:

```
properties:
  foo:
    type: int
    default: 3
```

If property `foo` is missing in a matching node, then the output will be as if `foo = <3>;` had appeared in the DTS (except YAML data types are used for the default value).

Note that combining `default:` with `required: true` will raise an error.

For rules related to `default` in upstream Zephyr bindings, see *Rules for default values*.

See *Example property definitions* for examples. Putting `default:` on any property type besides those used in *Example property definitions* will raise an error.

enum The `enum:` line is followed by a list of values the property may contain. If a property value in DTS is not in the `enum:` list in the binding, an error is raised. See *Example property definitions* for examples.

const This specifies a constant value the property must take. It is mainly useful for constraining the values of common properties for a particular piece of hardware.

Warning

It is an abuse of this feature to use it to name properties in unconventional ways.

For example, this feature is not meant for cases like naming a property `my-pin`, then assigning it to the "gpio" specifier space using this feature. Properties which refer to GPIOs should use conventional names, i.e. end in `-gpios` or `-gpio`.

specifier-space This property, if present, manually sets the specifier space associated with a property with type `phandle-array`.

Normally, the specifier space is encoded implicitly in the property name. A property named `foos` with type `phandle-array` implicitly has specifier space `foo`. As a special case, `*-gpios` properties have specifier space "gpio", so that `foo-gpios` will have specifier space "gpio" rather than "foo-gpio".

You can use `specifier-space` to manually provide a space if using this convention would result in an awkward or unconventional name.

For example:

```
compatible: ...
properties:
  bar:
    type: phandle-array
    specifier-space: my-custom-space
```

Above, the `bar` property's specifier space is set to "my-custom-space".

You could then use the property in a devicetree like this:

```
controller1: custom-controller@1000 {
        #my-custom-space-cells = <2>;
};

controller2: custom-controller@2000 {
        #my-custom-space-cells = <1>;
};

my-node {
        bar = <&controller1 10 20>, <&controller2 30>;
};
```

Generally speaking, you should reserve this feature for cases where the implicit specifier space naming convention doesn't work. One appropriate example is an `mboxes` property with specifier space "mbox", not "mboxe". You can write this property as follows:

```
properties:
  mboxes:
    type: phandle-array
    specifier-space: mbox
```

Child-binding `child-binding` can be used when a node has children that all share the same properties. Each child gets the contents of `child-binding` as its binding, though an explicit `compatible = ...` on the child node takes precedence, if a binding is found for it.

Consider a binding for a PWM LED node like this one, where the child nodes are required to have a `pwms` property:

```
pwmleds {
        compatible = "pwm-leds";

        red_pwm_led {
                pwms = <&pwm3 4 15625000>;
        };
        green_pwm_led {
                pwms = <&pwm3 0 15625000>;
        };
        /* ... */
};
```

The binding would look like this:

```
compatible: "pwm-leds"

child-binding:
  description: LED that uses PWM

  properties:
    pwms:
      type: phandle-array
      required: true
```

`child-binding` also works recursively. For example, this binding:

```
compatible: foo

child-binding:
  child-binding:
    properties:
      my-property:
        type: int
        required: true
```

will apply to the `grandchild` node in this DTS:

```
parent {
        compatible = "foo";
        child {
                grandchild {
                        my-property = <123>;
                };
        };
};
```

Bus If the node is a bus controller, use `bus:` in the binding to say what type of bus. For example, a binding for a SPI peripheral on an SoC would look like this:

```
compatible: "manufacturer,spi-peripheral"
bus: spi
# ...
```

The presence of this key in the binding informs the build system that the children of any node matching this binding appear on this type of bus.

This in turn influences the way `on-bus:` is used to match bindings for the child nodes.

For a single bus supporting multiple protocols, e.g. I3C and I2C, the `bus:` in the binding can have a list as value:

```
compatible: "manufacturer,i3c-controller"
bus: [i3c, i2c]
# ...
```

On-bus If the node appears as a device on a bus, use `on-bus:` in the binding to say what type of bus.

For example, a binding for an external SPI memory chip should include this line:

```
on-bus: spi
```

And a binding for an I2C based temperature sensor should include this line:

```
on-bus: i2c
```

When looking for a binding for a node, the build system checks if the binding for the parent node contains `bus: <bus type>`. If it does, then only bindings with a matching `on-bus: <bus type>` and bindings without an explicit `on-bus` are considered. Bindings with an explicit `on-bus: <bus type>` are searched for first, before bindings without an explicit `on-bus`. The search repeats for each item in the node's `compatible` property, in order.

This feature allows the same device to have different bindings depending on what bus it appears on. For example, consider a sensor device with compatible `manufacturer,sensor` which can be used via either I2C or SPI.

The sensor node may therefore appear in the devicetree as a child node of either an SPI or an I2C controller, like this:

```
spi-bus@0 {
   /* ... some compatible with 'bus: spi', etc. ... */

   sensor@0 {
       compatible = "manufacturer,sensor";
       reg = <0>;
       /* ... */
   };
};

i2c-bus@0 {
   /* ... some compatible with 'bus: i2c', etc. ... */

   sensor@79 {
       compatible = "manufacturer,sensor";
       reg = <79>;
       /* ... */
   };
};
```

You can write two separate binding files which match these individual sensor nodes, even though they have the same compatible:

```
# manufacturer,sensor-spi.yaml, which matches sensor@0 on the SPI bus:
compatible: "manufacturer,sensor"
on-bus: spi

# manufacturer,sensor-i2c.yaml, which matches sensor@79 on the I2C bus:
```

(continues on next page)

(continued from previous page)

```
compatible: "manufacturer,sensor"
properties:
  uses-clock-stretching:
    type: boolean
on-bus: i2c
```

Only `sensor@79` can have a `use-clock-stretching` property. The bus-sensitive logic ignores `manufacturer,sensor-i2c.yaml` when searching for a binding for `sensor@0`.

Examples If you feel you want to provide a minimal example for your binding, you can use it like this:

```
description: ...

properties:
 ...

examples:
  - |
    leds {
      compatible = "gpio-leds";

      uled: led {
      gpios = <&gpioe 12 GPIO_ACTIVE_HIGH>;
      };
    };
```

Specifier cell names (*-cells) This section documents how to name the cells in a specifier within a binding. These concepts are discussed in detail later in this guide in *phandle-array properties*.

Consider a binding for a node whose phandle may appear in a `phandle-array` property, like the PWM controllers `pwm1` and `pwm2` in this example:

```
pwm1: pwm@deadbeef {
    compatible = "foo,pwm";
    #pwm-cells = <2>;
};

pwm2: pwm@deadbeef {
    compatible = "bar,pwm";
    #pwm-cells = <1>;
};

my-node {
    pwms = <&pwm1 1 2000>, <&pwm2 3000>;
};
```

The bindings for compatible `"foo,pwm"` and `"bar,pwm"` must give a name to the cells that appear in a PWM specifier using `pwm-cells:`, like this:

```
# foo,pwm.yaml
compatible: "foo,pwm"
...
pwm-cells:
  - channel
```

(continues on next page)

(continued from previous page)

```
  - period

# bar,pwm.yaml
compatible: "bar,pwm"
...
pwm-cells:
  - period
```

A `*-names` (e.g. `pwm-names`) property can appear on the node as well, giving a name to each entry.

This allows the cells in the specifiers to be accessed by name, e.g. using APIs like `DT_PWMS_CHANNEL_BY_NAME`.

If the specifier is empty (e.g. `#clock-cells = <0>`), then `*-cells` can either be omitted (recommended) or set to an empty array. Note that an empty array is specified as e.g. `clock-cells: []` in YAML.

Include Bindings can include other files, which can be used to share common property definitions between bindings. Use the `include:` key for this. Its value is either a string or a list.

In the simplest case, you can include another file by giving its name as a string, like this:

```
include: foo.yaml
```

If any file named `foo.yaml` is found (see *Where bindings are located* for the search process), it will be included into this binding.

Included files are merged into bindings with a simple recursive dictionary merge. The build system will check that the resulting merged binding is well-formed. It is allowed to include at any level, including `child-binding`, like this:

```
# foo.yaml will be merged with content at this level
include: foo.yaml

child-binding:
  # bar.yaml will be merged with content at this level
  include: bar.yaml
```

It is an error if a key appears with a different value in a binding and in a file it includes, with one exception: a binding can have `required: true` for a *property definition* for which the included file has `required: false`. The `required: true` takes precedence, allowing bindings to strengthen requirements from included files.

Note that weakening requirements by having `required: false` where the included file has `required: true` is an error. This is meant to keep the organization clean.

The file base.yaml contains definitions for many common properties. When writing a new binding, it is a good idea to check if `base.yaml` already defines some of the needed properties, and include it if it does.

Note that you can make a property defined in base.yaml obligatory like this, taking *reg* as an example:

```
reg:
  required: true
```

This relies on the dictionary merge to fill in the other keys for `reg`, like `type`.

To include multiple files, you can use a list of strings:

```
include:
  - foo.yaml
  - bar.yaml
```

This includes the files `foo.yaml` and `bar.yaml`. (You can write this list in a single line of YAML as `include: [foo.yaml, bar.yaml]`.)

When including multiple files, any overlapping `required` keys on properties in the included files are ORed together. This makes sure that a `required: true` is always respected.

In some cases, you may want to include some property definitions from a file, but not all of them. In this case, `include:` should be a list, and you can filter out just the definitions you want by putting a mapping in the list, like this:

```
include:
  - name: foo.yaml
    property-allowlist:
      - i-want-this-one
      - and-this-one
  - name: bar.yaml
    property-blocklist:
      - do-not-include-this-one
      - or-this-one
```

Each map element must have a `name` key which is the filename to include, and may have `property-allowlist` and `property-blocklist` keys that filter which properties are included.

You cannot have a single map element with both `property-allowlist` and `property-blocklist` keys. A map element with neither `property-allowlist` nor `property-blocklist` is valid; no additional filtering is done.

You can freely intermix strings and mappings in a single `include:` list:

```
include:
  - foo.yaml
  - name: bar.yaml
    property-blocklist:
      - do-not-include-this-one
      - or-this-one
```

Finally, you can filter from a child binding like this:

```
include:
  - name: bar.yaml
    child-binding:
      property-allowlist:
        - child-prop-to-allow
```

Nexus nodes and maps All `phandle-array` type properties support mapping through `*-map` properties, e.g. `gpio-map`, as defined by the Devicetree specification.

This is used, for example, to define connector nodes for common breakout headers, such as the `arduino_header` nodes that are conventionally defined in the devicetrees for boards with Arduino compatible expansion headers.

Rules for upstream bindings This section includes general rules for writing bindings that you want to submit to the upstream Zephyr Project. (You don't need to follow these rules for bindings you don't intend to contribute to the Zephyr Project, but it's a good idea.)

Decisions made by the Zephyr devicetree maintainer override the contents of this section. If that happens, though, please let them know so they can update this page, or you can send a patch yourself.

Contents

- *Always check for existing bindings*
- *General rules*
  - *File names*
  - *Recommendations are requirements*
  - *Descriptions*
  - *Naming conventions*
- *Rules for vendor prefixes*
- *Rules for default values*
- *The `zephyr,` prefix*

Always check for existing bindings Zephyr aims for devicetree *Source compatibility with other operating systems*. Therefore, if there is an existing binding for your device in an authoritative location, you should try to replicate its properties when writing a Zephyr binding, and you must justify any Zephyr-specific divergences.

In particular, this rule applies if:

- There is an existing binding in the mainline Linux kernel. See `Documentation/devicetree/bindings` in Linus's tree for existing bindings and the Linux devicetree documentation for more information.
- Your hardware vendor provides an official binding outside of the Linux kernel.

General rules Wherever possible, when writing Devicetree bindings for Zephyr, try to follow the same design guidelines laid out by Linux.

File names Bindings which match a compatible must have file names based on the compatible.

- For example, a binding for compatible `vnd,foo` must be named `vnd,foo.yaml`.
- If the binding is bus-specific, you can append the bus to the file name; for example, if the binding YAML has `on-bus: bar`, you may name the file `vnd,foo-bar.yaml`.

Recommendations are requirements All recommendations in *default* are requirements when submitting the binding.

In particular, if you use the `default:` feature, you must justify the value in the property's description.

Descriptions There are only two acceptable ways to write property `description:` strings.

If your description is short, it's fine to use this style:

```
description: my short string
```

If your description is long or spans multiple lines, you must use this style:

```
title: I'm sure you need a short title.

description: |
  My very long string
  goes here.
  Look at all these lines!
```

This | style prevents YAML parsers from removing the newlines in multi-line descriptions. This in turn makes these long strings display properly in the *Bindings index*.

If using the binding's properties gets complicated, you can use examples to provide a minimal node. e.g.:

```
description: ...

properties:
 ...

examples:
  - |
    leds {
      compatible = "gpio-leds";

      uled: led {
      gpios = <&gpioe 12 GPIO_ACTIVE_HIGH>;
      };
    };
```

Naming conventions Do not use uppercase letters (`A` through `Z`) or underscores (`_`) in property names. Use lowercase letters (`a` through `z`) instead of uppercase. Use dashes (`-`) instead of underscores. (The one exception to this rule is if you are replicating a well-established binding from somewhere like Linux.)

Rules for vendor prefixes The following general rules apply to vendor prefixes in *compatible* properties.

- If your device is manufactured by a specific vendor, then its compatible should have a vendor prefix.

  If your binding describes hardware with a well known vendor from the list in dts/bindings/vendor-prefixes.txt, you must use that vendor prefix.

- If your device is not manufactured by a specific hardware vendor, do **not** invent a vendor prefix. Vendor prefixes are not mandatory parts of compatible properties, and compatibles should not include them unless they refer to an actual vendor. There are some exceptions to this rule, but the practice is strongly discouraged.

- Do not submit additions to Zephyr's `dts/bindings/vendor-prefixes.txt` file unless you also include users of the new prefix. This means at least a binding and a devicetree using the vendor prefix, and should ideally include a device driver handling that compatible.

  For custom bindings, you can add a custom `dts/bindings/vendor-prefixes.txt` file to any directory in your *DTS_ROOT*. The devicetree tooling will respect these prefixes, and will not generate warnings or errors if you use them in your own bindings or devicetrees.

- We sometimes synchronize Zephyr's vendor-prefixes.txt file with the Linux kernel's equivalent file; this process is exempt from the previous rule.

- If your binding is describing an abstract class of hardware with Zephyr specific drivers handling the nodes, it's usually best to use `zephyr` as the vendor prefix. See *Zephyr Project (zephyr)* for examples.

Rules for default values In any case where `default:` is used in a devicetree binding, the `description:` for that property **must** explain *why* the value was selected and any conditions that would make it necessary to provide a different value. Additionally, if changing one property would require changing another to create a consistent configuration, then those properties should be made required.

There is no need to document the default value itself; this is already present in the *Bindings index* output.

There is a risk in using `default:` when the value in the binding may be incorrect for a particular board or hardware configuration. For example, defaulting the capacity of the connected power cell in a charging IC binding is likely to be incorrect. For such properties it's better to make the property `required: true`, forcing the user to make an explicit choice.

Driver developers should use their best judgment as to whether a value can be safely defaulted. Candidates for default values include:

- delays that would be different only under unusual conditions (such as intervening hardware)
- configuration for devices that have a standard initial configuration (such as a USB audio headset)
- defaults which match the vendor-specified power-on reset value (as long as they are independent from other properties)

Examples of how to write descriptions according to these rules:

```
properties:
  cs-interval:
    type: int
    default: 0
    description: |
      Minimum interval between chip select deassertion and assertion.
      The default corresponds to the reset value of the register field.
  hold-time-ms:
    type: int
    default: 20
    description: |
      Amount of time to hold the power enable GPIO asserted before
      initiating communication. The default was recommended in the
      manufacturer datasheet, and would only change under very
      cold temperatures.
```

Some examples of what **not** to do, and why:

```
properties:
  # Description doesn't mention anything about the default
  foo:
    type: int
    default: 1
    description: number of foos

  # Description mentions the default value instead of why it
  # was chosen
  bar:
    type: int
    default: 2
    description: bar size; default is 2

  # Explanation of the default value is in a comment instead
```

(continues on next page)

(continued from previous page)

```
  # of the description. This won't be shown in the bindings index.
  baz:
    type: int
    # This is the recommended value chosen by the manufacturer.
    default: 2
    description: baz time in milliseconds
```

The `zephyr,` prefix You must add this prefix to property names in the following cases:

- Zephyr-specific extensions to bindings we share with upstream Linux. One example is the `zephyr,vref-mv` ADC channel property which is common to ADC controllers defined in dts/bindings/adc/adc-controller.yaml. This channel binding is partially shared with an analogous Linux binding, and Zephyr-specific extensions are marked as such with the prefix.
- Configuration values that are specific to a Zephyr device driver. One example is the `zephyr, lazy-load` property in the `ti,bq274xx` binding. Though devicetree in general is a hardware description and configuration language, it is Zephyr's only mechanism for configuring driver behavior for an individual `struct device`. Therefore, as a compromise, we do allow some software configuration in Zephyr's devicetree bindings, as long as they use this prefix to show that they are Zephyr specific.

You may use the `zephyr,` prefix when naming a devicetree compatible that is specific to Zephyr. One example is `zephyr,ipc-openamp-static-vrings`. In this case, it's permitted but not required to add the `zephyr,` prefix to properties defined in the binding.

Devicetree access from C/C++

This guide describes Zephyr's `<zephyr/devicetree.h>` API for reading the devicetree from C source files. It assumes you're familiar with the concepts in *Introduction to devicetree* and *Devicetree bindings*. See *Devicetree Reference* for reference material.

A note for Linux developers Linux developers familiar with devicetree should be warned that the API described here differs significantly from how devicetree is used on Linux.

Instead of generating a C header with all the devicetree data which is then abstracted behind a macro API, the Linux kernel would instead read the devicetree data structure in its binary form. The binary representation is parsed at runtime, for example to load and initialize device drivers.

Zephyr does not work this way because the size of the devicetree binary and associated handling code would be too large to fit comfortably on the relatively constrained devices Zephyr supports.

Node identifiers To get information about a particular devicetree node, you need a *node identifier* for it. This is a just a C macro that refers to the node.

These are the main ways to get a node identifier:

By path
: Use `DT_PATH()` along with the node's full path in the devicetree, starting from the root node. This is mostly useful if you happen to know the exact node you're looking for.

By node label
: Use `DT_NODELABEL()` to get a node identifier from a *node label*. Node labels are often provided by SoC `.dtsi` files to give nodes names that match the SoC datasheet, like `i2c1`, `spi2`, etc.

By alias
: Use `DT_ALIAS()` to get a node identifier for a property of the special `/aliases` node. This is sometimes done by applications (like blinky, which uses the `led0` alias) that need to refer to

some device of a particular type ("the board's user LED") but don't care which one is used. You may also use `DT_HAS_ALIAS()` to verify whether an alias node exists.

By instance number
This is done primarily by device drivers, as instance numbers are a way to refer to individual nodes based on a matching compatible. Get these with `DT_INST()`, but be careful doing so. See below.

By chosen node
Use `DT_CHOSEN()` to get a node identifier for `/chosen` node properties.

By parent/child
Use `DT_PARENT()` and `DT_CHILD()` to get a node identifier for a parent or child node, starting from a node identifier you already have.

Two node identifiers which refer to the same node are identical and can be used interchangeably.

Here's a DTS fragment for some imaginary hardware we'll return to throughout this file for examples:

```
/dts-v1/;

/ {
        aliases {
                sensor-controller = &i2c1;
        };

        soc {
                i2c1: i2c@40002000 {
                        compatible = "vnd,soc-i2c";
                        label = "I2C_1";
                        reg = <0x40002000 0x1000>;
                        status = "okay";
                        clock-frequency = <100000>;
                };
        };
};
```

Here are a few ways to get node identifiers for the `i2c@40002000` node:

- `DT_PATH(soc, i2c_40002000)`
- `DT_NODELABEL(i2c1)`
- `DT_ALIAS(sensor_controller)`
- `DT_INST(x, vnd_soc_i2c)` for some unknown number `x`. See the `DT_INST()` documentation for details.

Important

Non-alphanumeric characters like dash (-) and the at sign (@) in devicetree names are converted to underscores (_). The names in a DTS are also converted to lowercase.

Node identifiers are not values There is no way to store one in a variable. You cannot write:

```
/* These will give you compiler errors: */

void *i2c_0 = DT_INST(0, vnd_soc_i2c);
unsigned int i2c_1 = DT_INST(1, vnd_soc_i2c);
long my_i2c = DT_NODELABEL(i2c1);
```

If you want something short to save typing, use C macros:

```
/* Use something like this instead: */

#define MY_I2C DT_NODELABEL(i2c1)

#define INST(i) DT_INST(i, vnd_soc_i2c)
#define I2C_0 INST(0)
#define I2C_1 INST(1)
```

Property access The right API to use to read property values depends on the node and property.

- *Checking properties and values*
- *Simple properties*
- *reg properties*
- *interrupts properties*
- *phandle properties*

Checking properties and values You can use `DT_NODE_HAS_PROP()` to check if a node has a property. For the *example devicetree* above:

```
DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), clock_frequency)  /* expands to 1 */
DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), not_a_property)   /* expands to 0 */
```

Simple properties Use `DT_PROP(node_id, property)` to read basic integer, boolean, string, numeric array, and string array properties.

For example, to read the `clock-frequency` property's value in the *above example*:

```
DT_PROP(DT_PATH(soc, i2c_40002000), clock_frequency)  /* This is 100000, */
DT_PROP(DT_NODELABEL(i2c1), clock_frequency)          /* and so is this, */
DT_PROP(DT_ALIAS(sensor_controller), clock_frequency) /* and this. */
```

Important

The DTS property `clock-frequency` is spelled `clock_frequency` in C. That is, properties also need special characters converted to underscores. Their names are also forced to lowercase.

Properties with `string` and `boolean` types work the exact same way. The `DT_PROP()` macro expands to a string literal in the case of strings, and the number 0 or 1 in the case of booleans. For example:

```
#define I2C1 DT_NODELABEL(i2c1)

DT_PROP(I2C1, status)  /* expands to the string literal "okay" */
```

Note

Don't use DT_NODE_HAS_PROP() for boolean properties. Use DT_PROP() instead as shown above. It will expand to either 0 or 1 depending on if the property is present or absent.

Properties with type `array`, `uint8-array`, and `string-array` work similarly, except `DT_PROP()` expands to an array initializer in these cases. Here is an example devicetree fragment:

```
foo: foo@1234 {
        a = <1000 2000 3000>; /* array */
        b = [aa bb cc dd];    /* uint8-array */
        c = "bar", "baz";     /* string-array */
};
```

Its properties can be accessed like this:

```
#define FOO DT_NODELABEL(foo)

int a[] = DT_PROP(FOO, a);           /* {1000, 2000, 3000} */
unsigned char b[] = DT_PROP(FOO, b); /* {0xaa, 0xbb, 0xcc, 0xdd} */
char* c[] = DT_PROP(FOO, c);         /* {"foo", "bar"} */
```

You can use `DT_PROP_LEN()` to get logical array lengths in number of elements.

```
size_t a_len = DT_PROP_LEN(FOO, a); /* 3 */
size_t b_len = DT_PROP_LEN(FOO, b); /* 4 */
size_t c_len = DT_PROP_LEN(FOO, c); /* 2 */
```

`DT_PROP_LEN()` cannot be used with the special `reg` or `interrupts` properties. These have alternative macros which are described next.

reg properties See *Important properties* for an introduction to `reg`.

Given a node identifier `node_id`, `DT_NUM_REGS(node_id)` is the total number of register blocks in the node's `reg` property.

You **cannot** read register block addresses and lengths with `DT_PROP(node, reg)`. Instead, if a node only has one register block, use `DT_REG_ADDR` or `DT_REG_SIZE`:

- `DT_REG_ADDR(node_id)`: the given node's register block address
- `DT_REG_SIZE(node_id)`: its size

Use `DT_REG_ADDR_BY_IDX` or `DT_REG_SIZE_BY_IDX` instead if the node has multiple register blocks:

- `DT_REG_ADDR_BY_IDX(node_id, idx)`: address of register block at index `idx`
- `DT_REG_SIZE_BY_IDX(node_id, idx)`: size of block at index `idx`

The `idx` argument to these must be an integer literal or a macro that expands to one without requiring any arithmetic. In particular, `idx` cannot be a variable. This won't work:

```
/* This will cause a compiler error. */

for (size_t i = 0; i < DT_NUM_REGS(node_id); i++) {
        size_t addr = DT_REG_ADDR_BY_IDX(node_id, i);
}
```

interrupts properties See *Important properties* for a brief introduction to `interrupts`.

Given a node identifier `node_id`, `DT_NUM_IRQS(node_id)` is the total number of interrupt specifiers in the node's `interrupts` property.

The most general purpose API macro for accessing these is `DT_IRQ_BY_IDX`:

```
DT_IRQ_BY_IDX(node_id, idx, val)
```

Here, idx is the logical index into the interrupts array, i.e. it is the index of an individual interrupt specifier in the property. The val argument is the name of a cell within the interrupt specifier. To use this macro, check the bindings file for the node you are interested in to find the val names.

Most Zephyr devicetree bindings have a cell named irq, which is the interrupt number. You can use DT_IRQN as a convenient way to get a processed view of this value.

Warning

Here, "processed" reflects Zephyr's devicetree *Scripts and tools*, which change the irq number in *zephyr.dts* to handle hardware constraints on some SoCs and in accordance with Zephyr's multilevel interrupt numbering.

This is currently not very well documented, and you'll need to read the scripts' source code and existing drivers for more details if you are writing a device driver.

Note

See *Phandles* for a detailed guide to phandles.

phandle properties Property values can refer to other nodes using the &another-node phandle syntax introduced in *Writing property values*. Properties which contain phandles have type phandle, phandles, or phandle-array in their bindings. We'll call these "phandle properties" for short.

You can convert a phandle to a node identifier using DT_PHANDLE, DT_PHANDLE_BY_IDX, or DT_PHANDLE_BY_NAME, depending on the type of property you are working with.

One common use case for phandle properties is referring to other hardware in the tree. In this case, you usually want to convert the devicetree-level phandle to a Zephyr driver-level *struct device*. See *Get a struct device from a devicetree node* for ways to do that.

Another common use case is accessing specifier values in a phandle array. The general purpose APIs for this are DT_PHA_BY_IDX and DT_PHA. There are also hardware-specific shorthands like DT_GPIO_CTLR_BY_IDX, DT_GPIO_CTLR, DT_GPIO_PIN_BY_IDX, DT_GPIO_PIN, DT_GPIO_FLAGS_BY_IDX, and DT_GPIO_FLAGS.

See DT_PHA_HAS_CELL_AT_IDX and DT_PROP_HAS_IDX for ways to check if a specifier value is present in a phandle property.

Other APIs Here are pointers to some other available APIs.

- DT_CHOSEN, DT_HAS_CHOSEN: for properties of the special /chosen node
- DT_HAS_COMPAT_STATUS_OKAY, DT_NODE_HAS_COMPAT: global- and node-specific tests related to the compatible property
- DT_BUS: get a node's bus controller, if there is one
- DT_ENUM_IDX: for properties whose values are among a fixed list of choices
- *Fixed flash partitions*: APIs for managing fixed flash partitions. Also see *Flash map*, which wraps this in a more user-friendly API.

Device driver conveniences Special purpose macros are available for writing device drivers, which usually rely on *instance identifiers*.

To use these, you must define DT_DRV_COMPAT to the compat value your driver implements support for. This compat value is what you would pass to DT_INST.

If you do that, you can access the properties of individual instances of your compatible with less typing, like this:

```
#include <zephyr/devicetree.h>

#define DT_DRV_COMPAT my_driver_compat

/* This is same thing as DT_INST(0, my_driver_compat): */
DT_DRV_INST(0)

/*
 * This is the same thing as
 * DT_PROP(DT_INST(0, my_driver_compat), clock_frequency)
 */
DT_INST_PROP(0, clock_frequency)
```

See *Instance-based APIs* for a generic API reference.

Hardware specific APIs Convenience macros built on top of the above APIs are also defined to help readability for hardware specific code. See *Hardware specific APIs* for details.

Generated macros While the `zephyr/devicetree.h` API is not generated, it does rely on a generated C header which is put into every application build directory: *devicetree_generated.h*. This file contains macros with devicetree data.

These macros have tricky naming conventions which the *Devicetree API* API abstracts away. They should be considered an implementation detail, but it's useful to understand them since they will frequently be seen in compiler error messages.

This section contains an Augmented Backus-Naur Form grammar for these generated macros, with examples and more details in comments. See **RFC 7405** (which extends **RFC 5234**) for a syntax specification.

```
; An RFC 7405 ABNF grammar for devicetree macros.
;
; This does *not* cover macros pulled out of DT via Kconfig,
; like CONFIG_SRAM_BASE_ADDRESS, etc. It only describes the
; ones that start with DT_ and are directly generated.

; ---------------------------------------------------------------------
; dt-macro: the top level nonterminal for a devicetree macro
;
; A dt-macro starts with uppercase "DT_", and is one of:
;
; - a <node-macro>, generated for a particular node
; - some <other-macro>, a catch-all for other types of macros
dt-macro = node-macro / other-macro

; ---------------------------------------------------------------------
; node-macro: a macro related to a node

; A macro about a property value
node-macro =  property-macro
; A macro about the pinctrl properties in a node.
node-macro =/ pinctrl-macro
; A macro about the GPIO hog properties in a node.
node-macro =/ gpiohogs-macro
; A macro about the map properties in a node.
```

; ------------------------------------------------------------------
; property-macro: a macro related to a node property
;
; These combine a node identifier with a "lowercase-and-underscores form"
; property name. The value expands to something related to the property's
; value.
;
; The optional prop-suf suffix is when there's some specialized
; subvalue that deserves its own macro, like the macros for an array
; property's individual elements
;
; The "plain vanilla" macro for a property's value, with no prop-suf,
; looks like this:
;
;   DT_N_<node path>_P_<property name>
;
; Components:
;
; - path-id: node's devicetree path converted to a C token
; - prop-id: node's property name converted to a C token
; - prop-suf: an optional property-specific suffix
property-macro =  %s"DT_N" path-id %s"_P_" prop-id [prop-suf]

; ------------------------------------------------------------------
; path-id: a node's path-based macro identifier
;
; This in "lowercase-and-underscores" form. I.e. it is
; the node's devicetree path converted to a C token by changing:
;
; - each slash (/) to _S_
; - all letters to lowercase
; - non-alphanumerics characters to underscores
;
; For example, the leaf node "bar-BAZ" in this devicetree:
;
;   / {
;           foo@123 {
;                   bar-BAZ {};
;           };
;   };
;
; has path-id "_S_foo_123_S_bar_baz".
path-id = 1*( %s"_S_" dt-name )
```

(continues on next page)

(continued from previous page)

```
; ---------------------------------------------------------------------
; prop-id: a property identifier
;
; A property name converted to a C token by changing:
;
; - all letters to lowercase
; - non-alphanumeric characters to underscores
;
; Example node:
;
;   chosen {
;       zephyr,console = &uart1;
;       WHY,AM_I_SHOUTING = "unclear";
;   };
;
; The 'zephyr,console' property has prop-id 'zephyr_console'.
; 'WHY,AM_I_SHOUTING' has prop-id 'why_am_i_shouting'.
prop-id = dt-name

; ---------------------------------------------------------------------
; prop-suf: a property-specific macro suffix
;
; Extra macros are generated for properties:
;
; - that are special to the specification ("reg", "interrupts", etc.)
; - with array types (uint8-array, phandle-array, etc.)
; - with "enum:" in their bindings
; - that have zephyr device API specific macros for phandle-arrays
; - related to phandle specifier names ("foo-names")
;
; Here are some examples:
;
; - _EXISTS: property, index or name existence flag
; - _SIZE: logical property length
; - _IDX_<i>: values of individual array elements
; - _IDX_<DIGIT>_VAL_<dt-name>: values of individual specifier
;   cells within a phandle array
; - _ADDR_<i>: for reg properties, the i-th register block address
; - _LEN_<i>: for reg properties, the i-th register block length
;
; The different cases are not exhaustively documented here to avoid
; this file going stale. Please see devicetree.h if you need to know
; the details.
prop-suf = 1*( "_" gen-name ["_" dt-name] )

other-macro =/ %s"DT_FOREACH_OKAY_INST_" dt-name
other-macro =/ %s"DT_FOREACH_OKAY_INST_VARGS_" dt-name
; E.g.: #define DT_CHOSEN_zephyr_flash
other-macro =/ %s"DT_CHOSEN_" dt-name
; Declares that a compatible has at least one node on a bus.
; Example:
;
;   #define DT_COMPAT_vnd_dev_BUS_spi 1
other-macro =/ %s"DT_COMPAT_" dt-name %s"_BUS_" dt-name
; Declares that a compatible has at least one status "okay" node.
; Example:
;
;   #define DT_COMPAT_HAS_OKAY_vnd_dev 1
other-macro =/ %s"DT_COMPAT_HAS_OKAY_" dt-name
; Currently used to allow mapping a lowercase-and-underscores "label"
; property to a fixed-partitions node. See the flash map API docs
; for an example.
other-macro =/ %s"DT_COMPAT_" dt-name %s"_LABEL_" dt-name

; ------------------------------------------------------------------
; alternate-id: another way to specify a node besides a path-id
;
; Example devicetree:
;
;   / {
;           aliases {
;                   dev = &dev_1;
;           };
;
;           soc {
;               dev_1: device@123 {
;                   compatible = "vnd,device";
;               };
;           };
;   };
;
; Node device@123 has these alternate-id values:
;
; - ALIAS_dev
; - NODELABEL_dev_1
; - INST_0_vnd_device
;
; The full alternate-id macros are:
;
;   #define DT_N_INST_0_vnd_device     DT_N_S_soc_S_device_123
;   #define DT_N_ALIAS_dev             DT_N_S_soc_S_device_123
;   #define DT_N_NODELABEL_dev_1       DT_N_S_soc_S_device_123
;
; These mainly exist to allow pasting an alternate-id macro onto a
```

(continues on next page)

(continued from previous page)

```
; "_P_<prop-id>" to access node properties given a node's alias, etc.
;
; Notice that "inst"-type IDs have a leading instance identifier,
; which is generated by the devicetree scripts. The other types of
; alternate-id begin immediately with names taken from the devicetree.
alternate-id =  ( %s"ALIAS" / %s"NODELABEL" ) dt-name
alternate-id =/ %s"INST_" 1*DIGIT "_" dt-name

; ---------------------------------------------------------------------
; miscellaneous helper definitions

; A dt-name is one or more:
; - lowercase ASCII letters (a-z)
; - numbers (0-9)
; - underscores ("_")
;
; They are the result of converting names or combinations of names
; from devicetree to a valid component of a C identifier by
; lowercasing letters (in practice, this is a no-op) and converting
; non-alphanumeric characters to underscores.
;
; You'll see these referred to as "lowercase-and-underscores" forms of
; various devicetree identifiers throughout the documentation.
dt-name = 1*( lower / DIGIT / "_" )

; gen-name is used as a stand-in for a component of a generated macro
; name which does not come from devicetree (dt-name covers that case).
;
; - uppercase ASCII letters (a-z)
; - numbers (0-9)
; - underscores ("_")
gen-name = upper 1*( upper / DIGIT / "_" )

; "lowercase ASCII letter" turns out to be pretty annoying to specify
; in RFC-7405 syntax.
;
; This is just ASCII letters a (0x61) through z (0x7a).
lower = %x61-7A

; "uppercase ASCII letter" in RFC-7405 syntax
upper = %x41-5A
```

Phandles

The devicetree concept of a *phandle* is very similar to pointers in C. You can use phandles to refer to nodes in devicetree similarly to the way you can use pointers to refer to structures in C.

Contents

- *Getting phandles*

  - *Manually specifying a space*
- *Naming the cells in a specifier*
- *See also*

Getting phandles The usual way to get a phandle for a devicetree node is from one of its node labels. For example, with this devicetree:

```
/ {
        lbl_a: node-1 {};
        lbl_b: lbl_c: node-2 {};
};
```

You can write the phandle for:

- `/node-1` as `&lbl_a`
- `/node-2` as either `&lbl_b` or `&lbl_c`

Notice how the `&nodelabel` devicetree syntax is similar to the "address of" C syntax.

Note

"Type" in this section refers to one of the type names documented in *Properties* in the devicetree bindings documentation.

Using phandles Here are the main ways you will use phandles.

One node: phandle type You can use phandles to refer to `node-b` from `node-a`, where `node-b` is related to `node-a` in some way.

One common example is when `node-a` represents some hardware that generates an interrupt, and `node-b` represents the interrupt controller that receives the asserted interrupt. In this case, you could write:

```
node_b: node-b {
        interrupt-controller;
};

node-a {
```

(continues on next page)

(continued from previous page)

```
        interrupt-parent = <&node_b>;
};
```

This uses the standard `interrupt-parent` property defined in the devicetree specification to capture the relationship between the two nodes.

These properties have type `phandle`.

Zero or more nodes: phandles type You can use phandles to make an array of references to other nodes.

One common example occurs in *pin control*. Pin control properties like `pinctrl-0`, `pinctrl-1` etc. may contain multiple phandles, each of which "points" to a node containing information related to pin configuration for that hardware peripheral. Here's an example of six phandles in a single property:

```
pinctrl-0 = <&quadspi_clk_pe10 &quadspi_ncs_pe11
             &quadspi_bk1_io0_pe12 &quadspi_bk1_io1_pe13
             &quadspi_bk1_io2_pe14 &quadspi_bk1_io3_pe15>;
```

These properties have type `phandles`.

Zero or more nodes with metadata: phandle-array type You can use phandles to refer to and configure one or more resources that are "owned" by some other node.

This is the most complex case. There are examples and more details in the next section.

These properties have type `phandle-array`.

phandle-array properties These properties are commonly used to specify a resource that is owned by another node along with additional metadata about the resource.

High level description Usually, properties with this type are written like `phandle-array-prop` in this example:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>, <&baz 4 5>;
};
```

That is, the property's value is written as a comma-separated sequence of "groups", where each "group" is written inside of angle brackets (`< ... >`). Each "group" starts with a phandle (`&foo`, `&bar`, `&baz`). The values that follow the phandle in each "group" are called *specifiers*. There are three specifiers in the above example:

1. `1 2`
2. `3`
3. `4 5`

The phandle in each "group" is used to "point" to the hardware that controls the resource you are interested in. The specifier describes the resource itself, along with any additional necessary metadata.

The rest of this section describes a common example. Subsequent sections document more rules about how to use phandle-array properties in practice.

Example phandle-arrays: GPIOs Perhaps the most common use case for phandle-array properties is specifying one or more GPIOs on your SoC that another chip on your board connects to. For that reason, we'll focus on that use case here. However, there are **many other use cases** that are handled in devicetree with phandle-array properties.

For example, consider an external chip with an interrupt pin that is connected to a GPIO on your SoC. You will typically need to provide that GPIO's information (GPIO controller and pin number) to the *device driver* for that chip. You usually also need to provide other metadata about the GPIO, like whether it is active low or high, what kind of internal pull resistor within the SoC should be enabled in order to communicate with the device, etc., to the driver.

In the devicetree, there will be a node that represents the GPIO controller that controls a group of pins. This reflects the way GPIO IP blocks are usually developed in hardware. Therefore, there is no single node in the devicetree that represents a GPIO pin, and you can't use a single phandle to represent it.

Instead, you would use a phandle-array property, like this:

```
my-external-ic {
        irq-gpios = <&gpioX pin flags>;
};
```

In this example, `irq-gpios` is a phandle-array property with just one "group" in its value. `&gpioX` is the phandle for the GPIO controller node that controls the pin. `pin` is the pin number (0, 1, 2, ...). `flags` is a bit mask describing pin metadata (for example `(GPIO_ACTIVE_LOW | GPIO_PULL_UP)`); see include/zephyr/dt-bindings/gpio/gpio.h for more details.

The device driver handling the `my-external-ic` node can then use the `irq-gpios` property's value to set up interrupt handling for the chip as it is used on your board. This lets you configure the device driver in devicetree, without changing the driver's source code.

Such properties can contain multiple values as well:

```
my-other-external-ic {
        handshake-gpios = <&gpioX pinX flagsX>, <&gpioY pinY flagsY>;
};
```

The above example specifies two pins:

- `pinX` on the GPIO controller with phandle `&gpioX`, flags `flagsX`
- `pinY` on `&gpioY`, flags `flagsY`

You may be wondering how the "pin and flags" convention is established and enforced. To answer this question, we'll need to introduce a concept called specifier spaces before moving on to some information about devicetree bindings.

Specifier spaces *Specifier spaces* are a way to allow nodes to describe how you should use them in phandle-array properties.

We'll start with an abstract, high level description of how specifier spaces work in DTS files, before moving on to a concrete example and providing references to further reading for how this all works in practice using DTS files and bindings files.

High level description As described above, a phandle-array property is a sequence of "groups" of phandles followed by some number of cells:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>;
};
```

The cells that follow each phandle are called a *specifier*. In this example, there are two specifiers:

1. 1 2: two cells
2. 3: one cell

Every phandle-array property has an associated *specifier space*. This sounds complex, but it's really just a way to assign a meaning to the cells that follow each phandle in a hardware specific way. Every specifier space has a unique name. There are a few "standard" names for commonly used hardware, but you can create your own as well.

Devicetree nodes encode the number of cells that must appear in a specifier, by name, using the `#SPACE_NAME-cells` property. For example, let's assume that `phandle-array-prop`'s specifier space is named `baz`. Then we would need the `foo` and `bar` nodes to have the following `#baz-cells` properties:

```
foo: node@1000 {
        #baz-cells = <2>;
};

bar: node@2000 {
        #baz-cells = <1>;
};
```

Without the `#baz-cells` property, the devicetree tooling would not be able to validate the number of cells in each specifier in `phandle-array-prop`.

This flexibility allows you to write down an array of hardware resources in a single devicetree property, even though the amount of metadata you need to describe each resource might be different for different nodes.

A single node can also have different numbers of cells in different specifier spaces. For example, we might have:

```
foo: node@1000 {
        #baz-cells = <2>;
        #bob-cells = <1>;
};
```

With that, if `phandle-array-prop-2` has specifier space `bob`, we could write:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>;
        phandle-array-prop-2 = <&foo 4>;
};
```

This flexibility allows you to have a node that manages multiple different kinds of resources at the same time. The node describes the amount of metadata needed to describe each kind of resource (how many cells are needed in each case) using different `#SPACE_NAME-cells` properties.

Example specifier space: gpio From the above example, you're already familiar with how one specifier space works: in the "gpio" space, specifiers almost always have two cells:

1. a pin number
2. a bit mask of flags related to the pin

Therefore, almost all GPIO controller nodes you will see in practice will look like this:

```
gpioX: gpio-controller@deadbeef {
        gpio-controller;
        #gpio-cells = <2>;
};
```

Associating properties with specifier spaces Above, we have described that:

- each phandle-array property has an associated specifier space
- specifier spaces are identified by name
- devicetree nodes use `#SPECIFIER_NAME-cells` properties to configure the number of cells which must appear in a specifier

In this section, we explain how phandle-array properties get their specifier spaces.

High level description In general, a `phandle-array` property named `foos` implicitly has specifier space `foo`. For example:

```
properties:
  dmas:
    type: phandle-array
  pwms:
    type: phandle-array
```

The `dmas` property's specifier space is "dma". The `pwms` property's specifier space is `pwm`.

Special case: GPIO `*-gpios` properties are special-cased so that e.g. `foo-gpios` resolves to `#gpio-cells` rather than `#foo-gpio-cells`.

Manually specifying a space You can manually specify the specifier space for any `phandle-array` property. See *specifier-space*.

Naming the cells in a specifier You should name the cells in each specifier space your hardware supports when writing bindings. For details on how to do this, see *Specifier cell names (*-cells)*.

This allows C code to query information about and retrieve the values of cells in a specifier by name using devicetree APIs like these:

- `DT_PHA_BY_IDX`
- `DT_PHA_BY_NAME`

This feature and these macros are used internally by numerous hardware-specific APIs. Here are a few examples:

- `DT_GPIO_PIN_BY_IDX`
- `DT_PWMS_CHANNEL_BY_IDX`
- `DT_DMAS_CELL_BY_NAME`
- `DT_IO_CHANNELS_INPUT_BY_IDX`
- `DT_CLOCKS_CELL_BY_NAME`

- *Properties*: how to write bindings for properties with phandle types (`phandle`, `phandles`, `phandle-array`)
- *specifier-space*: how to manually specify a phandle-array property's specifier space

The /zephyr,user node

Zephyr's devicetree scripts handle the /zephyr,user node as a special case: you can put essentially arbitrary properties inside it and retrieve their values without having to write a binding. It is meant as a convenient container when only a few simple properties are needed.

> **Note**
>
> This node is meant for sample code and user applications. It should not be used in the upstream Zephyr source code for device drivers, subsystems, etc.

Simple values You can store numeric or array values in /zephyr,user if you want them to be configurable at build time via devicetree.

For example, with this devicetree overlay:

```
/ {
	zephyr,user {
		boolean;
		bytes = [81 82 83];
		number = <23>;
		numbers = <1>, <2>, <3>;
		string = "text";
		strings = "a", "b", "c";
	};
};
```

You can get the above property values in C/C++ code like this:

```
#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

DT_PROP(ZEPHYR_USER_NODE, boolean) // 1
DT_PROP(ZEPHYR_USER_NODE, bytes)   // {0x81, 0x82, 0x83}
DT_PROP(ZEPHYR_USER_NODE, number)  // 23
DT_PROP(ZEPHYR_USER_NODE, numbers) // {1, 2, 3}
DT_PROP(ZEPHYR_USER_NODE, string)  // "text"
DT_PROP(ZEPHYR_USER_NODE, strings) // {"a", "b", "c"}
```

Devices You can store *phandles* in /zephyr,user if you want to be able to reconfigure which devices your application uses in simple cases using devicetree overlays.

For example, with this devicetree overlay:

```
/ {
	zephyr,user {
		handle = <&gpio0>;
		handles = <&gpio0>, <&gpio1>;
	};
};
```

You can convert the phandles in the handle and handles properties to device pointers like this:

```
/*
 * Same thing as:
 *
 * ... my_dev = DEVICE_DT_GET(DT_NODELABEL(gpio0));
 */
```

(continues on next page)

(continued from previous page)

```
const struct device *my_device =
     DEVICE_DT_GET(DT_PROP(ZEPHYR_USER_NODE, handle));

/*
 * Same thing as:
 *
 * ... *my_devices[] = {
 *         DEVICE_DT_GET(DT_NODELABEL(gpio0)),
 *         DEVICE_DT_GET(DT_NODELABEL(gpio1))
 * };
 */
const struct device *my_devices[] = {
     DT_FOREACH_PROP_ELEM_SEP(ZEPHYR_USER_NODE, handles, DEVICE_DT_GET_BY_IDX, (,))
};
```

GPIOs The `/zephyr,user` node is a convenient place to store application-specific GPIOs that you want to be able to reconfigure with a devicetree overlay.

For example, with this devicetree overlay:

```
#include <zephyr/dt-bindings/gpio/gpio.h>

/ {
     zephyr,user {
             signal-gpios = <&gpio0 1 GPIO_ACTIVE_HIGH>;
     };
};
```

You can convert the pin defined in `signal-gpios` to a `struct gpio_dt_spec` in your source code, then use it like this:

```
#include <zephyr/drivers/gpio.h>

#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

const struct gpio_dt_spec signal =
        GPIO_DT_SPEC_GET(ZEPHYR_USER_NODE, signal_gpios);

/* Configure the pin */
gpio_pin_configure_dt(&signal, GPIO_OUTPUT_INACTIVE);

/* Set the pin to its active level */
gpio_pin_set_dt(&signal, 1);
```

(See `gpio_dt_spec`, `GPIO_DT_SPEC_GET`, and `gpio_pin_configure_dt()` for details on these APIs.)

Devicetree HOWTOs

This page has step-by-step advice for getting things done with devicetree.

> **Tip**
>
> See *Troubleshooting devicetree* for troubleshooting advice.

Get your devicetree and generated header A board's devicetree (*BOARD.dts*) pulls in common node definitions via `#include` preprocessor directives. This at least includes the SoC's `.dtsi`. One way to figure out the devicetree's contents is by opening these files, e.g. by looking in `dts/<ARCH>/<vendor>/<soc>.dtsi`, but this can be time consuming.

If you just want to see the "final" devicetree for your board, build an application and open the `zephyr.dts` file in the build directory.

> **Tip**
>
> You can build hello_world to see the "base" devicetree for your board without any additional changes from *overlay files*.

For example, using the qemu_cortex_m3 board to build hello_world:

```
# --cmake-only here just forces CMake to run, skipping the
# build process to save time.
west build -b qemu_cortex_m3 samples/hello_world --cmake-only
```

You can change `qemu_cortex_m3` to match your board.

CMake prints the input and output file locations like this:

```
-- Found BOARD.dts: .../zephyr/boards/arm/qemu_cortex_m3/qemu_cortex_m3.dts
-- Generated zephyr.dts: .../zephyr/build/zephyr/zephyr.dts
-- Generated devicetree_generated.h: .../
↪zephyr/build/zephyr/include/generated/zephyr/devicetree_generated.h
```

The `zephyr.dts` file is the final devicetree in DTS format.

The `devicetree_generated.h` file is the corresponding generated header.

See *Input and output files* for details about these files.

Get a struct device from a devicetree node When writing Zephyr applications, you'll often want to get a driver-level *struct device* corresponding to a devicetree node.

For example, with this devicetree fragment, you might want the struct device for `serial@40002000`:

```
/ {
        soc {
                serial0: serial@40002000 {
                        status = "okay";
                        current-speed = <115200>;
                        /* ... */
                };
        };

        aliases {
                my-serial = &serial0;
        };
```

(continues on next page)

(continued from previous page)

```
        chosen {
                zephyr,console = &serial0;
        };
};
```

Start by making a *node identifier* for the device you are interested in. There are different ways to do this; pick whichever one works best for your requirements. Here are some examples:

```
/* Option 1: by node label */
#define MY_SERIAL DT_NODELABEL(serial0)

/* Option 2: by alias */
#define MY_SERIAL DT_ALIAS(my_serial)

/* Option 3: by chosen node */
#define MY_SERIAL DT_CHOSEN(zephyr_console)

/* Option 4: by path */
#define MY_SERIAL DT_PATH(soc, serial_40002000)
```

Once you have a node identifier there are two ways to proceed. One way to get a device is to use `DEVICE_DT_GET`:

```
const struct device *const uart_dev = DEVICE_DT_GET(MY_SERIAL);

if (!device_is_ready(uart_dev)) {
        /* Not ready, do not use */
        return -ENODEV;
}
```

There are variants of `DEVICE_DT_GET` such as `DEVICE_DT_GET_OR_NULL`, `DEVICE_DT_GET_ONE` or `DEVICE_DT_GET_ANY`. This idiom fetches the device pointer at build-time, which means there is no runtime penalty. This method is useful if you want to store the device pointer as configuration data. But because the device may not be initialized, or may have failed to initialize, you must verify that the device is ready to be used before passing it to any API functions. (This check is done for you by `device_get_binding()`.)

In some situations the device cannot be known at build-time, e.g., if it depends on user input like in a shell application. In this case you can get the `struct device` by combining `device_get_binding()` with the device name:

```
const char *dev_name = /* TODO: insert device name from user */;
const struct device *uart_dev = device_get_binding(dev_name);
```

You can then use `uart_dev` with *Universal Asynchronous Receiver-Transmitter (UART)* API functions like `uart_configure()`. Similar code will work for other device types; just make sure you use the correct API for the device.

If you're having trouble, see *Troubleshooting devicetree*. The first thing to check is that the node has `status = "okay"`, like this:

```
#define MY_SERIAL DT_NODELABEL(my_serial)

#if DT_NODE_HAS_STATUS(MY_SERIAL, okay)
const struct device *const uart_dev = DEVICE_DT_GET(MY_SERIAL);
#else
#error "Node is disabled"
#endif
```

If you see the `#error` output, make sure to enable the node in your devicetree. In some situations your code will compile but it will fail to link with a message similar to:

```
...undefined reference to `__device_dts_ord_N'
collect2: error: ld returned 1 exit status
```

This likely means there's a Kconfig issue preventing the device driver from being built, resulting in a reference that does not exist. If your code compiles successfully, the last thing to check is if the device is ready, like this:

```
if (!device_is_ready(uart_dev)) {
     printk("Device not ready\n");
}
```

If you find that the device is not ready, it likely means that the device's initialization function failed. Enabling logging or debugging driver code may help in such situations. Note that you can also use `device_get_binding()` to obtain a reference at runtime. If it returns `NULL` it can either mean that device's driver failed to initialize or that it does not exist.

Find a devicetree binding *Devicetree bindings* are YAML files which declare what you can do with the nodes they describe, so it's critical to be able to find them for the nodes you are using.

If you don't have them already, *Get your devicetree and generated header*. To find a node's binding, open the generated header file, which starts with a list of nodes in a block comment:

```
/*
 * [...]
 * Nodes in dependency order (ordinal and path):
 *   0   /
 *   1   /aliases
 *   2   /chosen
 *   3   /flash@0
 *   4   /memory@20000000
 *          (etc.)
 * [...]
 */
```

Make note of the path to the node you want to find, like `/flash@0`. Search for the node's output in the file, which starts with something like this if the node has a matching binding:

```
/*
 * Devicetree node:
 *   /flash@0
 *
 * Binding (compatible = soc-nv-flash):
 *   $ZEPHYR_BASE/dts/bindings/mtd/soc-nv-flash.yaml
 * [...]
 */
```

See *Check for missing bindings* for troubleshooting.

Set devicetree overlays Devicetree overlays are explained in *Introduction to devicetree*. The CMake variable `DTC_OVERLAY_FILE` contains a space- or semicolon-separated list of overlay files to use. If `DTC_OVERLAY_FILE` specifies multiple files, they are included in that order by the C preprocessor. A file in a Zephyr module can be referred to by escaping the Zephyr module dir variable like `\${ZEPHYR_<module>_MODULE_DIR}/<path-to>/dts.overlay` when setting the DTC_OVERLAY_FILE variable.

You can set `DTC_OVERLAY_FILE` to contain exactly the files you want to use. Here is an *example* using `west build`.

If you don't set **DTC_OVERLAY_FILE**, the build system will follow these steps, looking for files in your application configuration directory to use as devicetree overlays:

1. If the file `socs/<SOC>_<BOARD_QUALIFIERS>.overlay` exists, it will be used.
2. If the file `boards/<BOARD>.overlay` exists, it will be used in addition to the above.
3. If the current board has *multiple revisions* and `boards/<BOARD>_<revision>.overlay` exists, it will be used in addition to the above.
4. If one or more files have been found in the previous steps, the build system stops looking and just uses those files.
5. Otherwise, if `<BOARD>.overlay` exists, it will be used, and the build system will stop looking for more files.
6. Otherwise, if `app.overlay` exists, it will be used.

Extra devicetree overlays may be provided using `EXTRA_DTC_OVERLAY_FILE` which will still allow the build system to automatically use devicetree overlays described in the above steps.

The build system appends overlays specified in `EXTRA_DTC_OVERLAY_FILE` to the overlays in `DTC_OVERLAY_FILE` when processing devicetree overlays. This means that changes made via `EXTRA_DTC_OVERLAY_FILE` have higher precedence than those made via `DTC_OVERLAY_FILE`.

All configuration files will be taken from the application's configuration directory except for files with an absolute path that are given with the `DTC_OVERLAY_FILE` or `EXTRA_DTC_OVERLAY_FILE` argument.

See *Application Configuration Directory* on how the application configuration directory is defined.

Using *Shields* will also add devicetree overlay files.

The **DTC_OVERLAY_FILE** value is stored in the CMake cache and used in successive builds.

The *build system* prints all the devicetree overlays it finds in the configuration phase, like this:

```
-- Found devicetree overlay: .../some/file.overlay
```

Use devicetree overlays See *Set devicetree overlays* for how to add an overlay to the build.

Overlays can override node property values in multiple ways. For example, if your BOARD.dts contains this node:

```
/ {
        soc {
                serial0: serial@40002000 {
                        status = "okay";
                        current-speed = <115200>;
                        /* ... */
                };
        };
};
```

These are equivalent ways to override the `current-speed` value in an overlay:

```
/* Option 1 */
&serial0 {
     current-speed = <9600>;
};

/* Option 2 */
&{/soc/serial@40002000} {
```

(continues on next page)

(continued from previous page)

```
        current-speed = <9600>;
};
```

We'll use the `&serial0` style for the rest of these examples.

You can add aliases to your devicetree using overlays: an alias is just a property of the `/aliases` node. For example:

```
/ {
        aliases {
                my-serial = &serial0;
        };
};
```

Chosen nodes work the same way. For example:

```
/ {
        chosen {
                zephyr,console = &serial0;
        };
};
```

To delete a property (in addition to deleting properties in general, this is how to set a boolean property to false if it's true in BOARD.dts):

```
&serial0 {
        /delete-property/ some-unwanted-property;
};
```

You can add subnodes using overlays. For example, to configure a SPI or I2C child device on an existing bus node, do something like this:

```
/* SPI device example */
&spi1 {
        my_spi_device: temp-sensor@0 {
                compatible = "...";
                label = "TEMP_SENSOR_0";
                /* reg is the chip select number, if needed;
                 * If present, it must match the node's unit address. */
                reg = <0>;

                /* Configure other SPI device properties as needed.
                 * Find your device's DT binding for details. */
                spi-max-frequency = <DT_FREQ_M(4)>;
        };
};

/* I2C device example */
&i2c2 {
        my_i2c_device: touchscreen@76 {
                compatible = "...";
                label = "TOUCHSCREEN";
                /* reg is the I2C device address.
                 * It must match the node's unit address. */
                reg = <76>;

                /* Configure other I2C device properties as needed.
                 * Find your device's DT binding for details. */
```

(continues on next page)

(continued from previous page)

```
    };
};
```

Other bus devices can be configured similarly:

- create the device as a subnode of the parent bus
- set its properties according to its binding

Assuming you have a suitable device driver associated with the `my_spi_device` and `my_i2c_device` compatibles, you should now be able to enable the driver via Kconfig and *get the struct device* for your newly added bus node, then use it with that driver API.

Write device drivers using devicetree APIs "Devicetree-aware" *device drivers* should create a `struct device` for each `status = "okay"` devicetree node with a particular *compatible* (or related set of compatibles) supported by the driver.

Writing a devicetree-aware driver begins by defining a *devicetree binding* for the devices supported by the driver. Use existing bindings from similar drivers as a starting point. A skeletal binding to get started needs nothing more than this:

```
description: <Human-readable description of your binding>
compatible: "foo-company,bar-device"
include: base.yaml
```

See *Find a devicetree binding* for more advice on locating existing bindings.

After writing your binding, your driver C file can then use the devicetree API to find `status = "okay"` nodes with the desired compatible, and instantiate a `struct device` for each one. There are two options for instantiating each `struct device`: using instance numbers, and using node labels.

In either case:

- Each `struct device`'s name should be set to its devicetree node's `label` property. This allows the driver's users to *Get a struct device from a devicetree node* in the usual way.
- Each device's initial configuration should use values from devicetree properties whenever practical. This allows users to configure the driver using *devicetree overlays*.

Examples for how to do this follow. They assume you've already implemented the device-specific configuration and data structures and API functions, like this:

```
/* my_driver.c */
#include <zephyr/drivers/some_api.h>

/* Define data (RAM) and configuration (ROM) structures: */
struct my_dev_data {
    /* per-device values to store in RAM */
};
struct my_dev_cfg {
    uint32_t freq; /* Just an example: initial clock frequency in Hz */
    /* other configuration to store in ROM */
};

/* Implement driver API functions (drivers/some_api.h callbacks): */
static int my_driver_api_func1(const struct device *dev, uint32_t *foo) { /* ...␣
↪*/ }
static int my_driver_api_func2(const struct device *dev, uint64_t bar) { /* ... */␣
↪}
static struct some_api my_api_funcs = {
```

(continues on next page)

(continued from previous page)

```
    .func1 = my_driver_api_func1,
    .func2 = my_driver_api_func2,
};
```

Option 1: create devices using instance numbers Use this option, which uses *Instance-based APIs*, if possible. However, they only work when devicetree nodes for your driver's `compatible` are all equivalent, and you do not need to be able to distinguish between them.

To use instance-based APIs, begin by defining `DT_DRV_COMPAT` to the lowercase-and-underscores version of the compatible that the device driver supports. For example, if your driver's compatible is `"vnd,my-device"` in devicetree, you would define `DT_DRV_COMPAT` to `vnd_my_device` in your driver C file:

```
/*
 * Put this near the top of the file. After the includes is a good place.
 * (Note that you can therefore run "git grep DT_DRV_COMPAT drivers" in
 * the zephyr Git repository to look for example drivers using this style).
 */
#define DT_DRV_COMPAT vnd_my_device
```

Important

As shown, the DT_DRV_COMPAT macro should have neither quotes nor special characters. Remove quotes and convert special characters to underscores when creating `DT_DRV_COMPAT` from the compatible property.

Finally, define an instantiation macro, which creates each `struct device` using instance numbers. Do this after defining `my_api_funcs`.

```
/*
 * This instantiation macro is named "CREATE_MY_DEVICE".
 * Its "inst" argument is an arbitrary instance number.
 *
 * Put this near the end of the file, e.g. after defining "my_api_funcs".
 */
#define CREATE_MY_DEVICE(inst)                                          \
    static struct my_dev_data my_data_##inst = {                        \
            /* initialize RAM values as needed, e.g.: */                \
            .freq = DT_INST_PROP(inst, clock_frequency),                \
    };                                                                  \
    static const struct my_dev_cfg my_cfg_##inst = {                    \
            /* initialize ROM values as needed. */                      \
    };                                                                  \
    DEVICE_DT_INST_DEFINE(inst,                                         \
                          my_dev_init_function,                         \
                          NULL,                                         \
                          &my_data_##inst,                              \
                          &my_cfg_##inst,                               \
                          MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY,      \
                          &my_api_funcs);
```

Notice the use of APIs like `DT_INST_PROP` and `DEVICE_DT_INST_DEFINE` to access devicetree node data. These APIs retrieve data from the devicetree for instance number `inst` of the node with compatible determined by `DT_DRV_COMPAT`.

Finally, pass the instantiation macro to `DT_INST_FOREACH_STATUS_OKAY`:

```
/* Call the device creation macro for each instance: */
DT_INST_FOREACH_STATUS_OKAY(CREATE_MY_DEVICE)
```

DT_INST_FOREACH_STATUS_OKAY expands to code which calls CREATE_MY_DEVICE once for each enabled node with the compatible determined by DT_DRV_COMPAT. It does not append a semicolon to the end of the expansion of CREATE_MY_DEVICE, so the macro's expansion must end in a semicolon or function definition to support multiple devices.

Option 2: create devices using node labels Some device drivers cannot use instance numbers. One example is an SoC peripheral driver which relies on vendor HAL APIs specialized for individual IP blocks to implement Zephyr driver callbacks. Cases like this should use DT_NODELABEL to refer to individual nodes in the devicetree representing the supported peripherals on the SoC. The devicetree.h *Generic APIs* can then be used to access node data.

For this to work, your *SoC's dtsi file* must define node labels like mydevice0, mydevice1, etc. appropriately for the IP blocks your driver supports. The resulting devicetree usually looks something like this:

```
/ {
        soc {
                mydevice0: dev@0 {
                        compatible = "vnd,my-device";
                };
                mydevice1: dev@1 {
                        compatible = "vnd,my-device";
                };
        };
};
```

The driver can use the mydevice0 and mydevice1 node labels in the devicetree to operate on specific device nodes:

```
/*
 * This is a convenience macro for creating a node identifier for
 * the relevant devices. An example use is MYDEV(0) to refer to
 * the node with label "mydevice0".
 */
#define MYDEV(idx) DT_NODELABEL(mydevice ## idx)

/*
 * Define your instantiation macro; "idx" is a number like 0 for mydevice0
 * or 1 for mydevice1. It uses MYDEV() to create the node label from the
 * index.
 */
#define CREATE_MY_DEVICE(idx)                                           \
    static struct my_dev_data my_data_##idx = {                         \
            /* initialize RAM values as needed, e.g.: */                \
            .freq = DT_PROP(MYDEV(idx), clock_frequency),               \
    };                                                                  \
    static const struct my_dev_cfg my_cfg_##idx = { /* ... */ };        \
    DEVICE_DT_DEFINE(MYDEV(idx),                                        \
                     my_dev_init_function,                              \
                     NULL,                                              \
                     &my_data_##idx,                                    \
                     &my_cfg_##idx,                                     \
                     MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY,           \
                     &my_api_funcs)
```

Notice the use of APIs like DT_PROP and DEVICE_DT_DEFINE to access devicetree node data.

Finally, manually detect each enabled devicetree node and use CREATE_MY_DEVICE to instantiate each struct device:

```
#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice0), okay)
CREATE_MY_DEVICE(0)
#endif

#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice1), okay)
CREATE_MY_DEVICE(1)
#endif
```

Since this style does not use DT_INST_FOREACH_STATUS_OKAY(), the driver author is responsible for calling CREATE_MY_DEVICE() for every possible node, e.g. using knowledge about the peripherals available on supported SoCs.

Device drivers that depend on other devices At times, one struct device depends on another struct device and requires a pointer to it. For example, a sensor device might need a pointer to its SPI bus controller device. Some advice:

- Write your devicetree binding in a way that permits use of *Hardware specific APIs* from devicetree.h if possible.
- In particular, for bus devices, your driver's binding should include a file like dts/bindings/spi/spi-device.yaml which provides common definitions for devices addressable via a specific bus. This enables use of APIs like DT_BUS to obtain a node identifier for the bus node. You can then *Get a struct device from a devicetree node* for the bus in the usual way.

Search existing bindings and device drivers for examples.

Applications that depend on board-specific devices One way to allow application code to run unmodified on multiple boards is by supporting a devicetree alias to specify the hardware specific portions, as is done in the blinky sample. The application can then be configured in *BOARD.dts* files or via *devicetree overlays*.

Troubleshooting devicetree

Here are some tips for fixing misbehaving devicetree related code.

See *Devicetree HOWTOs* for other "HOWTO" style information.

Important

Try this first, before doing anything else.

Try again with a pristine build directory See *Pristine Builds* for examples, or just delete the build directory completely and retry.

This is general advice which is especially applicable to debugging devicetree issues, because the outputs are created during the CMake configuration phase, and are not always regenerated when one of their inputs changes.

Use Devicetree diagnostics tool (DT Doctor) An optional Devicetree diagnostics tool is available to help diagnose Devicetree issues. It can be enabled by passing the -DZEPHYR_SCA_VARIANT=dtdoctor argument to *west build*.

See *Devicetree diagnostics (dtdoctor)* for more information.

Make sure <devicetree.h> is included Unlike Kconfig symbols, the `devicetree.h` header must be included explicitly.

Many Zephyr header files rely on information from devicetree, so including some other API may transitively include `devicetree.h`, but that's not guaranteed.

undefined reference to `__device_dts_ord_<N>` This usually happens on a line like this:

```
const struct device *dev = DEVICE_DT_GET(NODE_ID);
```

where `NODE_ID` is a valid *node identifier*, but no device driver has allocated a `struct device` for this devicetree node. You thus get a linker error, because you're asking for a pointer to a device that isn't defined.

To fix it, you need to make sure that:

1. The node is enabled: the node must have `status = "okay";`.

   (Recall that a missing `status` property means the same thing as `status = "okay";`; see *Important properties* for more information about `status`).

2. A device driver responsible for allocating the `struct device` is enabled. That is, the Kconfig option which makes the build system compile the driver sources into your application needs to be set to `y`.

   (See *Setting Kconfig configuration values* for more information on setting Kconfig options.)

Below, `<build>` means your build directory.

Making sure the node is enabled:

To find the devicetree node you need to check, use the number `<N>` from the linker error. Look for this number in the list of nodes at the top of `<build>/zephyr/include/generated/zephyr/devicetree_generated.h`. For example, if `<N>` is 15, and your `devicetree_generated.h` file looks like this, the node you are interested in is `/soc/i2c@deadbeef`:

```
/*
 * Generated by gen_defines.py
 *
 * DTS input file:
 *   <build>/zephyr/zephyr.dts.pre
 *
 * Directories with bindings:
 *   $ZEPHYR_BASE/dts/bindings
 *
 * Node dependency ordering (ordinal and path):
 *   0   /
 *   1   /aliases
[...]
 *   15  /soc/i2c@deadbeef
[...]
```

Now look for this node in `<build>/zephyr/zephyr.dts`, which is the final devicetree for your application build. (See *Get your devicetree and generated header* for information and examples.)

If the node has `status = "disabled";` in `zephyr.dts`, then you need to enable it by setting `status = "okay";`, probably by using a devicetree *overlay*. For example, if `zephyr.dts` looks like this:

```
i2c0: i2c@deadbeef {
        status = "disabled";
};
```

Then you should put this into your devicetree overlay and *Try again with a pristine build directory*:

```
&i2c0 {
        status = "okay";
};
```

Make sure that you see `status = "okay";` in `zephyr.dts` after you rebuild.

Making sure the device driver is enabled:

The first step is to figure out which device driver is responsible for handling your devicetree node and allocating devices for it. To do this, you need to start with the `compatible` property in your devicetree node, and find the driver that allocates `struct device` instances for that compatible.

If you're not familiar with how devices are allocated from devicetree nodes based on compatible properties, the ZDS 2021 talk A deep dive into the Zephyr 2.5 device model may be a useful place to start, along with the *Device Driver Model* pages. See *Important properties* and the Devicetree specification for more information about `compatible`.

There is currently no documentation for what device drivers exist and which devicetree compatibles they are associated with. You will have to figure this out by reading the source code:

- Look in drivers for the appropriate subdirectory that corresponds to the API your device implements
- Look inside that directory for relevant files until you figure out what the driver is, or realize there is no such driver.

Often, but not always, you can find the driver by looking for a file that sets the `DT_DRV_COMPAT` macro to match your node's `compatible` property, except lowercased and with special characters converted to underscores. For example, if your node's compatible is `vnd,foo-device`, look for a file with this line:

```
#define DT_DRV_COMPAT vnd_foo_device
```

Important

This **does not always work** since not all drivers use `DT_DRV_COMPAT`.

If you find a driver, you next need to make sure the Kconfig option that compiles it is enabled. (If you don't find a driver, and you are sure the compatible property is correct, then you need to write a driver. Writing drivers is outside the scope of this documentation page.)

Continuing the above example, if your devicetree node looks like this now:

```
i2c0: i2c@deadbeef {
        compatible = "nordic,nrf-twim";
        status = "okay";
};
```

Then you would look inside of drivers/i2c for the driver file that handles the compatible `nordic,nrf-twim`. In this case, that is drivers/i2c/i2c_nrfx_twim.c. Notice how even in cases where `DT_DRV_COMPAT` is not set, you can use information like driver file names as clues.

Once you know the driver you want to enable, you need to make sure its Kconfig option is set to `y`. You can figure out which Kconfig option is needed by looking for a line similar to this one in the `CMakeLists.txt` file in the drivers subdirectory. Continuing the above example, drivers/i2c/CMakeLists.txt has a line that looks like this:

```
zephyr_library_sources_ifdef(CONFIG_NRFX_TWIM       i2c_nrfx_twim.c)
```

This means that `CONFIG_NRFX_TWIM` must be set to `y` in `<build>/zephyr/.config` file.

If your driver's Kconfig is not set to `y`, you need to figure out what you need to do to make that happen. Often, this will happen automatically as soon as you enable the devicetree node. Otherwise, it is sometimes as simple as adding a line like this to your application's `prj.conf` file and then making sure to *Try again with a pristine build directory*:

```
CONFIG_FOO=y
```

where `CONFIG_FOO` is the option that `CMakeLists.txt` uses to decide whether or not to compile the driver.

However, there may be other problems in your way, such as unmet Kconfig dependencies that you also have to enable before you can enable your driver.

Consult the Kconfig file that defines `CONFIG_FOO` (for your value of `FOO`) for more information.

Make sure you're using the right names Remember that:

- In C/C++, devicetree names must be lowercased and special characters must be converted to underscores. Zephyr's generated devicetree header has DTS names converted in this way into the C tokens used by the preprocessor-based `<devicetree.h>` API.
- In overlays, use devicetree node and property names the same way they would appear in any DTS file. Zephyr overlays are just DTS fragments.

For example, if you're trying to **get** the `clock-frequency` property of a node with path `/soc/i2c@12340000` in a C/C++ file:

```
/*
 * foo.c: lowercase-and-underscores names
 */

/* Don't do this: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c@1234000), clock-frequency)
/*                                          ^              ^
 *                                   @ should be _     - should be _  */

/* Do this instead: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c_1234000), clock_frequency)
/*                                          ^              ^           */
```

And if you're trying to **set** that property in a devicetree overlay:

```
/*
 * foo.overlay: DTS names with special characters, etc.
 */

/* Don't do this; you'll get devicetree errors. */
&{/soc/i2c_12340000/} {
     clock_frequency = <115200>;
};

/* Do this instead. Overlays are just DTS fragments. */
&{/soc/i2c@12340000/} {
     clock-frequency = <115200>;
};
```

Look at the preprocessor output To save preprocessor output files, enable the `CONFIG_COMPILER_SAVE_TEMPS` option. For example, to build hello_world with west with this option set, use:

```
west build -b BOARD samples/hello_world -- -DCONFIG_COMPILER_SAVE_TEMPS=y
```

This will create a preprocessor output file named `foo.c.i` in the build directory for each source file `foo.c`.

You can then search for the file in the build directory to see what your devicetree macros expanded to. For example, on macOS and Linux, using `find` to find `main.c.i`:

```
$ find build -name main.c.i
build/CMakeFiles/app.dir/src/main.c.i
```

It's usually easiest to run a style formatter on the results before opening them. For example, to use `clang-format` to reformat the file in place:

```
clang-format -i build/CMakeFiles/app.dir/src/main.c.i
```

You can then open the file in your favorite editor to view the final C results after preprocessing.

Do not track macro expansion Compiler messages for devicetree errors can sometimes be very long. This typically happens when the compiler prints a message for every step of a complex macro expansion that has several intermediate expansion steps.

To prevent the compiler from doing this, you can disable the `CONFIG_COMPILER_TRACK_MACRO_EXPANSION` option. This typically reduces the output to one message per error.

For example, to build hello_world with west and this option disabled, use:

```
west build -b BOARD samples/hello_world -- -
↪DCONFIG_COMPILER_TRACK_MACRO_EXPANSION=n
```

Validate properties If you're getting a compile error reading a node property, check your node identifier and property. For example, if you get a build error on a line that looks like this:

```
int baud_rate = DT_PROP(DT_NODELABEL(my_serial), current_speed);
```

Try checking the node by adding this to the file and recompiling:

```
#if !DT_NODE_EXISTS(DT_NODELABEL(my_serial))
#error "whoops"
#endif
```

If you see the "whoops" error message when you rebuild, the node identifier isn't referring to a valid node. *Get your devicetree and generated header* and debug from there.

Some hints for what to check next if you don't see the "whoops" error message:

- did you *Make sure you're using the right names*?
- does the *property exist*?
- does the node have a *matching binding*?
- does the binding define the property?

Check for missing bindings See *Devicetree bindings* for information about bindings, and *Bindings index* for information on bindings built into Zephyr.

If the build fails to *Find a devicetree binding* for a node, then either the node's `compatible` property is not defined, or its value has no matching binding. If the property is set, check for typos in its name. In a devicetree source file, `compatible` should look like `"vnd,some-device"` – *Make sure you're using the right names*.

If your binding file is not under `zephyr/dts`, you may need to set *DTS_ROOT*; see *Where bindings are located*.

Errors with DT_INST_() APIs If you're using an API like `DT_INST_PROP()`, you must define `DT_DRV_COMPAT` to the lowercase-and-underscores version of the compatible you are interested in. See *Option 1: create devices using instance numbers*.

Devicetree versus Kconfig

Along with devicetree, Zephyr also uses the Kconfig language to configure the source code. Whether to use devicetree or Kconfig for a particular purpose can sometimes be confusing. This section should help you decide which one to use.

In short:

- Use devicetree to describe **hardware** and its **boot-time configuration**. Examples include peripherals on a board, boot-time clock frequencies, interrupt lines, etc.
- Use Kconfig to configure **software support** to build into the final image. Examples include whether to add networking support, which drivers are needed by the application, etc.

In other words, devicetree mainly deals with hardware, and Kconfig with software.

For example, consider a board containing a SoC with 2 UART, or serial port, instances.

- The fact that the board has this UART **hardware** is described with two UART nodes in the devicetree. These provide the UART type (via the `compatible` property) and certain settings such as the address range of the hardware peripheral registers in memory (via the `reg` property).
- Additionally, the UART **boot-time configuration** is also described with devicetree. This could include configuration such as the RX IRQ line's priority and the UART baud rate. These may be modifiable at runtime, but their boot-time configuration is described in devicetree.
- From the application code, both UART are interchangeable and using one or the other has no impact, it is only a matter of board design. It is pure **hardware configuration** and should be done with devicetree.
- Whether or not to include **software support** for UART in the build is controlled via Kconfig. Applications which do not need to use the UARTs can remove the driver source code from the build using Kconfig, even though the board's devicetree still includes UART nodes.

As another example, consider a device with a 2.4GHz, multi-protocol radio supporting both the Bluetooth Low Energy and 802.15.4 wireless technologies.

- Devicetree should be used to describe the presence of the radio **hardware**, what driver or drivers it's compatible with, etc.
- **Boot-time configuration** for the radio, such as TX power in dBm, should also be specified using devicetree.
- On the application, using one or the other protocol will not get the same code into play, but the same hardware will be used. This is relevant to **software configuration**.
- Kconfig should determine which **software features** should be built for the radio, such as selecting a BLE or 802.15.4 protocol stack.

As another example, Kconfig options that formerly enabled a particular instance of a driver (that is itself enabled by Kconfig) have been removed. The devices are selected individually using devicetree's *status* keyword on the corresponding hardware instance.

There are **exceptions** to these rules:

- Because Kconfig is unable to flexibly control some instance-specific driver configuration parameters, such as the size of an internal buffer, these options may be defined in devicetree. However, to make clear that they are specific to Zephyr drivers and not hardware

description or configuration these properties should be prefixed with `zephyr,`, e.g. `zephyr,random-mac-address` in the common Ethernet devicetree properties.

- Devicetree's `chosen` keyword, which allows the user to select a specific instance of a hardware device to be used for a particular purpose. An example of this is selecting a particular UART for use as the system's console.

Automatic Kconfig symbols from devicetree During the devicetree processing step, CMake runs scripts/dts/gen_driver_kconfig_dts.py, which scans all *DTS root* directories, including dts/bindings and writes `Kconfig.dts` into the build's `KCONFIG_BINARY_DIR` (for example `<build>/zephyr` or `<build>/<image>/zephyr` in case of *Sysbuild (System build)*). For each `compatible = "vendor,chip"` that appears in a binding, the generated file contains:

```
DT_COMPAT_VENDOR_CHIP := vendor,chip

config DT_HAS_VENDOR_CHIP_ENABLED
        def_bool $(dt_compat_enabled,$(DT_COMPAT_VENDOR_CHIP))
```

The assignment keeps the literal `compatible` string available to the preprocessor functions described in *Custom Kconfig Preprocessor Functions*, so that Kconfig files can call helpers such as `$(dt_compat_on_bus,$(DT_COMPAT_<compatible>),i2c)`. Characters like `-`, `,` and `@` are converted to underscores when the symbol names are created.

The hidden boolean symbol becomes `CONFIG_DT_HAS_<compatible>_ENABLED` after Kconfig runs. Its value tracks whether the current devicetree contains at least one node with that `compatible` whose *status* is `okay`. Symbols for enabling drivers should almost certainly be `default y` and have `depends on CONFIG_DT_HAS_<compatible>_ENABLED`, for example:

```
config SENSOR_VENDOR_CHIP
        bool "Vendor Chip sensor"
        default y
        depends on DT_HAS_VENDOR_CHIP_ENABLED
```

Because these symbols are generated automatically, adding a new binding with a `compatible` property is all that is required to make the corresponding `DT_HAS_<compatible>_ENABLED` and `DT_COMPAT_<compatible>` constructs available to Kconfig.

5.2.2 Devicetree Reference

These pages contain reference material for Zephyr's devicetree APIs and built-in bindings.

For the platform-independent details, see the Devicetree specification.

Devicetree API

This is a reference page for the `<zephyr/devicetree.h>` API. The API is macro based. Use of these macros has no impact on scheduling. They can be used from any calling context and at file scope.

Some of these – the ones beginning with `DT_INST_` – require a special macro named `DT_DRV_COMPAT` to be defined before they can be used; these are discussed individually below. These macros are generally meant for use within *device drivers*, though they can be used outside of drivers with appropriate care.

Contents

  - *Reset Controller*
  - *SPI*
- *Chosen nodes*
- *Zephyr-specific chosen nodes*

Generic APIs The APIs in this section can be used anywhere and do not require `DT_DRV_COMPAT` to be defined.

Node identifiers and helpers A *node identifier* is a way to refer to a devicetree node at C preprocessor time. While node identifiers are not C values, you can use them to access devicetree data in C rvalue form using, for example, the *Property access* API.

The root node `/` has node identifier `DT_ROOT`. You can create node identifiers for other devicetree nodes using `DT_PATH`, `DT_NODELABEL`, `DT_ALIAS`, and `DT_INST`.

There are also `DT_PARENT` and `DT_CHILD` macros which can be used to create node identifiers for a given node's parent node or a particular child node, respectively.

The following macros create or operate on node identifiers.

Node identifiers and helpers

Related code samples

- GPIO with custom Devicetree bindingUse custom Devicetree binding to control a GPIO.

Property access The following general-purpose macros can be used to access node properties. There are special-purpose APIs for accessing the *ranges property*, *reg property* and *interrupts property*.

Property values can be read using these macros even if the node is disabled, as long as it has a matching binding.

Property accessors

`ranges` property Use these APIs instead of *Property access* to access the `ranges` property. Because this property's semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings. However, they take on special semantics when the node's binding indicates it is a PCIe bus node, as defined in the PCI Bus Binding to: IEEE Std 1275-1994 Standard for Boot (Initialization Configuration) Firmware

ranges property

`reg` property Use these APIs instead of *Property access* to access the `reg` property. Because this property's semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings.

reg property

`interrupts` property Use these APIs instead of *Property access* to access the `interrupts` property.

Because this property's semantics are defined by the devicetree specification, some of these macros can be used even for nodes without matching bindings. This does not apply to macros which take cell names as arguments.

interrupts property

For-each macros The `DT_FOREACH_ANCESTOR` macro allows iterating over the ancestor node of a devicetree node. Additionally, the `DT_FOREACH_CHILD` macro allows iterating over the children of a devicetree node.

There are special-purpose for-each macros, like `DT_INST_FOREACH_STATUS_OKAY`, but these require `DT_DRV_COMPAT` to be defined before use.

"For-each" macros

Existence checks This section documents miscellaneous macros that can be used to test if a node exists, how many nodes of a certain type exist, whether a node has certain properties, etc. Some macros used for special purposes (such as `DT_IRQ_HAS_IDX` and all macros which require `DT_DRV_COMPAT`) are documented elsewhere on this page.

Existence checks

Related code samples

- GPIO with custom Devicetree bindingUse custom Devicetree binding to control a GPIO.

Inter-node dependencies The `devicetree.h` API has some support for tracking dependencies between nodes. Dependency tracking relies on a binary "depends on" relation between devicetree nodes, which is defined as the transitive closure of the following "directly depends on" relation:

- every non-root node directly depends on its parent node
- a node directly depends on any nodes its properties refer to by phandle
- a node directly depends on its `interrupt-parent` if it has an `interrupts` property
- a parent node inherits all dependencies from its child nodes

A *dependency ordering* of a devicetree is a list of its nodes, where each node `n` appears earlier in the list than any nodes that depend on `n`. A node's *dependency ordinal* is then its zero-based index in that list. Thus, for two distinct devicetree nodes `n1` and `n2` with dependency ordinals `d1` and `d2`, we have:

- `d1 != d2`
- if `n1` depends on `n2`, then `d1 > d2`
- `d1 > d2` does **not** necessarily imply that `n1` depends on `n2`

The Zephyr build system chooses a dependency ordering of the final devicetree and assigns a dependency ordinal to each node. Dependency related information can be accessed using the following macros. The exact dependency ordering chosen is an implementation detail, but cyclic dependencies are detected and cause errors, so it's safe to assume there are none when using these macros.

There are instance number-based conveniences as well; see `DT_INST_DEP_ORD` and subsequent documentation.

Dependency tracking

Bus helpers Zephyr's devicetree bindings language supports a `bus:` key which allows bindings to declare that nodes with a given compatible describe system buses. In this case, child nodes are considered to be on a bus of the given type, and the following APIs may be used.

Bus helpers

Instance-based APIs These are recommended for use within device drivers. To use them, define `DT_DRV_COMPAT` to the lowercase-and-underscores compatible the device driver implements support for. Here is an example devicetree fragment:

```
serial@40001000 {
        compatible = "vnd,serial";
        status = "okay";
        current-speed = <115200>;
};
```

Example usage, assuming `serial@40001000` is the only enabled node with compatible `vnd,serial`:

```
#define DT_DRV_COMPAT vnd_serial
DT_DRV_INST(0)                  // node identifier for serial@40001000
DT_INST_PROP(0, current_speed)  // 115200
```

Warning

Be careful making assumptions about instance numbers. See DT_INST for the API guarantees.

As shown above, the DT_INST_* APIs are conveniences for addressing nodes by instance number. They are almost all defined in terms of one of the *Generic APIs*. The equivalent generic API can be found by removing INST_ from the macro name. For example, DT_INST_PROP(inst, prop) is equivalent to DT_PROP(DT_DRV_INST(inst), prop). Similarly, DT_INST_REG_ADDR(inst) is equivalent to DT_REG_ADDR(DT_DRV_INST(inst)), and so on. There are some exceptions: DT_ANY_INST_ON_BUS_STATUS_OKAY and DT_INST_FOREACH_STATUS_OKAY are special-purpose helpers without straightforward generic equivalents.

Since DT_DRV_INST() requires DT_DRV_COMPAT to be defined, it's an error to use any of these without that macro defined.

Note that there are also helpers available for specific hardware; these are documented in *Hardware specific APIs*.

Instance-based devicetree APIs

Hardware specific APIs The following APIs can also be used by including <devicetree.h>; no additional include is needed.

CAN These conveniences may be used for nodes which describe CAN controllers/transceivers, and properties related to them.

Devicetree CAN API

Clocks These conveniences may be used for nodes which describe clock sources, and properties related to them.

Devicetree Clocks API

DMA These conveniences may be used for nodes which describe direct memory access controllers or channels, and properties related to them.

Devicetree DMA API

Display These conveniences may be used for nodes which describe display controllers, and properties related to them.

Devicetree Display API

Fixed flash partitions These conveniences may be used for the special-purpose fixed-partitions compatible used to encode information about flash memory partitions in the device tree. See See fixed-partition for more details.

Devicetree Fixed Partition API

GPIO These conveniences may be used for nodes which describe GPIO controllers/pins, and properties related to them.

Devicetree GPIO API

HWSpinlock These conveniences may be used for nodes which describe hardware spinlock, and properties related to them.

Devicetree HW spinlock API

IO channels These are commonly used by device drivers which need to use IO channels (e.g. ADC or DAC channels) for conversion.

Devicetree IO Channels API

MBOX These conveniences may be used for nodes which describe MBOX controllers/users, and properties related to them.

Devicetree MBOX API

NVMEM These conveniences may be used for nodes which describe Non-Volatile Memory, and properties related to them.

NVMEM Devicetree Helpers

Ordinals These conveniences may be used for nodes which describe Dependency tracking, and properties related to them.

Dependency tracking

Pinctrl (pin control) These are used to access pin control properties by name or index.

Devicetree nodes may have properties which specify pin control (sometimes known as pin mux) settings. These are expressed using `pinctrl-<index>` properties within the node, where the `<index>` values are contiguous integers starting from 0. These may also be named using the `pinctrl-names` property.

Here is an example:

```
node {
    ...
    pinctrl-0 = <&foo &bar ...>;
    pinctrl-1 = <&baz ...>;
    pinctrl-names = "default", "sleep";
};
```

Above, `pinctrl-0` has name `"default"`, and `pinctrl-1` has name `"sleep"`. The `pinctrl-<index>` property values contain phandles. The `&foo`, `&bar`, etc. phandles within the properties point to nodes whose contents vary by platform, and which describe a pin configuration for the node.

Pin control

PWM These conveniences may be used for nodes which describe PWM controllers and properties related to them.

Devicetree PWMs API

Reset Controller These conveniences may be used for nodes which describe reset controllers and properties related to them.

Devicetree Reset Controller API

SPI These conveniences may be used for nodes which describe either SPI controllers or devices, depending on the case.

Devicetree SPI API

Chosen nodes The special `/chosen` node contains properties whose values describe system-wide settings. The `DT_CHOSEN()` macro can be used to get a node identifier for a chosen node.

Chosen nodes

Zephyr-specific chosen nodes The following table documents some commonly used Zephyr-specific chosen nodes.

Sometimes, a chosen node's label property will be used to set the default value of a Kconfig option which in turn configures a hardware-specific device. This is usually for backwards compatibility in cases when the Kconfig option predates devicetree support in Zephyr. In other cases, there is no Kconfig option, and the devicetree node is used directly in the source code to select a device.

Table 1: Zephyr-specific chosen properties

Property	Purpose
zephyr,bt-c2h-uart	Selects the UART used for host communication in the bluetooth_hci_uart
zephyr,bt-mon-uart	Sets UART device used for the Bluetooth monitor logging
zephyr,bt-hci	Selects the HCI device used by the Bluetooth host stack
zephyr,camera	Video input device, typically a camera.
zephyr,canbus	Sets the default CAN controller
zephyr,code-partition	Flash partition that the Zephyr image's text section should be linked into
zephyr,console	Sets UART device used by console driver
zephyr,crc	Selects the CRC device used as an accelerator by the CRC subsystem
zephyr,display	Sets the default display controller
zephyr,dtcm	Data Tightly Coupled Memory node on some Arm SoCs
zephyr,entropy	A device which can be used as a system-wide entropy source
zephyr,flash	A node whose `reg` is sometimes used to set the defaults for `CONFIG_FLASH_BASE_ADDRESS` and `CONFIG_FLASH_SIZE`
zephyr,flash-controller	The node corresponding to the flash controller device for the `zephyr,flash` node
zephyr,gdbstub-uart	Sets UART device used by the *GDB stub* subsystem
zephyr,ieee802154	Used by the networking subsystem to set the IEEE 802.15.4 device
zephyr,ipc	Used by the OpenAMP subsystem to specify the inter-process communication (IPC) device
zephyr,ipc_shm	A node whose `reg` is used by the OpenAMP subsystem to determine the base address and size of the shared memory (SHM) usable for interprocess-communication (IPC)
zephyr,ipc_rsc_table	Specifies a memory region that will be used for the OpenAMP resource table. Only needed if `CONFIG_OPENAMP_COPY_RSC_TABLE` is enabled.
zephyr,itcm	Instruction Tightly Coupled Memory node on some Arm SoCs
zephyr,log-uart	Sets the UART device(s) used by the logging subsystem's UART backend. If defined, the UART log backend would output to the devices listed in this node.
zephyr,ocm	On-chip memory node on Xilinx Zynq-7000 and ZynqMP SoCs
zephyr,osdp-uart	Sets UART device used by OSDP subsystem
zephyr,ot-uart	Used by the OpenThread to specify UART device for Spinel protocol
zephyr,pcie-controller	The node corresponding to the PCIe Controller
zephyr,ppp-uart	Sets UART device used by PPP

continues on next page

Table 1 – continued from previous page

Property	Purpose
zephyr,settings-partition	Fixed partition node. If defined this selects the partition used by the NVS and FCB settings backends.
zephyr,shell-uart	Sets UART device used by serial shell backend
zephyr,sram	A node whose `reg` sets the base address and size of SRAM memory available to the Zephyr image, used during linking
zephyr,tracing-uart	Sets UART device used by tracing subsystem
zephyr,uart-mcumgr	UART used for *Device Management*
zephyr,uart-pipe	Sets UART device used by serial pipe driver
zephyr,led-strip	A LED-strip node which is used to determine the timings of the WS2812 GPIO driver
zephyr,touch	Touchscreen controller device node. When LVGL is used, if `CONFIG_LV_Z_POINTER_FROM_CHOSEN_TOUCH` is enabled, an LVGL pointer input device is created using the touchscreen controller as its input source.
zephyr,videoenc	Video encoder device, typically an H264 or MJPEG video encoder.
mcuboot,ram-load-dev	When a Zephyr application is built to be loaded to RAM by MCUboot, with `CONFIG_MCUBOOT_BOOTLOADER_MODE_SINGLE_APP_RAM_LOAD`, this property is used to tell MCUboot the load address of the image, which will be the `reg` of the chosen node.
zephyr,boot-mode	Used for *Boot mode* selection, part of *Retention System*, which specifies what image on a device should be booted.

Bindings index

This page documents the available devicetree bindings. See *Devicetree bindings* for an introduction to the Zephyr bindings file format.

Vendor index This section contains an index of hardware vendors. Click on a vendor's name to go to the list of bindings for that vendor.

Bindings by vendor This section contains available bindings, grouped by vendor. Within each group, bindings are listed by the "compatible" property they apply to, like this:

Vendor name (vendor prefix)

- <compatible-A>
- <compatible-B> (on <bus-name> bus)
- <compatible-C>
- ...

The text "(on <bus-name> bus)" appears when bindings may behave differently depending on the bus the node appears on. For example, this applies to some sensor device nodes, which may appear as children of either I2C or SPI bus nodes.

5.3 Configuration System (Kconfig)

The Zephyr kernel and subsystems can be configured at build time to adapt them for specific application and platform needs. Configuration is handled through Kconfig, which is the same configuration system used by the Linux kernel. The goal is to support configuration without having to change any source code.

Configuration options (often called *symbols*) are defined in `Kconfig` files, which also specify dependencies between symbols that determine what configurations are valid. Symbols can be grouped into menus and sub-menus to keep the interactive configuration interfaces organized.

The output from Kconfig is a header file `autoconf.h` with macros that can be tested at build time. Code for unused features can be compiled out to save space.

The following sections explain how to set Kconfig configuration options, go into detail on how Kconfig is used within the Zephyr project, and have some tips and best practices for writing `Kconfig` files.

5.3.1 Interactive Kconfig interfaces

There are two interactive configuration interfaces available for exploring the available Kconfig options and making temporary changes: `menuconfig` and `guiconfig`. `menuconfig` is a curses-based interface that runs in the terminal, while `guiconfig` is a graphical configuration interface.

> **Note**
>
> The configuration can also be changed by editing `zephyr/.config` in the application build directory by hand. Using one of the configuration interfaces is often handier, as they correctly handle dependencies between configuration symbols.
>
> If you try to enable a symbol with unsatisfied dependencies in `zephyr/.config`, the assignment will be ignored and overwritten when re-configuring.

To make a setting permanent, you should set it in a `*.conf` file, as described in *Setting Kconfig configuration values*.

Tip

Saving a minimal configuration file (with e.g. `D` in menuconfig) and inspecting it can be handy when making settings permanent. The minimal configuration file only lists symbols that differ from their default value.

To run one of the configuration interfaces, do this:

1. Build your application as usual using either `west` or `cmake`:

   Using west:

   ```
   west build -b <board>
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build
   cmake -GNinja -DBOARD=<board> ..
   ninja
   ```

2. To run the terminal-based `menuconfig` interface, use either of these commands:

   ```
   west build -t menuconfig
   ```

   ```
   ninja menuconfig
   ```

   To run the graphical `guiconfig`, use either of these commands:

   ```
   west build -t guiconfig
   ```

   ```
   ninja guiconfig
   ```

   Note

   If you get an import error for `tkinter` when trying to run `guiconfig`, you are missing required packages. See *Install Linux Host Dependencies*. The package you need is usually called something like `python3-tk`/`python3-tkinter`.

   `tkinter` is not included by default in many Python installations, despite being part of the standard library.

   The two interfaces are shown below:

   `guiconfig` always shows the help text and other information related to the currently selected item in the bottom window pane. In the terminal interface, press ? to view the same information.

   Note

   If you prefer to work in the `guiconfig` interface, then it's a good idea to check any changes to Kconfig files you make in *single-menu mode*, which is toggled via a checkbox at the top. Unlike full-tree mode, single-menu mode will distinguish between symbols defined with `config` and symbols defined with `menuconfig`, showing you what things would look like in the `menuconfig` interface.

Modified

3. Change configuration values in the `menuconfig` interface as follows:

   - Navigate the menu with the arrow keys. Common Vim key bindings are supported as well.
   - Use `Space` and `Enter` to enter menus and toggle values. Menus appear with `--->` next to them. Press `ESC` to return to the parent menu.

     Boolean configuration options are shown with *[ ]* brackets, while numeric and string-valued configuration symbols are shown with *( )* brackets. Symbol values that can't be changed are shown as `-` or `-*-`.

     > **Note**
     >
     > You can also press `Y` or `N` to set a boolean configuration symbol to the corresponding value.

   - Press `?` to display information about the currently selected symbol, including its help text. Press `ESC` or `Q` to return from the information display to the menu.

   In the `guiconfig` interface, either click on the image next to the symbol to change its value, or double-click on the row with the symbol (this only works if the symbol has no children, as double-clicking a symbol with children open/closes its menu instead).

   `guiconfig` also supports keyboard controls, which are similar to `menuconfig`.

4. Pressing `Q` in the `menuconfig` interface will bring up the save-and-quit dialog (if there are changes to save):

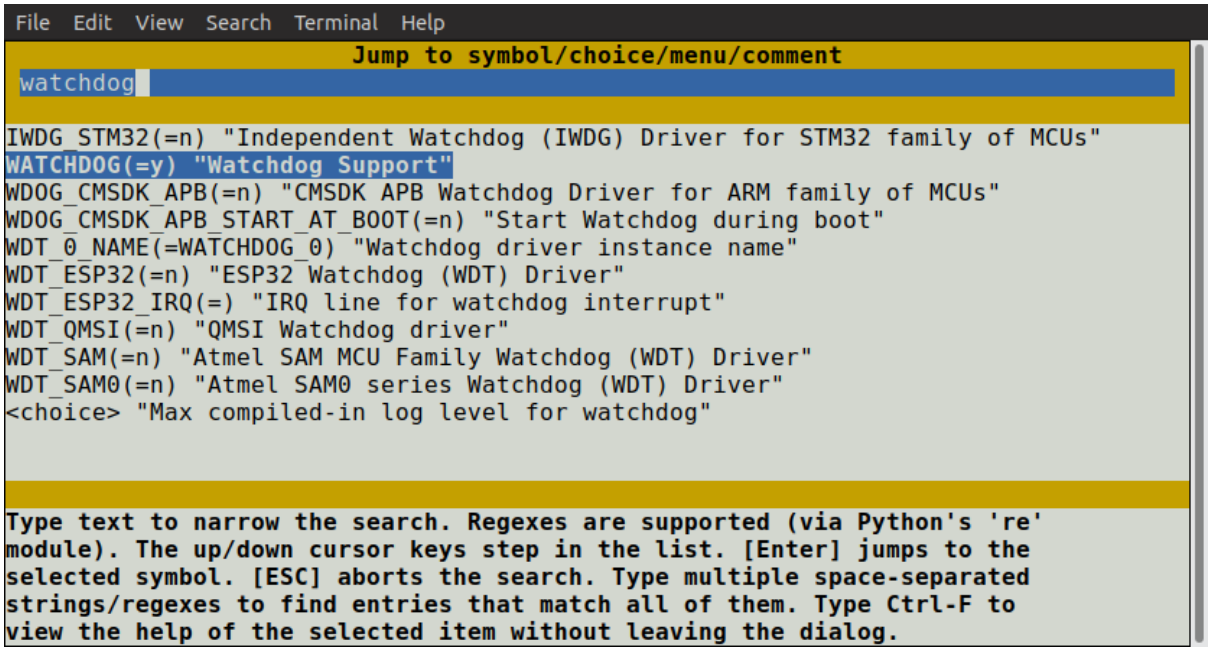
   Press `Y` to save the kernel configuration options to the default filename (`zephyr/.config`). You will typically save to the default filename unless you are experimenting with different configurations.

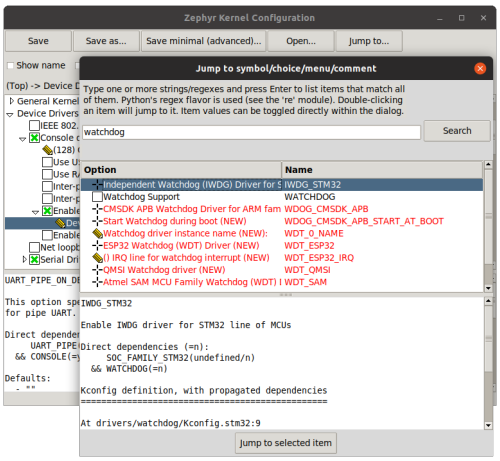
   The `guiconfig` interface will also prompt for saving the configuration on exit if it has been modified.

   > **Note**

> The configuration file used during the build is always `zephyr/.config`. If you have another saved configuration that you want to build with, copy it to `zephyr/.config`. Make sure to back up your original configuration file.
>
> Also note that filenames starting with `.` are not listed by `ls` by default on Linux and macOS. Use the `-a` flag to see them.

Finding a symbol in the menu tree and navigating to it can be tedious. To jump directly to a symbol, press the `/` key (this also works in `guiconfig`). This brings up the following dialog, where you can search for symbols by name and jump to them. In `guiconfig`, you can also change symbol values directly within the dialog.





If you jump to a symbol that isn't currently visible (e.g., due to having unsatisfied dependencies), then *show-all mode* will be enabled. In show-all mode, all symbols are displayed, including currently invisible symbols. To turn off show-all mode, press `A` in `menuconfig` or `Ctrl-A` in `guiconfig`.

Note

Show-all mode can't be turned off if there are no visible items in the current menu.

To figure out why a symbol you jumped to isn't visible, inspect its dependencies, either by pressing ? in `menuconfig` or in the information pane at the bottom in `guiconfig`. If you discover that the symbol depends on another symbol that isn't enabled, you can jump to that symbol in turn to see if it can be enabled.

Note

In `menuconfig`, you can press `Ctrl-F` to view the help of the currently selected item in the jump-to dialog without leaving the dialog.

For more information on `menuconfig` and `guiconfig`, see the Python docstrings at the top of menuconfig.py and guiconfig.py.

5.3.2 Tracing values to their source

The merged configuration saved to `zephyr/.config` contains the result of applying the user configuration file to the whole tree of Kconfig files. This process can be hard to follow, especially when invisible symbols are being implicitly selected from anywhere in the tree. To help with this, the `traceconfig` target can be used to generate a file in the build directory that details how each symbol got its final value.

After building the Zephyr project as usual, the Kconfig trace can be generated with either of these commands:

```
west build -t traceconfig
```

```
ninja traceconfig
```

Note

The generated information is only useful on a clean build, because otherwise the `.config` file "pins" all settings to a specific value (as described in *Stuck symbols*). Therefore, it is recommended to run a *pristine build* before generating the trace.

The output will be in the `zephyr/kconfig-trace.md` file in the build directory. This file is best viewed within IDEs to take advantage of Markdown elements (tables, highlighting, clickable links), but can easily be understood even when opened directly with any text editor.

The report is divided in three sections:

1. Visible symbols
2. Invisible symbols
3. Unset symbols

For sections 1 and 2, a table is presented where each symbol is shown with its type, name, and current value. The fourth column details the kind of statement that resulted in the value being applied, and can be one of the following:

- *assigned*, when an explicit assignment, of the form `CONFIG_xxx=y`, is read from a config file;
- *default*, when there was no user assignment, but an applicable default value was read from Kconfig tree;

- *selected* or *implied*, when a `select` or `imply` statement from a separate symbol caused the symbol to be set.

The fifth column details the location for the source statement. For the first two kinds of statements, the exact location (file name and line number) is provided; in the latter cases, it contains the expressions that resulted in the symbol being set.

Finally, section 3 simply lists all undefined symbols. These have no additional information since they never received a value by any of the above means.

5.3.3 Setting Kconfig configuration values

The *menuconfig and guiconfig interfaces* can be used to test out configurations during application development. This page explains how to make settings permanent.

All Kconfig options can be searched in the Kconfig search page.

Note

Before making changes to Kconfig files, it's a good idea to also go through the *Kconfig - Tips and Best Practices* page.

Visible and invisible Kconfig symbols

When making Kconfig changes, it's important to understand the difference between *visible* and *invisible* symbols.

- A visible symbol is a symbol defined with a prompt. Visible symbols show up in the interactive configuration interfaces (hence *visible*), and can be set in configuration files.

  Here's an example of a visible symbol:

  ```
  config FPU
     bool "Support floating point operations"
     depends on HAS_FPU
  ```

  The symbol is shown like this in `menuconfig`, where it can be toggled:

  ```
  [ ] Support floating point operations
  ```

- An *invisible* symbol is a symbol without a prompt. Invisible symbols are not shown in the interactive configuration interfaces, and users have no direct control over their value. They instead get their value from defaults or from other symbols.

  Here's an example of an invisible symbol:

  ```
  config CPU_HAS_FPU
     bool
     help
       This symbol is y if the CPU has a hardware floating point unit.
  ```

  In this case, `CPU_HAS_FPU` is enabled through other symbols having `select CPU_HAS_FPU`.

Setting symbols in configuration files

Visible symbols can be configured by setting them in configuration files. The initial configuration is produced by merging a `*_defconfig` file for the board with application settings, usually from `prj.conf`. See *The Initial Configuration* below for more details.

Assignments in configuration files use this syntax:

```
CONFIG_<symbol name>=<value>
```

There should be no spaces around the equals sign.

`bool` symbols can be enabled or disabled by setting them to `y` or `n`, respectively. The `FPU` symbol from the example above could be enabled like this:

```
CONFIG_FPU=y
```

Note

A boolean symbol can also be set to `n` with a comment formatted like this:

```
# CONFIG_SOME_OTHER_BOOL is not set
```

This is the format you will see in the merged configuration saved to `zephyr/.config` in the build directory.

This style is accepted for historical reasons: Kconfig configuration files can be parsed as makefiles (though Zephyr doesn't use this). Having `n`-valued symbols correspond to unset variables simplifies tests in Make.

Other symbol types are assigned like this:

```
CONFIG_SOME_STRING="cool value"
CONFIG_SOME_INT=123
```

Comments use a #:

```
# This is a comment
```

Assignments in configuration files are only respected if the dependencies for the symbol are satisfied. A warning is printed otherwise. To figure out what the dependencies of a symbol are, use one of the *interactive configuration interfaces* (you can jump directly to a symbol with /), or look up the symbol in the Kconfig search page.

The Initial Configuration

The initial configuration for an application comes from merging configuration settings from three sources:

1. A `BOARD`-specific configuration file stored in `boards/<VENDOR>/<BOARD>/<BOARD>_defconfig`
2. Any CMake cache entries prefix with `CONFIG_`
3. The application configuration

The application configuration can come from the sources below (each file is known as a Kconfig fragment, which are then merged to get the final configuration used for a particular build). By default, `prj.conf` is used.

1. If `CONF_FILE` is set, the configuration file(s) specified in it are merged and used as the application configuration. `CONF_FILE` can be set in various ways:
    1. In `CMakeLists.txt`, before calling `find_package(Zephyr)`
    2. By passing `-DCONF_FILE=<conf file(s)>`, either directly or via `west`
    3. From the CMake variable cache
2. Otherwise, if `boards/<BOARD>.conf` exists in the application configuration directory, the result of merging it with `prj.conf` is used.

3. Otherwise, if board revisions are used and boards/<BOARD>_<revision>.conf exists in the application configuration directory, the result of merging it with prj.conf and boards/<BOARD>.conf is used.
4. Otherwise, prj.conf is used from the application configuration directory. If it does not exist then a fatal error will be emitted.

Furthermore, applications can have SoC Kconfig fragments added to the configuration, the file socs/<SOC>_<BOARD_QUALIFIERS>.conf will be applied if it exists, after the main project configuration has been applied and before any board Kconfig fragments files have been applied.

All configuration files will be taken from the application's configuration directory except for files with an absolute path that are given with the CONF_FILE, EXTRA_CONF_FILE, DTC_OVERLAY_FILE, and EXTRA_DTC_OVERLAY_FILE arguments. For these, a file in a Zephyr module can be referred by escaping the Zephyr module dir variable like this \${ZEPHYR_<module>_MODULE_DIR}/<path-to>/<file> when setting any of said variables in the application's CMakeLists.txt.

See *Application Configuration Directory* on how the application configuration directory is defined.

If a symbol is assigned both in <BOARD>_defconfig and in the application configuration, the value set in the application configuration takes precedence.

The merged configuration is saved to zephyr/.config in the build directory.

As long as zephyr/.config exists and is up-to-date (is newer than any BOARD and application configuration files), it will be used in preference to producing a new merged configuration. zephyr/.config is also the configuration that gets modified when making changes in the *interactive configuration interfaces*.

Tracking Kconfig symbols

It is possible to create Kconfig symbols which takes the default value of another Kconfig symbol.

This is valuable when you want a symbol specific to an application or subsystem but do not want to rely directly on the common symbol. For example, you might want to decouple the settings so they can be independently configured, or to ensure you always have a locally named setting, even if the external setting name changes. is later changed.

For example, consider the common FOO_STRING setting where a subsystem wants to have a SUB_FOO_STRING but still allow for customization.

This can be done like this:

```
config FOO_STRING
        string "Foo"
        default "foo"

config SUB_FOO_STRING
        string "Sub-foo"
        default FOO_STRING
```

This ensures that the default value of SUB_FOO_STRING is identical to FOO_STRING while still allows users to configure both settings independently.

It is also possible to make SUB_FOO_STRING invisible and thereby keep the two symbols in sync, unless the value of the tracking symbol is changed in a defconfig file.

```
config FOO_STRING
        string "Foo"
        default "foo"

config SUB_FOO_STRING
```

(continues on next page)

(continued from previous page)

```
        string
        default FOO_STRING
        help
          Hidden symbol which follows FOO_STRING
          Can be changed through *.defconfig files.
```

Configuring invisible Kconfig symbols

When making changes to the default configuration for a board, you might have to configure invisible symbols. This is done in `boards/<VENDOR>/<BOARD>/Kconfig.defconfig`, which is a regular `Kconfig` file.

> **Note**
>
> Assignments in `.config` files have no effect on invisible symbols, so this scheme is not just an organizational issue.

Assigning values in `Kconfig.defconfig` relies on defining a Kconfig symbol in multiple locations. As an example, say we want to set `FOO_WIDTH` below to 32:

```
config FOO_WIDTH
    int
```

To do this, we extend the definition of `FOO_WIDTH` as follows, in `Kconfig.defconfig`:

```
if BOARD_MY_BOARD

config FOO_WIDTH
    default 32

endif
```

> **Note**
>
> Since the type of the symbol (`int`) has already been given at the first definition location, it does not need to be repeated here. Only giving the type once at the "base" definition of the symbol is a good idea for reasons explained in *Common Kconfig shorthands*.

`default` values in `Kconfig.defconfig` files have priority over `default` values given on the "base" definition of a symbol. Internally, this is implemented by including the `Kconfig.defconfig` files first. Kconfig uses the first `default` with a satisfied condition, where an empty condition corresponds to `if y` (is always satisfied).

Note that conditions from surrounding top-level `if`s are propagated to symbol properties, so the above `default` is equivalent to `default 32 if BOARD_MY_BOARD`.

Multiple symbol definitions When a symbol is defined in multiple locations, each definition acts as an independent symbol that happens to share the same name. This means that properties are not appended to previous definitions. If the conditions for **ANY** definition result in the symbol resolving to `y`, the symbol will be `y`. It is therefore not possible to make the dependencies of a symbol more restrictive by defining it in multiple locations.

For example, the dependencies of the symbol `FOO` below are satisfied if either `DEP1` **OR** `DEP2` are true, it does not require both:

```
config FOO
   ...
   depends on DEP1

config FOO
   ...
   depends on DEP2
```

Warning

Symbols without explicit dependencies still follow the above rule. A symbol without any dependencies will result in the symbol always being assignable. The definition below will result in FOO always being enabled by default, regardless of the value of DEP1.

```
config FOO
   bool "FOO"
   depends on DEP1

config FOO
   default y
```

This dependency weakening can be avoided with the *configdefault* extension if the desire is only to add a new default without modifying any other behaviour of the symbol.

Note

When making changes to `Kconfig.defconfig` files, always check the symbol's direct dependencies in one of the *interactive configuration interfaces* afterwards. It is often necessary to repeat dependencies from the base definition of the symbol to avoid weakening a symbol's dependencies.

Motivation for Kconfig.defconfig files One motivation for this configuration scheme is to avoid making fixed BOARD-specific settings configurable in the interactive configuration interfaces. If all board configuration were done via `<BOARD>_defconfig`, all symbols would have to be visible, as values given in `<BOARD>_defconfig` have no effect on invisible symbols.

Having fixed settings be user-configurable would clutter up the configuration interfaces and make them harder to understand, and would make it easier to accidentally create broken configurations.

When dealing with fixed board-specific settings, also consider whether they should be handled via *devicetree* instead.

Configuring choices There are two ways to configure a Kconfig `choice`:

1. By setting one of the choice symbols to `y` in a configuration file.

   Setting one choice symbol to `y` automatically gives all other choice symbols the value `n`.

   If multiple choice symbols are set to `y`, only the last one set to `y` will be honored (the rest will get the value `n`). This allows a choice selection from a board `defconfig` file to be overridden from an application `prj.conf` file.

2. By changing the `default` of the choice in `Kconfig.defconfig`.

   As with symbols, changing the default for a choice is done by defining the choice in multiple locations. For this to work, the choice must have a name.

As an example, assume that a choice has the following base definition (here, the name of the choice is FOO):

```
choice FOO
    bool "Foo choice"
    default B

config A
    bool "A"

config B
    bool "B"

endchoice
```

To change the default symbol of FOO to A, you would add the following definition to Kconfig.defconfig:

```
choice FOO
    default A
endchoice
```

The Kconfig.defconfig method should be used when the dependencies of the choice might not be satisfied. In that case, you're setting the default selection whenever the user makes the choice visible.

More Kconfig resources The *Kconfig - Tips and Best Practices* page has some tips for writing Kconfig files.

The kconfiglib.py docstring (at the top of the file) goes over how symbol values are calculated in detail.

5.3.4 Kconfig - Tips and Best Practices

This page covers some Kconfig best practices and explains some Kconfig behaviors and features that might be cryptic or that are easily overlooked.

What to turn into Kconfig options

When deciding whether something belongs in Kconfig, it helps to distinguish between symbols that have prompts and symbols that don't.

If a symbol has a prompt (e.g. `bool "Enable foo"`), then the user can change the symbol's value in the `menuconfig` or `guiconfig` interface (see *Interactive Kconfig interfaces*), or by manually editing configuration files. Conversely, a symbol without a prompt can never be changed directly by the user, not even by manually editing configuration files.

Only put a prompt on a symbol if it makes sense for the user to change its value.

Symbols without prompts are called *hidden* or *invisible* symbols, because they don't show up in `menuconfig` and `guiconfig`. Symbols that have prompts can also be invisible, when their dependencies are not satisfied.

Symbols without prompts can't be configured directly by the user (they derive their value from other symbols), so less restrictions apply to them. If some derived setting is easier to calculate in Kconfig than e.g. during the build, then do it in Kconfig, but keep the distinction between symbols with and without prompts in mind.

See the *optional prompts* section for a way to deal with settings that are fixed on some machines and configurable on other machines.

What not to turn into Kconfig options

In Zephyr, Kconfig configuration is done after selecting a target board. In general, it does not make sense to use Kconfig for a value that corresponds to a fixed machine-specific setting. Usu-

ally, such settings should be handled via *devicetree* instead.

In particular, avoid adding new Kconfig options of the following types:

Options that specify a device in the system by name For example, if you are writing an I2C device driver, avoid creating an option named `MY_DEVICE_I2C_BUS_NAME` for specifying the bus node your device is controlled by. See *Device drivers that depend on other devices* for alternatives.

Similarly, if your application depends on a hardware-specific PWM device to control an RGB LED, avoid creating an option like `MY_PWM_DEVICE_NAME`. See *Applications that depend on board-specific devices* for alternatives.

Options that specify fixed hardware configuration For example, avoid Kconfig options specifying a GPIO pin.

An alternative applicable to device drivers is to define a GPIO specifier with type phandle-array in the device binding, and using the *GPIO* devicetree API from C. Similar advice applies to other cases where devicetree.h provides *Hardware specific APIs* for referring to other nodes in the system. Search the source code for drivers using these APIs for examples.

An application-specific devicetree *binding* to identify board specific properties may be appropriate. See tests/drivers/gpio/gpio_basic_api for an example.

For applications, see blinky for a devicetree-based alternative.

`select` statements

The `select` statement is used to force one symbol to `y` whenever another symbol is `y`. For example, the following code forces `CONSOLE` to `y` whenever `USB_CONSOLE` is `y`:

```
config CONSOLE
     bool "Console support"

...

config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
```

This section covers some pitfalls and good uses for `select`.

`select` pitfalls `select` might seem like a generally useful feature at first, but can cause configuration issues if overused.

For example, say that a new dependency is added to the `CONSOLE` symbol above, by a developer who is unaware of the `USB_CONSOLE` symbol (or simply forgot about it):

```
config CONSOLE
     bool "Console support"
     depends on STRING_ROUTINES
```

Enabling `USB_CONSOLE` now forces `CONSOLE` to `y`, even if `STRING_ROUTINES` is `n`.

To fix the problem, the `STRING_ROUTINES` dependency needs to be added to `USB_CONSOLE` as well:

```
config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
     depends on STRING_ROUTINES
```

(continues on next page)

(continued from previous page)

```
...

config STRING_ROUTINES
     bool "Include string routines"
```

More insidious cases with dependencies inherited from `if` and `menu` statements are common.

An alternative attempt to solve the issue might be to turn the `depends on` into another `select`:

```
config CONSOLE
     bool "Console support"
     select STRING_ROUTINES

...

config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
```

In practice, this often amplifies the problem, because any dependencies added to `STRING_ROUTINES` now need to be copied to both `CONSOLE` and `USB_CONSOLE`.

In general, whenever the dependencies of a symbol are updated, the dependencies of all symbols that (directly or indirectly) select it have to be updated as well. This is very often overlooked in practice, even for the simplest case above.

Chains of symbols selecting each other should be avoided in particular, except for simple helper symbols, as covered below in *Using select for helper symbols*.

Liberal use of `select` also tends to make Kconfig files harder to read, both due to the extra dependencies and due to the non-local nature of `select`, which hides ways in which a symbol might get enabled.

Alternatives to `select` For the example in the previous section, a better solution is usually to turn the `select` into a `depends on`:

```
config CONSOLE
     bool "Console support"

...

config USB_CONSOLE
     bool "USB console support"
     depends on CONSOLE
```

This makes it impossible to generate an invalid configuration, and means that dependencies only ever have to be updated in a single spot.

An objection to using `depends on` here might be that configuration files that enable `USB_CONSOLE` now also need to enable `CONSOLE`:

```
CONFIG_CONSOLE=y
CONFIG_USB_CONSOLE=y
```

This comes down to a trade-off, but if enabling `CONSOLE` is the norm, then a mitigation is to make `CONSOLE` default to `y`:

```
config CONSOLE
     bool "Console support"
     default y
```

This gives just a single assignment in configuration files:

```
CONFIG_USB_CONSOLE=y
```

Note that configuration files that do not want `CONSOLE` enabled now have to explicitly disable it:

```
CONFIG_CONSOLE=n
```

Using `select` for helper symbols A good and safe use of `select` is for setting "helper" symbols that capture some condition. Such helper symbols should preferably have no prompt or dependencies.

For example, a helper symbol for indicating that a particular CPU/SoC has an FPU could be defined as follows:

```
config CPU_HAS_FPU
     bool
     help
       If y, the CPU has an FPU

...

config SOC_FOO
     bool "FOO SoC"
     select CPU_HAS_FPU

...

config SOC_BAR
     bool "BAR SoC"
     select CPU_HAS_FPU
```

This makes it possible for other symbols to check for FPU support in a generic way, without having to look for particular architectures:

```
config FPU
     bool "Support floating point operations"
     depends on CPU_HAS_FPU
```

The alternative would be to have dependencies like the following, possibly duplicated in several spots:

```
config FPU
     bool "Support floating point operations"
     depends on SOC_FOO || SOC_BAR || ...
```

Invisible helper symbols can also be useful without `select`. For example, the following code defines a helper symbol that has the value `y` if the machine has some arbitrarily-defined "large" amount of memory:

```
config LARGE_MEM
     def_bool MEM_SIZE >= 64
```

Note

This is short for the following:

```
config LARGE_MEM
  bool
  default MEM_SIZE >= 64
```

`select` recommendations In summary, here are some recommended practices for `select`:

- Avoid selecting symbols with prompts or dependencies. Prefer `depends on`. If `depends on` causes annoying bloat in configuration files, consider adding a Kconfig default for the most common value.

  Rare exceptions might include cases where you're sure that the dependencies of the selecting and selected symbol will never drift out of sync, e.g. when dealing with two simple symbols defined close to one another within the same `if`.

  Common sense applies, but be aware that `select` often causes issues in practice. `depends on` is usually a cleaner and safer solution.

- Select simple helper symbols without prompts and dependencies however much you like. They're a great tool for simplifying Kconfig files.

- An exemption are buses like I2C and SPI, and following the same thought process things like MFD as well. Drivers on these buses should use `select` to allow the automatic activation of the necessary bus drivers when devices on the bus are enabled in the devicetree.

```
config ADC_FOO
   bool "external SPI ADC foo driver"
   select SPI
```

(Lack of) conditional includes

`if` blocks add dependencies to each item within the `if`, as if `depends on` was used.

A common misunderstanding related to `if` is to think that the following code conditionally includes the file `Kconfig.other`:

```
if DEP
source "Kconfig.other"
endif
```

In reality, there are no conditional includes in Kconfig. `if` has no special meaning around a `source`.

> **Note**
>
> Conditional includes would be impossible to implement, because `if` conditions may contain (either directly or indirectly) forward references to symbols that haven't been defined yet.

Say that `Kconfig.other` above contains this definition:

```
config FOO
     bool "Support foo"
```

In this case, `FOO` will end up with this definition:

```
config FOO
     bool "Support foo"
     depends on DEP
```

Note that it is redundant to add `depends on DEP` to the definition of `FOO` in `Kconfig.other`, because the `DEP` dependency has already been added by `if DEP`.

In general, try to avoid adding redundant dependencies. They can make the structure of the Kconfig files harder to understand, and also make changes more error-prone, since it can be hard to spot that the same dependency is added twice.

"Stuck" symbols in menuconfig and guiconfig

There is a common subtle gotcha related to interdependent configuration symbols with prompts. Consider these symbols:

```
config FOO
     bool "Foo"

config STACK_SIZE
     hex "Stack size"
     default 0x200 if FOO
     default 0x100
```

Assume that the intention here is to use a larger stack whenever `FOO` is enabled, and that the configuration initially has `FOO` disabled. Also, remember that Zephyr creates an initial configuration in `zephyr/.config` in the build directory by merging configuration files (including e.g. `prj.conf`). This configuration file exists before `menuconfig` or `guiconfig` is run.

When first entering the configuration interface, the value of `STACK_SIZE` is 0x100, as expected. After enabling `FOO`, you might reasonably expect the value of `STACK_SIZE` to change to 0x200, but it stays as 0x100.

To understand what's going on, remember that `STACK_SIZE` has a prompt, meaning it is user-configurable, and consider that all Kconfig has to go on from the initial configuration is this:

```
CONFIG_STACK_SIZE=0x100
```

Since Kconfig can't know if the 0x100 value came from a `default` or was typed in by the user, it has to assume that it came from the user. Since `STACK_SIZE` is user-configurable, the value from the configuration file is respected, and any symbol defaults are ignored. This is why the value of `STACK_SIZE` appears to be "frozen" at 0x100 when toggling `FOO`.

The right fix depends on what the intention is. Here's some different scenarios with suggestions:

- If `STACK_SIZE` can always be derived automatically and does not need to be user-configurable, then just remove the prompt:

  ```
  config STACK_SIZE
     hex
     default 0x200 if FOO
     default 0x100
  ```

  Symbols without prompts ignore any value from the saved configuration.

- If `STACK_SIZE` should usually be user-configurable, but needs to be set to 0x200 when `FOO` is enabled, then disable its prompt when `FOO` is enabled, as described in *optional prompts*:

  ```
  config STACK_SIZE
     hex "Stack size" if !FOO
     default 0x200 if FOO
     default 0x100
  ```

- If `STACK_SIZE` should usually be derived automatically, but needs to be set to a custom value in rare circumstances, then add another option for making `STACK_SIZE` user-configurable:

```
config CUSTOM_STACK_SIZE
   bool "Use a custom stack size"
   help
     Enable this if you need to use a custom stack size. When disabled, a
     suitable stack size is calculated automatically.

config STACK_SIZE
   hex "Stack size" if CUSTOM_STACK_SIZE
   default 0x200 if FOO
   default 0x100
```

As long as `CUSTOM_STACK_SIZE` is disabled, `STACK_SIZE` will ignore the value from the saved configuration.

It is a good idea to try out changes in the `menuconfig` or `guiconfig` interface, to make sure that things behave the way you expect. This is especially true when making moderately complex changes like these.

Assignments to promptless symbols in configuration files

Assignments to hidden (promptless, also called *invisible*) symbols in configuration files are always ignored. Hidden symbols get their value indirectly from other symbols, via e.g. `default` and `select`.

A common source of confusion is opening the output configuration file (`zephyr/.config`), seeing a bunch of assignments to hidden symbols, and assuming that those assignments must be respected when the configuration is read back in by Kconfig. In reality, all assignments to hidden symbols in `zephyr/.config` are ignored by Kconfig, like for other configuration files.

To understand why `zephyr/.config` still includes assignments to hidden symbols, it helps to realize that `zephyr/.config` serves two separate purposes:

1. It holds the saved configuration, and
2. it holds configuration output. `zephyr/.config` is parsed by the CMake files to let them query configuration settings, for example.

The assignments to hidden symbols in `zephyr/.config` are just configuration output. Kconfig itself ignores assignments to hidden symbols when calculating symbol values.

Note

A *minimal configuration*, which can be generated from within the *menuconfig and guiconfig interfaces*, could be considered closer to just a saved configuration, without the full configuration output.

`depends on` and `string`/`int`/`hex` symbols

`depends on` works not just for `bool` symbols, but also for `string`, `int`, and `hex` symbols (and for choices).

The Kconfig definitions below will hide the `FOO_DEVICE_FREQUENCY` symbol and disable any configuration output for it when `FOO_DEVICE` is disabled.

```
config FOO_DEVICE
     bool "Foo device"

config FOO_DEVICE_FREQUENCY
     int "Foo device frequency"
     depends on FOO_DEVICE
```

In general, it's a good idea to check that only relevant symbols are ever shown in the menuconfig/guiconfig interface. Having FOO_DEVICE_FREQUENCY show up when FOO_DEVICE is disabled (and possibly hidden) makes the relationship between the symbols harder to understand, even if code never looks at FOO_DEVICE_FREQUENCY when FOO_DEVICE is disabled.

menuconfig symbols

If the definition of a symbol FOO is immediately followed by other symbols that depend on FOO, then those symbols become children of FOO. If FOO is defined with config FOO, then the children are shown indented relative to FOO. Defining FOO with menuconfig FOO instead puts the children in a separate menu rooted at FOO.

menuconfig has no effect on evaluation. It's just a display option.

menuconfig can cut down on the number of menus and make the menu structure easier to navigate. For example, say you have the following definitions:

```
menu "Foo subsystem"

config FOO_SUBSYSTEM
     bool "Foo subsystem"

if FOO_SUBSYSTEM

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

config FOO_FREQUENCY
     int "Foo frequency"

... lots of other FOO-related symbols

endif # FOO_SUBSYSTEM

endmenu
```

In this case, it's probably better to get rid of the menu and turn FOO_SUBSYSTEM into a menuconfig symbol:

```
menuconfig FOO_SUBSYSTEM
     bool "Foo subsystem"

if FOO_SUBSYSTEM

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

config FOO_FREQUENCY
     int "Foo frequency"

... lots of other FOO-related symbols

endif # FOO_SUBSYSTEM
```

In the menuconfig interface, this will be displayed as follows:

```
[*] Foo subsystem  --->
```

Note that making a symbol without children a menuconfig is meaningless. It should be avoided, because it looks identical to a symbol with all children invisible:

```
[*] I have no children  ----
[*] All my children are invisible  ----
```

Commas in macro arguments

Kconfig uses commas to separate macro arguments. This means a construct like this will fail:

```
config FOO
    bool
    default y if $(dt_chosen_enabled,"zephyr,bar")
```

To solve this problem, create a variable with the text and use this variable as argument, as follows:

```
DT_CHOSEN_ZEPHYR_BAR := zephyr,bar

config FOO
    bool
    default y if $(dt_chosen_enabled,$(DT_CHOSEN_ZEPHYR_BAR))
```

Note

A variable DT_COMPAT_*VND_MY_DEVICE* := *vnd,my-device* is automatically created by Zephyr for every compatible found in Devicetree bindings; there is no need to define such variables. See *Automatic Kconfig symbols from devicetree* for details.

Checking changes in menuconfig/guiconfig

When adding new symbols or making other changes to Kconfig files, it is a good idea to look up the symbols in *menuconfig or guiconfig* afterwards. To get to a symbol quickly, use the jump-to feature (press /).

Here are some things to check:

- Are the symbols placed in a good spot? Check that they appear in a menu where they make sense, close to related symbols.

  If one symbol depends on another, then it's often a good idea to place it right after the symbol it depends on. It will then be shown indented relative to the symbol it depends on in the menuconfig interface, and in a separate menu rooted at the symbol in guiconfig. This also works if several symbols are placed after the symbol they depend on.

- Is it easy to guess what the symbols do from their prompts?
- If many symbols are added, do all combinations of values they can be set to make sense?

  For example, if two symbols FOO_SUPPORT and NO_FOO_SUPPORT are added, and both can be enabled at the same time, then that makes a nonsensical configuration. In this case, it's probably better to have a single FOO_SUPPORT symbol.

- Are there any duplicated dependencies?

This can be checked by selecting a symbol and pressing ? to view the symbol information. If there are duplicated dependencies, then use the `Included via ...` path shown in the symbol information to figure out where they come from.

Checking changes with `scripts/kconfig/lint.py`

After you make Kconfig changes, you can use the scripts/kconfig/lint.py script to check for some potential issues, like unused symbols and symbols that are impossible to enable. Use `--help` to see available options.

Some checks are necessarily a bit heuristic, so a symbol being flagged by a check does not necessarily mean there's a problem. If a check returns a false positive e.g. due to token pasting in C (`CONFIG_FOO_##index##_BAR`), just ignore it.

When investigating an unknown symbol `FOO_BAR`, it is a good idea to run `git grep FOO_BAR` to look for references. It is also a good idea to search for some components of the symbol name with e.g. `git grep FOO` and `git grep BAR`, as it can help uncover token pasting.

Style recommendations and shorthands

This section gives some style recommendations and explains some common Kconfig shorthands.

Factoring out common dependencies If a sequence of symbols/choices share a common dependency, the dependency can be factored out with an `if`.

As an example, consider the following code:

```
config FOO
	bool "Foo"
	depends on DEP

config BAR
	bool "Bar"
	depends on DEP

choice
	prompt "Choice"
	depends on DEP

config BAZ
	bool "Baz"

config QAZ
	bool "Qaz"

endchoice
```

Here, the `DEP` dependency can be factored out like this:

```
if DEP

config FOO
	bool "Foo"

config BAR
	bool "Bar"

choice
	prompt "Choice"
```

(continues on next page)

(continued from previous page)

```
config BAZ
     bool "Baz"

config QAZ
     bool "Qaz"

endchoice

endif # DEP
```

Note

Internally, the second version of the code is transformed into the first.

If a sequence of symbols/choices with shared dependencies are all in the same menu, the dependency can be put on the menu itself:

```
menu "Foo features"
     depends on FOO_SUPPORT

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

endmenu
```

If `FOO_SUPPORT` is `n`, the entire menu disappears.

Redundant defaults `bool` symbols implicitly default to `n`, and `string` symbols implicitly default to the empty string. Therefore, `default n` and `default ""` are (almost) always redundant.

The recommended style in Zephyr is to skip redundant defaults for `bool` and `string` symbols. That also generates clearer documentation: (*Implicitly defaults to n* instead of *n if <dependencies, possibly inherited>*).

Defaults *should* always be given for `int` and `hex` symbols, however, as they implicitly default to the empty string. This is partly for compatibility with the C Kconfig tools, though an implicit 0 default might be less likely to be what was intended compared to other symbol types as well.

The one case where `default n`/`default ""` is not redundant is when defining a symbol in multiple locations and wanting to override e.g. a `default y` on a later definition. Note that a `default n` does not override a previously defined `default y`.

That is, FOO will be set to `n` in the example below. If the `default n` was omitted in the first definition, FOO would have been set to `y`.

```
config FOO
   bool "foo"
   default n

config FOO
   bool "foo"
   default y
```

In the following example FOO will get the value y.

```
config FOO
   bool "foo"
   default y

config FOO
   bool "foo"
   default n
```

Common Kconfig shorthands Kconfig has two shorthands that deal with prompts and defaults.

- `<type> "prompt"` is a shorthand for giving a symbol/choice a type and a prompt at the same time. These two definitions are equal:

```
config FOO
   bool "foo"
```

```
config FOO
   bool
   prompt "foo"
```

  The first style, with the shorthand, is preferred in Zephyr.

- `def_<type> <value>` is a shorthand for giving a type and a value at the same time. These two definitions are equal:

```
config FOO
   def_bool BAR && BAZ
```

```
config FOO
   bool
   default BAR && BAZ
```

Using both the `<type> "prompt"` and the `def_<type> <value>` shorthand in the same definition is redundant, since it gives the type twice.

The `def_<type> <value>` shorthand is generally only useful for symbols without prompts, and somewhat obscure.

Note

For a symbol defined in multiple locations (e.g., in a `Kconfig.defconfig` file in Zephyr), it is best to only give the symbol type for the "base" definition of the symbol, and to use `default` (instead of `def_<type> value`) for the remaining definitions. That way, if the base definition of the symbol is removed, the symbol ends up without a type, which generates a warning that points to the other definitions. That makes the extra definitions easier to discover and remove.

Prompt strings For a Kconfig symbol that enables a driver/subsystem FOO, consider having just "Foo" as the prompt, instead of "Enable Foo support" or the like. It will usually be clear in the context of an option that can be toggled on/off, and makes things consistent.

Style See *Coding Style Guidelines* for style guidelines.

Lesser-known/used Kconfig features

This section lists some more obscure Kconfig behaviors and features that might still come in handy.

The `imply` statement The `imply` statement is similar to `select`, but respects dependencies and doesn't force a value. For example, the following code could be used to enable USB keyboard support by default on the FOO SoC, while still allowing the user to turn it off:

```
config SOC_FOO
     bool "FOO SoC"
     imply USB_KEYBOARD

...

config USB_KEYBOARD
     bool "USB keyboard support"
```

`imply` acts like a suggestion, whereas `select` forces a value.

Optional prompts A condition can be put on a symbol's prompt to make it optionally configurable by the user. For example, a value `MASK` that's hardcoded to 0xFF on some boards and configurable on others could be expressed as follows:

```
config MASK
     hex "Bitmask" if HAS_CONFIGURABLE_MASK
     default 0xFF
```

Note

This is short for the following:

```
config MASK
  hex
  prompt "Bitmask" if HAS_CONFIGURABLE_MASK
  default 0xFF
```

The `HAS_CONFIGURABLE_MASK` helper symbol would get selected by boards to indicate that `MASK` is configurable. When `MASK` is configurable, it will also default to 0xFF.

Optional choices Defining a choice with the `optional` keyword allows the whole choice to be toggled off to select none of the symbols:

```
choice
     prompt "Use legacy protocol"
     optional

config LEGACY_PROTOCOL_1
     bool "Legacy protocol 1"

config LEGACY_PROTOCOL_2
     bool "Legacy protocol 2"

endchoice
```

In the `menuconfig` interface, this will be displayed e.g. as `[*] Use legacy protocol (Legacy protocol 1) --->`, where the choice can be toggled off to enable neither of the symbols.

`visible if` conditions Putting a `visible if` condition on a menu hides the menu and all the symbols within it, while still allowing symbol default values to kick in.

As a motivating example, consider the following code:

```
menu "Foo subsystem"
     depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_1
     int "Foo setting 1"
     default 1

config FOO_SETTING_2
     int "Foo setting 2"
     default 2

endmenu
```

When `HAS_CONFIGURABLE_FOO` is `n`, no configuration output is generated for `FOO_SETTING_1` and `FOO_SETTING_2`, as the code above is logically equivalent to the following code:

```
config FOO_SETTING_1
     int "Foo setting 1"
     default 1
     depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_2
     int "Foo setting 2"
     default 2
     depends on HAS_CONFIGURABLE_FOO
```

If we want the symbols to still get their default values even when `HAS_CONFIGURABLE_FOO` is `n`, but not be configurable by the user, then we can use `visible if` instead:

```
menu "Foo subsystem"
     visible if HAS_CONFIGURABLE_FOO

config FOO_SETTING_1
     int "Foo setting 1"
     default 1

config FOO_SETTING_2
     int "Foo setting 2"
     default 2

endmenu
```

This is logically equivalent to the following:

```
config FOO_SETTING_1
     int "Foo setting 1" if HAS_CONFIGURABLE_FOO
     default 1

config FOO_SETTING_2
     int "Foo setting 2" if HAS_CONFIGURABLE_FOO
     default 2
```

Note

See the *optional prompts* section for the meaning of the conditions on the prompts.

When `HAS_CONFIGURABLE_FOO` is `n`, we now get the following configuration output for the symbols, instead of no output:

```
...
CONFIG_FOO_SETTING_1=1
CONFIG_FOO_SETTING_2=2
...
```

Other resources

The *Intro to symbol values* section in the Kconfiglib docstring goes over how symbols values are calculated in more detail.

5.3.5 Custom Kconfig Preprocessor Functions

Kconfiglib supports custom Kconfig preprocessor functions written in Python. These functions are defined in scripts/kconfig/kconfigfunctions.py.

Note

The official Kconfig preprocessor documentation can be found here.

See the Python docstrings in scripts/kconfig/kconfigfunctions.py for detailed documentation. Most of the custom preprocessor functions are used to get devicetree information into Kconfig. For example, the default value of a Kconfig symbol can be fetched from a devicetree `reg` property.

Devicetree-related Functions

The functions listed below are used to get devicetree information into Kconfig. The `*_int` version of each function returns the value as a decimal integer, while the `*_hex` version returns a hexadecimal value starting with `0x`.

```
$(dt_alias_enabled,<node alias>)
$(dt_chosen_bool_prop, <property in /chosen>, <prop>)
$(dt_chosen_enabled,<property in /chosen>)
$(dt_chosen_has_compat,<property in /chosen>,<compatible string>)
$(dt_chosen_label,<property in /chosen>)
$(dt_chosen_partition,addr_hex,<chosen>[,<index>,<unit>])
$(dt_chosen_partition,addr_int,<chosen>[,<index>,<unit>])
$(dt_chosen_path,<property in /chosen>)
$(dt_chosen_reg_addr_hex,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_addr_int,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_size_hex,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_size_int,<property in /chosen>[,<index>,<unit>])
$(dt_compat_all_has_prop,<compatible string>,<prop>[,<value>])
$(dt_compat_any_has_prop,<compatible string>,<prop>[,<value>])
$(dt_compat_any_on_bus,<compatible string>,<prop>)
$(dt_compat_enabled,<compatible string>)
$(dt_compat_enabled_num,<compatible string>)
$(dt_compat_on_bus,<compatible string>,<bus>)
```

(continues on next page)

(continued from previous page)

```
$(dt_gpio_hogs_enabled)
$(dt_has_compat,<compatible string>)
$(dt_node_array_prop_has_val,<node path>,<prop>,<value>)
$(dt_node_array_prop_hex,<node path>,<prop>,<index>[,<unit>])
$(dt_node_array_prop_int,<node path>,<prop>,<index>[,<unit>])
$(dt_node_bool_prop,<node path>,<prop>)
$(dt_node_has_compat,<node path>,<compatible string>)
$(dt_node_has_prop,<node path>,<prop>)

$(dt_nodelabel_exists,<node label>)
$(dt_nodelabel_has_compat,<node label>,<compatible string>)
$(dt_nodelabel_has_prop,<node label>,<prop>)
$(dt_nodelabel_path,<node label>)
$(dt_nodelabel_reg_addr_hex,<node label>[,<index>,<unit>])
$(dt_nodelabel_reg_addr_int,<node label>[,<index>,<unit>])
$(dt_nodelabel_reg_size_hex,<node label>[,<index>,<unit>])
$(dt_nodelabel_reg_size_int,<node label>[,<index>,<unit>])
$(dt_path_enabled,<node path>)
```

Integer functions

The functions listed below can be used to do arithmetic operations on integer variables, such as addition, subtraction and more. Functions with and without the `_hex` suffix in their names return hexadecimal and decimal values respectively.

```
$(add,<value>[,value]...)
$(add_hex,<value>[,value]...)
$(dec,<value>[,value]...)
$(dec_hex,<value>[,value]...)
$(div,<value>[,value]...)
$(div_hex,<value>[,value]...)
$(inc,<value>[,value]...)
$(inc_hex,<value>[,value]...)
$(max,<value>[,value]...)
$(max_hex,<value>[,value]...)
$(min,<value>[,value]...)
$(min_hex,<value>[,value]...)
$(mod,<value>[,value]...)
$(mod_hex,<value>[,value]...)
$(mul,<value>[,value]...)
$(mul_hex,<value>[,value]...)
$(sub,<value>[,value]...)
```

(continues on next page)

(continued from previous page)

```
$(sub_hex,<value>[,value]...)
```

String functions

The functions listed below can be used to modify string variables.

```
$(normalize_upper,<string>)
$(substring,<string>,<start>[,<stop>])
```

Other functions

Functions to perform specific operations, currently only a check if a shield name is specified.

```
$(shields_list_contains,<shield name>)
```

Example Usage Assume that the devicetree for some board looks like this:

```
{
     soc {
             #address-cells = <1>;
             #size-cells = <1>;

             spi0: spi@10014000 {
                     compatible = "sifive,spi0";
                     reg = <0x10014000 0x1000 0x20010000 0x3c0900>;
                     reg-names = "control", "mem";
                     ...
             };
};
```

The second entry in `reg` in `spi@1001400` (`<0x20010000 0x3c0900>`) corresponds to `mem`, and has the address `0x20010000`. This address can be inserted into Kconfig as follows:

```
config FLASH_BASE_ADDRESS
     default $(dt_node_reg_addr_hex,/soc/spi@1001400,1)
```

After preprocessor expansion, this turns into the definition below:

```
config FLASH_BASE_ADDRESS
     default 0x20010000
```

5.3.6 Kconfig extensions

Zephyr uses the Kconfiglib implementation of Kconfig, which includes some Kconfig extensions:

- Default values can be applied to existing symbols without *weakening* the symbols dependencies through the use of `configdefault`.

  ```
  config FOO
      bool "FOO"
      depends on BAR

  configdefault FOO
      default y if FIZZ
  ```

  The statement above is equivalent to:

```
config FOO
    bool "Foo"
    default y if FIZZ
    depends on BAR
```

`configdefault` symbols cannot contain any fields other than `default`, however they can be wrapped in `if` statements. The two statements below are equivalent:

```
configdefault FOO
    default y if BAR

if BAR
configdefault FOO
    default y
endif # BAR
```

- Environment variables in `source` statements are expanded directly, meaning no "bounce" symbols with `option env="ENV_VAR"` need to be defined.

  Note

  `option env` has been removed from the C tools as of Linux 4.18 as well.

  The recommended syntax for referencing environment variables is `$(FOO)` rather than `$FOO`. This uses the new Kconfig preprocessor. The `$FOO` syntax for expanding environment variables is only supported for backwards compatibility.

- The `source` statement supports glob patterns and includes each matching file. A pattern is required to match at least one file.

  Consider the following example:

  ```
  source "foo/bar/*/Kconfig"
  ```

  If the pattern `foo/bar/*/Kconfig` matches the files `foo/bar/baz/Kconfig` and `foo/bar/qaz/Kconfig`, the statement above is equivalent to the following two `source` statements:

  ```
  source "foo/bar/baz/Kconfig"
  source "foo/bar/qaz/Kconfig"
  ```

  If no files match the pattern, an error is generated.

  The wildcard patterns accepted are the same as for the Python glob module.

  For cases where it's okay for a pattern to match no files (or for a plain filename to not exist), a separate `osource` (*optional source*) statement is available. `osource` is a no-op if no file matches.

  Note

  `source` and `osource` are analogous to `include` and `-include` in Make.

- An `rsource` statement is available for including files specified with a relative path. The path is relative to the directory of the `Kconfig` file that contains the `rsource` statement.

  As an example, assume that `foo/Kconfig` is the top-level `Kconfig` file, and that `foo/bar/Kconfig` has the following statements:

```
source "qaz/Kconfig1"
rsource "qaz/Kconfig2"
```

This will include the two files `foo/qaz/Kconfig1` and `foo/bar/qaz/Kconfig2`.

`rsource` can be used to create `Kconfig` "subtrees" that can be moved around freely.

`rsource` also supports glob patterns.

A drawback of `rsource` is that it can make it harder to figure out where a file gets included, so only use it if you need it.

- An `orsource` statement is available that combines `osource` and `rsource`.

  For example, the following statement will include `Kconfig1` and `Kconfig2` from the current directory (if they exist):

```
orsource "Kconfig[12]"
```

- `def_int`, `def_hex`, and `def_string` keywords are available, analogous to `def_bool`. These set the type and add a `default` at the same time.
- A symbol name can be associated to `choice` groups using the `choice <symbol>` syntax. Such choices, called *named choices*, can be modified from places other than their initial definition. For example, the following statements define the named choice `FOOBAR`:

```
choice FOOBAR
        prompt "Example choice"
        default BAR

config FOO
        bool "Foo"

config BAR
        bool "Bar"

endchoice
```

The following statements could then be used, in a `Kconfig.defconfig` file for example, to override the default option of choice `FOOBAR`:

```
# Note how "prompt" is not present here
choice FOOBAR
    default FOO
endchoice
```

> **Note**
>
> The *named choices* feature originates from Linux, but it is no longer supported in Linux since kernel release 6.9, and has thus become a Kconfiglib language extension.

Users interested in optimizing their configuration for security should refer to the Zephyr Security Guide's section on the *Hardening Tool*.

5.4 Snippets

Snippets are a way to save build system settings in one place, and then use those settings when you build any Zephyr application. This lets you save common configuration separately when it applies to multiple different applications.

Some example use cases for snippets are:

- changing your board's console backend from a "real" UART to a USB CDC-ACM UART
- enabling frequently-used debugging options
- applying interrelated configuration settings to your "main" CPU and a co-processor core on an AMP SoC

The following pages document this feature.

5.4.1 Using Snippets

> **Tip**
>
> See *Built-in snippets* for a list of snippets that are provided by Zephyr.

Snippets have names. You use snippets by giving their names to the build system.

With west build

To use a snippet named `foo` when building an application `app`:

```
west build -S foo app
```

To use multiple snippets:

```
west build -S snippet1 -S snippet2 [...] app
```

With cmake

If you are running CMake directly instead of using `west build`, use the `SNIPPET` variable. This is a whitespace- or semicolon-separated list of snippet names you want to use. For example:

```
cmake -Sapp -Bbuild -DSNIPPET="snippet1;snippet2" [...]
cmake --build build
```

Application required snippets

If an application should always be compiled with a given snippet, it can be added to that application's `CMakeLists.txt` file. For example:

```
if(NOT snippet1 IN_LIST SNIPPET)
  set(SNIPPET snippet1 ${SNIPPET} CACHE STRING "" FORCE)
endif()

find_package(Zephyr ....)
```

5.4.2 Built-in snippets

Zephyr Bluetooth LE Controller (bt-ll-sw-split)

You can build with this snippet by following the instructions in *the snippets usage page*. When building with `west`, you can do:

```
west build -S bt-ll-sw-split [...]
```

Overview This selects the Zephyr Bluetooth LE Controller.

Requirements Hardware support for:

- CONFIG_BT

CDC-ACM Console Snippet (cdc-acm-console)

```
west build -S cdc-acm-console [...]
```

Overview This snippet redirects serial console output to a CDC ACM UART. The USB device which should be used is configured using *Devicetree*.

Requirements Hardware support for:

- CONFIG_USB_DEVICE_STACK
- CONFIG_SERIAL
- CONFIG_CONSOLE
- CONFIG_UART_CONSOLE
- CONFIG_UART_LINE_CTRL

A devicetree node with node label zephyr_udc0 that points to an enabled USB device node with driver support. This should look roughly like this in *your devicetree*:

```
zephyr_udc0: usbd@deadbeef {
     compatible = "vnd,usb-device";
     /* ... */
};
```

Espressif snippets

Espressif Flash 128MB

Overview This snippet allows users to select the 128MB SPI flash variant of the ESP32 chips.

Espressif Flash 16MB

Overview This snippet allows users to select the 16MB SPI flash variant of the ESP32 chips.

Espressif Flash 2MB

Overview This snippet allows users to select the 2MB SPI flash variant of the ESP32 chips.

Espressif Flash 32MB

Overview This snippet allows users to select the 32MB SPI flash variant of the ESP32 chips.

Espressif Flash 4MB

Overview This snippet allows users to select the 4MB SPI flash variant of the ESP32 chips.

Espressif Flash 64MB

Overview This snippet allows users to select the 64MB SPI flash variant of the ESP32 chips.

Espressif Flash 8MB

Overview This snippet allows users to select the 8MB SPI flash variant of the ESP32 chips.

Espressif PSRAM 2MB

Overview This snippet allows users to select the 2MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM 4MB

Overview This snippet allows users to select the 4MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM 8MB

Overview This snippet allows users to select the 8MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM relocations

Overview This snippet allows users to enable the flash sections to be relocated to PSRAM.

Espressif PSRAM Wi-Fi buffers

Overview This snippet allows users to configure Wi-Fi buffers to use PSRAM.

Native Simulator support for hci_uart Snippet (hci-uart-native-sim)

```
west build -S hci-uart-native-sim [...]
```

Overview This snippet allows to use hci_uart connected to the host computer with the Native Simulator. It is useful for testing with a real Bluetooth controller, such as a device running Zephyr.

Nordic snippets

Nordic FLPR snippet with execution in place (nordic-flpr-xip)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic FLPR (Fast Lightweight Peripheral Processor) from application core. FLPR code is to be executed from RRAM, so the FLPR image must be built for the `xip` board variant, or with `CONFIG_XIP` enabled.

Nordic FLPR snippet with execution from SRAM (nordic-flpr)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic FLPR (Fast Lightweight Peripheral Processor) from application core. FLPR code is to be executed from SRAM, so the FLPR image must be built without the `xip` board variant, or with `CONFIG_XIP` disabled.

Nordic Dictionary-based STM logging snippet (nordic-log-stm-dict)

Overview This snippet allows users to build Zephyr with the dictionary-based logging to the Coresight STM stimulus ports. Data is collected in ETR buffer. Data from ETR buffer is output on UART.

Nordic Dictionary-based STM to TPIU logging snippet (nordic-log-stm-tpiu-dict)

Overview This snippet allows users to build Zephyr with the dictionary-based logging to the Coresight STM stimulus ports. Data is written to the TPIU interface and can be captured with nrfutil trace to translate into a human-readable format.

Nordic Standalone STM logging snippet (nordic-log-stm)

Overview This snippet allows users to build Zephyr with the logging to the Coresight STM stimulus ports. Data is collected in ETR buffer. Data from ETR buffer is decoded and human-readable data is output on the UART.

Nordic boot PPR snippet with execution in place (nordic-ppr-xip)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic PPR (Peripheral Processor) from another core. PPR code is to be executed from MRAM, so the PPR image must be built for the `xip` board variant, or with `CONFIG_XIP` enabled.

Nordic PPR snippet (nordic-ppr)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic PPR (Peripheral Processor) from another core.

NUS Console Snippet (nus-console)

```
west build -S nus-console [...]
```

Overview This snippet redirects serial console output to a UART over NUS (Bluetooth LE) instance. The Bluetooth Serial device used shall be configured using *Devicetree*.

Requirements Hardware support for:

- `CONFIG_BT`
- `CONFIG_BT_PERIPHERAL`
- `CONFIG_BT_ZEPHYR_NUS`
- `CONFIG_SERIAL`
- `CONFIG_CONSOLE`
- `CONFIG_UART_CONSOLE`

RAM Console Snippet (ram-console)

```
west build -S ram-console [...]
```

Overview This snippet redirects console output to a RAM buffer. The RAM console buffer is a global array located in RAM region by default, whose address is unknown before building. The RAM console driver also supports using a dedicated section for the RAM console buffer with prefined address.

How to enable RAM console buffer section Add board dts overlay to this snippet to add property `zephyr,ram-console` in the chosen node and memory-region node with compatible string `zephyr,memory-region` as the following:

```
/ {
    chosen {
        zephyr,ram-console = &snippet_ram_console;
    };

   snippet_ram_console: memory@93d00000 {
        compatible = "zephyr,memory-region";
        reg = <0x93d00000 DT_SIZE_K(4)>;
        zephyr,memory-region = "RAM_CONSOLE";
   };
};
```

RAM Tracing Snippet (ram-tracing)

```
west build -S ram-tracing [...]
```

Overview This snippet enables CTF Tracing using the RAM backend.

After connecting to the target in GDB, you can dump the RAM tracing data to a binary file:

```
(gdb) dump binary memory ram_tracing.bin ram_tracing ram_tracing+8192
```

Using Babeltrace[1], you can view the binary file as a CTF trace:

```

RP2040/RP2350 boot mode retention setup (rp2-boot-mode-retention)

Overview This snippet sets up an RP2040/RP2350 based board for retaining the set boot mode via properly configured retained mem in SRAM, enabling the necessary Kconfig symbols for the retained mem drivers and retention system.

RTT Console Snippet (rtt-console)

Overview This snippet enables console output to SEGGER RTT.

Requirements Support for:

- CONFIG_HAS_SEGGER_RTT

SystemView RTT Tracing Snippet (rtt-tracing)

```
west build -S rtt-tracing [...]
```

Overview This snippet enables SEGGER SystemView RTT support with the tracing subsystem.

Requirements Hardware support for:

- CONFIG_HAS_SEGGER_RTT

Semihost Tracing Snippet (semihost-tracing)

```
west build -S semihost-tracing [...]
```

Overview This snippet enables CTF Tracing using semihosting on a target that supports it.

Using Qemu, you can run the example application and generate a CTF trace file using semihosting. The trace file can then be viewed using Babeltrace[1].

```
(gdb) dump binary memory ram_tracing.bin ram_tracing ram_tracing+8192
```

Using Babeltrace[1], you can view the binary file as a CTF trace:

References

UART Console Snippet (uart-console)

Overview This snippet enables console output the chosen UART in `zephyr,console`.

Silicon Labs Packet Trace Interface (silabs-pti)

Overview This snippet allows users to build Zephyr applications for Silicon Labs Series 2 devices where radio packets are emitted over the Packet Trace Interface for use by debugging tools.

```
west build -S silabs-pti [...]
```

Requirements Hardware support for `silabs,pti`.

A pinctrl configuration with nodelabel `pti_default` containing PTI pinout.

Slot1 partition snippet (slot1-partition)

```
west build -S slot1-partition [...]
```

Overview This snippet changes the chosen flash partition to be the `slot1_partition` node, this can be used to build for the alternate slot in MCUboot direct-xip or firmware loader modes.

Requirements Partition mapping correct setup in devicetree, for example:

```
&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                boot_partition: partition@0 {
                        label = "mcuboot";
                        reg = <0x00000000 0x0000c000>;
                };

                slot0_partition: partition@c000 {
                        label = "image-0";
                        reg = <0x0000c000 0x00076000>;
                };

                slot1_partition: partition@82000 {
                        label = "image-1";
                        reg = <0x00082000 0x00076000>;
                };

                /*
                 * The flash starting at 0x000f8000 and ending at
                 * 0x000fffff is reserved for use by the application.
                 */

                /*
                 * Storage partition will be used by FCB/LittleFS/NVS
                 * if enabled.
                 */
                storage_partition: partition@f8000 {
                        label = "storage";
                        reg = <0x000f8000 0x00008000>;
                };
        };
};
```

SocketCAN on Native Simulator Snippet (socketcan-native-sim)

```
west build -S socketcan-native-sim [...]
```

Overview This snippet allows to configure Controller Area Network (CAN) samples with Linux SocketCAN support on native_sim.

By default, the native simulator expects a SocketCAN network device called `zcan0` (specified in boards/native/native_sim/native_sim.dts). This name can be added as an alternative name for

an existing SocketCAN network device (here, a newly created virtual CAN network device `vcan0`) using a command like the following:

```
sudo modprobe vcan
sudo ip link add dev vcan0 type vcan
sudo ip link property add dev vcan0 altname zcan0
```

The SocketCAN device must be configured and brought up before running the native simulator:

```
sudo ip link set vcan0 up
```

USB/IP on Native Simulator Snippet (usbip-native-sim)

```
west build -S usbip-native-sim [...]
```

Overview This snippet allows to configure USB device samples with USB/IP support on a native simulator. When building samples with this snippet, you need to provide samples DTC overlays using the EXTRA_DTC_OVERLAY_FILE argument.

This snippet is experimental, the behavior may change without notice.

Video Software Generator Snippet (video-sw-generator)

```
west build -S video-sw-generator [...]
```

Overview This snippet instantiate a fake video source generating a test pattern continuously for test purpose. It is selected as the `zephyr,camera` *Devicetree* chosen node.

Requirements No hardware support is required besides sufficient memory for the video resolution declared by `CONFIG_VIDEO_BUFFER_POOL_HEAP_SIZE`.

Wi-Fi snippets

Wi-Fi Credentials Snippet (wifi-credential)

```
west build  -S wifi-credentials [...]
```

Can also be used along with the *Wi-Fi Enterprise Snippet (wifi-enterprise)* snippet.

```
west build  -S "wifi-enterprise,wifi-credentials" [...]
```

Overview This snippet enables Wi-Fi credentials support.

Requirements Hardware support for:

- `CONFIG_WIFI`
- `CONFIG_WIFI_USE_NATIVE_NETWORKING`
- `CONFIG_WIFI_NM_WPA_SUPPLICANT`
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE`

Wi-Fi Enterprise Snippet (wifi-enterprise)

```
west build  -S wifi-enterprise [...]
```

Can also be used along with the *Wi-Fi IPv4 Snippet (wifi-ipv4)* snippet.

```
west build  -S "wifi-enterprise,wifi-ipv4" [...]
```

Overview This snippet enables enterprise Wi-Fi support in supported networking samples.

See *Wi-Fi Management* for more information on the usage.

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING
- CONFIG_WIFI_NM_WPA_SUPPLICANT
- CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE

Wi-Fi IPv4 and IPv6 Snippet (wifi-ip)

```
west build -S wifi-ip [...]
```

Overview This snippet enables IPv4 and IPv6 Wi-Fi support in supported networking samples. The sample execution is postponed until Wi-Fi connectivity is established.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING

Wi-Fi IPv4 Snippet (wifi-ipv4)

```
west build -S wifi-ipv4 [...]
```

Overview This snippet enables IPv4 Wi-Fi support in supported networking samples. The sample execution is postponed until Wi-Fi connectivity is established.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING

Wi-Fi IPv6 Snippet (wifi-ipv6)

```
west build -S wifi-ipv6 [...]
```

Overview This snippet enables IPv6 Wi-Fi support in supported networking samples. The sample execution is postponed until Wi-Fi connectivity is established.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- `CONFIG_WIFI`
- `CONFIG_WIFI_USE_NATIVE_NETWORKING`

Xen Dom0: universal snippet for XEN control domain

Overview This snippet allows user to build Zephyr as a Xen initial domain (Dom0). The feature is implemented as configuration snippet to allow support for any compatible platform.

How to add support of a new board

- add board dt overlay to this snippet which deletes UART nodes.
- in application dt overlay add correct memory and hypervisor nodes, based on regions Xen picked for Domain-0 on your setup.

Programming Correct snippet designation for Xen must be entered when you invoke `west build`. For example:

```
west build -b qemu_cortex_a53 -S xen_dom0 samples/synchronization
```

QEMU example with Xen Overlay for qemu_cortex_a53 board, that is present in snippets/xen_dom0/boards/ directory of this snippet is QEMU Xen control domain example.

To run such setup, you need to:

- fetch and build Xen (e.g. RELEASE-4.17.0) for arm64 platform
- take and compile sample device tree from `example/` directory
- build your Zephyr sample/application with `xen_dom0` snippet and start it as Xen control domain

Important notice regarding device tree Xen allocates addresses used for Dom0 image and grant tables/extended regions dynamically so they may differ on specific setups (they depend on memory banks location and size, application image size, hypervisor load address used by bootloader etc.). Since Zephyr does not parse device tree in runtime and is not a position independent executable, it needs to know exact values on build time. To make it you need to build your final binary, try to boot it with Xen and analyze the hypervisor output to get exact addresses for your setup. They will look as follows:

Grant table region (first reg in hypervisor node):

```
(XEN) Grant table range: 0x00000088080000-0x000000880c0000
```

Extended regions (2nd and further regs in hypervisor node):

```
(XEN) [    0.928173] d0: extended region 2: 0x40000000->0x47e00000
```

Zephyr Dom0 memory:

```
(XEN) Allocating 1:1 mappings for dom0:
(XEN) BANK[0] 0x00000060000000-0x00000070000000 (256MB)
```

Device tree nodes, that should be added by application overlay for provided example (based on R-Car H3ULCB with extended region):

```
hypervisor: hypervisor@88080000 {
    compatible = "xen,xen";
    reg = <0x0 0x88080000 0x0 0x40000 0x0 0x40000000 0x0 0x7e00000>;
    interrupts = <GIC_PPI 0x0 IRQ_TYPE_EDGE IRQ_DEFAULT_PRIORITY>;
    interrupt-parent = <&gic>;
    status = "okay";
};

ram: memory@60000000 {
    device_type = "mmio-sram";
    reg = <0x00 0x60000000 0x00 DT_SIZE_M(256)>;
};
```

Start the example For starting you can use QEMU from Zephyr SDK by following command:

```
<path to Zephyr SDK>/sysroots/x86_64-pokysdk-linux/usr/bin/qemu-system-aarch64 -
↪cpu cortex-a53 \
-m 6G -nographic -machine virt,gic-version=3,virtualization=true -chardev␣
↪stdio,id=con,mux=on \
-serial chardev:con -mon chardev=con,mode=readline -pidfile qemu.pid \
-device loader,file=<path to Zephyr app build>/zephyr.bin,addr=0x40600000 \
-dtb <path to DTB>/xen.dtb -kernel <path to Xen build>/xen
```

This will start you a Xen hypervisor with your application as Xen control domain. To make it usable, you can add zephyr-xenlib by Xen-troops library to your project. It'll provide basic domain management functionalities - domain creation and configuration.

XIAO UART/Serial Console Snippet (xiao-serial-console)

Overview This snippet enables console output over the standard XIAO UART pins, setting `zephyr,console` to `&xiao_serial`.

5.4.3 Writing Snippets

- *Basics*
- *Namespacing*
- *Where snippets are located*
- *Processing order*
- *Devicetree overlays (`.overlay`)*
- *`.conf` files*
- *Sysbuild `.conf` files*
- *`DTS_EXTRA_CPPFLAGS`*
- *Board-specific settings*

- *By name*
- *By regular expression*
- *Board revisions*

Basics

Snippets are defined using YAML files named `snippet.yml`.

A `snippet.yml` file contains the name of the snippet, along with additional build system settings, like this:

```
name: snippet-name
# ... build system settings go here ...
```

Build system settings go in other keys in the file as described later on in this page.

You can combine settings whenever they appear under the same keys. For example, you can combine a snippet-specific devicetree overlay and a `.conf` file like this:

```
name: foo
append:
  EXTRA_DTC_OVERLAY_FILE: foo.overlay
  EXTRA_CONF_FILE: foo.conf
```

In addition, snippets can also be applied to sysbuild configuration like so:

```
name: foo
append:
  SB_EXTRA_CONF_FILE: sb.conf
  EXTRA_CONF_FILE: app.conf
```

Namespacing

When writing devicetree overlays in a snippet, use `snippet_<name>` or `snippet-<name>` as a namespace prefix when choosing names for node labels, node names, etc. This avoids namespace conflicts.

For example, if your snippet is named `foo-bar`, write your devicetree overlays like this:

```
chosen {
        zephyr,baz = &snippet_foo_bar_dev;
};

snippet_foo_bar_dev: device@12345678 {
        /* ... */
};
```

Where snippets are located

The build system looks for snippets in these places:

1. In directories configured by the `SNIPPET_ROOT` CMake variable. This always includes the zephyr repository (so snippets/ is always a source of snippets).

   Additional directories can be added manually at CMake time.

   The variable is a whitespace- or semicolon-separated list of directories which may contain snippet definitions.

For each directory in the list, the build system looks for `snippet.yml` files underneath a subdirectory named `snippets/`, if one exists.

For example, if **SNIPPET_ROOT** is set to `/foo;/bar`, the build system will look for `snippet.yml` files underneath the following subdirectories:

- `/foo/snippets/`
- `/bar/snippets/`

The `snippet.yml` files can be nested anywhere underneath these locations.

2. In any *module* whose `module.yml` file provides a `snippet_root` setting.

   For example, in a zephyr module named `baz`, you can add this to your `module.yml` file:

   ```
   settings:
     snippet_root: .
   ```

   And then any `snippet.yml` files in `baz/snippets` will automatically be discovered by the build system, just as if the path to `baz` had appeared in **SNIPPET_ROOT**.

Processing order

Snippets are processed in the order they are listed in the **SNIPPET** variable, or in the order of the `-S` arguments if using west.

To apply `bar` after `foo`:

```
cmake -Sapp -Bbuild -DSNIPPET="foo;bar" [...]
cmake --build build
```

The same can be achieved with west as follows:

```
west build -S foo -S bar [...] app
```

When multiple snippets set the same configuration, the configuration value set by the last processed snippet ends up in the final configurations.

For instance, if `foo` sets `CONFIG_FOO=1` and `bar` sets `CONFIG_FOO=2` in the above example, the resulting final configuration will be `CONFIG_FOO=2` because `bar` is processed after `foo`.

This principle applies to both Kconfig fragments (`.conf` files) and devicetree overlays (`.overlay` files).

Devicetree overlays (`.overlay`)

This `snippet.yml` adds `foo.overlay` to the build:

```
name: foo
append:
  EXTRA_DTC_OVERLAY_FILE: foo.overlay
```

The path to `foo.overlay` is relative to the directory containing `snippet.yml`.

`.conf` files

This `snippet.yml` adds `foo.conf` to the build:

```
name: foo
append:
  EXTRA_CONF_FILE: foo.conf
```

The path to `foo.conf` is relative to the directory containing `snippet.yml`.

Sysbuild .conf files

This snippet.yml adds foo.conf to the sysbuild configuration:

```
name: foo
append:
  SB_EXTRA_CONF_FILE: foo.conf
```

The path to foo.conf is relative to the directory containing snippet.yml.

DTS_EXTRA_CPPFLAGS

This snippet.yml adds DTS_EXTRA_CPPFLAGS CMake Cache variables to the build:

```
name: foo
append:
  DTS_EXTRA_CPPFLAGS: -DMY_DTS_CONFIGURE
```

Adding these flags enables control over the content of a devicetree file.

Board-specific settings

You can write settings that only apply to some boards.

The settings described here are applied in **addition** to snippet settings that apply to all boards. (This is similar, for example, to the way that an application with both prj.conf and boards/foo.conf files will use both .conf files in the build when building for board foo, instead of just boards/foo.conf)

By name

```
name: ...
boards:
  bar: # settings for board "bar" go here
    append:
      EXTRA_DTC_OVERLAY_FILE: bar.overlay
  baz: # settings for board "baz" go here
    append:
      EXTRA_DTC_OVERLAY_FILE: baz.overlay
```

The above example uses bar.overlay when building for board bar, and baz.overlay when building for baz.

By regular expression You can enclose the board name in slashes (/) to match the name against a regular expression in the CMake syntax. The regular expression must match the entire board name.

For example:

```
name: foo
boards:
  /my_vendor_.*/:
    append:
      EXTRA_DTC_OVERLAY_FILE: my_vendor.overlay
```

The above example uses devicetree overlay my_vendor.overlay when building for either board my_vendor_board1 or my_vendor_board2. It would not use the overlay when building for either another_vendor_board or x_my_vendor_board.

Board revisions Specific configuration for revisions of boards is also supported which will be applied after the common files:

```
name: foo
boards:
  bar:
    append:
      # Base file will be applied first
      EXTRA_DTC_OVERLAY_FILE: first.overlay
    revisions:
      "0.7.0":
        append:
          # Will be applied on top of common board file
          EXTRA_DTC_OVERLAY_FILE: extra_0_7_0.overlay
```

The above example will use `first.overlay` for all revisions of the `bar` board, and will also include `extra_0_7_0.overlay` when building for revision `0.7.0` of the `bar` board (`bar@0.7.0`).

5.4.4 Snippets Design

This page documents design goals for the snippets feature. Further information can be found in Issue #51834.

- **extensible**: for example, it is possible to add board support for an existing built-in snippet without modifying the zephyr repository
- **composable**: it is possible to use multiple snippets at once, for example using:

  ```
  west build -S <snippet1> -S <snippet2> ...
  ```

- **able to combine multiple types of configuration**: snippets make it possible to store multiple different types of build system settings in one place, and apply them all together
- **specializable**: for example, it is possible to customize a snippet's behavior for a particular board, or board revision
- **future-proof and backwards-compatible**: arbitrary future changes to the snippets feature will be possible without breaking backwards compatibility for older snippets
- **applicable to purely "software" changes**: unlike the shields feature, snippets do not assume the presence of a "daughterboard", "shield", "hat", or any other type of external assembly which is connected to the main board
- **DRY** (don't repeat yourself): snippets allow you to skip unnecessary repetition; for example, you can apply the same board-specific configuration to boards `foo` and `bar` by specifying `/(foo|bar)/` as a regular expression for the settings, which will then apply to both boards

5.5 Zephyr CMake Package

The Zephyr CMake package is a convenient way to create a Zephyr-based application.

> **Note**
>
> The *Application types* section introduces the application types used in this page.

The Zephyr CMake package ensures that CMake can automatically select a Zephyr installation to use for building the application, whether it is a *Zephyr repository application*, a *Zephyr workspace application*, or a *Zephyr freestanding application*.

When developing a Zephyr-based application, then a developer simply needs to write `find_package(Zephyr)` in the beginning of the application `CMakeLists.txt` file.

To use the Zephyr CMake package it must first be exported to the CMake user package registry. This means creating a reference to the current Zephyr installation inside the CMake user package registry.

Ubuntu

In Linux, the CMake user package registry is found in:

`~/.cmake/packages/Zephyr`

macOS

In macOS, the CMake user package registry is found in:

`~/.cmake/packages/Zephyr`

Windows

In Windows, the CMake user package registry is found in:

`HKEY_CURRENT_USER\Software\Kitware\CMake\Packages\Zephyr`

The Zephyr CMake package allows CMake to automatically find a Zephyr base. One or more Zephyr installations must be exported. Exporting multiple Zephyr installations may be useful when developing or testing Zephyr freestanding applications, Zephyr workspace application with vendor forks, etc..

5.5.1 Zephyr CMake package export (west)

When installing Zephyr using *west* then it is recommended to export Zephyr using `west zephyr-export`.

5.5.2 Zephyr CMake package export (without west)

Zephyr CMake package is exported to the CMake user package registry using the following commands:

```
cmake -P <PATH-TO-ZEPHYR>/share/zephyr-package/cmake/zephyr_export.cmake
```

This will export the current Zephyr to the CMake user package registry.

To also export the Zephyr Unittest CMake package, run the following command in addition:

```
cmake -P <PATH-TO-ZEPHYR>/share/zephyrunittest-package/cmake/zephyr_export.cmake
```

5.5.3 Zephyr Base Environment Setting

The Zephyr CMake package search functionality allows for explicitly specifying a Zephyr base using an environment variable.

To do this, use the following `find_package()` syntax:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

This syntax instructs CMake to first search for Zephyr using the Zephyr base environment setting *ZEPHYR_BASE* and then use the normal search paths.

5.5.4 Zephyr CMake Package Search Order

When Zephyr base environment setting is not used for searching, the Zephyr installation matching the following criteria will be used:

- A Zephyr repository application will use the Zephyr in which it is located. For example:

```
<projects>/zephyr-workspace/zephyr
└── samples
    └── hello_world
```

  in this example, `hello_world` will use `<projects>/zephyr-workspace/zephyr`.

- Zephyr workspace application will use the Zephyr that share the same workspace. For example:

```
<projects>/zephyr-workspace
├── zephyr
├── ...
└── my_applications
     └── my_first_app
```

  in this example, `my_first_app` will use `<projects>/zephyr-workspace/zephyr` as this Zephyr is located in the same workspace as the Zephyr workspace application.

Note

The root of a Zephyr workspace is identical to `west topdir` if the workspace was installed using `west`

- Zephyr freestanding application will use the Zephyr registered in the CMake user package registry. For example:

```
<projects>/zephyr-workspace-1
└── zephyr                        (Not exported to CMake)

<projects>/zephyr-workspace-2
└── zephyr                        (Exported to CMake)

<home>/app
├── CMakeLists.txt
├── prj.conf
└── src
    └── main.c
```

  in this example, only `<projects>/zephyr-workspace-2/zephyr` is exported to the CMake package registry and therefore this Zephyr will be used by the Zephyr freestanding application `<home>/app`.

  If user wants to test the application with `<projects>/zephyr-workspace-1/zephyr`, this can be done by using the Zephyr Base environment setting, meaning set `ZEPHYR_BASE=<projects>/zephyr-workspace-1/zephyr`, before running CMake.

  Note

  The Zephyr package selected on the first CMake invocation will be used for all subsequent builds. To change the Zephyr package, for example to test the application using Zephyr base environment setting, then it is necessary to do a pristine build first (See *Rebuilding an Application*).

5.5.5 Zephyr CMake Package Version

When writing an application then it is possible to specify a Zephyr version number `x.y.z` that must be used in order to build the application.

Specifying a version is especially useful for a Zephyr freestanding application as it ensures the application is built with a minimal Zephyr version.

It also helps CMake to select the correct Zephyr to use for building, when there are multiple Zephyr installations in the system.

For example:

```
find_package(Zephyr 2.2.0)
project(app)
```

will require app to be built with Zephyr 2.2.0 as minimum. CMake will search all exported candidates to find a Zephyr installation which matches this version criteria.

Thus it is possible to have multiple Zephyr installations and have CMake automatically select between them based on the version number provided, see CMake package version for details.

For example:

```
<projects>/zephyr-workspace-2.a
└── zephyr                        (Exported to CMake)

<projects>/zephyr-workspace-2.b
└── zephyr                        (Exported to CMake)

<home>/app
├── CMakeLists.txt
├── prj.conf
└── src
    └── main.c
```

in this case, there are two released versions of Zephyr installed at their own workspaces. Workspace 2.a and 2.b, corresponding to the Zephyr version.

To ensure app is built with minimum version `2.a` the following `find_package` syntax may be used:

```
find_package(Zephyr 2.a)
project(app)
```

Note that both `2.a` and `2.b` fulfill this requirement.

CMake also supports the keyword `EXACT`, to ensure an exact version is used, if that is required. In this case, the application CMakeLists.txt could be written as:

```
find_package(Zephyr 2.a EXACT)
project(app)
```

In case no Zephyr is found which satisfies the version required, as example, the application specifies

```
find_package(Zephyr 2.z)
project(app)
```

then an error similar to below will be printed:

```
Could not find a configuration file for package "Zephyr" that is compatible
with requested version "2.z".

The following configuration files were considered but not accepted:

↪<projects>/zephyr-workspace-2.a/zephyr/share/zephyr-package/cmake/ZephyrConfig.cmake,␣
↪version: 2.a.0

↪<projects>/zephyr-workspace-2.b/zephyr/share/zephyr-package/cmake/ZephyrConfig.cmake,␣
↪version: 2.b.0
```

Note

It can also be beneficial to specify a version number for Zephyr repository applications and Zephyr workspace applications. Specifying a version in those cases ensures the application will only build if the Zephyr repository or workspace is matching. This can be useful to avoid accidental builds when only part of a workspace has been updated.

5.5.6 Multiple Zephyr Installations (Zephyr workspace)

Testing out a new Zephyr version, while at the same time keeping the existing Zephyr in the workspace untouched is sometimes beneficial.

Or having both an upstream Zephyr, Vendor specific, and a custom Zephyr in same workspace.

For example:

```
<projects>/zephyr-workspace
├── zephyr
├── zephyr-vendor
├── zephyr-custom
├── ...
└── my_applications
    └── my_first_app
```

in this setup, `find_package(Zephyr)` has the following order of precedence for selecting which Zephyr to use:

- Project name: `zephyr`
- First project, when Zephyr projects are ordered lexicographical, in this case.
  - `zephyr-custom`
  - `zephyr-vendor`

This means that `my_first_app` will use `<projects>/zephyr-workspace/zephyr`.

It is possible to specify a Zephyr preference list in the application.

A Zephyr preference list can be specified as:

```
set(ZEPHYR_PREFER "zephyr-custom" "zephyr-vendor")
find_package(Zephyr)

project(my_first_app)
```

the `ZEPHYR_PREFER` is a list, allowing for multiple Zephyrs. If a Zephyr is specified in the list, but not found in the system, it is simply ignored and `find_package(Zephyr)` will continue to the next candidate.

This allows for temporary creation of a new Zephyr release to be tested, without touching current Zephyr. When testing is done, the `zephyr-test` folder can simply be removed. Such a CMakeLists.txt could look as:

```
set(ZEPHYR_PREFER "zephyr-test")
find_package(Zephyr)

project(my_first_app)
```

5.5.7 Zephyr Build Configuration CMake packages

There are two Zephyr Build configuration packages which provide control over the build settings in Zephyr in a more generic way. These packages are:

- **ZephyrBuildConfiguration**: Applies to all Zephyr applications in the workspace
- **ZephyrAppConfiguration**: Applies only to the application you are currently building

They are similar to the per-user `.zephyrrc` file that can be used to set *Environment Variables*, but they set CMake variables instead. They also allow you to automatically share the build configuration among all users through the project repository. They also allow more advanced use cases, such as loading of additional CMake boilerplate code.

The Zephyr Build Configuration CMake packages will be loaded in the Zephyr boilerplate code after initial properties and `ZEPHYR_BASE` has been defined, but before CMake code execution. The ZephyrBuildConfiguration is included first and ZephyrAppConfiguration afterwards. That means the application-specific package could override the workspace settings, if needed. This allows the Zephyr Build Configuration CMake packages to setup or extend properties such as: `DTS_ROOT`, `BOARD_ROOT`, `TOOLCHAIN_ROOT` / other toolchain setup, fixed overlays, and any other property that can be controlled. It also allows inclusion of additional boilerplate code.

To provide a ZephyrBuildConfiguration or ZephyrAppConfiguration, create `ZephyrBuildConfig.cmake` and/or `ZephyrAppConfig.cmake` respectively and place them in the appropriate location. The CMake `find_package` mechanism will search for these files with the steps below. Other default CMake package search paths and hints are disabled and there is no version checking implemented for these packages. This also means that these packages cannot be installed in the CMake package registry. The search steps are:

1. If `ZephyrBuildConfiguration_ROOT`, or `ZephyrAppConfiguration_ROOT` respectively, is set, search within this prefix path. If a matching file is found, execute this file. If no matching file is found, go to step 2.
2. Search within `${ZEPHYR_BASE}/../*`, or `${APPLICATION_SOURCE_DIR}` respectively. If a matching file is found, execute this file. If no matching file is found, abort the search.

It is recommended to place the files in the default paths from step 2, but with the `<PackageName>_ROOT` variables you have the flexibility to place them anywhere. This is especially necessary for freestanding applications, for which the default path to ZephyrBuildConfiguration usually does not work. In this case the `<PackageName>_ROOT` variables can be set on the CMake command line, **before** `find_package(Zephyr ...)`, as environment variable or from a CMake cache initialization file with the `-C` command line option.

> **Note**
>
> The `<PackageName>_ROOT` variables, as well as the default paths, are just the prefixes to the search path. These prefixes get combined with additional path suffixes, which together form the actual search path. Any combination that honors the CMake package search procedure is valid and will work.

If you want to completely disable the search for these packages, you can use the special CMake `CMAKE_DISABLE_FIND_PACKAGE_<PackageName>` variable

for that. Just set `CMAKE_DISABLE_FIND_PACKAGE_ZephyrBuildConfiguration` or `CMAKE_DISABLE_FIND_PACKAGE_ZephyrAppConfiguration` to `TRUE` to disable the package.

An example folder structure could look like this:

```
<projects>/zephyr-workspace
├── zephyr
├── ...
├── manifest repo (can be named anything)
|    └── cmake/ZephyrBuildConfig.cmake
├── ...
└── zephyr application
     └── share/zephyrapp-package/cmake/ZephyrAppConfig.cmake
```

A sample `ZephyrBuildConfig.cmake` can be seen below.

```
# ZephyrBuildConfig.cmake sample code

# To ensure final path is absolute and does not contain ../.. in variable.
get_filename_component(APPLICATION_PROJECT_DIR
                       ${CMAKE_CURRENT_LIST_DIR}/../../..
                       ABSOLUTE
)

# Add this project to list of board roots
list(APPEND BOARD_ROOT ${APPLICATION_PROJECT_DIR})

# Default to GNU Arm Embedded toolchain if no toolchain is set
if(NOT ENV{ZEPHYR_TOOLCHAIN_VARIANT})
    set(ZEPHYR_TOOLCHAIN_VARIANT gnuarmemb)
    find_program(GNU_ARM_GCC arm-none-eabi-gcc)
    if(NOT ${GNU_ARM_GCC} STREQUAL GNU_ARM_GCC-NOTFOUND)
        # The toolchain root is located above the path to the compiler.
        get_filename_component(GNUARMEMB_TOOLCHAIN_PATH ${GNU_ARM_GCC}/../..␣
↪ABSOLUTE)
    endif()
endif()
```

5.5.8 Zephyr CMake package source code

The Zephyr CMake package source code in share/zephyr-package/cmake and share/zephyrunittest-package/cmake contains the CMake config package which is used by the CMake `find_package` function.

It also contains code for exporting Zephyr as a CMake config package.

The following is an overview of the files in these directories:

`ZephyrConfigVersion.cmake`
: The Zephyr package version file. This file is called by CMake to determine if this installation fulfils the requirements specified by user when calling `find_package(Zephyr ...)`. It is also responsible for detection of Zephyr repository or workspace only installations.

`ZephyrUnittestConfigVersion.cmake`
: Same responsibility as `ZephyrConfigVersion.cmake`, but for unit tests. Includes `ZephyrConfigVersion.cmake`.

`ZephyrConfig.cmake`
: The Zephyr package file. This file is called by CMake to for the package meeting which fulfils the requirements specified by user when calling `find_package(Zephyr ...)`. This file is responsible for sourcing of boilerplate code.

`ZephyrUnittestConfig.cmake`
: Same responsibility as `ZephyrConfig.cmake`, but for unit tests. Includes `ZephyrConfig.cmake`.

`zephyr_package_search.cmake`
: Common file used for detection of Zephyr repository and workspace candidates. Used by `ZephyrConfigVersion.cmake` and `ZephyrConfig.cmake` for common code.

`zephyr_export.cmake`
: See *Zephyr CMake package export (without west)*.

5.6 Sysbuild (System build)

Sysbuild is a higher-level build system that can be used to combine multiple other build systems together. It is a higher-level layer that combines one or more Zephyr build systems and optional additional build systems into a hierarchical build system.

For example, you can use sysbuild to build a Zephyr application together with the MCUboot bootloader, flash them both onto your device, and debug the results.

Sysbuild works by configuring and building at least a Zephyr application and, optionally, as many additional projects as you want. The additional projects can be either Zephyr applications or other types of builds you want to run.

Like Zephyr's *build system*, sysbuild is written in CMake and uses *Kconfig*.

5.6.1 Definitions

The following are some key concepts used in this document:

Single-image build
: When sysbuild is used to create and manage just one Zephyr application's build system.

Multi-image build
: When sysbuild is used to manage multiple build systems. The word "image" is used because your main goal is usually to generate the binaries of the firmware application images from each build system.

Domain
: Every Zephyr CMake build system managed by sysbuild.

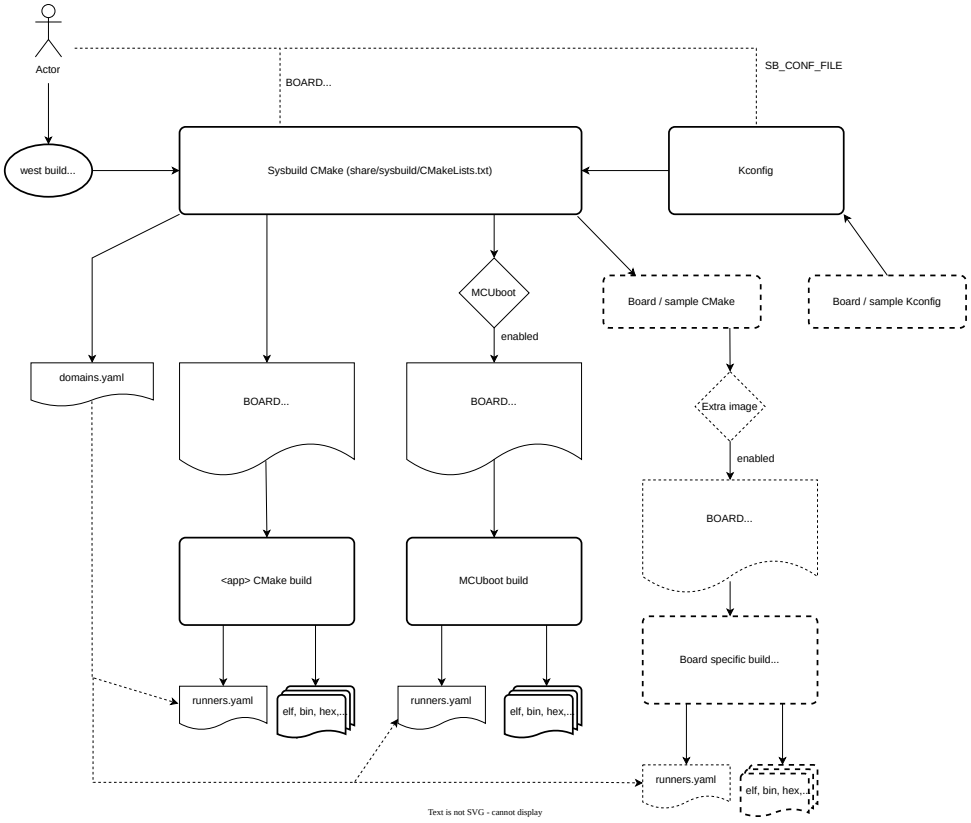
Multi-domain
: When more than one Zephyr CMake build system (domain) is managed by sysbuild.

5.6.2 Architectural Overview

This figure is an overview of sysbuild's inputs, outputs, and user interfaces:

The following are some key sysbuild features indicated in this figure:

- You can run sysbuild either with *west build* or directly via `cmake`.
- You can use sysbuild to generate application images from each build system, shown above as ELF, BIN, and HEX files.
- You can configure sysbuild or any of the build systems it manages using various configuration variables. These variables are namespaced so that sysbuild can direct them to the right build system. In some cases, such as the `BOARD` variable, these are shared among multiple build systems.
- Sysbuild itself is also configured using Kconfig. For example, you can instruct sysbuild to build the MCUboot bootloader, as well as to build and link your main Zephyr application as an MCUboot-bootable image, using sysbuild's Kconfig files.



- Sysbuild integrates with west's *Building, Flashing and Debugging* commands. It does this by managing the *Configuration Options*, and specifically the `runners.yaml` files that each Zephyr build system will contain. These are packaged into a global view of how to flash and debug each build system in a `domains.yaml` file generated and managed by sysbuild.
- Build names are prefixed with the target name and an underscore, for example the sysbuild target is prefixed with `sysbuild_` and if MCUboot is enabled as part of sysbuild, it will be prefixed with `mcuboot_`. This also allows for running things like menuconfig with the prefix, for example (if using ninja) `ninja sysbuild_menuconfig` to configure sysbuild or (if using make) `make mcuboot_menuconfig`.

5.6.3 Building with sysbuild

As mentioned above, you can run sysbuild via `west build` or `cmake`.

`west build`

Here is an example. For details, see *Sysbuild (multi-domain builds)* in the `west build` documentation.

```
west build -b reel_board --sysbuild samples/hello_world
```

Tip

To configure `west build` to use `--sysbuild` by default from now on, run:

```
west config build.sysbuild True
```

Since sysbuild supports both single- and multi-image builds, this lets you use sysbuild all the time, without worrying about what type of build you are running.

To turn this off, run this before generating your build system:

```
west config build.sysbuild False
```

To turn this off for just one `west build` command, run:

```
west build --no-sysbuild ...
```

cmake

Here is an example using CMake and Ninja.

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world␣
↪share/sysbuild
ninja -Cbuild
```

To use sysbuild directly with CMake, you must specify the sysbuild project as the source folder, and give `-DAPP_DIR=<path-to-sample>` as an extra CMake argument or set APP_DIR as environment variable. `APP_DIR` is the path to the main Zephyr application managed by sysbuild.

Tip

The environment variables, `CMAKE_BUILD_PARALLEL_LEVEL` and `VERBOSE`, can be used to control the build process when using sysbuild with CMake and ninja.

To set number of jobs for ninja for all sysbuild images, set the CMAKE_BUILD_PARALLEL_LEVEL environment variable and invoke the build with `cmake --build`, for example:

```
CMAKE_BUILD_PARALLEL_LEVEL=<n> cmake --build .
```

For verbose output of all images, use:

```
VERBOSE=1 cmake --build .
```

5.6.4 Configuration namespacing

When building a single Zephyr application without sysbuild, all CMake cache settings and Kconfig build options given on the command line as `-D<var>=<value>` or `-DCONFIG_<var>=<value>` are handled by the Zephyr build system.

However, when sysbuild combines multiple Zephyr build systems, there could be Kconfig settings exclusive to sysbuild (and not used by any of the applications). To handle this, sysbuild has namespaces for configuration variables. You can use these namespaces to direct settings either to sysbuild itself or to a specific Zephyr application managed by sysbuild using the information in these sections.

The following example shows how to build hello_world with MCUboot enabled, applying to both images debug optimizations:

west build

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -DCONFIG_DEBUG_OPTIMIZATIONS=y -
↪Dmcuboot_CONFIG_DEBUG_OPTIMIZATIONS=y
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -DCONFIG_DEBUG_OPTIMIZATIONS=y -
```

(continues on next page)

(continued from previous page)

```
↪Dmcuboot_CONFIG_DEBUG_OPTIMIZATIONS=y share/sysbuild
ninja -Cbuild
```

See the following subsections for more information.

CMake variable namespacing

CMake variable settings can be passed to CMake using `-D<var>=<value>` on the command line. You can also set Kconfig options via CMake as `-DCONFIG_<var>=<value>` or `-D<namespace>_CONFIG_<var>=<value>`.

Since sysbuild is the entry point for the build system, and sysbuild is written in CMake, all CMake variables are first processed by sysbuild.

Sysbuild creates a namespace for each domain. The namespace prefix is the domain's application name. See *Adding Zephyr applications to sysbuild* for more information.

To set the variable `<var>` in the namespace `<namespace>`, use this syntax:

```
-D<namespace>_<var>=<value>
```

For example, to set the CMake variable `FOO` in the `my_sample` application build system to the value `BAR`, run the following commands:

`west build`

```
west build --sysbuild ... -- -Dmy_sample_FOO=BAR
```

`cmake`

```
cmake -Dmy_sample_FOO=BAR ...
```

Kconfig namespacing

To set the sysbuild Kconfig option `<var>` to the value `<value>`, use this syntax:

```
-DSB_CONFIG_<var>=<value>
```

In the previous example, `SB_CONFIG` is the namespace prefix for sysbuild's Kconfig options.

To set a Zephyr application's Kconfig option instead, use this syntax:

```
-D<namespace>_CONFIG_<var>=<value>
```

In the previous example, `<namespace>` is the application name discussed above in *CMake variable namespacing*.

For example, to set the Kconfig option `FOO` in the `my_sample` application build system to the value `BAR`, run the following commands:

`west build`

```
west build --sysbuild ... -- -Dmy_sample_CONFIG_FOO=BAR
```

`cmake`

```
cmake -Dmy_sample_CONFIG_FOO=BAR ...
```

Tip

When no <namespace> is used, the Kconfig setting is passed to the main Zephyr application my_sample.

This means that passing -DCONFIG_<var>=<value> and -Dmy_sample_CONFIG_<var>=<value> are equivalent.

This allows you to build the same application with or without sysbuild using the same syntax for setting Kconfig values at CMake time. For example, the following commands will work in the same way:

```
west build -b <board> my_sample -- -DCONFIG_FOO=BAR
west build -b <board> --sysbuild my_sample -- -DCONFIG_FOO=BAR
```

5.6.5 Sysbuild flashing using west flash

You can use *west flash* to flash applications with sysbuild.

When invoking west flash on a build consisting of multiple images, each image is flashed in sequence. Extra arguments such as --runner jlink are passed to each invocation.

For more details, see *Multi-domain flashing*.

5.6.6 Sysbuild debugging using west debug

You can use west debug to debug the main application, whether you are using sysbuild or not. Just follow the existing *west debug* guide to debug the main sample.

To debug a different domain (Zephyr application), such as mcuboot, use the --domain argument, as follows:

```
west debug --domain mcuboot
```

For more details, see *Multi-domain debugging*.

5.6.7 Building a sample with MCUboot

Sysbuild supports MCUboot natively.

To build a sample like hello_world with MCUboot, enable MCUboot and build and flash the sample as follows:

west build

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y share/sysbuild
ninja -Cbuild
```

This builds hello_world and mcuboot for the reel_board, and then flashes both the mcuboot and hello_world application images to the board.

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

Note

The deprecated MCUBoot Kconfig option `CONFIG_ZEPHYR_TRY_MASS_ERASE` will perform a full chip erase when flashed. If this option is enabled, then flashing only MCUBoot, for example using `west flash --domain mcuboot`, may erase the entire flash, including the main application image.

5.6.8 Sysbuild Kconfig file

You can set sysbuild's Kconfig options for a single application using configuration files. By default, sysbuild looks for a configuration file named `sysbuild.conf` in the application top-level directory.

In the following example, there is a `sysbuild.conf` file that enables building and flashing with MCUboot whenever sysbuild is used:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
└── sysbuild.conf
```

```
SB_CONFIG_BOOTLOADER_MCUBOOT=y
```

You can set a configuration file to use with the `-DSB_CONF_FILE=<sysbuild-conf-file>` CMake build setting.

For example, you can create `sysbuild-mcuboot.conf` and then specify this file when building with sysbuild, as follows:

`west build`

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONF_FILE=sysbuild-mcuboot.conf
```

`cmake`

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONF_FILE=sysbuild-mcuboot.conf share/sysbuild
ninja -Cbuild
```

5.6.9 Sysbuild targets

Sysbuild creates build targets for each image (including sysbuild itself) for the following modes:

- menuconfig
- hardenconfig
- guiconfig

For the main application (as is the same without using sysbuild) these can be ran normally without any prefix. For other images (including sysbuild), these are ran with a prefix of the image name and an underscore e.g. `sysbuild_` or `mcuboot_`, using ninja or make - for details on how to run image build targets that do not have mapped build targets in sysbuild, see the *Dedicated image build targets* section.

5.6.10 Dedicated image build targets

Not all build targets for images are given equivalent prefixed build targets when sysbuild is used, for example build targets like `ram_report`, `rom_report`, `footprint`, `puncover` and `pahole` are not

exposed. When using *Trusted Firmware*, the build targets prefixed with `tfm_` and `bl2_` are also not exposed, for example: `tfm_rom_report` and `bl2_ram_report`. To run these build targets, the build directory of the image can be provided to west/ninja/make along with the name of the build target to execute and it will run.

`west`

Assuming that a project has been configured and built using `west` using sysbuild with mcuboot enabled in the default `build` folder location, the `rom_report` build target for `mcuboot` can be ran with:

```
west build -d build/mcuboot -t rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
west build -d build/<app_name> -t tfm_rom_report
```

`ninja`

Assuming that a project has been configured using `cmake` and built using `ninja` using sysbuild with mcuboot enabled, the `rom_report` build target for `mcuboot` can be ran with:

```
ninja -C mcuboot rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
ninja -C <app_name> -t tfm_rom_report
```

`make`

Assuming that a project has been configured using `cmake` and built using `make` using sysbuild with mcuboot enabled, the `rom_report` build target for `mcuboot` can be ran with:

```
make -C mcuboot rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
make -C <app_name> -t tfm_rom_report
```

5.6.11 Adding Zephyr applications to sysbuild

You can use the `ExternalZephyrProject_Add()` function to add Zephyr applications as sysbuild domains. Call this CMake function from your application's `sysbuild.cmake` file, or any other CMake file you know will run as part sysbuild CMake invocation.

A variant image can also added using the `ExternalZephyrVariantProject_Add()` function which will duplicate an existing image in the sysbuild project, and allows for slight differences in configuration. An example use case for this feature is to change the chosen flash node of an image but having the rest of the configuration identical to the base image. When this is used, neither sysbuild itself nor the image will have the extra Kconfig targets made for it such as menuconfig, guiconfig, hardenconfig or traceconfig, as the base image can be used for viewing/adjusting these instead.

Targeting the same board

To include `my_sample` as another sysbuild domain, targeting the same board as the main image, use this example:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
```

(continues on next page)

(continued from previous page)

```
  SOURCE_DIR <path-to>/my_sample
)
```

This could be useful, for example, if your board requires you to build and flash an SoC-specific bootloader along with your main application.

Targeting a different board

In sysbuild and Zephyr CMake build system a board may refer to:

- A physical board with a single core SoC.
- A specific core on a physical board with a multi-core SoC, such as nrf5340dk.
- A specific SoC on a physical board with multiple SoCs, such as nrf9160dk_nrf9160 and nrf9160dk_nrf52840.

If your main application, for example, is built for `mps2/an521/cpu0`, and your helper application must target the `mps2/an521/cpu1` board target, add a CMake function call that is structured as follows:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
  SOURCE_DIR <path-to>/my_sample
  BOARD mps2/an521/cpu1
)
```

This could be useful, for example, if your main application requires another helper Zephyr application to be built and flashed alongside it, but the helper runs on another core in your SoC.

Targeting conditionally using Kconfig

You can control whether extra applications are included as sysbuild domains using Kconfig.

If the extra application image is specific to the board or an application, you can create two additional files: `sysbuild.cmake` and `Kconfig.sysbuild`.

For an application, this would look like this:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
├── Kconfig.sysbuild
└── sysbuild.cmake
```

In the previous example, `sysbuild.cmake` would be structured as follows:

```
if(SB_CONFIG_SECOND_SAMPLE)
  ExternalZephyrProject_Add(
    APPLICATION second_sample
    SOURCE_DIR <path-to>/second_sample
  )
endif()
```

`Kconfig.sysbuild` would be structured as follows:

```
source "sysbuild/Kconfig"

config SECOND_SAMPLE
```

(continues on next page)

(continued from previous page)

```
        bool "Second sample"
        default y
```

This will include `second_sample` by default, while still allowing you to disable it using the Kconfig option `SECOND_SAMPLE`.

For more information on setting sysbuild Kconfig options, see *Kconfig namespacing*.

Building without flashing

You can mark `my_sample` as a build-only application in this manner:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
  SOURCE_DIR <path-to>/my_sample
  BUILD_ONLY TRUE
)
```

As a result, `my_sample` will be built as part of the sysbuild build invocation, but it will be excluded from the default image sequence used by `west flash`. Instead, you may use the outputs of this domain for other purposes - for example, to produce a secondary image for DFU, or to merge multiple images together.

You can also replace `TRUE` with another boolean constant in CMake, such as a Kconfig option, which would make `my_sample` conditionally build-only.

Note

Applications marked as build-only can still be flashed manually, using `west flash --domain my_sample`. As such, the `BUILD_ONLY` option only controls the default behavior of `west flash`.

Zephyr application configuration

When adding a Zephyr application to sysbuild, such as MCUboot, then the configuration files from the application (MCUboot) itself will be used.

When integrating multiple applications with each other, then it is often necessary to make adjustments to the configuration of extra images.

Sysbuild gives users the ability of creating Kconfig fragments or devicetree overlays that will be used together with the application's default configuration. Sysbuild also allows users to change *Application Configuration Directory* in order to give users full control of an image's configuration.

Zephyr application Kconfig fragment and devicetree overlay In the folder of the main application, create a Kconfig fragment or a devicetree overlay under a sysbuild folder, where the name of the file is `<image>.conf` or `<image>.overlay`, for example if your main application includes `my_sample` then create a `sysbuild/my_sample.conf` file or a devicetree overlay `sysbuild/my_sample.overlay`.

A Kconfig fragment could look as:

```
# sysbuild/my_sample.conf
CONFIG_FOO=n
```

Zephyr application configuration directory In the folder of the main application, create a new folder under `sysbuild/<image>/`. This folder will then be used as `APPLICATION_CONFIG_DIR` when building `<image>`. As an example, if your main application includes `my_sample` then create

a sysbuild/my_sample/ folder and place any configuration files in there as you would normally do:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
└── sysbuild
    └── my_sample
        ├── prj.conf
        ├── app.overlay
        └── boards
            ├── <board_A>.conf
            ├── <board_A>.overlay
            ├── <board_B>.conf
            └── <board_B>.overlay
```

All configuration files under the sysbuild/my_sample/ folder will now be used when my_sample is included in the build, and the default configuration files for my_sample will be ignored.

This give you full control on how images are configured when integrating those with application.

Sysbuild file suffix support File suffix support through the FILE_SUFFIX is supported in sysbuild (see *File Suffixes* for details on this feature in applications). For sysbuild, a globally provided option will be passed down to all images. In addition, the image configuration file will have this value applied and used (instead of the build type) if the file exists.

Given the example project:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
├── sysbuild.conf
├── sysbuild_test_key.conf
└── sysbuild
    ├── mcuboot.conf
    ├── mcuboot_max_log.conf
    └── my_sample.conf
```

- If FILE_SUFFIX is not defined and both mcuboot and my_sample images are included, mcuboot will use the mcuboot.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file. Sysbuild itself will use the sysbuild.conf Kconfig fragment file.
- If FILE_SUFFIX is set to max_log and both mcuboot and my_sample images are included, mcuboot will use the mcuboot_max_log.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file (as it will fallback to the file without the suffix). Sysbuild itself will use the sysbuild.conf Kconfig fragment file (as it will fallback to the file without the suffix).
- If FILE_SUFFIX is set to test_key and both mcuboot and my_sample images are included, mcuboot will use the mcuboot.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file (as it will fallback to the files without the suffix). Sysbuild itself will use the sysbuild_test_key.conf Kconfig fragment file. This can be used to apply a different sysbuild configuration, for example to use a different signing key in MCUboot and when signing the main application.

The FILE_SUFFIX can also be applied only to single images by prefixing the variable with the image name:

```
west build
```

```
west build -b reel_board --sysbuild file_suffix_example -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -Dmcuboot_FILE_SUFFIX="max_log"
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=<app_dir> -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -Dmcuboot_FILE_SUFFIX="max_log" share/sysbuild
ninja -Cbuild
```

Adding dependencies among Zephyr applications

Sometimes, in a multi-image build, you may want certain Zephyr applications to be configured or flashed in a specific order. For example, if you need some information from one application's build system to be available to another's, then the first thing to do is to add a configuration dependency between them. Separately, you can also add flashing dependencies to control the sequence of images used by `west flash`; this could be used if a specific flashing order is required by an SoC, a _runner_, or something else.

By default, sysbuild will configure and flash applications in the order that they are added, as `ExternalZephyrProject_Add()` calls are processed by CMake. You can use the `sysbuild_add_dependencies()` function to make adjustments to this order, according to your needs. Its usage is similar to the standard `add_dependencies()` function in CMake.

Here is an example of adding configuration dependencies for `my_sample`:

```
sysbuild_add_dependencies(IMAGE CONFIGURE my_sample sample_a sample_b)
```

This will ensure that sysbuild will run CMake for `sample_a` and `sample_b` (in some order) before doing the same for `my_sample`, when building these domains in a single invocation.

If you want to add flashing dependencies instead, then do it like this:

```
sysbuild_add_dependencies(IMAGE FLASH my_sample sample_a sample_b)
```

As a result, `my_sample` will be flashed after `sample_a` and `sample_b` (in some order), when flashing these domains in a single invocation.

Note

Adding flashing dependencies is not allowed for build-only applications. If `my_sample` had been created with `BUILD_ONLY TRUE`, then the above call to `sysbuild_add_dependencies()` would have produced an error.

5.6.12 Merged hex files

Sysbuild supports creating merged hex files, which will be created one per unique board target in a sysbuild project and can be enabled with `SB_CONFIG_MERGED_HEX_FILES`. The output filename format will be `merged_<NORMALIZED_BOARD_TARGET>.hex`. This is ideal for creating production images for deployment, it requires that all images output hex files. If a sysbuild project builds multiple images for the same board target but for **different** devices (e.g. 3 images for 3 different boards as part of a test), then this option should remain disabled. Hex files will be merged as per the flashing order they have been configured in, any overlapping data from previous addresses that conflicts with later merged hex files will be overwritten with the later hex file data - see *Adding dependencies among Zephyr applications* for how to configure the flashing order of sysbuild images.

5.6.13 Adding non-Zephyr applications to sysbuild

You can include non-Zephyr applications in a multi-image build using the standard CMake module ExternalProject. Please refer to the CMake documentation for usage details.

When using `ExternalProject`, the non-Zephyr application will be built as part of the sysbuild build invocation, but `west flash` or `west debug` will not be aware of the application. Instead, you must manually flash and debug the application.

5.6.14 Configuring sysbuild internal state

Because sysbuild is a CMake project in it's own right, it runs and sets up itself similar to a Zephyr application but using it's own CMake code. This means that some features, for example specifying variables in an application `CMakeLists.txt` (such as `BOARD_ROOT`) will not work, instead these must be set by using a *a module* or by using a custom sysbuild project file as `<application>/sysbuild/CMakeLists.txt`, for example:

```
# Place pre-sysbuild configuration items here

# For changing configuration that sysbuild itself uses:
# set(<var> <value>)
# list(APPEND <list> <value>)

# For changing configuration of other images:
# set(<image>_<var> <value> CACHE INTERNAL "<description>")

# Finds the sysbuild project and includes it with the new configuration
find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)
```

An example of adding a `BOARD_ROOT`:

```
list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/../<extra-board-root>)

find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)
```

This will pass the board root on to all images as part of a project, it does not need to be repeated in each image's `CMakeLists.txt` file.

5.6.15 Extending sysbuild

Sysbuild can be extended by other modules to give it additional functionality or include other configuration or images, an example could be to add support for another bootloader or external signing method.

Modules can be extended by adding custom CMake or Kconfig files as normal *modules* do, this will cause the files to be included in each image that is part of a project. Alternatively, there are *sysbuild-specific module extension* files which can be used to include CMake and Kconfig files for the overall sysbuild image itself, this is where e.g. a custom image for a particular board or SoC can be added.

Sysbuild images

Sysbuild can be used to add additional images to builds, these can be added by projects or boards though at present must be Zephyr applications.

Methods of adding images Images can be added to project or projects in various ways, multiple ways can be used simultaneously, they can be added in the following ways:

Applications Applications can add sysbuild images using the `sysbuild.cmake` file in the application directory, the inclusion of images can be controlled with a `Kconfig.sysbuild` file in the application directory.

Boards Boards can add sysbuild images by using the `sysbuild.cmake` file in the board directory, the inclusion of images can be controlled with a `Kconfig.sysbuild` file in the board directory.

SoCs SoCs can add sysbuild images by using the `sysbuild.cmake` file in the soc directory.

Modules *Modules (External projects)* can add sysbuild images with the `sysbuild-cmake` and `sysbuild-kconfig` options in a `module.yml` file, see *Sysbuild integration* for details.

Adding images Images can be added in one of two ways:

Single unchangeable image With this setup, the image to be added is fixed to a specific application and cannot be changed (although it cannot be changed to another image, the version of the image itself can be changed by use of a west manifest bringing in a different version of the application repo or from an alternate source, assuming that the image is in it's own repository).

> **Note**
>
> This method should only be used if the image is locked to a specific interface and has no extensibility.

An example of how to create such an image, this assumes that a *Zephyr application has been created*:

`Kconfig.sysbuild`

```
config MY_IMAGE
        bool "Include my amazing image"
        help
          If enabled, will include my amazing image in the build which does...
```

> **Note**
>
> Remember to have `source "share/sysbuild/Kconfig"` in the file if this is being applied in an application `Kconfig.sysbuild` file.

`sysbuild.cmake`

```
if(SB_CONFIG_MY_IMAGE)
  ExternalZephyrProject_Add(
    APPLICATION my_image
    SOURCE_DIR ${ZEPHYR_MY_IMAGE_MODULE_DIR}/path/to/my_image
  )
endif()
```

Additional dependency ordering can be set here if needed, see *Adding dependencies among Zephyr applications* for details, image configuration can also be set here, see *Image configuration* for details.

This image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_IMAGE=y
```

Extensible changeable image With this setup, the image to be added can be one of any number of possible applications which the user has selection over, this list of selections can also be extended downstream to add additional options for out-of-tree specific applications that are not available in upstream Zephyr. This is more complex to create but is the preferred method for adding images to upstream Zephyr.

`Kconfig.sysbuild`

```
config SUPPORT_OTHER_APP
        bool
        # Conditions can be placed here if this application type is only usable on␣
↪certain platforms
        default y

config SUPPORT_OTHER_APP_MY_IMAGE
        bool
        # Conditions can be placed here if this image is only usable on certain␣
↪platforms
        default y

choice OTHER_APP
        prompt "Other app image"
        # Defaults can be specified here if a default image should be loaded if␣
↪e.g. it is supported
        default OTHER_APP_NONE
        depends on SUPPORT_OTHER_APP

config OTHER_APP_IMAGE_NONE
        bool "None"
        help
          Do not Include an other app image in the build.

config OTHER_APP_IMAGE_MY_IMAGE
        bool "my_image"
        depends on SUPPORT_OTHER_APP_MY_IMAGE
        help
          Include my amazing image as the other app image to use, which does...

endchoice

config OTHER_APP_IMAGE_NAME
        string
        default "my_image" if OTHER_APP_IMAGE_MY_IMAGE
        help
          Name of other app image.

config OTHER_APP_IMAGE_PATH
        string
        default "$(ZEPHYR_MY_IMAGE_MODULE_DIR)/path/to/my_image" if␣
↪OTHER_APP_IMAGE_MY_IMAGE
        help
          Source directory of other app image.
```

> **Note**
>
> Remember to have `source "$(ZEPHYR_BASE)/share/sysbuild/Kconfig"` in the file if this is being applied in an application `Kconfig.sysbuild` file.

`sysbuild.cmake`

```
if(SB_CONFIG_OTHER_APP_IMAGE_PATH)
  ExternalZephyrProject_Add(
    APPLICATION ${SB_CONFIG_OTHER_APP_IMAGE_NAME}
    SOURCE_DIR ${SB_CONFIG_OTHER_APP_IMAGE_PATH}
  )
endif()
```

Additional dependency ordering can be set here if needed, see *Adding dependencies among Zephyr applications* for details, image configuration can also be set here, see *Image configuration* for details.

This secondary image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_IMAGE=y
```

This can then be extended by *Modules (External projects)* like so:

`Kconfig.sysbuild`

```
config SUPPORT_OTHER_APP_MY_SECOND_IMAGE
        bool
        default y

choice OTHER_APP

config OTHER_APP_IMAGE_MY_SECOND_IMAGE
        bool "my_second_image"
        depends on SUPPORT_OTHER_APP_MY_SECOND_IMAGE
        help
          Include my other amazing image as the other app image to use, which␣
↪does...

endchoice

config OTHER_APP_IMAGE_NAME
        default "my_second_image" if OTHER_APP_IMAGE_MY_SECOND_IMAGE

config OTHER_APP_IMAGE_PATH
        default "$(ZEPHYR_MY_SECOND_IMAGE_MODULE_DIR)/path/to/my_second_image" if␣
↪OTHER_APP_IMAGE_MY_SECOND_IMAGE
```

As can be seen, no additional CMake changes are needed to add an alternative image as the base CMake code will add the replacement image instead of the original image, if selected.

This alternative secondary image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_SECOND_IMAGE=y
```

Image configuration Sysbuild supports being able to set image configuration (Kconfig options) and also supports reading the output of image configuration (Kconfig) which can be used to allow an option to be added to sysbuild itself and then to configure it globally or selectively.

Setting image configuration

Kconfig Sysbuild can be used to set image configuration **before the CMake configuration of images takes place**. An important note about setting Kconfig options in images is that these are persistent and cannot be changed by the images. The following functions can be used to set configuration on an image:

```
set_config_bool(<image> CONFIG_<setting> <value>)
set_config_string(<image> CONFIG_<setting> <value>)
set_config_int(<image> CONFIG_<setting> <value>)
```

For example, to change the default image to output a hex file:

```
set_config_bool(${DEFAULT_IMAGE} CONFIG_BUILD_OUTPUT_HEX y)
```

These can safely be used in an application, board or SoC `sysbuild.cmake` file, as that file is included before the image CMake processes are invoked. When extending *sysbuild using modules* the pre-CMake hook should be used instead, for example:

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
  cmake_parse_arguments(PRE_CMAKE "" "" "IMAGES" ${ARGN})

  foreach(image ${PRE_CMAKE_IMAGES})
    set_config_bool(${image} CONFIG_BUILD_OUTPUT_HEX y)
  endforeach()
endfunction()
```

Image configuration script An image configuration script is a CMake file that can be used to configure an image with common configuration values, multiple can be used per image, the configuration should be transferable to different images to correctly configure them based upon options set in sysbuild. MCUboot configuration options are configured in both the application the MCUboot image using this method which allows sysbuild to be the central location for things like the signing key which are then kept in-sync in the main application bootloader images.

Inside image configuration scripts, the `ZCMAKE_APPLICATION` variable is set to the name of the application being configured, the `set_config_*` sysbuild CMake functions can be used to set configuration and the sysbuild Kconfig can be read, for example:

```
if(SB_CONFIG_BOOTLOADER_MCUBOOT AND "${SB_CONFIG_SIGNATURE_TYPE}" STREQUAL "NONE")
  set_config_bool(${ZCMAKE_APPLICATION} CONFIG_MCUBOOT_GENERATE_UNSIGNED_IMAGE y)
endif()
```

Image configuration script (module/application) Module/application image configuration scripts can be set from module or application code, this must be done in a `sysbuild.cmake` file for an application. This can be used to add an image configuration script as follows:

`sysbuild.cmake`

```
# This applies the image configuration script to the default image only
get_property(tmp_conf_scripts TARGET ${DEFAULT_IMAGE} PROPERTY IMAGE_CONF_SCRIPT)
list(APPEND tmp_conf_scripts "$
↪{CMAKE_SOURCE_DIR}/image_configurations/MY_CUSTOM_TYPE_image_default.cmake")
set_target_properties(${DEFAULT_IMAGE} PROPERTIES IMAGE_CONF_SCRIPT "$
↪{tmp_conf_scripts}")
```

Module CMake

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
  cmake_parse_arguments(PRE_CMAKE "" "" "IMAGES" ${ARGN})

  # This applies the image configuration script to all images
  foreach(image ${PRE_CMAKE_IMAGES})
    get_property(tmp_conf_scripts TARGET ${image} PROPERTY IMAGE_CONF_SCRIPT)
    list(APPEND tmp_conf_scripts "$
↪{CMAKE_SOURCE_DIR}/image_configurations/MY_CUSTOM_TYPE_image_default.cmake")
    set_target_properties(${image} PROPERTIES IMAGE_CONF_SCRIPT "$
↪{tmp_conf_scripts}")
  endforeach()
endfunction(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
```

Image configuration script (Zephyr-wide) Global Zephyr provided image configuration scripts, which allow specifying the type when using `ExternalZephyrProject_Add()` require changes to sysbuild code in Zephyr. This should only be added to when adding a new type that any project should be able to select, generally this should only be needed for upstream Zephyr though forked versions of Zephyr might use this to add additional types without restriction.

Image configuration has an allow-list of names which must be set in the Zephyr file share/sysbuild/cmake/modules/sysbuild_extensions.cmake in the `ExternalZephyrProject_Add` function. After adding a new type, it can be used when adding a sysbuild image, for example:

`sysbuild_extensions.cmake`

Full file path: `share/sysbuild/cmake/modules/sysbuild_extensions.cmake`

```
# ...
# Usage:
#   ExternalZephyrProject_Add(APPLICATION <name>
#                             SOURCE_DIR <dir>
#                             [BOARD <board> [BOARD_REVISION <revision>]]
#                             [APP_TYPE <MAIN|BOOTLOADER|MY_CUSTOM_TYPE>]
#   )
# ...
# APP_TYPE <MAIN|BOOTLOADER|MY_CUSTOM_TYPE>: Application type.
#                                            MAIN indicates this application is␣
↪the main application
#                                            and where user defined settings␣
↪should be passed on as-is
#                                            except for multi image build flags.
#                                            For example, -DCONF_FILES=<files>␣
↪will be passed on to the
#                                            MAIN_APP unmodified.
#                                            BOOTLOADER indicates this app is a␣
↪bootloader
#                                            MY_CUSTOM_TYPE indicates this app␣
↪is...
# ...
function(ExternalZephyrProject_Add)
  set(app_types MAIN BOOTLOADER MY_CUSTOM_TYPE)
# ...
```

`sysbuild.cmake`

```
if(SB_CONFIG_OTHER_APP_IMAGE_PATH)
  ExternalZephyrProject_Add(
    APPLICATION ${SB_CONFIG_OTHER_APP_IMAGE_NAME}
```

(continues on next page)

(continued from previous page)

```
    SOURCE_DIR ${SB_CONFIG_OTHER_APP_IMAGE_PATH}
    APP_TYPE MY_CUSTOM_TYPE
  )
endif()
```

MY_CUSTOM_TYPE_image_default.cmake

Full file path: share/sysbuild/image_configurations/MY_CUSTOM_TYPE_image_default.cmake

```
# Here, the ZCMAKE_APPLICATION variable will be replaced with the image being␣
↪configured
set_config_bool(${ZCMAKE_APPLICATION} CONFIG_BUILD_OUTPUT_HEX y)
```

Reading image configuration

Kconfig Kconfig values from images can be read by sysbuild **after the CMake configuration of images has taken place**. This can be used to check configuration or to adjust additional sysbuild tasks depending upon configuration. The following function can be used for this purpose:

```
sysbuild_get(<variable> IMAGE <image> [VAR <image-variable>] KCONFIG)
```

This function can only be used when *sysbuild is extended by a module* or inside of a sysbuild/CMakeLists.txt file after find_package(Sysbuild) has been used. An example of outputting values from all images is shown:

Module CMake

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "IMAGES" ${ARGN})

  foreach(image ${POST_CMAKE_IMAGES})
    # Note that the variable to read in to must not be set before using the␣
↪sysbuild_get() function
    set(tmp_val)
    sysbuild_get(tmp_val IMAGE ${image} VAR CONFIG_BUILD_OUTPUT_HEX KCONFIG)
    message(STATUS "Image ${image} build hex: ${tmp_val}")
  endforeach()
endfunction()
```

sysbuild/CMakeLists.txt

```
find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)

sysbuild_get(tmp_val IMAGE ${DEFAULT_IMAGE} VAR CONFIG_BUILD_OUTPUT_HEX KCONFIG)
message(STATUS "Image ${DEFAULT_IMAGE} build hex: ${tmp_val}")
```

5.6.16 Sysbuild and CMake presets

CMake presets can be used with Sysbuild but not all preset macros will work as expected.

Note

Using CMake presets with sysbuild requires CMake version 3.27 or higher.

As described in *Sysbuild (System build)* then sysbuild is a higher-level build system which means that when CMake presets are used together with sysbuild, then the preset is consumed and processed by sysbuild itself and result is passed to the application.

Running sysbuild with preset.

`west build`

Here is an example where preset `release` should be used. For details, see *Sysbuild (multi-domain builds)* in the `west build documentation`.

```
west build -b reel_board --sysbuild -- --preset=release samples/hello_world
```

`cmake`

Here is an example using CMake and Ninja.

```
APP_DIR=samples/hello_world cmake -Bbuild -GNinja -DBOARD=reel_board share/sysbuild
ninja -Cbuild
```

When using CMake presets with sysbuild then `APP_DIR` must be set in environment in order for Sysbuild CMake to be able to include the `CMakePresets.json` from the main Zephyr application's source directory.

Note

As sysbuild changes the top-level cmake project to its own directory, the cmake presets are parsed from there, the application's presets are included from this file verbatim. Therefore relative paths, and macros resolving relative to the source directory will not work as expected, but as relative to share/sysbuild, for example `${sourceDir}`.

The `${fileDir}` macro can be used to create portable paths relative to the application's directory.

5.7 Application version management

Zephyr supports an application version management system for applications which is built around the system that Zephyr uses for its own version system management. This allows applications to define a version file and have application (or module) code include the auto-generated file and be able to access it, just as they can with the kernel version. This version information is available from multiple scopes, including:

- Code (C/C++)
- Kconfig
- CMake
- Shell

which makes it a very versatile system for lifecycle management of applications. In addition, it can be used when building applications which target supported bootloaders (e.g. MCUboot) allowing images to be signed with correct version of the application automatically - no manual signing steps are required.

5.7.1 VERSION file

Application version information is set on a per-application basis in a file named `VERSION`, which must be placed at the base directory of the application, where the CMakeLists.txt file is located. This is a simple text file which contains the various version information fields, each on a newline. The basic `VERSION` file has the following structure:

```
VERSION_MAJOR =
VERSION_MINOR =
PATCHLEVEL =
VERSION_TWEAK =
EXTRAVERSION =
```

Each field and the values it supports is described below. Zephyr limits the value of each numeric field to a single byte (note that there may be further restrictions depending upon what the version is used for, e.g. bootloaders might only support some of these fields or might place limits on the maximum values of fields):

Field	Data type	Required
VERSION_MAJOR	Numerical (0-255)	X
VERSION_MINOR	Numerical (0-255)	X
PATCHLEVEL	Numerical (0-255)	X
VERSION_TWEAK	Numerical (0-255)	X
EXTRAVERSION	Alphanumerical (Lowercase a-z and 0-9) and “.” or “-”	

When an application is configured using CMake, the version file will be automatically processed, and will be checked automatically each time the version is changed, so CMake does not need to be manually re-ran for changes to this file.

For the sections below, examples are provided for the following `VERSION` file:

```
VERSION_MAJOR = 1
VERSION_MINOR = 2
PATCHLEVEL = 3
VERSION_TWEAK = 4
EXTRAVERSION = unstable.5
```

5.7.2 Use in code

To use the version information in application code, the version file must be included, then the fields can be freely used. The include file name is `app_version.h` (use `#include <zephyr/app_version.h>`), the following defines are available:

Define	Type	Field(s)	Example
APPVERSION	Numerical	VERSION_MAJOR (left shifted by 24 bits), VERSION_MINOR (left shifted by 16 bits), PATCHLEVEL (left shifted by 8 bits), VERSION_TWEAK	0x1020304
APP_VERSION_N	Numerical	VERSION_MAJOR (left shifted by 16 bits), VERSION_MINOR (left shifted by 8 bits), PATCHLEVEL	0x10203
APP_VERSION_N	Numerical	VERSION_MAJOR	1
APP_VERSION_N	Numerical	VERSION_MINOR	2
APP_PATCHLEV	Numerical	PATCHLEVEL	3
APP_TWEAK	Numerical	VERSION_TWEAK	4
APP_VERSION_S	String (quoted)	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION	“1.2.3-unstable.5”
APP_VERSION_E	String (quoted)	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION VERSION_TWEAK	“1.2.3-unstable.5+4”
APP_VERSION_T	String (quoted)	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, VERSION_TWEAK	“1.2.3+4”
APP_BUILD_VEI	String (unquoted)	None (value of `git describe --abbrev=12 --always` from application repository)	v3.3.0-18-g2c85d9224fca

5.7.3 Use in Kconfig

The following variables are available for usage in Kconfig files:

Variable	Type	Field(s)	Example
$(VERSION_MAJOR)	Numerical	VERSION_MAJOR	1
$(VERSION_MINOR)	Numerical	VERSION_MINOR	2
$(PATCHLEVEL)	Numerical	PATCHLEVEL	3
$(VERSION_TWEAK)	Numerical	VERSION_TWEAK	4
$(APPVERSION)	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION	1.2.3-unstable.5
$(APP_VERSION_EXTEN	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION, VERSION_TWEAK	1.2.3-unstable.5+4
$(APP_VERSION_TWEAI	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, VERSION_TWEAK	1.2.3+4

5.7.4 Use in CMake

The following variable are available for usage in CMake files:

Variable	Type	Field(s)	Example
APPVERSION	Numerical (hex)	VERSION_MAJOR (left shifted by 24 bits), VERSION_MINOR (left shifted by 16 bits), PATCHLEVEL (left shifted by 8 bits), VERSION_TWEAK	0x1020304
APP_VERSION_N	Numerical (hex)	VERSION_MAJOR (left shifted by 16 bits), VERSION_MINOR (left shifted by 8 bits), PATCHLEVEL	0x10203
APP_VERSION_M	Numerical	VERSION_MAJOR	1
APP_VERSION_M	Numerical	VERSION_MINOR	2
APP_PATCHLEVE	Numerical	PATCHLEVEL	3
APP_VERSION_T	Numerical	VERSION_TWEAK	4
APP_VERSION_S	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION	1.2.3-unstable.5
APP_VERSION_E	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION, VERSION_TWEAK	1.2.3-unstable.5+4
APP_VERSION_T	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, VERSION_TWEAK	1.2.3+4

5.7.5 Use in MCUboot-supported applications

No additional configuration needs to be done to the target application so long as it is configured to support MCUboot and a signed image is generated, the version information will be automatically included in the image data.

5.7.6 Use in Shell

When a shell interface is configured, the following commands are available to retrieve application version information:

Command	Variable	Example
app version	APP_VERSION_STRING	1.2.3-unstable.5
app version-extended	APP_VERSION_EXTENDED_STRING	1.2.3-unstable.5+4
app build-version	APP_BUILD_VERSION	v3.3.0-18-g2c85d9224fca

5.8 Flashing

5.8.1 Flashing configuration

Zephyr supports setting up configuration for flash runners (invoked from *west flash*) which allows for customising how commands are used when programming boards. This configuration is

used for *Sysbuild (System build)* projects and allows for configuring when commands are ran for groups of board targets. As an example: a multi-core SoC might want to only allow the `--erase` argument to be used once for all of the cores in the SoC which would prevent multiple erase tasks running in a single `west flash` invocation, which could wrongly clear the memory which is used by the other images being programmed.

Priority

Flashing configuration is singular, it will only be read from a single location, this configuration can reside in the following files starting with the highest priority:

- `soc.yml` (in soc folder)
- `board.yml` (in board folder)

Configuration

Configuration is applied in the yml file by using a `runners` map with a single `run_once` child, this then contains a map of commands as they would be provided to the flash runner e.g. `--reset` followed by a list which specifies the settings for each of these commands (these are grouped by flash runner, and by qualifiers/boards). Commands have associated runners that they apply to using a `runners` list value, this can contain `all` if it applies to all runners, otherwise must contain each runner that it applies to using the runner-specific name. Groups of board targets can be specified using the `groups` key which has a list of board target sets. Board targets are regular expression matches, for `soc.yml` files each set of board targets must be in a `qualifiers` key (only regular expression matches for board qualifiers are allowed, board names must be omitted from these entries). For `board.yml` files each set of board targets must be in a `boards` key, these are lists containing the matches which form a singular group. A final parameter `run` can be set to `first` which means that the command will be ran once with the first image flashing process per set of board targets, or to `last` which will be ran once for the final image flash per set of board targets.

An example flashing configuration for a `soc.yml` is shown below in which the `--recover` command will only be used once for any board targets which used the nRF5340 SoC application or network CPU cores, and will only reset the network or application core after all images for the respective core have been flashed.

```
runners:
  run_once:
    '--recover':
      - run: first
        runners:
          - nrfjprog
        groups:
          - qualifiers:
              - nrf5340/cpunet
              - nrf5340/cpuapp
              - nrf5340/cpuapp/ns
    '--reset':
      - run: last
        runners:
          - nrfjprog
          - jlink
        groups:
          - qualifiers:
              - nrf5340/cpunet
          - qualifiers:
              - nrf5340/cpuapp
              - nrf5340/cpuapp/ns
```

(continues on next page)

(continued from previous page)

```
    # Made up non-real world example to show how to specify different options␣
↪for different
    # flash runners
    - run: first
      runners:
        - some_other_runner
      groups:
        - qualifiers:
            - nrf5340/cpunet
        - qualifiers:
            - nrf5340/cpuapp
            - nrf5340/cpuapp/ns
```

Usage

Commands that are supported by flash runners can be used as normal when flashing non-sysbuild applications, the run once configuration will not be used. When flashing a sysbuild project with multiple images, the flash runner run once configuration will be applied.

For example, building the smp-svr sample for the nrf5340dk which will include MCUboot as a secondary image:

```
cmake -GNinja -Sshare/sysbuild/ -Bbuild -DBOARD=nrf5340dk/nrf5340/cpuapp -
↪DAPP_DIR=samples/subsys/mgmt/mcumgr/smp_svr
cmake --build build
```

Once built with an nrf5340dk connected, the following command can be used to flash the board with both applications and will only perform a single device recovery operation when programming the first image:

```
west flash --recover
```

If the above was ran without the flashing configuration, the recovery process would be ran twice and the device would be unbootable.

5.9 Signing Binaries

Binaries can be optionally signed as part of a build automatically using CMake code, there is also the ability to use `west sign` to sign binaries too, this page describes the former, the latter is documented on *Signing Binaries*.

5.9.1 MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the MCUboot bootloader using the imgtool program provided by its developers. You can both build and sign this type of application binary in one step by setting some Kconfig options. If you do, `west flash` will use the signed binaries.

Here is an example workflow, which builds and flashes MCUboot, as well as the hello_world application for chain-loading by MCUboot. Run these commands from the `zephyrproject` workspace you created in the *Getting Started Guide*.

```
west build -b YOUR_BOARD zephyr/samples/hello_world --sysbuild -d␣
↪build-hello-signed -- \
    -DSB_CONFIG_BOOTLOADER_MCUBOOT=y
```

(continues on next page)

(continued from previous page)

```
west flash -d build-hello-signed
```

Notes on the above commands:

- `YOUR_BOARD` should be changed to match your board
- The signing key value is the insecure default provided and used by MCUboot for development and testing
- You can change the `hello_world` application directory to any other application that can be loaded by MCUboot, such as the smp-svr sample.

For more information on these and other related configuration options, see:

- `SB_CONFIG_BOOTLOADER_MCUBOOT`: build the application for loading by MCUboot
- `SB_CONFIG_BOOT_SIGNATURE_KEY_FILE`: the key file to use when signing images. If you have your own key, change this appropriately
- `CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS`: optional additional command line arguments for `imgtool`
- `CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE`: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get "Access denied" issues, the recommended fix is to run `pip3 install imgtool`, then retry with a pristine build directory.

If your `west flash` *runner* uses an image format supported by imgtool, you should see something like this on your device's serial console when you run `west flash -d build-hello-signed`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1,␣
↪copy_done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,374] <inf> mcuboot: Swap type: none
[00:00:00.115,142] <inf> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.123,168] <inf> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
Hello World! nrf52840dk_nrf52840
```

Whether `west flash` supports this feature depends on your runner. The `nrfjprog` and `pyocd` runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.

5.9.2 Extending signing externally

The signing script used when running `west flash` can be extended or replaced to change features or introduce different signing mechanisms. By default with MCUboot enabled, signing is setup by the `cmake/mcuboot.cmake` file in Zephyr which adds extra post build commands for generating the signed images. The file used for signing can be replaced from a sysbuild scope (if being used) or from a zephyr/zephyr module scope, the priority of which is:

- Sysbuild
- Zephyr property
- Default MCUboot script (if enabled)

From sysbuild, `-D<target>_SIGNING_SCRIPT` can be used to set a signing script for a specific image or `-DSIGNING_SCRIPT` can be used to set a signing script for all images, for example:

```
west build -b <board> <application> -DSIGNING_SCRIPT=<file>
```

The zephyr property method is achieved by adjusting the `SIGNING_SCRIPT` property on the `zephyr_property_target`, ideally from by a module by using:

```
if(CONFIG_BOOTLOADER_MCUBOOT)
  set_target_properties(zephyr_property_target PROPERTIES SIGNING_SCRIPT $
↪{CMAKE_CURRENT_LIST_DIR}/custom_signing.cmake)
endif()
```

This will include the custom signing CMake file instead of the default Zephyr one when projects are built with MCUboot signing support enabled. The base Zephyr MCUboot signing file can be used as a reference for creating a new signing system or extending the default behaviour.

Chapter 6

Connectivity

6.1 Bluetooth

This section contains information regarding the Bluetooth stack of the Zephyr OS. You can use this information to understand the principles behind the operation of the layers and how they were implemented.

Zephyr includes a complete Bluetooth Low Energy stack from application to radio hardware, as well as portions of a Classical Bluetooth (BR/EDR) Host layer.

6.1.1 Supported features

Since its inception, Zephyr has had a strong focus on Bluetooth and, in particular, on Bluetooth Low Energy (LE). Through the contributions of several companies and individuals involved in existing open source implementations of the Bluetooth specification (Linux's BlueZ) as well as the design and development of Bluetooth LE radio hardware, the protocol stack in Zephyr has grown to be mature and feature-rich, as can be seen in the section below.

- Bluetooth v5.3 compliant
  - Highly configurable
    - Features, buffer sizes/counts, stack sizes, etc.
  - Portable to all architectures supported by Zephyr (including big and little endian, alignment flavors and more)
  - Support for *all combinations* of Host and Controller builds:
    - Controller-only (HCI) over UART, SPI, USB and IPC physical transports
    - Host-only over UART, SPI, and IPC (shared memory)
    - Combined (Host + Controller)
- *Bluetooth-SIG qualifiable*
  - Conformance tests run regularly on all layers (Controller and Host, except BT Classic) on Nordic Semiconductor hardware.
- *Bluetooth Low Energy Controller* (LE Link Layer)
  - Unlimited role and connection count, all roles supported
  - All v5.3 specification features supported (except a few minor items)
  - Concurrent multi-protocol support ready
  - Intelligent scheduling of roles to minimize overlap

  - Portable design to any open Bluetooth LE radio, currently supports Nordic Semiconductor nRF52x and nRF53x SoC Series, as well as proprietary radios
  - Supports little and big endian architectures, and abstracts the hard real-time specifics so that they can be encapsulated in a hardware-specific module
  - Support for Controller (HCI) builds over different physical transports
  - Isochronous channels
- *Bluetooth Host*
  - Generic Access Profile (GAP) with all possible LE roles
    - Peripheral & Central
    - Observer & Broadcaster
    - Multiple PHY support (2Mbit/s, Coded)
    - Extended Advertising
    - Periodic Advertising (including Sync Transfer)
  - GATT (Generic Attribute Profile)
    - Server (to be a sensor)
    - Client (to connect to sensors)
    - Enhanced ATT (EATT)
    - GATT Database Hash
    - GATT Multiple Notifications
  - Pairing support, including the Secure Connections feature from Bluetooth 4.2
  - Non-volatile storage support for permanent storage of Bluetooth-specific settings and data
  - Bluetooth Mesh support
    - Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
    - Both Provisioning roles and bearers supported (PB-ADV & PB-GATT)
    - Foundation Models included
    - Highly configurable, fits as small as 16k RAM devices
  - Basic Bluetooth BR/EDR (Classic) support
    - Generic Access Profile (GAP)
    - Logical Link Control and Adaptation Protocol (L2CAP)
    - Serial Port emulation (RFCOMM protocol)
    - Service Discovery Protocol (SDP)
  - Clean HCI driver abstraction
    - 3-Wire (H:5) & 5-Wire (H:4) UART
    - SPI
    - Local controller support as a virtual HCI driver
  - Verified with multiple popular controllers
  - Isochronous channels
  - *LE Audio*

6.1.2 Qualification

Qualification setup

The Zephyr Bluetooth host can be qualified using Bluetooth's PTS (Profile Tuning Suite) software. It is originally a manual process, but is automated by using the AutoPTS automation software.

The setup is described in more details in the pages linked below.

AutoPTS on Windows 10 with nRF52 board This tutorial shows how to setup AutoPTS client and server to run both on Windows 10. We use WSL1 with Ubuntu only to build a Zephyr project to an elf file, because Zephyr SDK is not available on Windows yet. Tutorial covers only nrf52840dk.

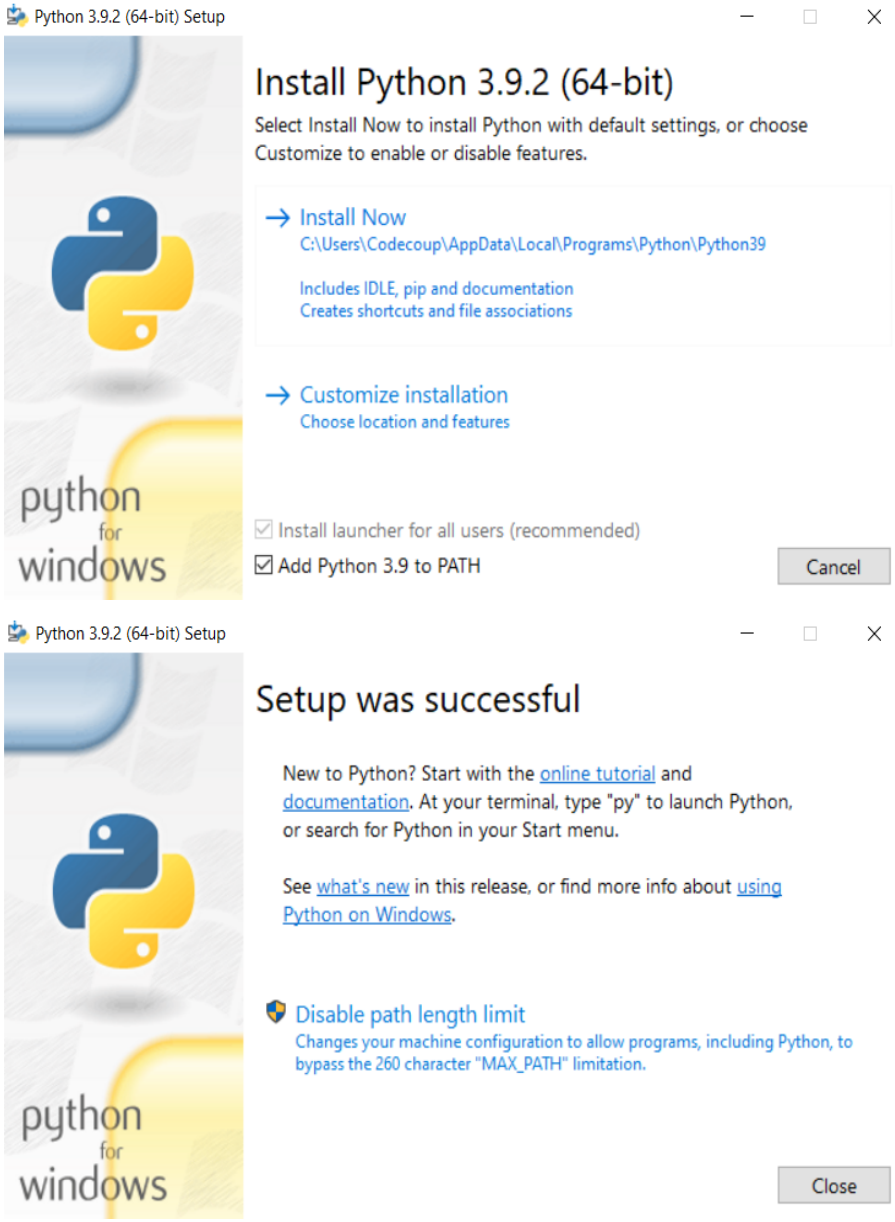
- *Update Windows and drivers*
- *Install Python 3*
- *Install Git*
- *Install PTS 8*
- *Setup Zephyr project for Windows*
- *Install nrftools*
- *Connect devices*
- *Flash board*
- *Setup auto-pts project*
- *Install socat.exe*
- *Running AutoPTS*
- *Troubleshooting*

Update Windows and drivers Update Windows in:

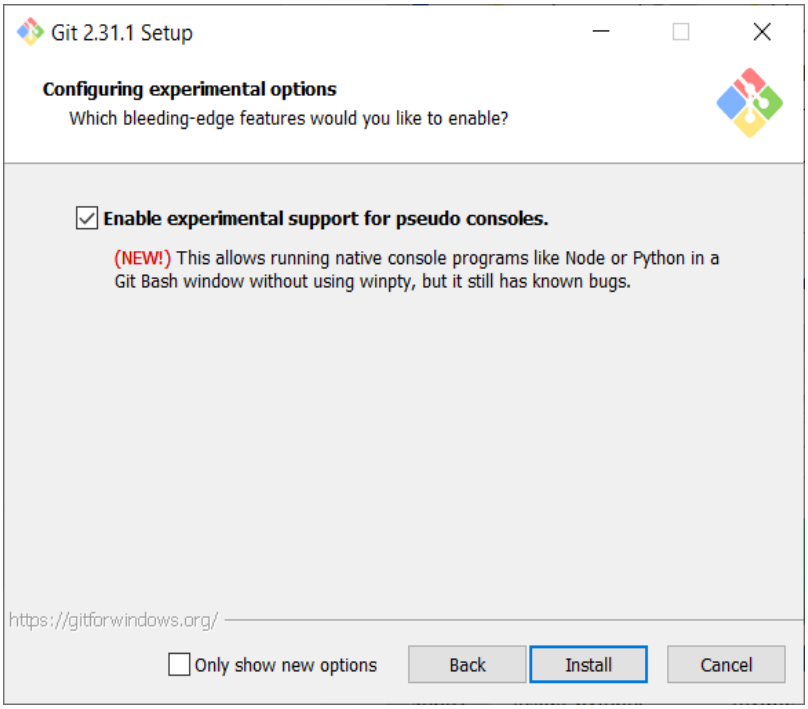
Start -> Settings -> Update & Security -> Windows Update

Update drivers, following the instructions from your hardware vendor.

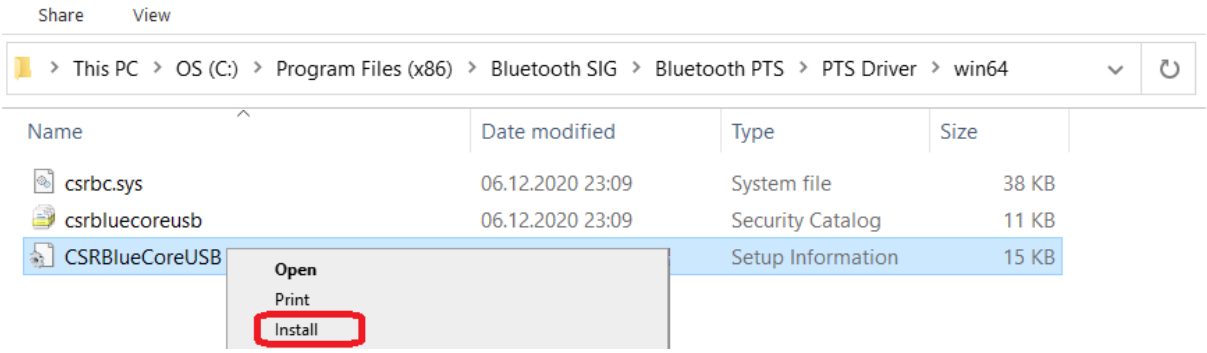
Install Python 3 Download and install Python 3. Setup was tested with versions >=3.8. Let the installer add the Python installation directory to the PATH and disable the path length limitation.



Install Git Download and install Git. During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.



Install PTS 8 Install latest PTS from https://www.bluetooth.org. Remember to install drivers from installation directory "C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf"

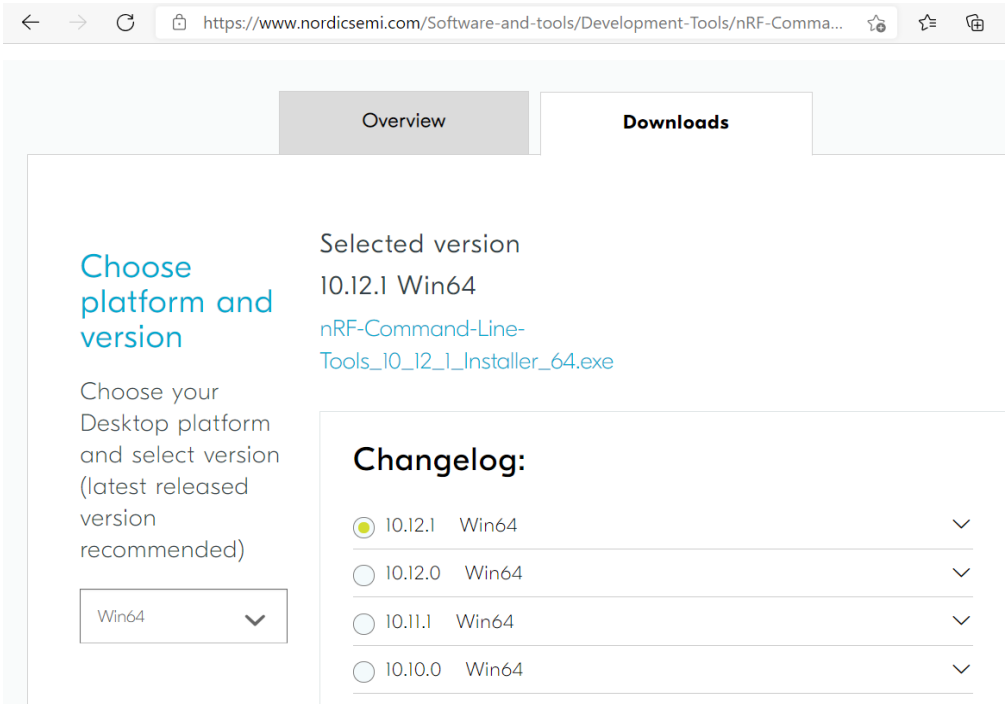


Note

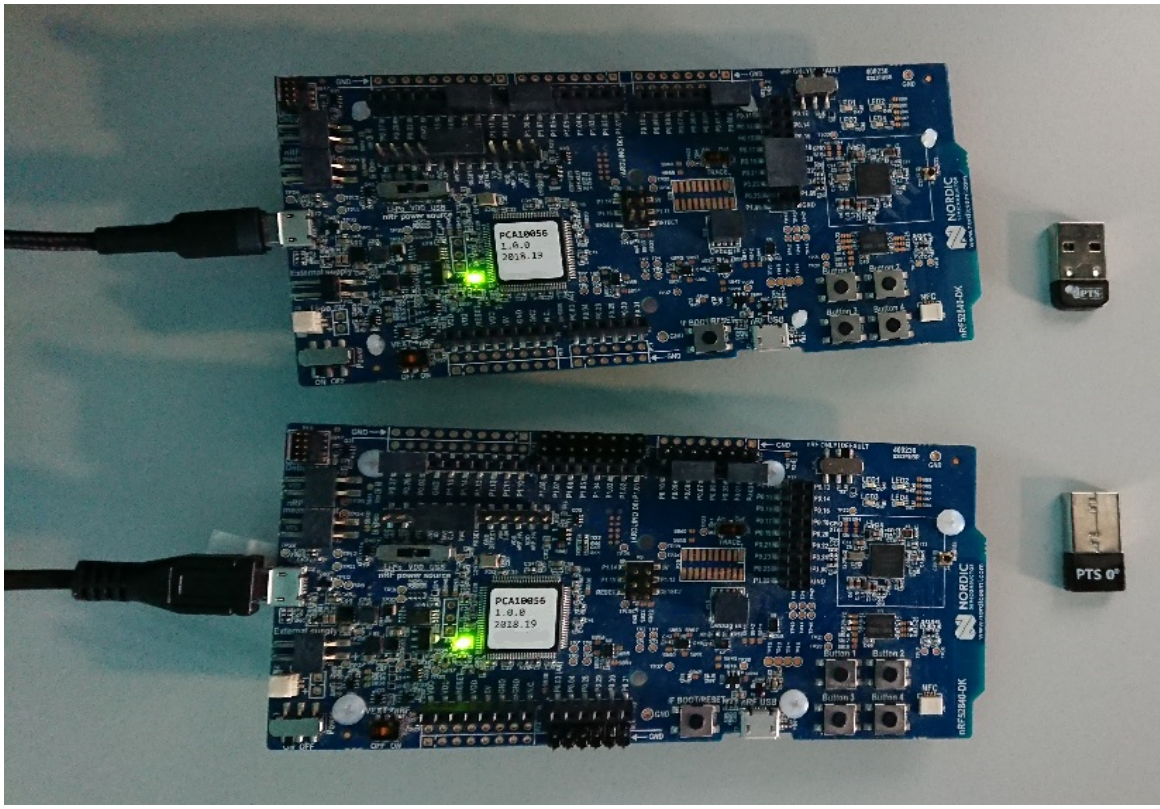
Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

Setup Zephyr project for Windows Perform Windows setup from Getting Started Guide.

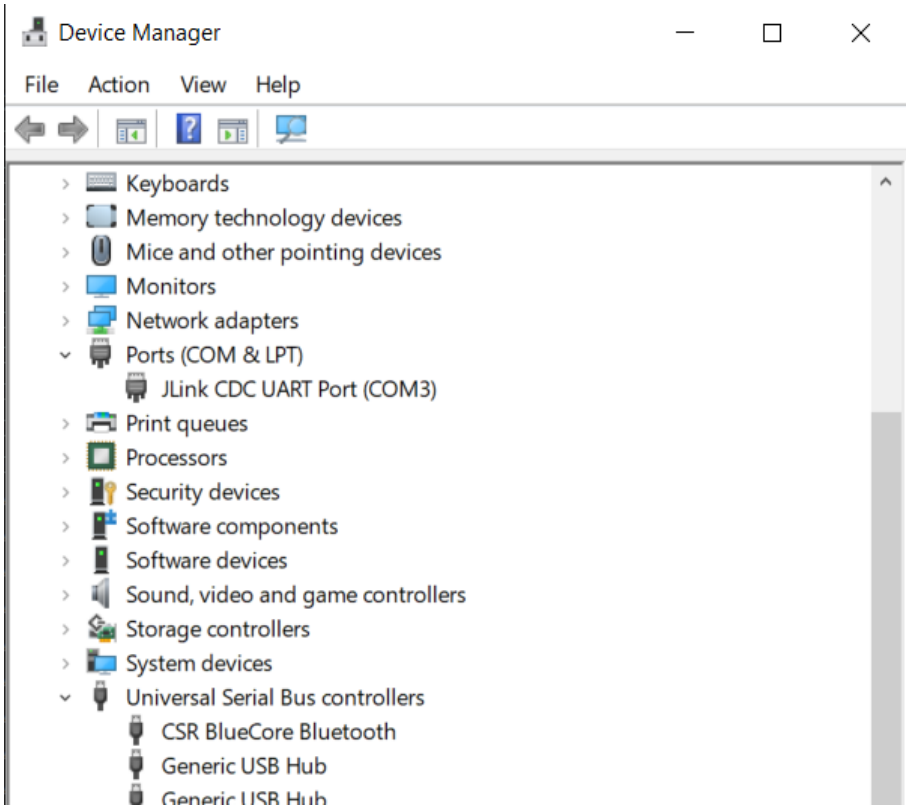
Install nrftools On Windows download latest nrftools (version >= 10.12.1) from site https://www.nordicsemi.com/Software-and-tools/Development-Tools/nRF-Command-Line-Tools/Download and run default install.



Connect devices



Flash board In Device Manager find COM port of your nrf board. In my case it is COM3.



In Git Bash, go to zephyrproject

```
cd ~/zephyrproject
```

Build the auto-pts tester app

```
west build -p auto -b nrf52840dk/nrf52840 zephyr/tests/bluetooth/tester/
```

You can display flashing options with:

```
west flash --help
```

and flash board with built earlier elf file:

```
west flash --skip-rebuild --board-dir /dev/ttyS2 --elf-file ~/
↪zephyrproject/build/zephyr/zephyr.elf
```

Note that west does not accept COMs, so use /dev/ttyS2 as the COM3 equivalent, /dev/ttyS2 as the COM3 equivalent, etc.(/dev/ttyS + decremented COM number).

Setup auto-pts project In Git Bash, clone project repo:

```
git clone https://github.com/auto-pts/auto-pts.git
```

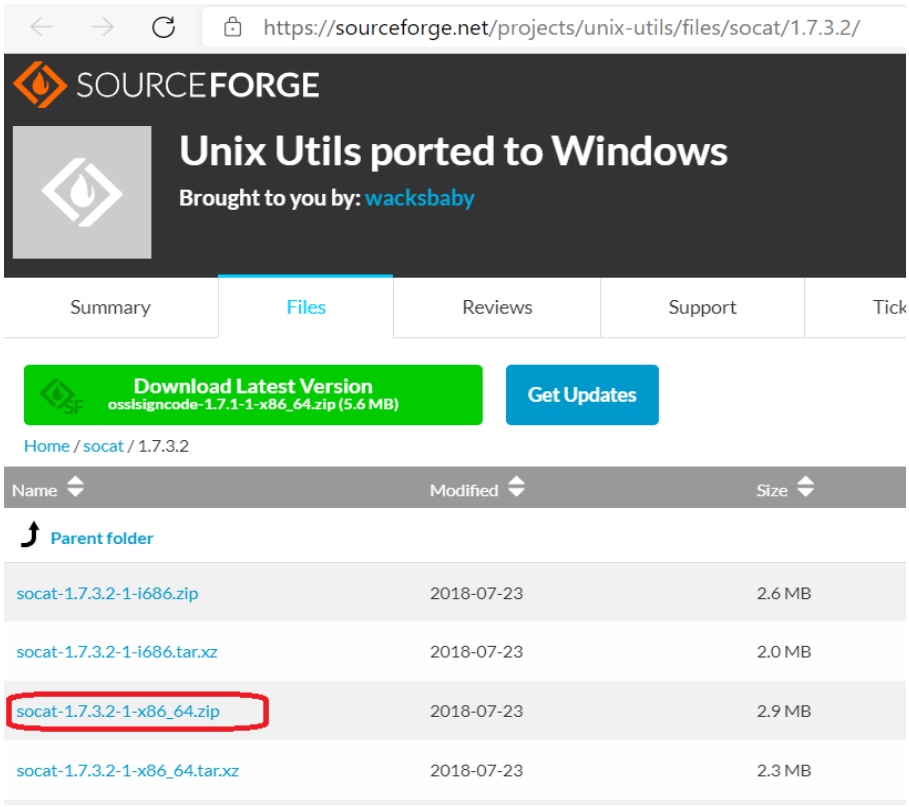
Go into the project folder:

```
cd auto-pts
```

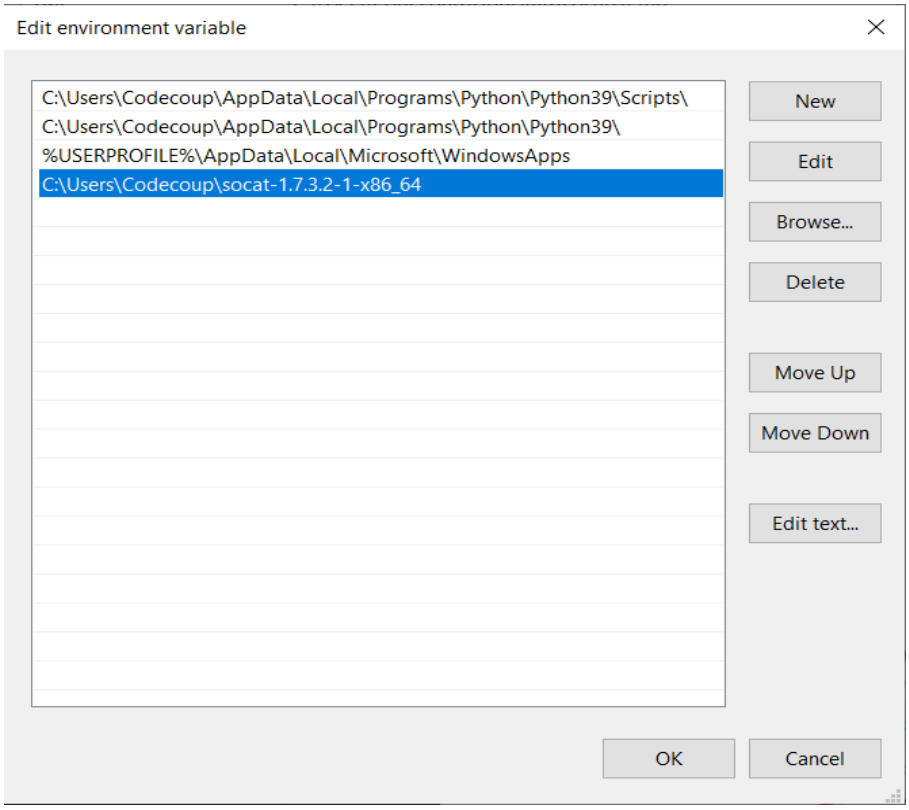
Install required python modules:

```
pip3 install --user wheel
pip3 install --user -r autoptsserver_requirements.txt
pip3 install --user -r autoptsclient_requirements.txt
```

Install socat.exe Download and extract socat.exe from https://sourceforge.net/projects/unix-utils/files/socat/1.7.3.2/ into folder ~/socat-1.7.3.2-1-x86_64/.

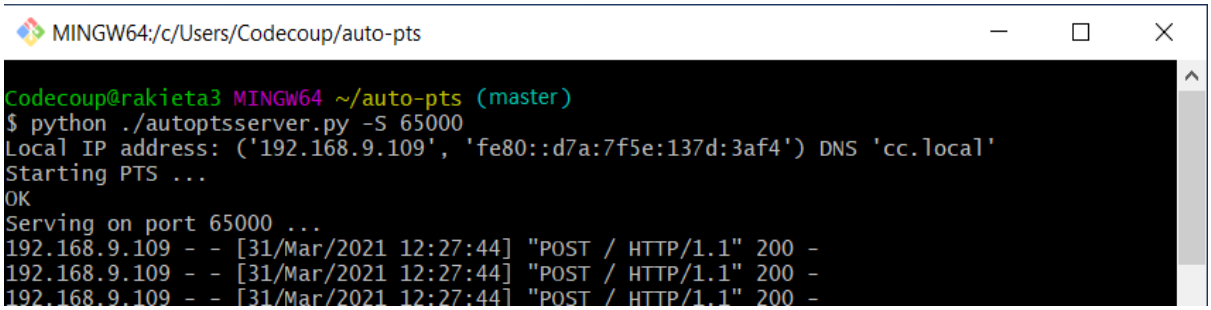


Add path to directory of socat.exe to PATH:



Running AutoPTS Server and client by default will run on localhost address. Run server:

```
python ./autoptsserver.py -S 65000
```



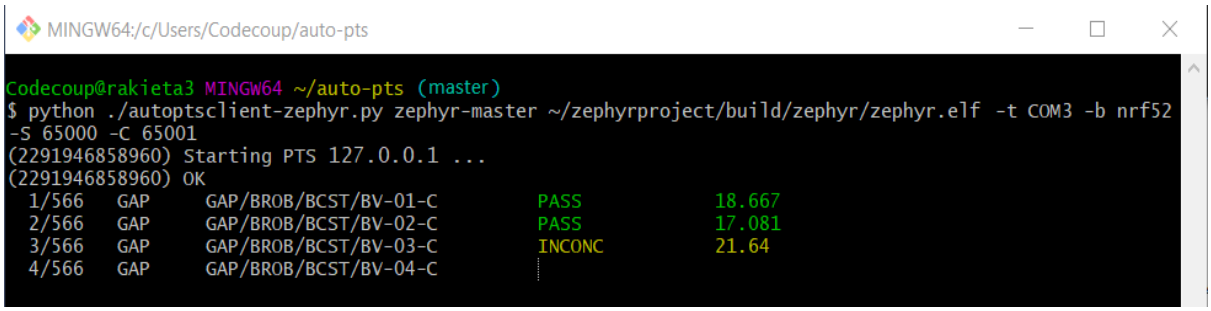
Note

If the error "ImportError: No module named pywintypes" appeared after the fresh setup, uninstall and install the pywin32 module:

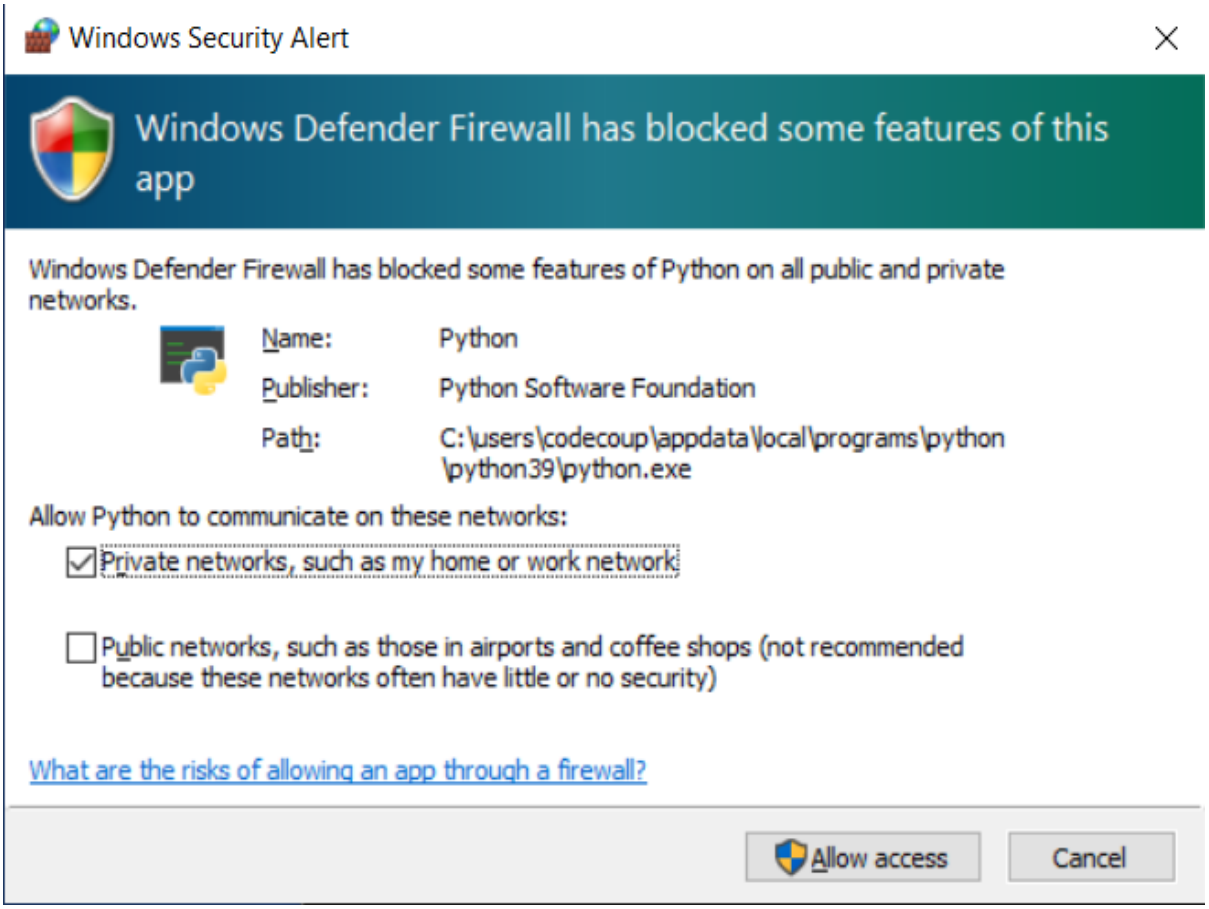
```
pip install --upgrade --force-reinstall pywin32
```

Run client:

```
python ./autoptsclient-zephyr.py zephyr-master ~/
↪zephyrproject/build/zephyr/zephyr.elf -t COM3 -b nrf52 -S 65000 -C 65001
```



At the first run, when Windows asks, enable connection through firewall:



Troubleshooting

- "When running actual hardware test mode, I have only BTP TIMEOUTs."

This is a problem with connection between auto-pts client and board. There are many possible causes. Try:

- Clean your auto-pts and zephyr repos with

Warning

This command will force the irreversible removal of all uncommitted files in the repo.

```
git clean -fdx
```

then build and flash tester elf again.

- If you have set up Windows on virtual machine, check if guest extensions are installed properly or change USB compatibility mode in VM settings to USB 2.0.
- Check, if firewall in not blocking python.exe or socat.exe.
- Check if board sends ready event after restart (hex 00 00 80 ff 00 00). Open serial connection to board with e.g. PuTTy with proper COM and baud rate. After board reset you should see some strings in console.
- Check if socat.exe creates tunnel to board. Run in console

```
socat.exe -x -v tcp-listen:65123 /dev/ttyS2,raw,b115200
```

where /dev/ttyS2 is the COM3 equivalent. Open PuTTY, set connection type to Raw, IP to 127.0.0.1, port to 65123. After board reset you should see some strings in console.

AutoPTS on Linux This tutorial shows how to setup AutoPTS client on Linux with AutoPTS server running on Windows 10 virtual machine. Tested with Ubuntu 20.4 and Linux Mint 20.4.

You must have a Zephyr development environment set up. See *Getting Started Guide* for details.

Supported methods to test zephyr bluetooth host:

- Testing Zephyr Host Stack on QEMU
- Testing Zephyr Host Stack on native_sim
- Testing Zephyr combined (controller + host) build on Real hardware (such as nRF52)

For running with QEMU or native_sim, see *Running on QEMU or native_sim*.

- *Setup Linux*
- *Setup Windows 10/11 virtual machine*
  - *Update Windows*
  - *Setup NAT*
  - *Setup static IP*
  - *Install Python 3*
  - *Install Git*
  - *Install PTS*
  - *Connect PTS dongle*
- *Connect devices (only required in the actual hardware test mode)*
- *Setup auto-pts project*
  - *AutoPTS client on Linux*
  - *Autopts server on Windows virtual machine*
- *Running AutoPTS*
  - *Testing Zephyr Host Stack on hardware*
  - *Testing Zephyr Host Stack on QEMU*
  - *Testing Zephyr Host Stack on native_sim*
- *Troubleshooting*
  - *After running one test, I need to restart my Windows virtual machine to run another, because of fail verdict from APICOM in PTS logs*
  - *I cannot start autoptsserver-zephyr.py. I always get a Python error*
  - *The PTS automation window keeps opening and closing*

Setup Linux Please follow *Getting Started Guide* on how to setup Linux for building and flashing applications.

Setup Windows 10/11 virtual machine Choose and install your hypervisor like VMWare Workstation(preferred) or VirtualBox. On VirtualBox could be some issues, if your host has fewer than 6 CPU.

Create Windows virtual machine instance. Make sure it has at least 2 cores and installed guest extensions.

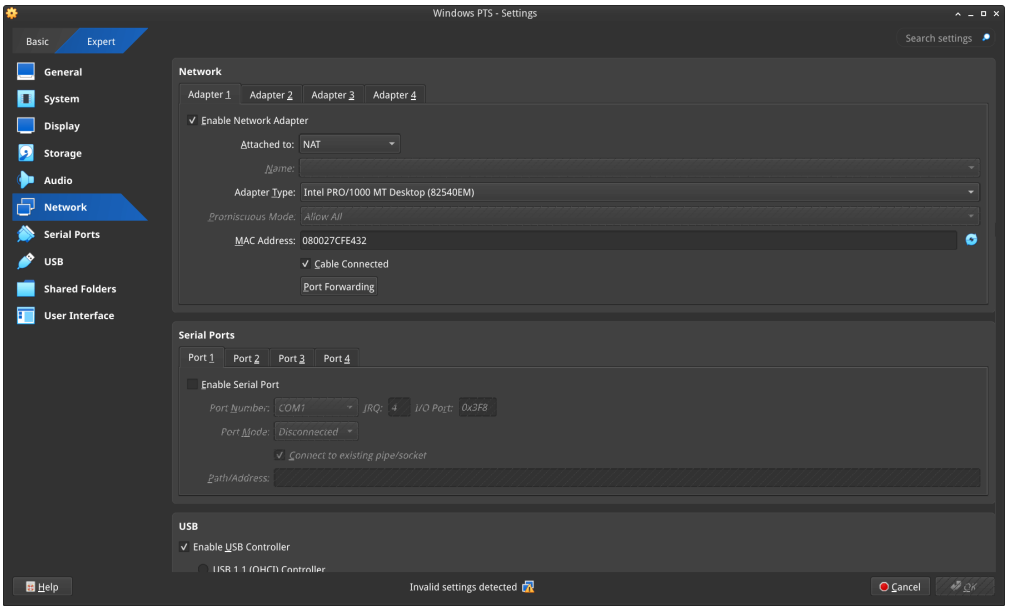
Setup tested with VirtualBox 7.2.4 and VMWare Workstation 16.1.1 Pro.

Update Windows Update Windows in:

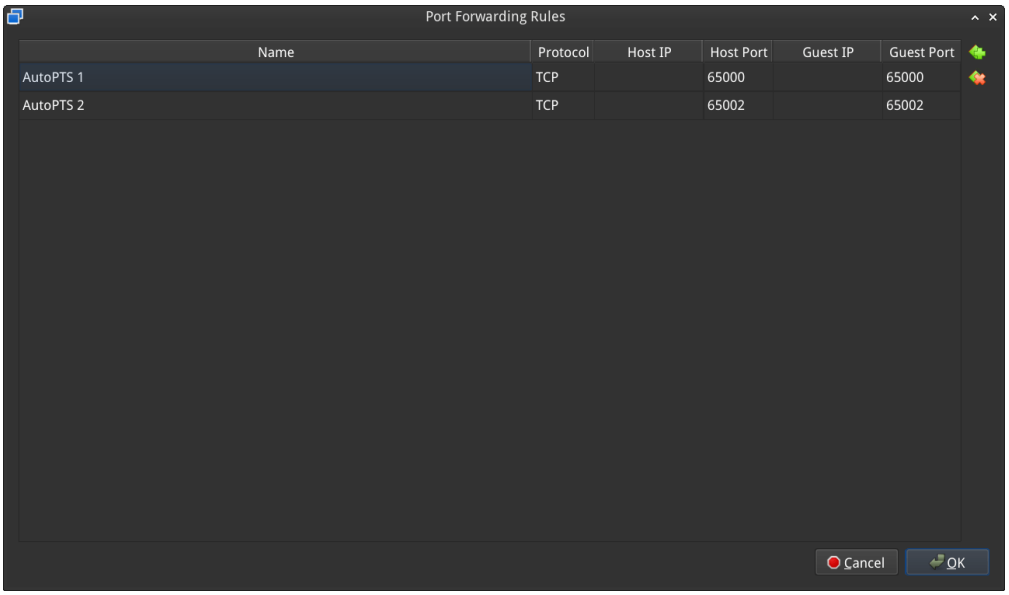
Start -> Settings -> Update & Security -> Windows Update

Setup NAT It is possible to use NAT and portforwarding to setup communication between a Linux host and a Windows guest. This is easiest setup for VirtualBox, and does not require any static IPs to be configured, and will not get blocked by the Windows Firewall.

VirtualBox Open virtual machine network settings. On adapter 1 you will have created by default NAT. Open the Port Forwarding menu an add the ports you want.

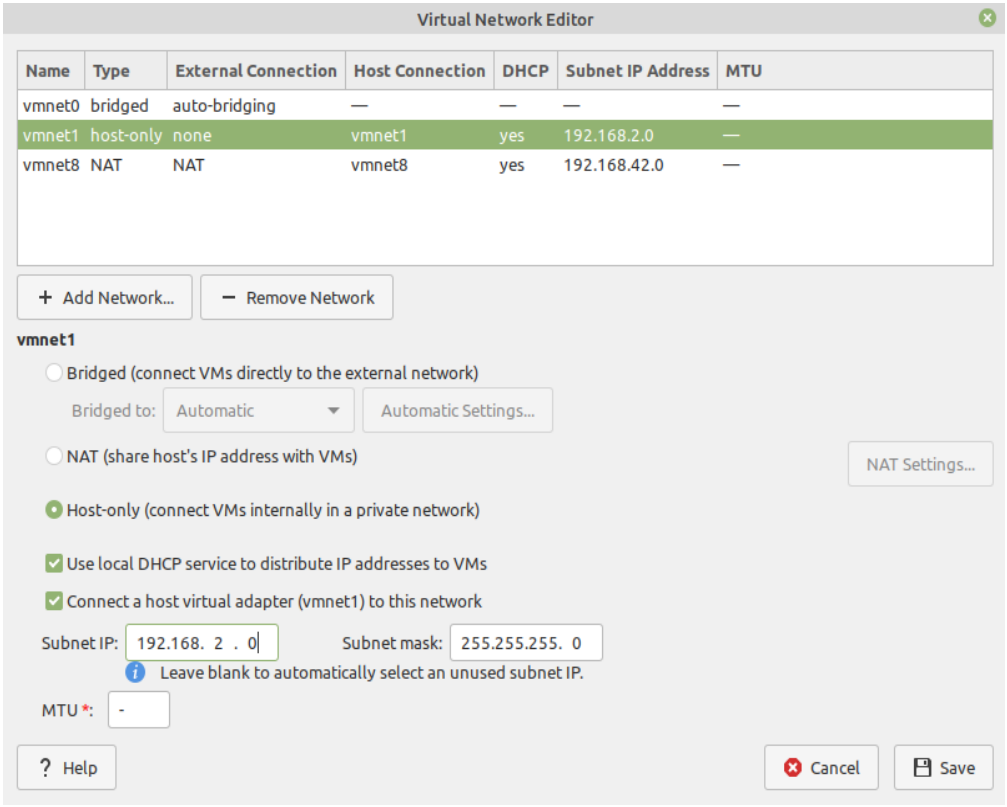


For example setting up the following will allow you to use `localhost:65000` and `localhost:65002` (or `127.0.0.0:65000` and `127.0.0.0:65002`) to connect to an AutoPTS Server in Windows running on ports 65000 and 65002.

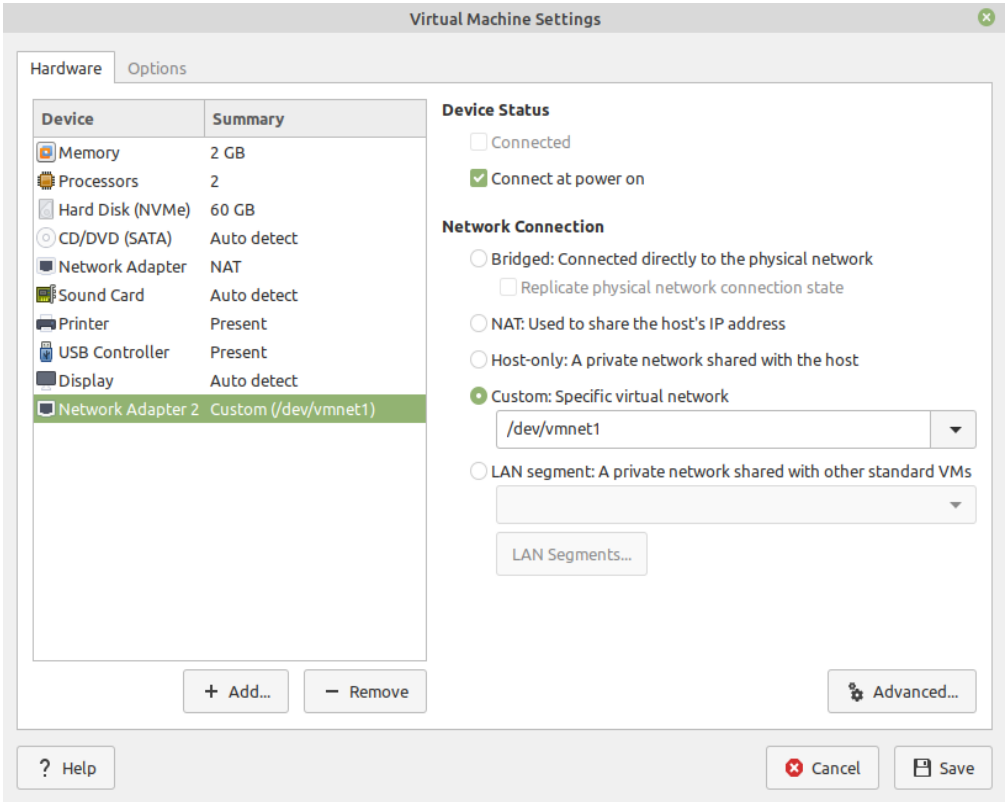


Setup static IP If you cannot or do not want to use NAT it is possible to configure a static IP.

VMWare Works On Linux, open Virtual Network Editor app and create network:



Open virtual machine network settings. Add custom adapter:



If you type 'ifconfig' in terminal, you should be able to find your host IP:

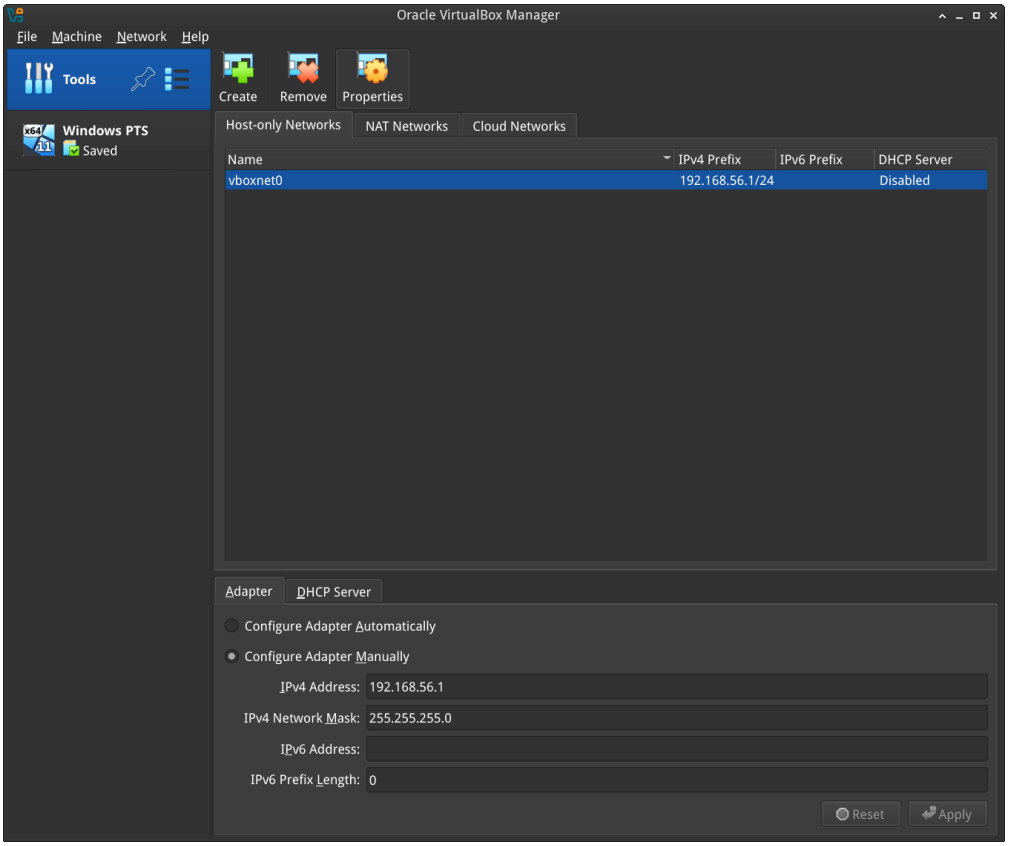
```
vmnet1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
        inet 192.168.2.1  netmask 255.255.255.0  broadcast 192.168.2.255
        inet6 fe80::250:56ff:fec0:1  prefixlen 64  scopeid 0x20<link>
        ether 00:50:56:c0:00:01  txqueuelen 1000  (Ethernet)
        RX packets 0  bytes 0 (0.0 B)
        RX errors 0  dropped 0  overruns 0  frame 0
        TX packets 42  bytes 0 (0.0 B)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

VirtualBox VirtualBox on Linux, macOS and Solaris Oracle VM VirtualBox will only allow IP addresses in `192.168.56.0/21` range to be assigned to host-only adapters, so if using a static address with VirtualBox this is the only address range you can use.

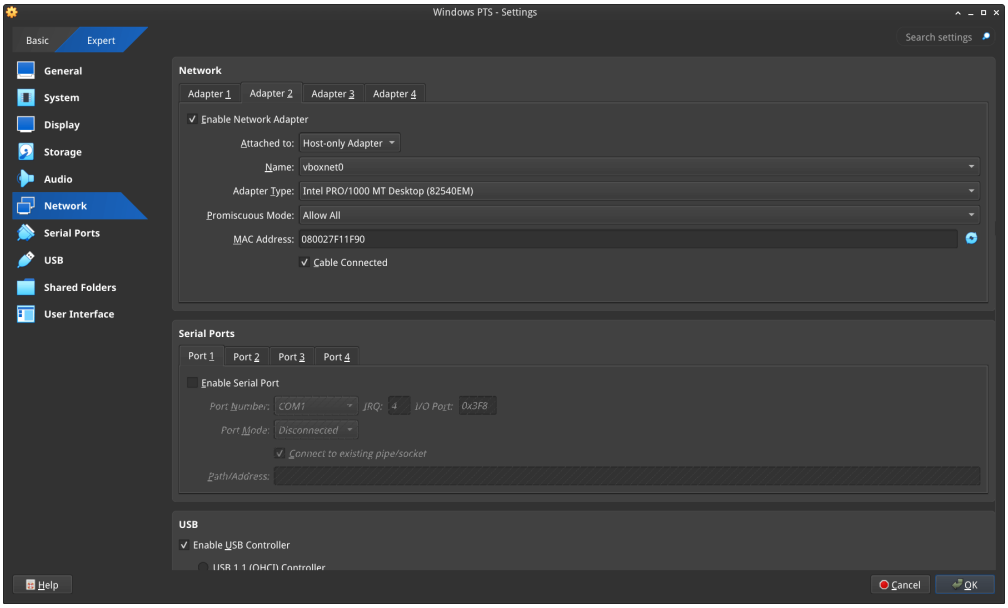
Go to:

File -> Tools -> Network Manager

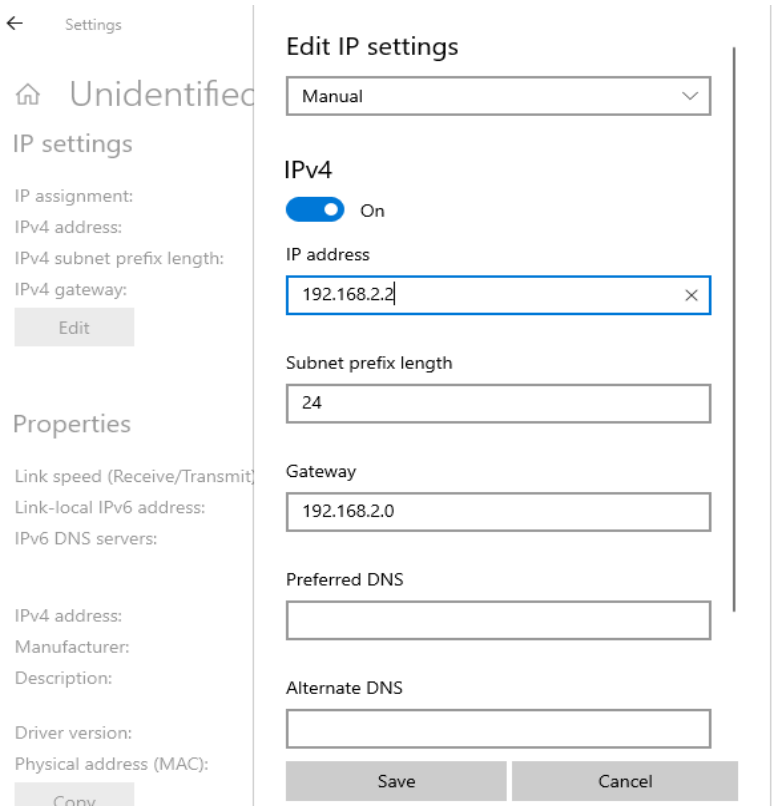
and create network:



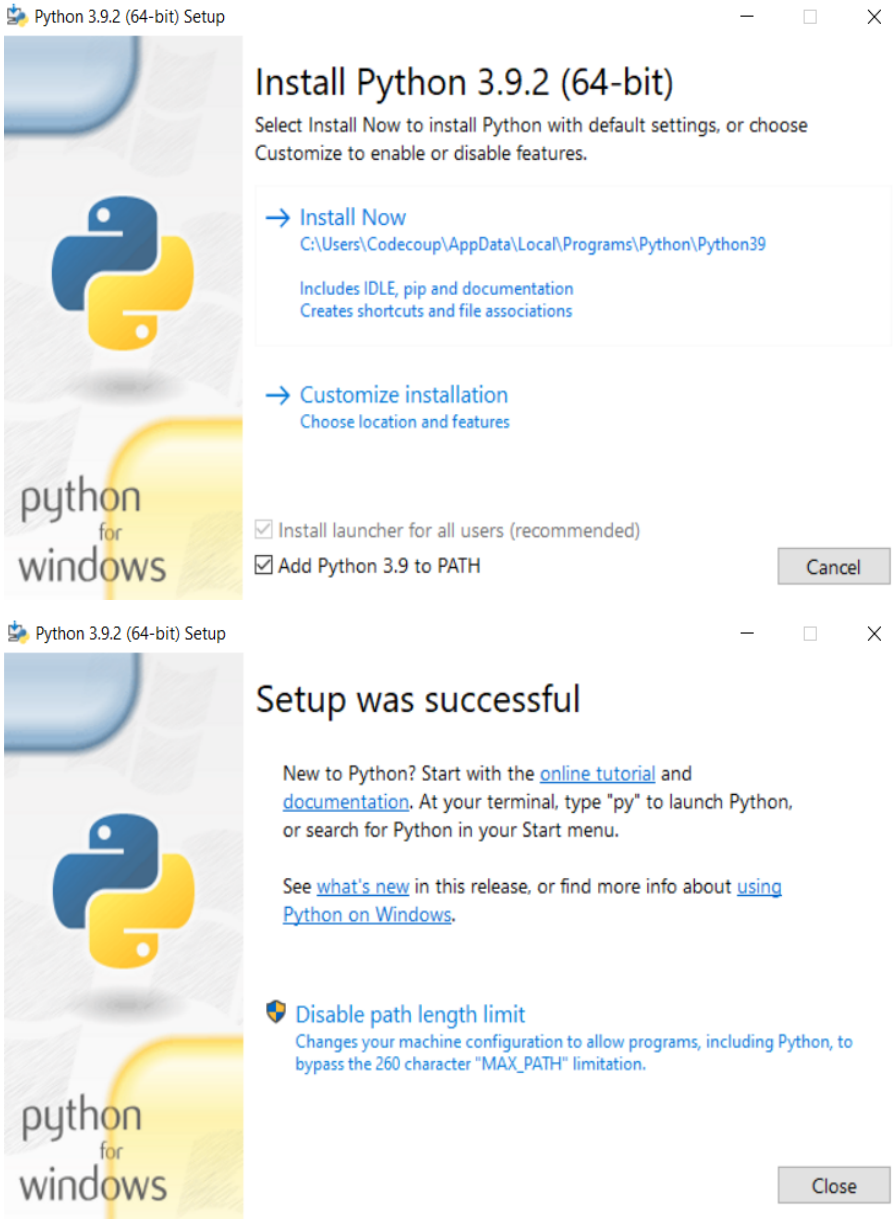
Open virtual machine network settings. On adapter 1 you will have created by default NAT. Add adapter 2:



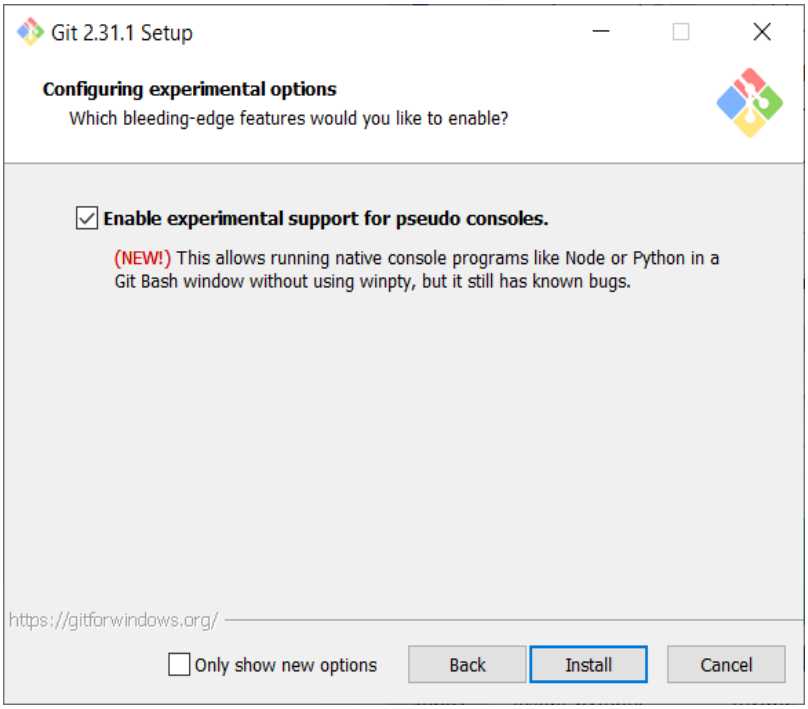
Windows Setup static IP on Windows virtual machine. Go to Settings -> Network & Internet -> Ethernet -> Unidentified network -> Edit and set:



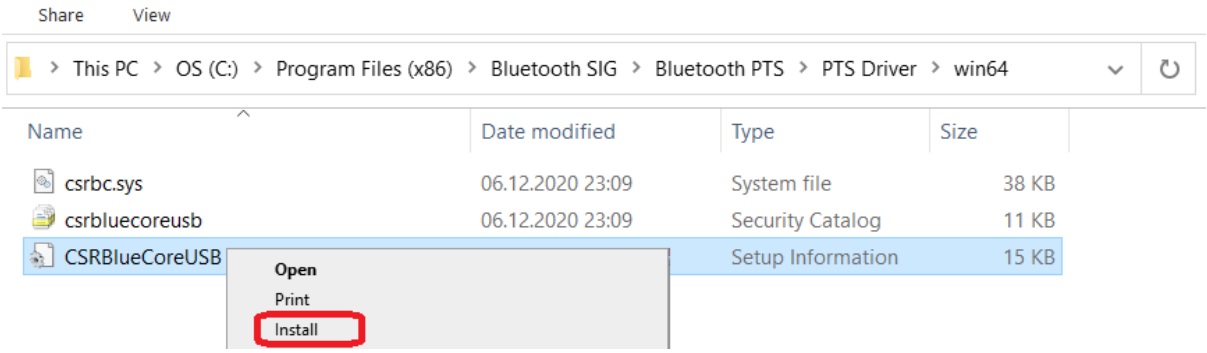
Install Python 3 Download and install latest Python 3 on Windows. Let the installer add the Python installation directory to the PATH and disable the path length limitation.



Install Git Download and install Git. During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.



Install PTS On Windows virtual machine, install the latest PTS from https://pts.bluetooth.com/download. Remember to install drivers from installation directory "C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf"



Note

Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

Connect PTS dongle With VirtualBox there should be no problem. Just find dongle in Devices -> USB and connect.

With VMWare you might need to use some trick, if you cannot find dongle in VM -> Removable Devices. Type in Linux terminal:

```
usb-devices
```

and find in output your PTS Bluetooth USB dongle

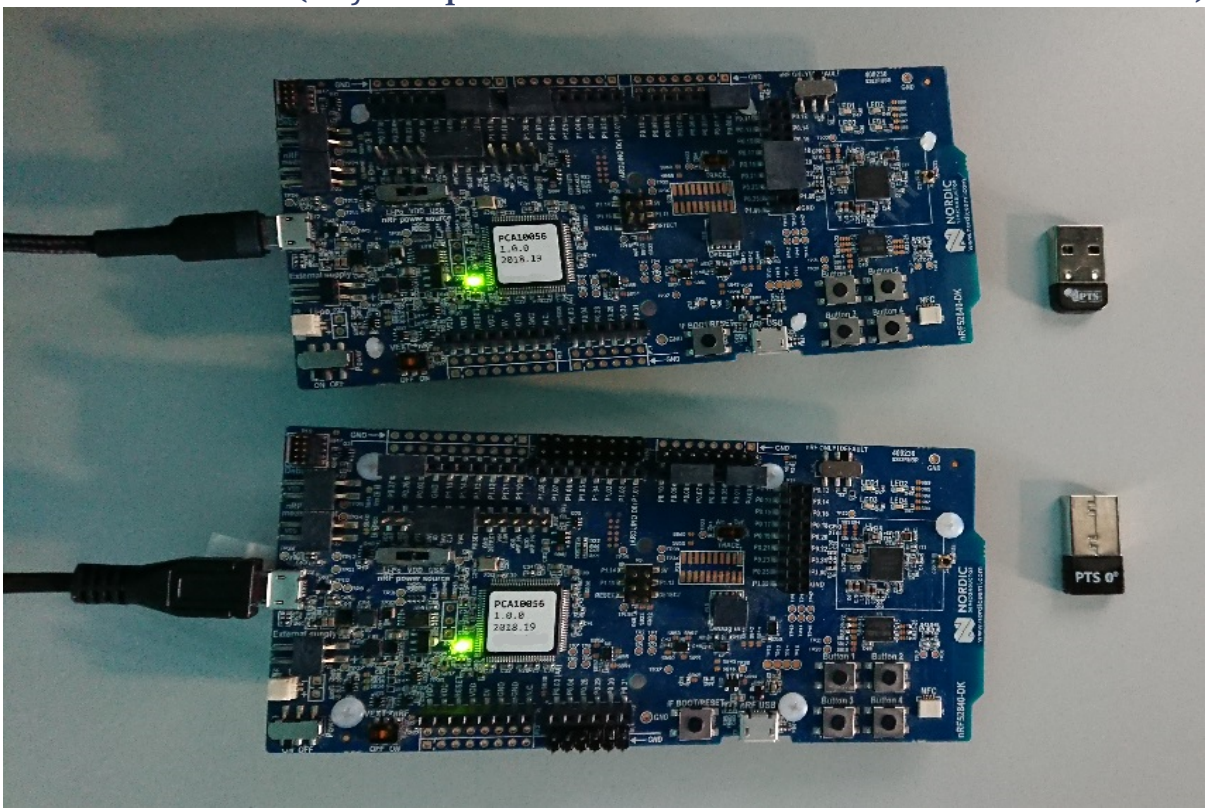
```
T:  Bus=01 Lev=01 Prnt=01 Port=01 Cnt=01 Dev#=  6 Spd=12  MxCh= 0
D:  Ver= 2.00 Cls=e0(wlcon) Sub=01 Prot=01 MxPS=64 #Cfgs=  1
P:  Vendor=0a12 ProdID=0001 Rev=25.20
S:  Product=CSR rck PTS Dongle
C:  #Ifs= 3 Cfg#= 1 Atr=c0 MxPwr=0mA
```

Note Vendor and ProdID number. Close VMWare Workstation and open .vmx of your virtual machine (path similar to /home/codecoup/vmware/Windows 10/Windows 10.vmx) in text editor. Write anywhere in the file following line:

```
usb.autoConnect.device0 = "0x0a12:0x0001"
```

just replace 0x0a12 with Vendor number and 0x0001 with ProdID number you found earlier.

Connect devices (only required in the actual hardware test mode)



Setup auto-pts project

AutoPTS client on Linux Clone auto-pts project:

```
git clone https://github.com/auto-pts/auto-pts.git
```

Install socat, that is used to transfer BTP data stream from UART's tty file:

```
sudo apt-get install python-setuptools socat
```

Install required python modules:

```
cd auto-pts
pip3 install --user -r autoptsclient_requirements.txt
```

Autopts server on Windows virtual machine In Git Bash, clone auto-pts project repo:

```
git clone https://github.com/auto-pts/auto-pts.git
```

Install required python modules:

```
cd auto-pts
pip3 install --user wheel
pip3 install --user -r autoptsserver_requirements.txt
```

Restart virtual machine.

Running AutoPTS Please follow the information from https://github.com/zephyrproject-rtos/zephyr/tree/main/tests/bluetooth/tester on how to build, flash and run the Bluetooth Tester application.

Server and client by default will run on localhost address. Run the server in the Windows virtual machine:

```
python ./autoptsserver.py
```

```
codecoup@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...
OK
Serving on port 65000 ...
```

See also https://github.com/auto-pts/auto-pts for additional information on how to run auto-pts.

Testing Zephyr Host Stack on hardware

```
python ./autoptsclient-zephyr.py zephyr-master -t /dev/ttyACM0 -b BOARD -i␣
↪SERVER_IP -l LOCAL_IP
```

Where `/dev/ttyACM0` is the tty for the board, `BOARD` is the board to use (e.g. `nrf53_audio`), `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Testing Zephyr Host Stack on QEMU A Bluetooth controller needs to be mounted. For running with HCI UART, please visit bluetooth_hci_uart.

```
python ./autoptsclient-zephyr.py zephyr-master BUILD_DIR/zephyr/zephyr.elf -i␣
↪SERVER_IP -l LOCAL_IP
```

Where `BUILD_DIR` is the build directory, `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Testing Zephyr Host Stack on native_sim When tester application has been built for native_sim it produces a `zephyr.exe` file, that can be run as a native Linux application. Depending on your system, you may need to perform the following steps to successfully run `zephyr.exe`.

Setting capabilities Since the application will need access to connect to a socket for HCI, you may need to perform the following

```
setcap cap_net_raw,cap_net_admin,cap_sys_admin+ep zephyr.exe
```

This is not required if you run `zephyr.exe` or `./autoptsclient-zephyr.py` with e.g. `sudo`.

Downing the HCI controller You may also need to "down" or "power off" the HCI controller before running `zephyr.exe`. This can be done either with `hciconfig` as

```
hciconfig hciX down
```

Where `hciX` is a value like `hci0`. You may run `hciconfig` to get a list of your HCI devices.

Since `hciconfig` is deprecated on some systems, you may need to use

```
btmgmt -i hciX power off
```

Similar to `hciconfig`, `btmgmt info` may be used to list current controllers and their states.

Both `hciconfig` and `btmgmt` may require `sudo` when powering down a controller.

Running the client The application can be run as

```
python ./autoptsclient-zephyr.py zephyr-master --hci HCI␣
↪BUILD_DIR/zephyr/zephyr.exe -i SERVER_IP -l LOCAL_IP
```

Where `HCI` is the HCI index, e.g. `0` or `1`, `BUILD_DIR` is the build directory, `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Troubleshooting

After running one test, I need to restart my Windows virtual machine to run another, because of fail verdict from APICOM in PTS logs It means your virtual machine has not enough processor cores or memory. Try to add more in settings. Note that a host with 4 CPUs could be not enough with VirtualBox as hypervisor. In this case, choose rather VMWare Workstation.

I cannot start autoptsserver-zephyr.py. I always get a Python error

```
codecoup@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...

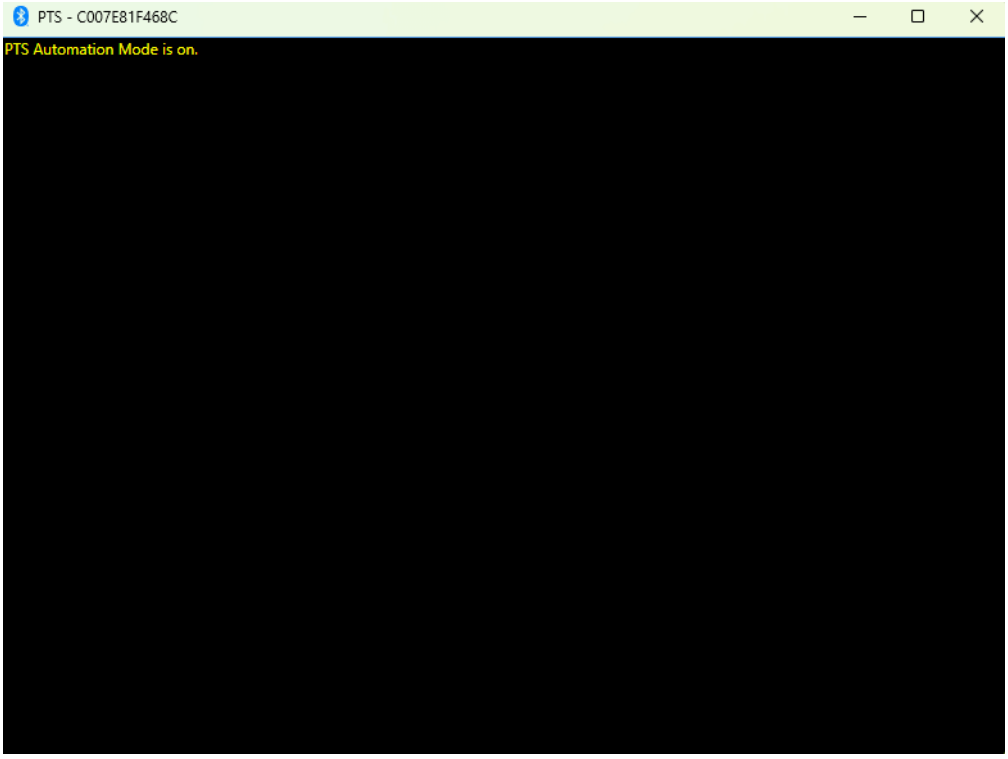
  File "<COMObject ProfileTuningSuite_6.PTSControlServer>", line 3, in GetPTSBluetoothAddress
pywintypes.com_error: (-2147352567, 'Exception occurred.', (0, 'PTS', '(HRESULT:0x849C0043) Error HResult!', None
, 0, -2070151101), None)
```

One or more of the following steps should help:

- Close all PTS Windows.
- Replug PTS bluetooth dongle.
- Delete temporary workspace. You will find it in auto-pts-code/workspaces/zephyr/zephyr-master/ as temp_zephyr-master. Be careful, do not remove the original one zephyr-master.pqw6.
- Restart Windows virtual machine.

The PTS automation window keeps opening and closing This indicates that it fails to capture a PTS dongle. If the AutoPTS server is able to find and use a PTS dongle, then the title of the window will show the Bluetooth address of the dongle. If this does not happen then ensure that the dongle is plugged in, updated and recognized by PTS.



If it still fails to run tests after this, please ensure that the Bluetooth Protocol Viewer is installed.

ICS Features

The Zephyr ICS file for the Host features can be downloaded here: `ICS_Zephyr_Bluetooth_Host.pts`.

Use the Bluetooth Qualification website to view and edit the ICS.

6.1.3 Stack Architecture

Overview

This page describes the software architecture of Zephyr's Bluetooth protocol stack.

> **Note**
>
> Zephyr supports mainly Bluetooth Low Energy (LE), the low-power version of the Bluetooth specification. Zephyr also has limited support for portions of the BR/EDR Host.

Bluetooth LE Layers There are 3 main layers that together constitute a full Bluetooth Low Energy protocol stack:

- **Host**: This layer sits right below the application, and is comprised of multiple (non real-time) network and transport protocols enabling applications to communicate with peer devices in a standard and interoperable way.
- **Controller**: The Controller implements the Link Layer (LE LL), the low-level, real-time protocol which provides, in conjunction with the Radio Hardware, standard-interoperable over-the-air communication. The LL schedules packet reception and transmission, guarantees the delivery of data, and handles all the LL control procedures.
- **Radio Hardware**: Hardware implements the required analog and digital baseband functional blocks that permit the Link Layer firmware to send and receive in the 2.4GHz band of the spectrum.

Host Controller Interface The Bluetooth Specification describes the format in which a Host must communicate with a Controller. This is called the Host Controller Interface (HCI) protocol. HCI can be implemented over a range of different physical transports like UART, SPI, or USB. This protocol defines the commands that a Host can send to a Controller and the events that it can expect in return, and also the format for user and protocol data that needs to go over the air. The HCI ensures that different Host and Controller implementations can communicate in a standard way making it possible to combine Hosts and Controllers from different vendors.

Configurations The three separate layers of the protocol and the standardized interface make it possible to implement the Host and Controller on different platforms. The two following configurations are commonly used:

- **Single-chip configuration**: In this configuration, a single microcontroller implements all three layers and the application itself. This can also be called a system-on-chip (SoC) implementation. In this case the Bluetooth Host and the Bluetooth Controller communicate directly through function calls and queues in RAM. The Bluetooth specification does not specify how HCI is implemented in this single-chip configuration and so how HCI commands, events, and data flows between the two can be implementation-specific. This configuration is well suited for those applications and designs that require a small footprint and the lowest possible power consumption, since everything runs on a single IC.
- **Dual-chip configuration**: This configuration uses two separate ICs, one running the Application and the Host, and a second one with the Controller and the Radio Hardware. This is sometimes also called a connectivity-chip configuration. This configuration allows for a wider variety of combinations of Hosts when using the Zephyr OS as a Controller. Since HCI ensures interoperability among Host and Controller implementations, including of course Zephyr's very own Bluetooth Host and Controller, users of the Zephyr Controller can choose to use whatever Host running on any platform they prefer. For example, the host can be the Linux Bluetooth Host stack (BlueZ) running on any processor capable of supporting Linux. The Host processor may of course also run Zephyr and the Zephyr OS Bluetooth Host. Conversely, combining an IC running the Zephyr Host with an external Controller that does not run Zephyr is also supported.

Build Types The Zephyr software stack as an RTOS is highly configurable, and in particular, the Bluetooth subsystem can be configured in multiple ways during the build process to include only the features and layers that are required to reduce RAM and ROM footprint as well as power consumption. Here's a short list of the different Bluetooth-enabled builds that can be produced from the Zephyr project codebase:

- **Controller-only build**: When built as a Bluetooth Controller, Zephyr includes the Link Layer and a special application. This application is different depending on the physical transport chosen for HCI:
  - bluetooth_hci_uart

  - bluetooth_hci_usb
  - bluetooth_hci_spi

  This application acts as a bridge between the UART, SPI or USB peripherals and the Controller subsystem, listening for HCI commands, sending application data and responding with events and received data. A build of this type sets the following Kconfig option values:

  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`
  - `CONFIG_BT_HCI_RAW=y`

  The controller itself needs to be enabled as well, typically by making sure the corresponding device tree node is enabled.

- **Host-only build**: A Zephyr OS Host build will contain the Application and the Bluetooth Host, along with an HCI driver (UART or SPI) to interface with an external Controller chip. A build of this type sets the following Kconfig option values:

  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`

  Additionally, if the platform supports also a local controller, it needs to be disabled, typically by disabling the corresponding device tree node. This is done together with enabling the device tree node for some other HCI driver and making sure that the `zephyr,bt-hci` device tree chosen property points at it.

  All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Host-only

- **Combined build**: This includes the Application, the Host and the Controller, and it is used exclusively for single-chip (SoC) configurations. A build of this type sets the following Kconfig option values:

  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`

  The controller itself needs to be enabled as well, typically by making sure the corresponding device tree node is enabled.

  All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Combined

The picture below shows the SoC or single-chip configuration when using a Zephyr combined build (a build that includes both a Bluetooth Host and a Controller in the same firmware image that is programmed onto the chip):

When using connectivity or dual-chip configurations, several Host and Controller combinations are possible, some of which are depicted below:

When using a Zephyr Host (left side of image), two instances of Zephyr OS must be built with different configurations, yielding two separate images that must be programmed into each of the chips respectively. The Host build image contains the application, the Bluetooth Host and the selected HCI driver (UART or SPI), while the Controller build runs either the bluetooth_hci_uart, or the bluetooth_hci_spi app to provide an interface to the Bluetooth Controller.

This configuration is not limited to using a Zephyr OS Host, as the right side of the image shows. One can indeed take one of the many existing GNU/Linux distributions, most of which include Linux's own Bluetooth Host (BlueZ), to connect it via UART or USB to one or more instances of the Zephyr OS Controller build. BlueZ as a Host supports multiple Controllers simultaneously for applications that require more than one Bluetooth radio operating at the same time but sharing the same Host stack.

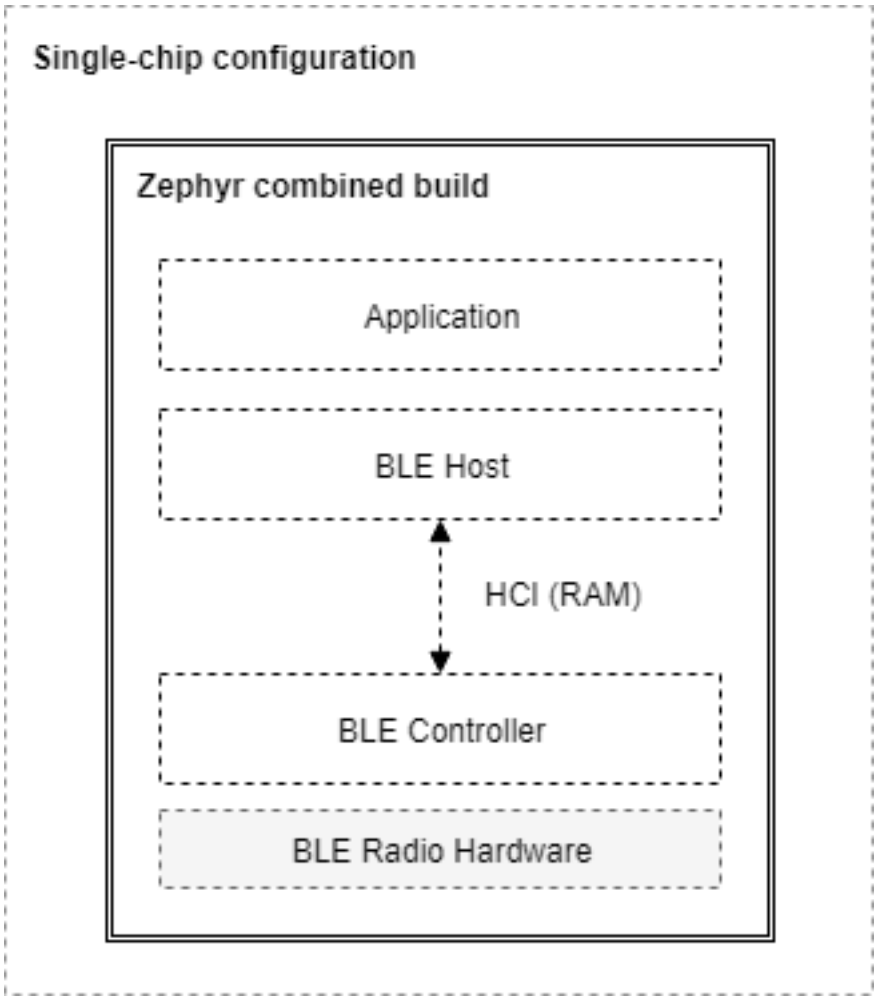


Fig. 1: A Combined build on a Single-Chip configuration

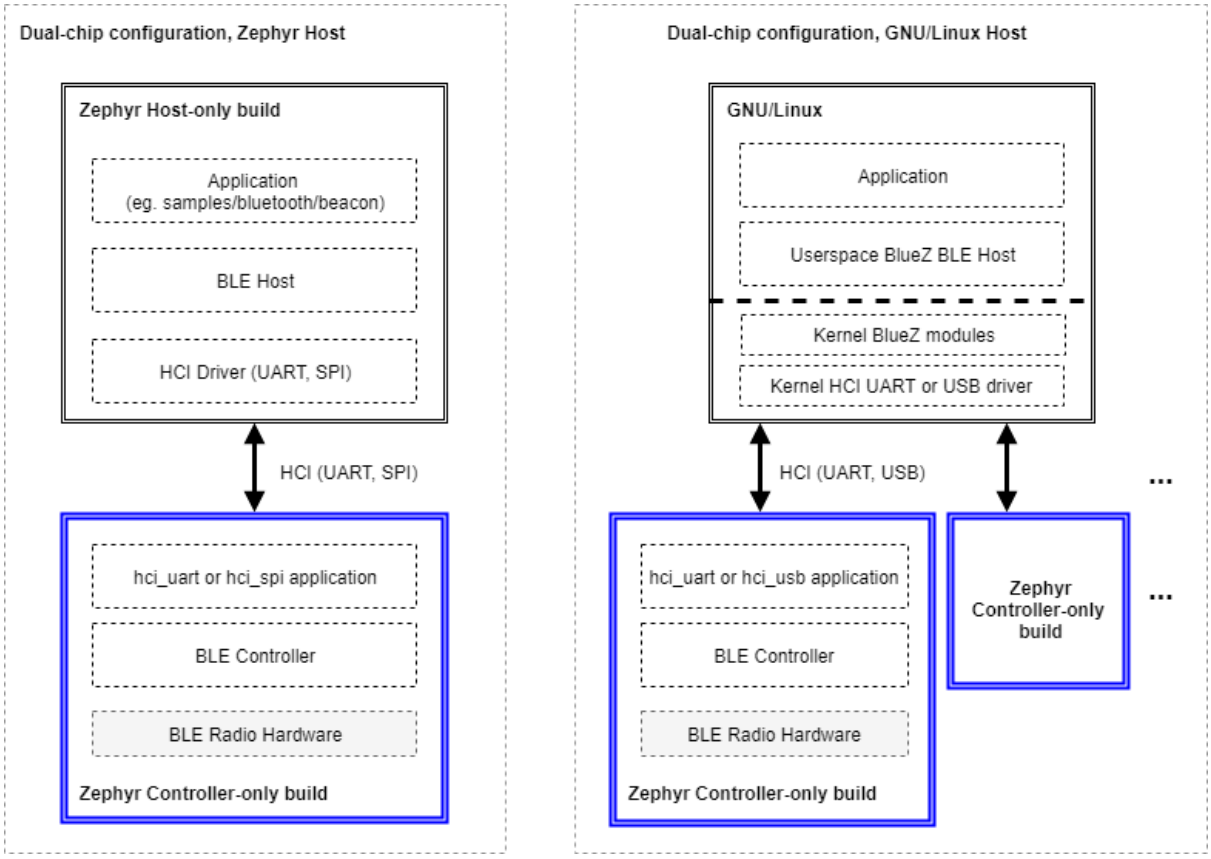

Fig. 2: Host-only and Controller-only builds on dual-chip configurations

Source tree layout

The stack is split up as follows in the source tree:

subsys/bluetooth/host
: *The host stack*. This is where the HCI command and event handling as well as connection tracking happens. The implementation of the core protocols such as L2CAP, ATT, and SMP is also here.

subsys/bluetooth/controller
: *Bluetooth LE Controller* implementation. Implements the controller-side of HCI, the Link Layer as well as access to the radio transceiver.

include/zephyr/bluetooth/
: *Public API* header files. These are the header files applications need to include in order to use Bluetooth functionality.

drivers/bluetooth/
: HCI transport drivers. Every HCI transport needs its own driver. For example, the two common types of UART transport protocols (3-Wire and 5-Wire) have their own drivers.

samples/bluetooth/
: Sample Bluetooth code. This is a good reference to get started with Bluetooth application development.

tests/bluetooth/
: Test applications. These applications are used to verify the functionality of the Bluetooth stack, but are not necessary the best source for sample code (see samples/bluetooth instead).

doc/connectivity/bluetooth/
: Extra documentation, such as PICS documents.

6.1.4 LE Host

The Bluetooth Host implements all the higher-level protocols and profiles, and most importantly, provides a high-level API for applications. The following diagram depicts the main protocol & profile layers of the host.

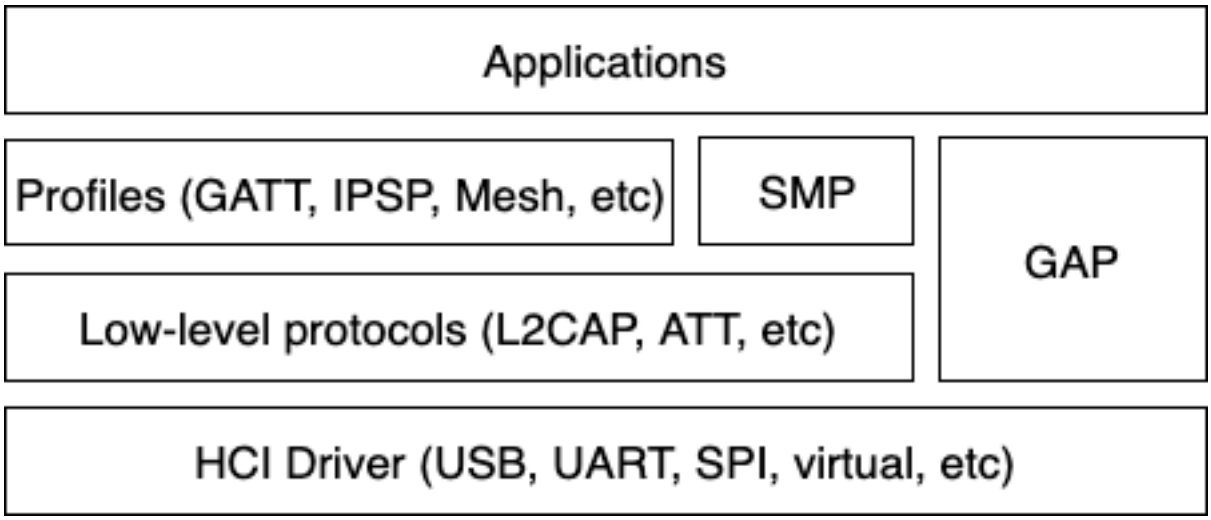

Fig. 3: Bluetooth Host protocol & profile layers.

Lowest down in the host stack sits a so-called HCI driver, which is responsible for abstracting away the details of the HCI transport. It provides a basic API for delivering data from the controller to the host, and vice-versa.

Perhaps the most important block above the HCI handling is the Generic Access Profile (GAP). GAP simplifies Bluetooth LE access by defining four distinct roles of Bluetooth usage:

- Connection-oriented roles
  - Peripheral (e.g. a smart sensor, often with a limited user interface)
  - Central (typically a mobile phone or a PC)
- Connection-less roles
  - Broadcaster (sending out Bluetooth LE advertisements, e.g. a smart beacon)
  - Observer (scanning for Bluetooth LE advertisements)

Each role comes with its own build-time configuration option: `CONFIG_BT_PERIPHERAL`, `CONFIG_BT_CENTRAL`, `CONFIG_BT_BROADCASTER` & `CONFIG_BT_OBSERVER`. Of the connection-oriented roles central implicitly enables observer role, and peripheral implicitly enables broadcaster role. Usually the first step when creating an application is to decide which roles are needed and go from there. Bluetooth Mesh is a slightly special case, requiring at least the observer and broadcaster roles, and possibly also the Peripheral role. This will be described in more detail in a later section.

Peripheral role

Most Zephyr-based Bluetooth LE devices will most likely be peripheral-role devices. This means that they perform connectable advertising and expose one or more GATT services. After registering services using the `bt_gatt_service_register()` API the application will typically start connectable advertising using the `bt_le_adv_start()` API.

There are several peripheral sample applications available in the tree, such as samples/bluetooth/peripheral_hr.

Central role

Central role may not be as common for Zephyr-based devices as peripheral role, but it is still a plausible one and equally well supported in Zephyr. Rather than accepting connections from other devices a central role device will scan for available peripheral device and choose one to connect to. Once connected, a central will typically act as a GATT client, first performing discovery of available services and then accessing one or more supported services.

To initially discover a device to connect to the application will likely use the `bt_le_scan_start()` API, wait for an appropriate device to be found (using the scan callback), stop scanning using `bt_le_scan_stop()` and then connect to the device using `bt_conn_le_create()`.

There are some sample applications for the central role available in the tree, such as samples/bluetooth/central_hr.

Observer role

An observer role device will use the `bt_le_scan_start()` API to scan for device, but it will not connect to any of them. Instead it will simply utilize the advertising data of found devices, combining it optionally with the received signal strength (RSSI).

Broadcaster role

A broadcaster role device will use the `bt_le_adv_start()` API to advertise specific advertising data, but the type of advertising will be non-connectable, i.e. other device will not be able to connect to it.

Connections

Connection handling and the related APIs can be found in the *Connection Management* section.

Security

To achieve a secure relationship between two Bluetooth devices a process called pairing is used. This process can either be triggered implicitly through the security properties of GATT services, or explicitly using the `bt_conn_set_security()` API on a connection object.

To achieve a higher security level, and protect against Man-In-The-Middle (MITM) attacks, it is recommended to use some out-of-band channel during the pairing. If the devices have a sufficient user interface this "channel" is the user itself. The capabilities of the device are registered using the `bt_conn_auth_cb_register()` API. The `bt_conn_auth_cb` struct that's passed to this API has a set of optional callbacks that can be used during the pairing - if the device lacks some feature the corresponding callback may be set to NULL. For example, if the device does not have an input method but does have a display, the `passkey_entry` and `passkey_confirm` callbacks would be set to NULL, but the `passkey_display` would be set to a callback capable of displaying a passkey to the user.

Depending on the local and remote security requirements & capabilities, there are four possible security levels that can be reached:

`BT_SECURITY_L1`
: No encryption and no authentication.

`BT_SECURITY_L2`
: Encryption but no authentication (no MITM protection).

`BT_SECURITY_L3`
: Encryption and authentication using the legacy pairing method from Bluetooth 4.0 and 4.1.

`BT_SECURITY_L4`
: Encryption and authentication using the LE Secure Connections feature available since Bluetooth 4.2.

> **Note**
>
> Mesh has its own security solution through a process called provisioning. It follows a similar procedure as pairing, but is done using separate mesh-specific APIs.

L2CAP

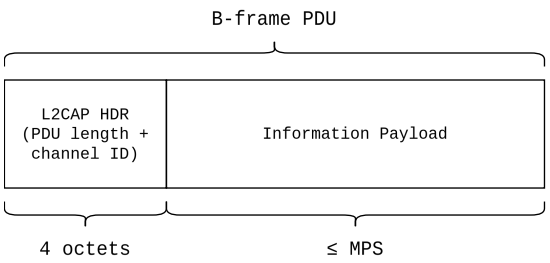
L2CAP stands for the Logical Link Control and Adaptation Protocol. It is a common layer for all communication over Bluetooth connections, however an application comes in direct contact with it only when using it in the so-called Connection-oriented Channels (CoC) mode. More information on this can be found in the *L2CAP API section*.

Terminology The definitions are from the Core Specification version 5.4, volume 3, part A 1.4.

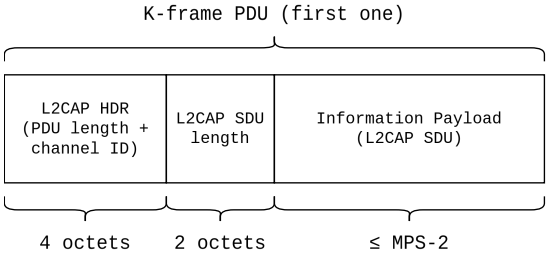
Term	Description
Upper layer	Layer above L2CAP, it exchanges data in form of SDUs. It may be an application or a higher level protocol.
Lower layer	Layer below L2CAP, it exchanges data in form of PDUs (or fragments). It is usually the HCI.
Service Data Unit (SDU)	Packet of data that L2CAP exchanges with the upper layer. This term is relevant only in Enhanced Retransmission mode, Streaming mode, Retransmission mode and Flow Control Mode, not in Basic L2CAP mode.
Protocol Data Unit (PDU)	Packet of data containing L2CAP data. PDUs always start with Basic L2CAP header. Types of PDUs for LE: *B-frames* and *K-frames*. Types of PDUs for BR/EDR: I-frames, S-frames, C-frames and G-frames.
Maximum Transmission Unit (MTU)	Maximum size of an SDU that the upper layer is capable of accepting.
Maximum Payload Size (MPS)	Maximum payload size that the L2CAP layer is capable of accepting. In Basic L2CAP mode, the MTU size is equal to MPS. In credit-based channels without segmentation, the MTU is MPS minus 2.
Basic L2CAP header	Present at the beginning of each PDU. It contains two fields, the PDU length and the Channel Identifier (CID).

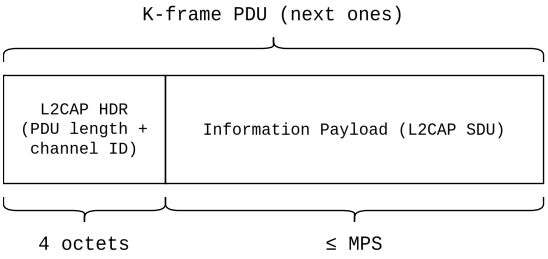
PDU Types

B-frame: Basic information frame PDU used in Basic L2CAP mode. It contains the payload received from the upper layer or delivered to the upper layer as its payload.



K-frame: Credit-based frame PDU used in LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode. It contains a SDU segment and additional protocol information.





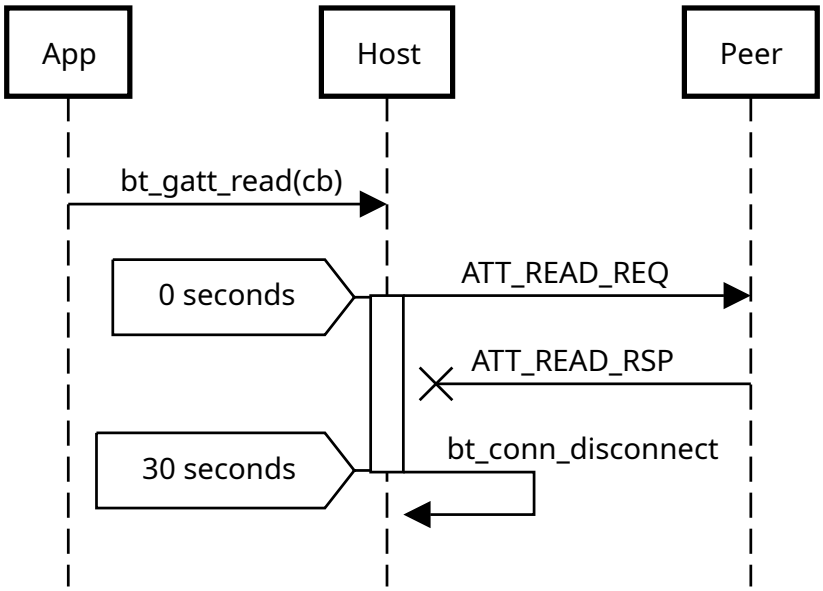
Relevant Kconfig

Kconfig symbol	Description
CONFIG_BT_BUF_ACL_RX_SIZE	Represents the MPS
CONFIG_BT_L2CAP_TX_MTU	Represents the L2CAP MTU
CONFIG_BT_L2CAP_DYNAMIC_CHANN	Enables LE Credit Based Flow Control and thus the stack may use *K-frame* PDUs

GATT

The Generic Attribute Profile is the most common means of communication over LE connections. A more detailed description of this layer and the API reference can be found in the *GATT API reference section*.

ATT timeout If the peer device does not respond to an ATT request (such as read or write) within the ATT timeout, the host will automatically initiate a disconnect. This simplifies error handling by reducing rare failure conditions to a common disconnection, allowing developers to manage unexpected disconnects without special cases for ATT timeouts.



Mesh

Mesh is a little bit special when it comes to the needed GAP roles. By default, mesh requires both observer and broadcaster role to be enabled. If the optional GATT Proxy feature is desired, then peripheral role should also be enabled.

The API reference for mesh can be found in the *Mesh API reference section*.

LE Audio

The LE audio is a set of profiles and services that utilizes GATT and Isochronous Channel to provide audio over Bluetooth Low Energy. The architecture and API references can be found in *Bluetooth Audio Architecture*.

Persistent storage

The Bluetooth host stack uses the settings subsystem to implement persistent storage to flash. This requires the presence of a flash driver and a designated "storage" partition on flash. A typical set of configuration options needed will look something like the following:

```
CONFIG_BT_SETTINGS=y
CONFIG_FLASH=y
CONFIG_FLASH_PAGE_LAYOUT=y
CONFIG_FLASH_MAP=y
CONFIG_NVS=y
CONFIG_SETTINGS=y
```

Once enabled, it is the responsibility of the application to call settings_load() after having initialized Bluetooth (using the `bt_enable()` API).

6.1.5 LE Audio Stack

Overall design

The overall design of the LE Audio stack is that the implementation follows the specifications as closely as possible, both in terms of structure but also naming. Most API functions are prefixed by the specification acronym (e.g. `bt_bap` for the Basic Audio Profile (BAP) and `bt_vcp` for the Volume Control Profile (VCP)). The functions are then further prefixed with the specific role from each profile where applicable (e.g. `bt_bap_unicast_client_discover()` and

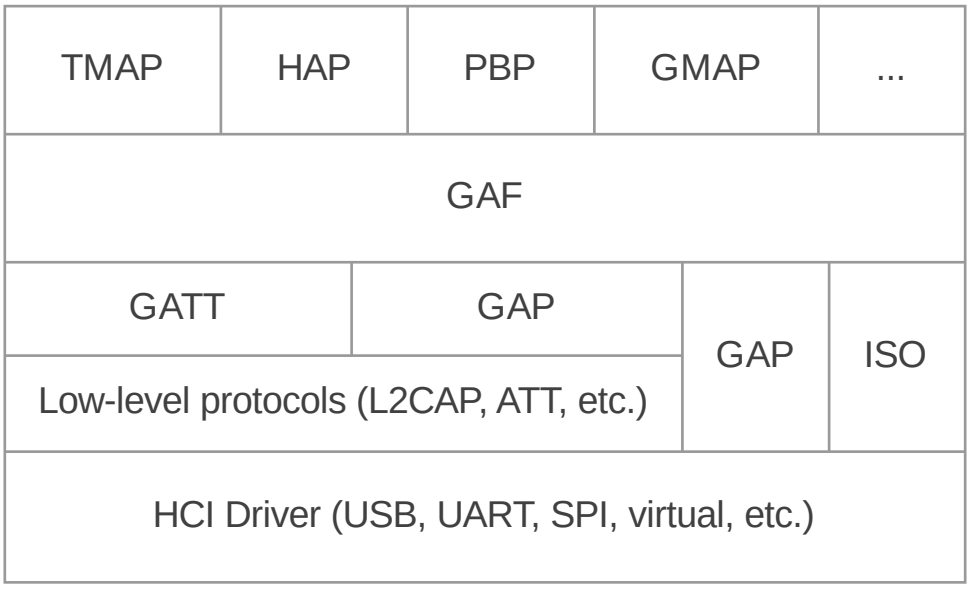


Fig. 4: Bluetooth Audio Architecture

`bt_vcp_vol_rend_set_vol()`). There are usually a function per procedure defined by the profile or service specifications, and additional helper or meta functions that do not correspond to procedures.

The structure of the files generally also follow this, where BAP related files are prefixed with `bap` and VCP related files are prefixed with `vcp`. If the file is specific for a profile role, the role is also embedded in the file name.

Generic Audio Framework (GAF)

The Generic Audio Framework (GAF) is considered the middleware of the Bluetooth LE Audio architecture. The GAF contains the profiles and services that allows higher layer applications and profiles to set up streams, change volume, control media and telephony and more. The GAF builds on GATT, GAP and isochronous channels (ISO).

GAF uses GAP to connect, advertise and synchronize to other devices. GAF uses GATT to configure streams, associate streams with content (e.g. media or telephony), control volume and more. GAF uses ISO for the audio streams themselves, both as unicast (connected) audio streams or broadcast (unconnected) audio streams.

GAF mandates the use of the LC3 codec, but also supports other codecs.

The top-level profiles TMAP and HAP are not part of the GAF, but rather provide top-level requirements for how to use the GAF.

GAF and the top layer profiles have been implemented in Zephyr with the following structure.

Profile Dependencies The LE Audio profiles depend on other profiles and services, as outlined in the following tables. In these tables 'Server' refers to acting in the GATT server role, and 'Client' refers to acting in the GATT client role for the specific service. If a profile role depends on another profile that depends on a service, then that dependency is implicitly also applied to that profile.

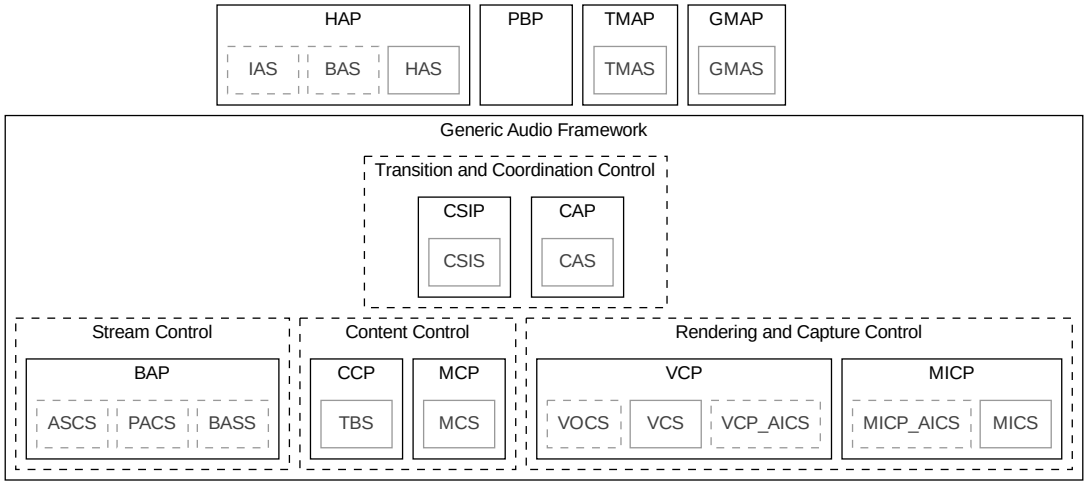

Fig. 5: Generic Audio Framework (GAF)

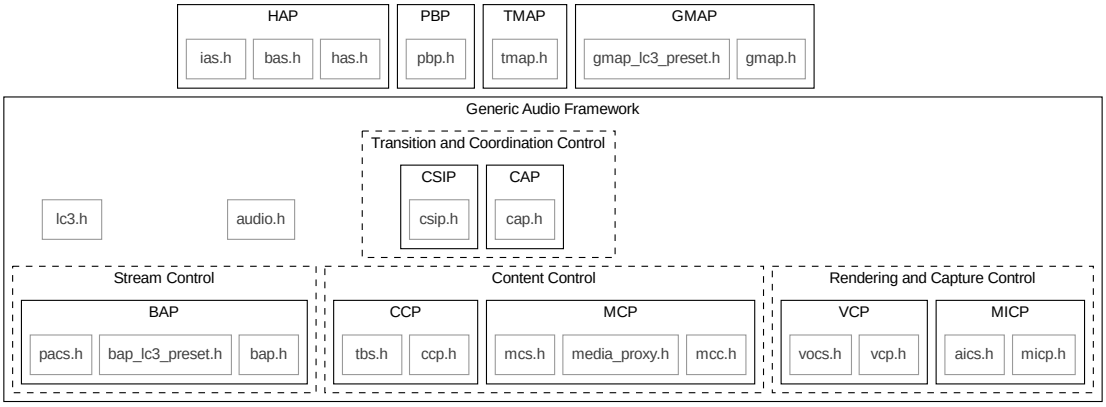

Fig. 6: Zephyr Generic Audio Framework

For example, if the CAP Acceptor uses the BAP Unicast Server role, then the requirements on the ASCS Server and PACS Server also apply to the CAP Acceptor.

The dependencies for Stream Control (BAP) are in the following table.

Table 1: BAP dependencies

	Unicast Server	Unicast Client	Broadcast Source	Broadcast Sink	Scan Delegator	Broadcast Assistant
BAP Scan Delegator				M		
ASCS Client		M				
ASCS Server	M					
PACS Client		M				O
PACS Server	M			M		
BASS Client						M
BASS Server					M	

Note:

- As the table shows, the Broadcast Source role has no dependencies on other LE Audio profiles or services

The dependencies for Content Control (MCP and CCP) are in the following tables.

Table 2: MCP dependencies

	Media Control Server	Media Control Client
GMCS Server	M	
GMCS Client		M
MCS Server	O	
MCS Client		O
OTS Server	O	
OTS Client		O

Table 3: CCP dependencies

	Call Control Server	Call Control Client
GTBS Server	M	
GTBS Client		M
TBS Server	M	
TBS Client		M

The dependencies for Rendering Control (MICP and VCP) are in the following tables.

Table 4: MICP dependencies

	Microphone Controller	Microphone Device
MICS Server	M	
MICS Client		M
AICS Server	O	
AICS Client		O

Table 5: VCP dependencies

	Volume Renderer	Volume Controller
VCS Server	M	
VCS Client		M
VOCS Server	O	
VOCS Client		O
AICS Server	O	
AICS Client		O

The last element in GAF is Transition and Coordination Control (CAP and CSIP) with the dependencies from the following tables.

Table 6: CAP dependencies

	Acceptor	Initiator	Commander
CAS Server	M		C.8
CAS Client		M	M
BAP Unicast Client		C.1	
BAP Unicast Server	C.2		
BAP Broadcast Source		C.1	
BAP Broadcast Sink	C.2		
BAP Broadcast Assistant			C.4, C.6
BAP Scan Delegator	C.3		C.6
VCP Volume Controller			C.6
VCP Volume Renderer	O		
MICP Microphone Controller			C.6
MICP Microphone Device	O		
CCP Call Control Server		O	
CCP Call Control Client	O		C.6
MCP Media Control Server		O	
MCP Media Control Client	O		C.6
CSIP Set Coordinator		C.5	M
CSIP Set Member	C.7		

Notes:

- C.1: Support at least one of BAP Unicast Client or BAP Broadcast Source
- C.2: Support at least one of BAP Unicast Server or BAP Broadcast Sink
- C.3: Mandatory if BAP Broadcast Sink
- C.4: Mandatory if BAP Scan Delegator
- C.5: Mandatory if BAP Unicast Client
- C.6: Support at least one
- C.7: Mandatory if part of a coordinated set
- C.8: Mandatory if the Commander transmits CAP announcements

Table 7: CSIP dependencies

	Set Member	Set Coordinator
CSIS Server	M	
CSIS Client		M

The dependencies of the higher level profiles (GMAP, HAP, PBP and TMAP) are listed in the following tables.

Table 8: GMAP dependencies

	Unicast Game Gateway	Unicast Game Terminal	Broadcast Game Sender	Broadcast Game Receiver
GMAS Server	M	M	O	M
GMAS Client	M	O	O	O
CAP Initiator	M		M	
CAP Acceptor		M		M
CAP Commander	M		M	
BAP Broadcast Source			M	
BAP Broadcast Sink				M
BAP Unicast Client	M			
BAP Unicast Server		M		
VCP Volume Controller	M			
VCP Volume Renderer		C.1		M
MICP Microphone Controller	O			
MICP Microphone Device		C.2		

Notes:

- C.1 Mandatory if the UGT supports the UGT Sink feature
- C.2 Optional if the UGT supports the UGT Source feature

Table 9: HAP dependencies

	Hearing Aid	Hearing Aid Unicast Client	Hearing Aid Remote Controller
HAS Client			M
HAS Server	M		
CAP Initiator		M	
CAP Acceptor	M		
CAP Commander			M
BAP Unicast Client		M	
BAP Unicast Server	M		
VCP Volume Controller			M
VCP Volume Renderer	M		
VOCS Server	C.1		
AICS Server	O		
MICP Microphone Controller			O
MICP Microphone Device	C.2		
CCP Call Control Client	O		
CCP Call Control Server		O	
CSIP Set Coordinator		M	M
CSIP Set Member	C.3		
BAS Server	C.4		
IAS Server	O		

Notes:

- C.1 Mandatory if the HA supports the Volume Baslance feature and is part of a Binaural Hearing Aid Set
- C.2 Mandatory if the HA supports the BAP Audio Source Role
- C.3 Mandatory if the HA is capable of being part of a Binaural Hearing Aid set
- C.4 If equipped with batteries
- C.5 If CCP Call Control Server is supported

Table 10: PBP dependencies

	Public Broadcast Source	Public Broadcast sink	Public Broadcast Assistant
CAP Initiator	M		
CAP Acceptor		M	
CAP Commander			M
BAP Broadcast Assistant			M

Table 11: TMAP dependencies

	Call Gateway	Call Terminal	Unicast Media Sender	Unicast Media Receiver	Broadcast Media Sender	Broadcast Media Receiver
TMAS Server	M	M	M	M	O	M
TMAS Client	O	O	O	O	O	O

Using the Bluetooth Audio Stack To use any of the profiles in the Bluetooth Audio Stack, including the top-level profiles outside of GAF, `CONFIG_BT_AUDIO` shall be enabled. This Kconfig option allows the enabling of the individual profiles inside of the Bluetooth Audio Stack. Each profile can generally be enabled on its own, but enabling higher-layer profiles (such as CAP, TMAP and HAP) will typically require enabling some of the lower layer profiles.

It is, however, possible to create a device that uses e.g. only Stream Control (with just the BAP), without using any of the content control or rendering/capture control profiles, or vice versa. Using the higher layer profiles will however typically provide a better user experience and better interoperability with other devices.

Common Audio Profile (CAP) The Common Audio Profile introduces restrictions and requirements on the lower layer profiles. The procedures in CAP works on one or more streams for one or more devices. Is it thus possible via CAP to do a single function call to setup multiple streams across multiple devices.

The figure below shows a complete structure of the procedures in CAP and how they correspond to procedures from the other profiles. The circles with I, A and C show whether the procedure has active involvement or requirements from the CAP Initiator, CAP Accept and CAP Commander roles respectively.

The API reference for CAP can be found in *Common Audio Profile*.

Stream Control (BAP) Stream control is implemented by the Basic Audio Profile. This profile defines multiple roles:

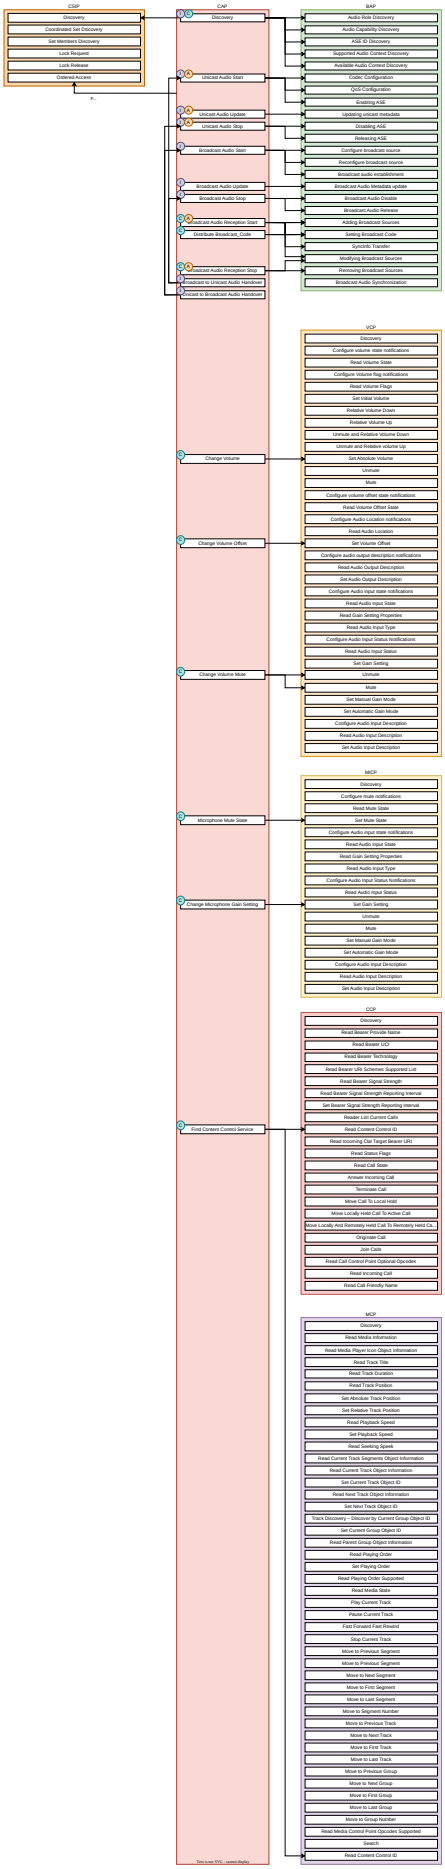

Fig. 7: Common Audio Profile Procedures

- Unicast Client
- Unicast Server
- Broadcast Source
- Broadcast Sink
- Scan Delegator
- Broadcast Assistant

Each role can be enabled individually, and it is possible to support more than one role.

Notes about the stream control services There are 3 services primarily used by stream control using the Basic Audio Profile.

Audio Stream Control Service (ASCS) ASCS is a service used exclusively for setting up unicast streams, and is located on the BAP Unicast Server device. The service exposes one or more endpoints that can either be a sink or source endpoint, from the perspective of the Unicast Server. That means a sink endpoint is always audio from the Unicast Client to the Unicast Server, and a source endpoint is always from the Unicast Server to the Unicast Client.

Unlike most other GATT services, ASCS requires that each characteristic in the service has unique data per client. This means that if a Unicast Server is connected to multiple Unicast Clients, the Unicast Clients are not able to see or control the endpoints configured by the other clients. For example if a person's smartphone is streaming audio to a headset, then the same person will not be able to see or control that stream from their smartwatch.

Broadcast Audio Scan Service (BASS) BASS is a service that is exclusively used by the Scan Delegator and Broadcast Assistant. The main purpose of the service is to offload scanning from low power peripherals to e.g. phones and PCs. Unlike ASCS where the data is required to be unique per client, the data in BASS (called receive states) are (usually) shared among all connected clients. That means it is possible for a person to tell their headphones to synchronize to a Broadcast Source using their phone, and then later tell their headphones to stop synchronizing using their smartwatch.

A Broadcast Assistant can be any device, and may only support this one role without any audio capabilities. This allows legacy devices that do not support periodic advertisements or isochronous channels to still provide an interface and scan offloading for peripherals. The Bluetooth SIG has provided a guide on how to develop such legacy Broadcast Assistants that can be found at https://www.bluetooth.com/bluetooth-resources/developing-auracast-receivers-with-an-assistant-application-for-legacy-smartphones/. An important note about this guide is that many operating systems (especially on phones), do not allow generic usage of the BASS UUID, effectively making it impossible to implement your own Broadcast Assistant, because you cannot access the BASS.

Published Audio Capabilities Service (PACS) PACS is used to expose a device's audio capabilities in Published Audio Capabilities (PAC) records. PACS is used by nearly all roles, where the Unicast Client and Broadcast Assistant will act as PACS clients, and Unicast Server and Broadcast Sink will act as PACS servers. These records contain information about the codec, and which values are supported by each codec. The values for the LC3 codec are defined by the Bluetooth Assigned numbers (https://www.bluetooth.com/specifications/assigned-numbers/), and the values for other codecs such as SBC are left undefined/implementation specific for BAP.

PACS also usually shares the same data between each connected client, but by using functions such as `bt_pacs_conn_set_available_contexts_for_conn()`, it is possible to set specific values for specific clients.

The API reference for stream control can be found in *Bluetooth Audio*.

Rendering and Capture Control Rendering and capture control is implemented by the Volume Control Profile (VCP) and Microphone Control Profile (MICP).

The VCP implementation supports the following roles

- Volume Control Service (VCS) Server
- Volume Control Service (VCS) Client

The MICP implementation supports the following roles

- Microphone Control Profile (MICP) Microphone Device (server)
- Microphone Control Profile (MICP) Microphone Controller (client)

The API reference for volume control can be found in *Bluetooth Volume Control*.

The API reference for Microphone Control can be found in *Bluetooth Microphone Control*.

Content Control Content control is implemented by the Call Control Profile (CCP) and Media Control Profile (MCP).

The CCP implementation is not yet implemented in Zephyr.

The MCP implementation supports the following roles

- Media Control Service (MCS) Server via the Media Proxy module
- Media Control Client (MCC)

The API reference for media control can be found in *Bluetooth Media Control*.

Generic TBS and Generic MCS Both the Telephone Bearer Service (TBS) used by CCP and the Media Control Service (MCS) used by MCP have the concept of generic instances of the services called Generic TBS (GTBS) and Generic MCS (GMCS).

While these share a common name prefix, the behavior of these two may be significantly different.

Generic TBS The TBS spec defines GTBS as

> GTBS provides a single point of access and exposes a representation of its internal telephone bearers into a single telephone bearer. This service provides telephone status and control of the device as a single unit with a single set of characteristics. It is left up to the implementation to determine what telephone bearer a characteristic of GTBS represents at any time. There is no specified manner of representing a characteristic from each individual TBS that resides on the device to the same characteristic of the GTBS.
>
> For example, if there is more than one TBS on a device and each has a unique telephone bearer name (e.g., Name1 and Name2), the way the GTBS represents the telephone bearer name is left up to the implementation. GTBS is suited for clients that do not need to access or control all the information available on specific telephone bearers.

This means that a GTBS instance represents one or more telephone bearers. A telephone bearer could be any application on a device that can handle (telephone) calls, such as the default Call application on a smartphone, but also other applications such as Signal, Discord, Teams, Slack, etc.

GTBS may be standalone (i.e. the device only has a GTBS instance without any TBS instances), and the behavior of the GTBS is mostly left up to the implementation. In Zephyr the implementation of GTBS is that it contains some generic information, such as the provider name which is defined to simply be “Generic TBS”, but the majority of the information in the GTBS instance in Zephyr has been implemented to be a union of the data of the other bearers. For example if you have a bearer for regular phone calls and Teams and have an active call in both bearers, then each of

those bearers will report a single call, but the GTBS instance will report 2 calls, making it possible for a simple Call Control Client to control all calls from a single bearer. Similarly the supported URIs for each bearer are also made into a union in GTBS, and when placing a call using the GTBS the server will pick the most suited bearer depending on the URI. For example calls with URI `tel` would go to the regular phone application, and calls with the URI `skype` would go to the Teams application.

In conclusion the GTBS implementation in Zephyr is a union of the non-generic telephone bearers.

Generic MCS The MCS spec defines GMCS as

> The GMCS provides status and control of media playback for the device as a single unit. An MCS instance describes and controls the media playback for a specific media player within the device. A device implements MCS instances to allow clients to access the separate internal media player entities.

and where the behavior of GMCS is defined as

> ... the behavior of MCS and GMCS is identical, and all the characteristics and the characteristics' behaviors are the same. The term "MCS" is used throughout the document. Unless otherwise specifically stated in this specification, the same meaning applies to GMCS as well.

This means that a GMCS instance works the same way as an MCS instance, and it follows that GMCS

> controls the media playback for a specific media player within the device

A media player on a device could be anything that plays media, such as a Spotify or Youtube application on a smartphone. Thus if a device has multiple MCS instances, then each of these control media for that specific application, but the GMCS also controls media playback for a specific media player. GMCS can thus be considered a pointer to a specific MCS instance, and control either e.g. Spotify or Youtube, but not both.

The MCS spec does however provide an example of GMCS where a device can

> Implement a GMCS that provides status and control of media playback for the device as a whole.

Which may indicate that an implementation may use GMCS to represent all media players with GMCS and not a specific media player as stated above. In the case where a device does not have any MCS instances and only GMCS, then GMCS will point to a generic instance.

The Zephyr implementation of MCS and GMCS is incomplete, and currently only supports instantiating a single instance that can either be an MCS or GMCS. This means that the implementation is neither complete nor spec-compliant.

Difference between GTBS and GMCS The definitions and implementations of GTBS and GMCS as stated above are notably different. GTBS works as a union between the other TBS instances (if any), and GMCS works as a pointer to a specific MCS instance (if any). This effectively means that a simple Call Control Client can control all calls just using GTBS, but a Media Control Client may only be able to control a single player using GMCS.

Coordinated Sets Coordinated Sets is implemented by the Coordinated Sets Identification Profile (CSIP).

The CSIP implementation supports the following roles

- Coordinated Set Identification Service (CSIP) Set Member
- Coordinated Set Identification Service (CSIP) Set Coordinator

The API reference for media control can be found in *Bluetooth Coordinated Sets*.

Specification correctness and data location The implementations are designed to ensure specification compliance as much as possible. When a specification introduces a requirement with e.g. a **shall** then the implementation should attempt to ensure that this requirement is always followed. Depending on the context of this, the implementation ensures this by rejecting invalid parameters from the application, or from the remote devices.

Some requirements from the specifications are not or can not be handled by the stack itself for various reasons. One reason when the stack cannot handle a requirement is if the data related to the requirement is exclusively controlled by the application. An example of this is the advertising data, where multiple services have requirements for what to advertise and when, but where both the advertising state and data is exclusively controlled by the application.

Oppositely there are also requirements from the specification, where the data related to the requirement is exclusively controlled by the stack. An example of this is the Volume Control Service (VCS) state, where the specifications mandate that the VCP Volume Renderer (VCS server) modify the values without a choice, e.g. when setting the absolutely volume. In cases like this the application is only notified about the change with a callback, but cannot reject the request (the stack will reject any invalid requests).

Generally when the data is simple (like the VCS state which only takes up a few bytes), the data is kept in and controlled by the stack, as this can ensure that the requirements can be handled by the stack, making it easier to use a profile role correctly. When the data is more complex (e.g. the PAC records), the data may be kept by the application and the stack only contains a reference to it. When the data is very application specific (e.g. advertising data), the data is kept in and controlled by the application.

As a rule of thumb, the return types of the callbacks for each profile implementation indicate whether the data is controlled by the stack or the application. For example all the callbacks for the VCP Volume Renderer have the return type of `void`, but the return type of the BAP Unicast Server callbacks are `int`, indicating that the application not only controls a lot of the Unicast Server data, but can also reject the requests. The choice of what the return type of the callbacks often depend on the specifications, and how much control the role has in a given context.

Things worth knowing or considering when using LE Audio This section describes a few things to consider when contributing to or using LE Audio in Zephyr. The things described by this section are not unique to Zephyr as they are defined by the specifications.

Security requirements All LE Audio services require Security Level 2 but where the key must be 128-bit and derived via an OOB method or via LE Secure connections. There is no Core-spec defined way of reporting this in GATT, as ATT does not have a specific error code for missing OOB method or LE Secure Connections (although there is a way to report wrong key size).

In Zephyr we do not force the device to always use these, as a device that uses LE Audio may also use other profiles and services that do not require such security. We guard all access to services using a custom security check implemented in subsys/bluetooth/audio/audio.c, where all LE Audio services must use the internal `BT_AUDIO_CHRC` macro for proper security verification.

Access to the LTK for encrypted SIRKs in CSIS The Coordinated Set Identification Service (CSIS) may encrypt the SIRK (set identity resolving key). The process of encrypting the SIRK requires the LTK as the encryption key, which is typically not exposed to higher layer implementations such as CSIS. This does not have any effect on the security though.

MTU requirements The Basic Audio Profile (BAP) has a requirement that both sides shall support a minimum ATT_MTU of at least 64 on the unenhanced ATT bearer or at least one enhanced ATT bearer. The requirement comes from the preferred (or sometimes mandatory) use of GATT Write Without Response, and where support for Write Long Characteristic Value is optional in most cases.

If a ASCS device supports values larger than the minimum ATT_MTU of 64 octets, then it shall support Read long Characteristic Value by setting `CONFIG_BT_ATT_PREPARE_COUNT` to a non-zero value.

6.1.6 LE Audio resources

This section contains some links and reference to resources that are useful for either contributors to the LE Audio Stack in Zephyr, LE Audio application developers or both.

The LE audio channel on Discord

Zephyr has a specific Discord channel for LE Audio development, which is open to all. Find it here at https://discordapp.com/channels/720317445772017664/1207326649591271434 or simply search for "bt-audio" from within Discord. Since the `#bt-audio` channel is open for all, we cannot discuss any specifications that are in development in that channel. For discussions that require a Bluetooth SIG membership we refer to the `#bt-sig` Discord channel found at https://discordapp.com/channels/720317445772017664/869172014018097162.

Zephyr weekly meetings

Anyone who is a Bluetooth SIG member and a Zephyr member can join the weekly meetings where we discuss and plan the development of LE Audio in Zephyr. You can find the time of the meetings by joining the Bluetooth-sig group at https://lists.zephyrproject.org/g/Bluetooth-sig.

Github project

LE Audio in Zephyr has its own Github project available at https://github.com/orgs/zephyrproject-rtos/projects/26. The project is mostly automated, and the LE Audio contributors almost only rely on the automated workflows to present the state of development. Anyone is able to pick any of the open issues and work on it. If you cannot assign the issue to yourself, please leave a comment in the issue itself or ping the Discord channel for help.

Bluetooth SIG errata for LE Audio

There are many specifications for LE Audio, and several of them are still being updated and developed. To get an overview of the errata for the LE Audio specifications you can visit

- Generic Audio (GA) errata https://bluetooth.atlassian.net/wiki/spaces/GA/pages/1634402349/GAWG+Errata+Lists
- Hearing Aid (HA) errata https://bluetooth.atlassian.net/wiki/spaces/HA/pages/1634140216/HA+WG+Errata+List
- Audio, Telephony and Automotive (ATA) errata https://bluetooth.atlassian.net/wiki/spaces/ATA/pages/1668481034/ATA+Errata+Lists

Access to errata requires a Bluetooth SIG membership.

Bluetooth SIG working groups for LE Audio

There are 3 working groups in the Bluetooth SIG related to LE Audio:

- Generic Audio (GA) https://www.bluetooth.org/groups/group.aspx?gId=665
- Hearing Aid (HA) https://www.bluetooth.org/groups/group.aspx?gId=605
- Audio, Telephony, and Automotive (ATA) https://www.bluetooth.org/groups/group.aspx?gId=659

By joining these groups you will also get emails from their respective mailing lists, where multiple questions and discussions are handled. The working groups also have scheduled weekly meetings, where issues and the development of the specifications are handled.

Access to the Bluetooth SIG working groups requires a Bluetooth SIG membership.

The LE Audio Book

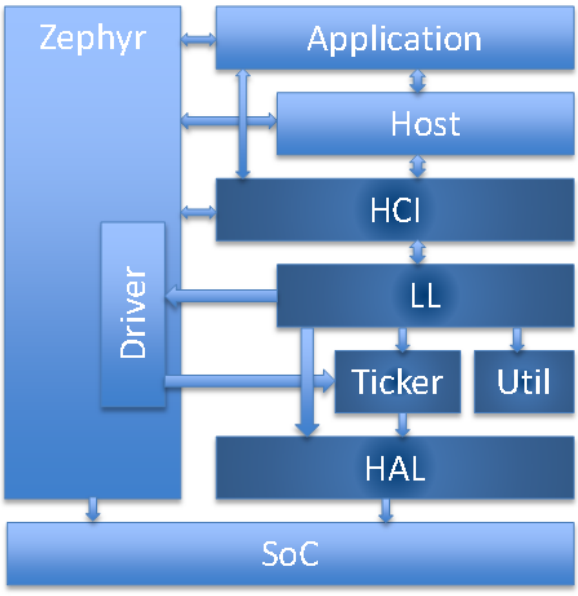
There is a free ebook on LE Audio at https://www.bluetooth.com/bluetooth-resources/le-audio-book/. The book was released in January 2022, and thus before some of the specifications were finalized, but also before some of the released updates to the specifications. Nevertheless the book still provides a good explanation for many of the concepts and ideas, but please refer to the individual specifications for technical information.

Bluetooth SIG informational papers, reports and guides

The Bluetooth SIG occasionally release new informational papers, report and guides. These can be found at https://www.bluetooth.com/bluetooth-resources/?tags=le-audio&keyword. Here you will also find the aforementioned LE Audio book, among many other good resources.

6.1.7 LE Controller

Overview

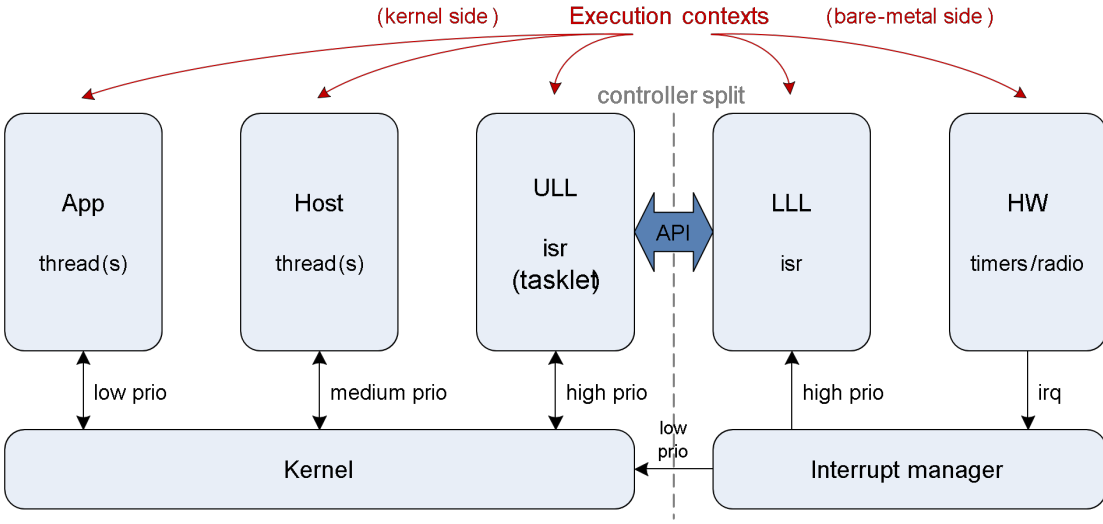


1. HCI
   - Host Controller Interface, Bluetooth standard
   - Provides Zephyr Bluetooth HCI Driver
2. HAL

- Hardware Abstraction Layer
- Vendor Specific, and Zephyr Driver usage

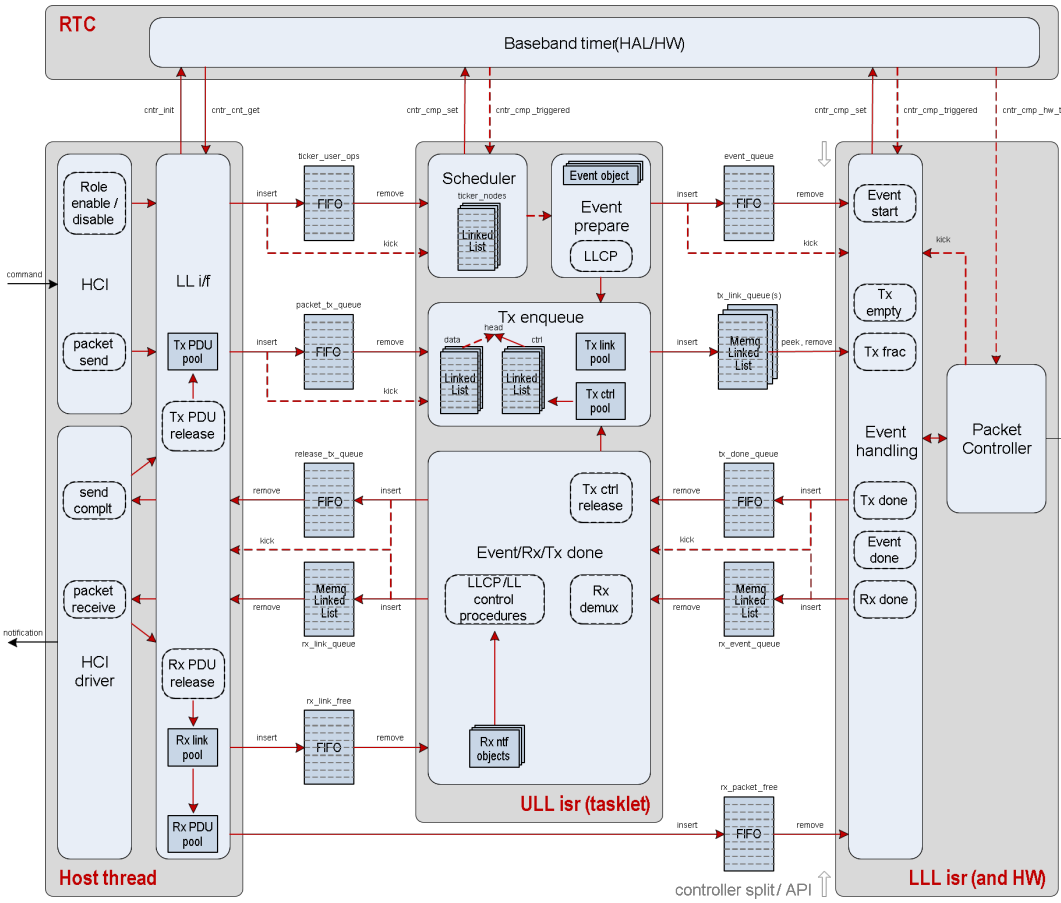
3. Ticker
   - Soft real time radio/resource scheduling
4. LL_SW
   - Software-based Link Layer implementation
   - States and roles, control procedures, packet controller
5. Util
   - Bare metal memory pool management
   - Queues of variable count, lockless usage
   - FIFO of fixed count, lockless usage
   - Mayfly concept based deferred ISR executions

Architecture

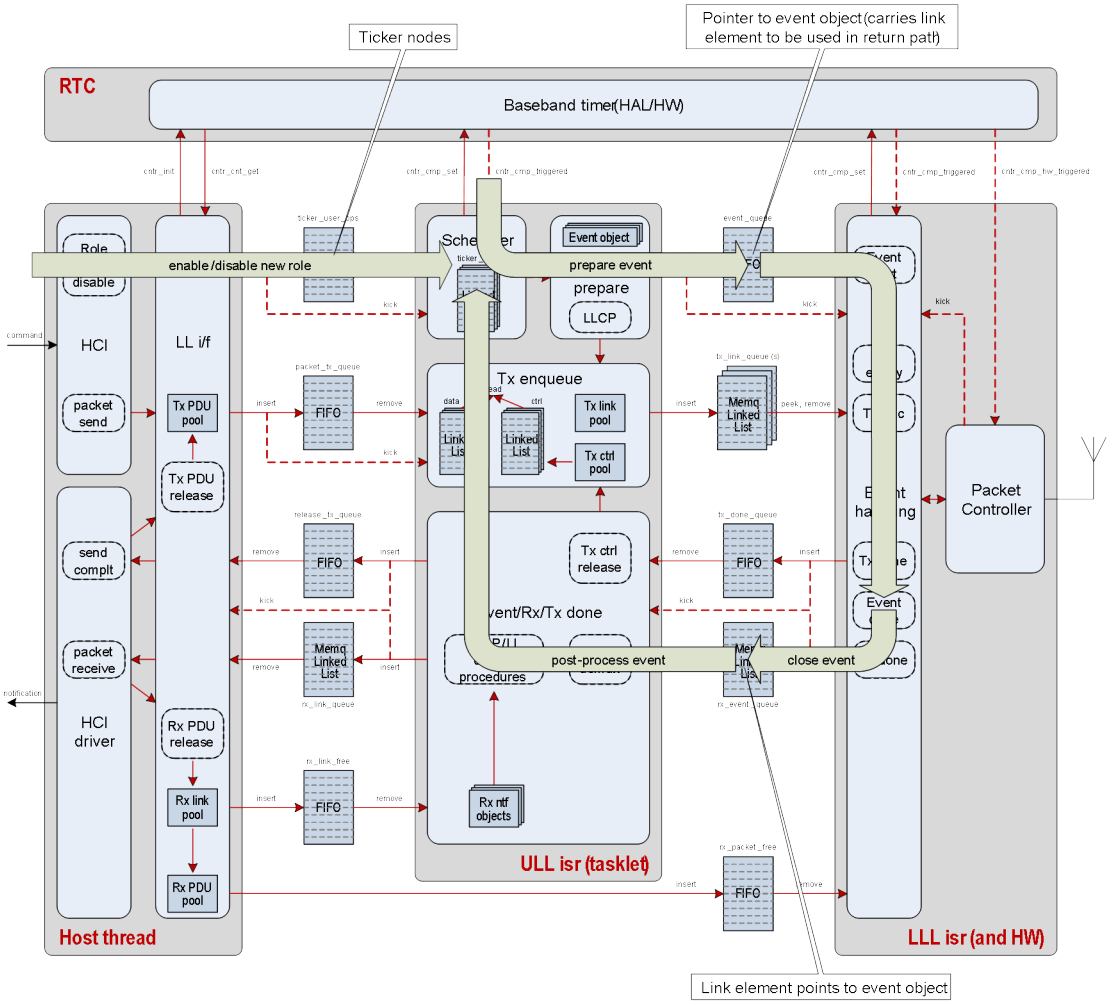


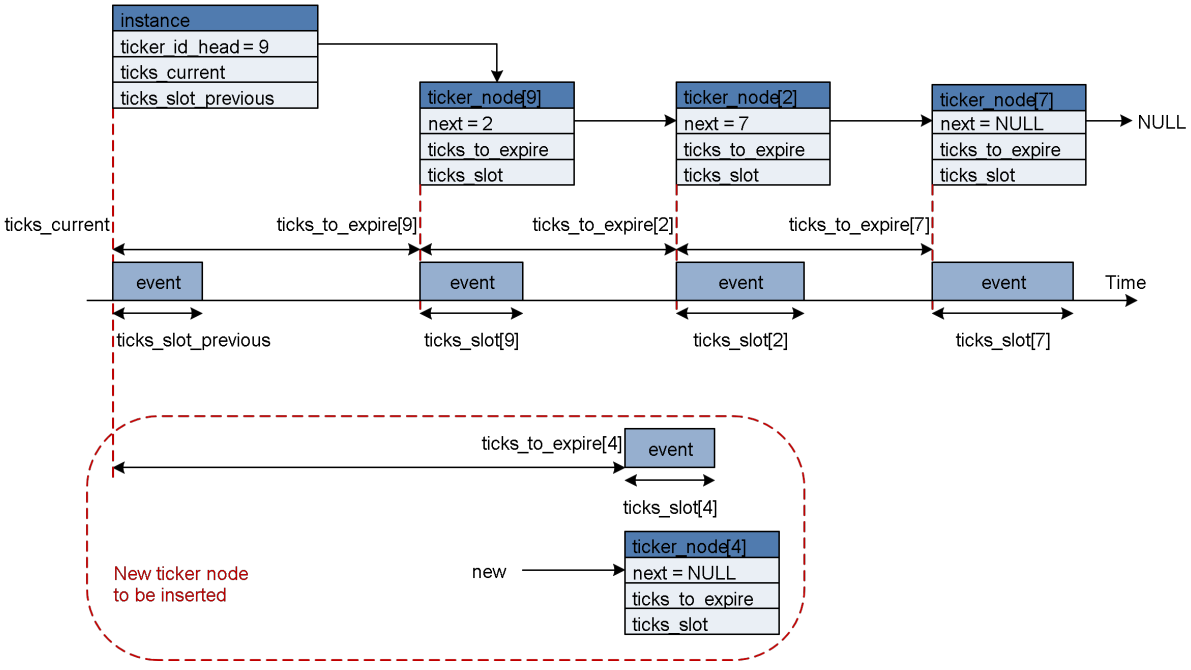
Execution Overview

Architecture Overview



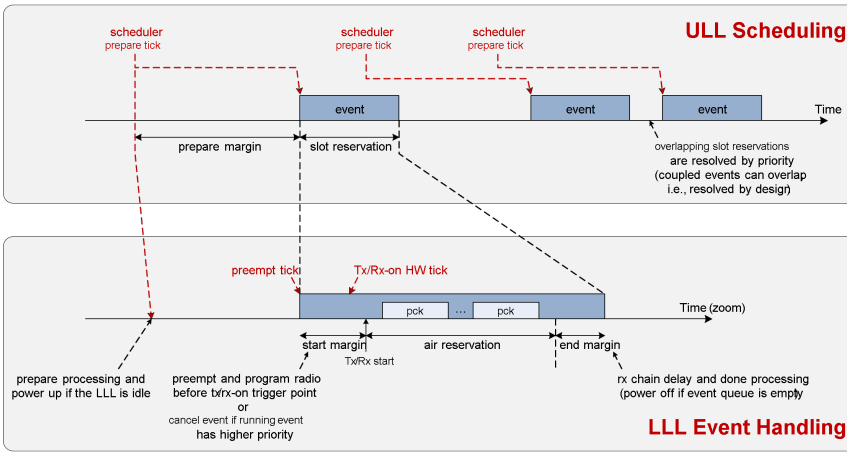
Scheduling



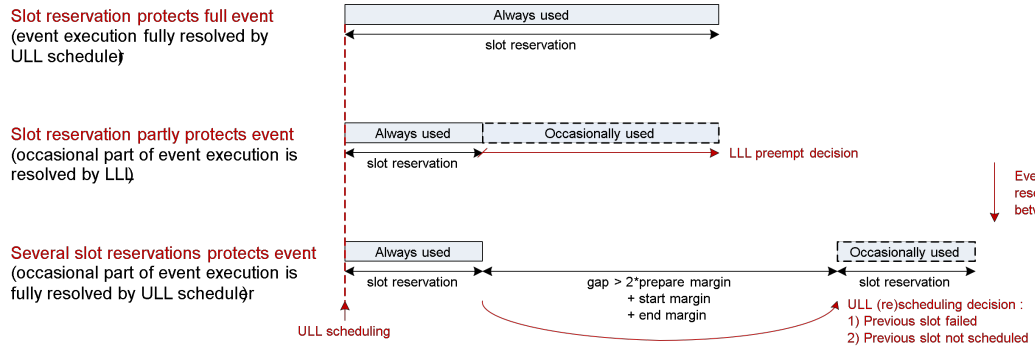


Ticker

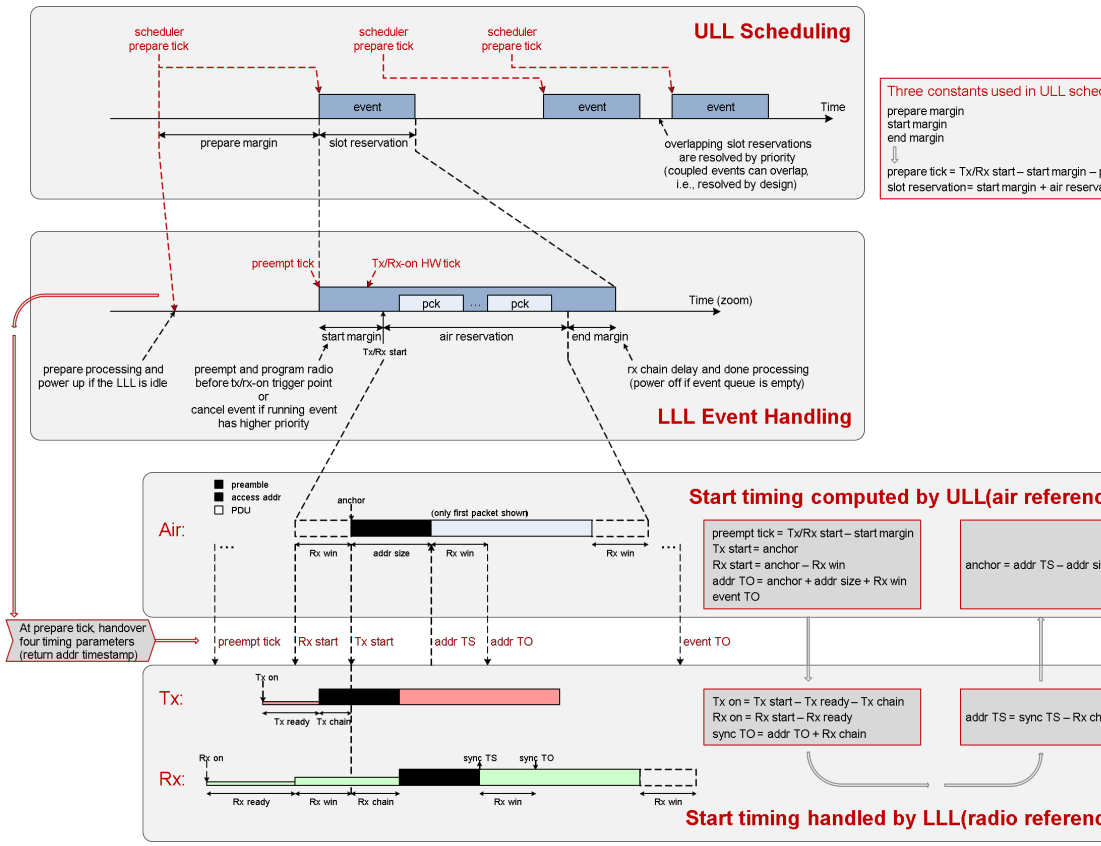
Upper Link Layer and Lower Link Layer



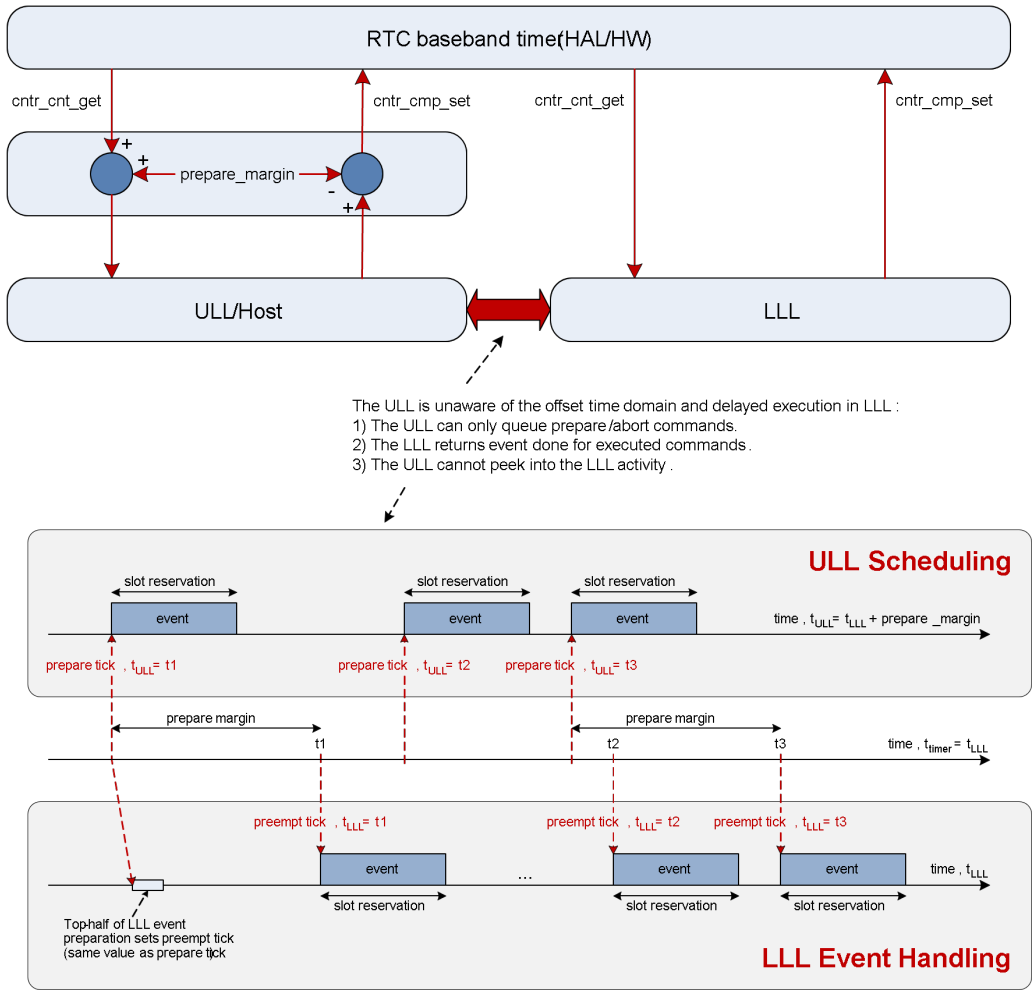
Scheduling Variants

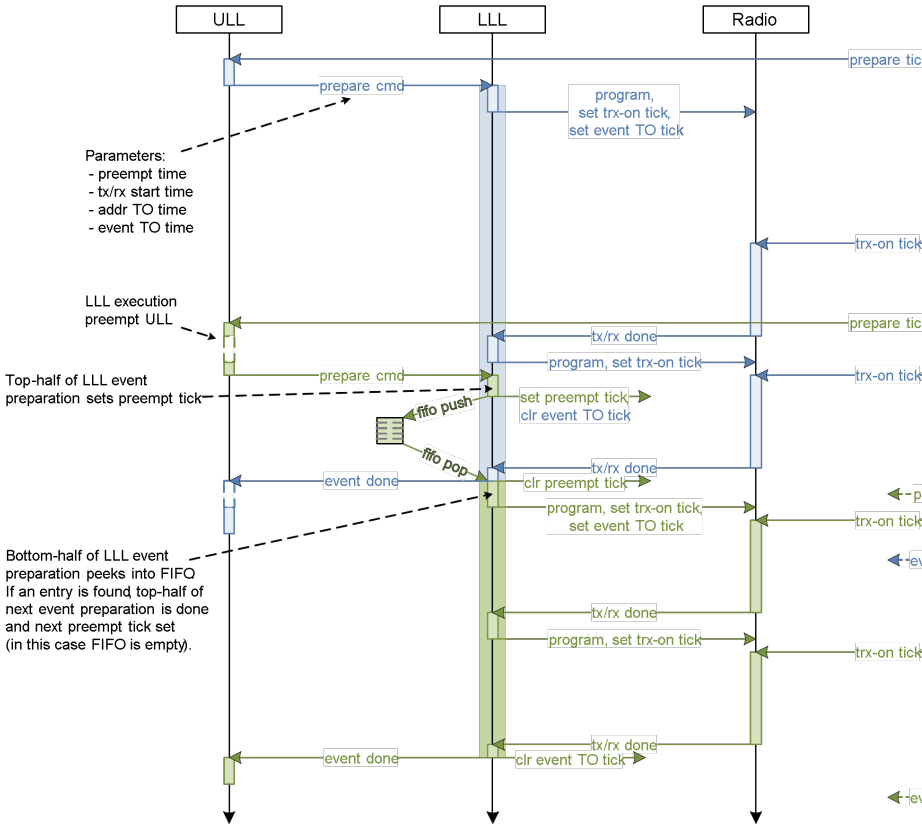


ULL and LLL Timing

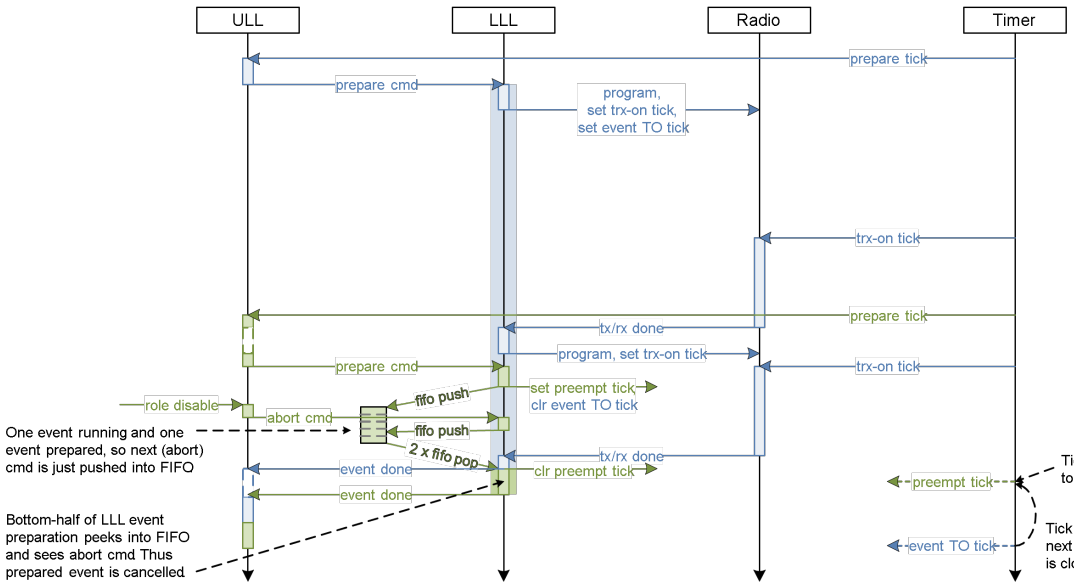


Event Handling

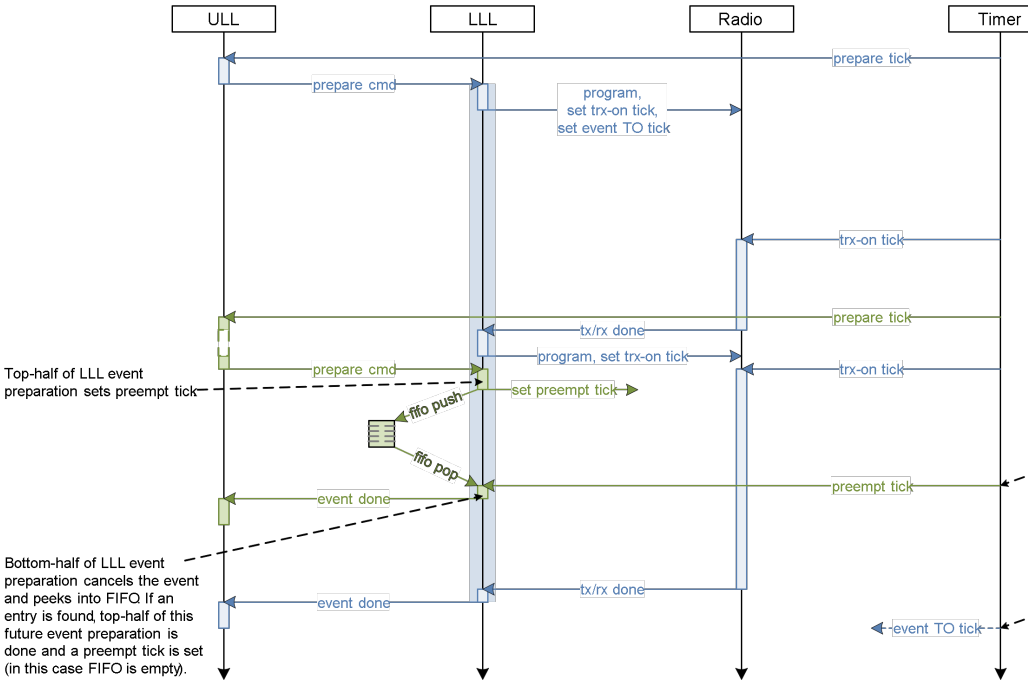




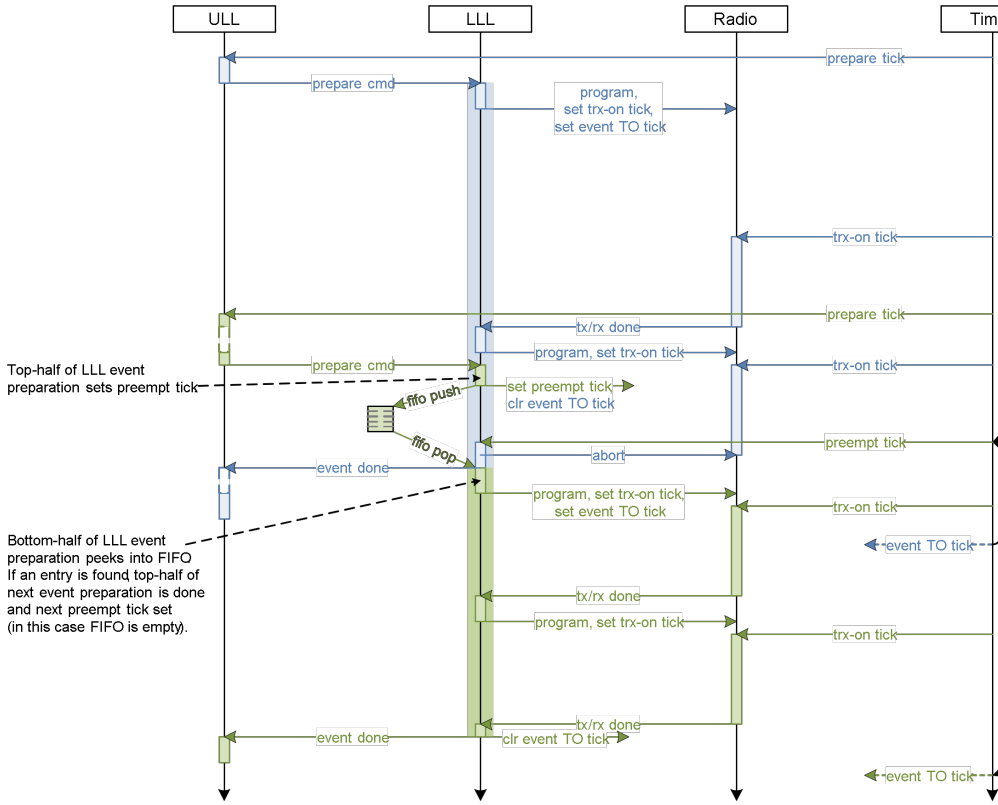
Scheduling Closely Spaced Events



Aborting Active Event

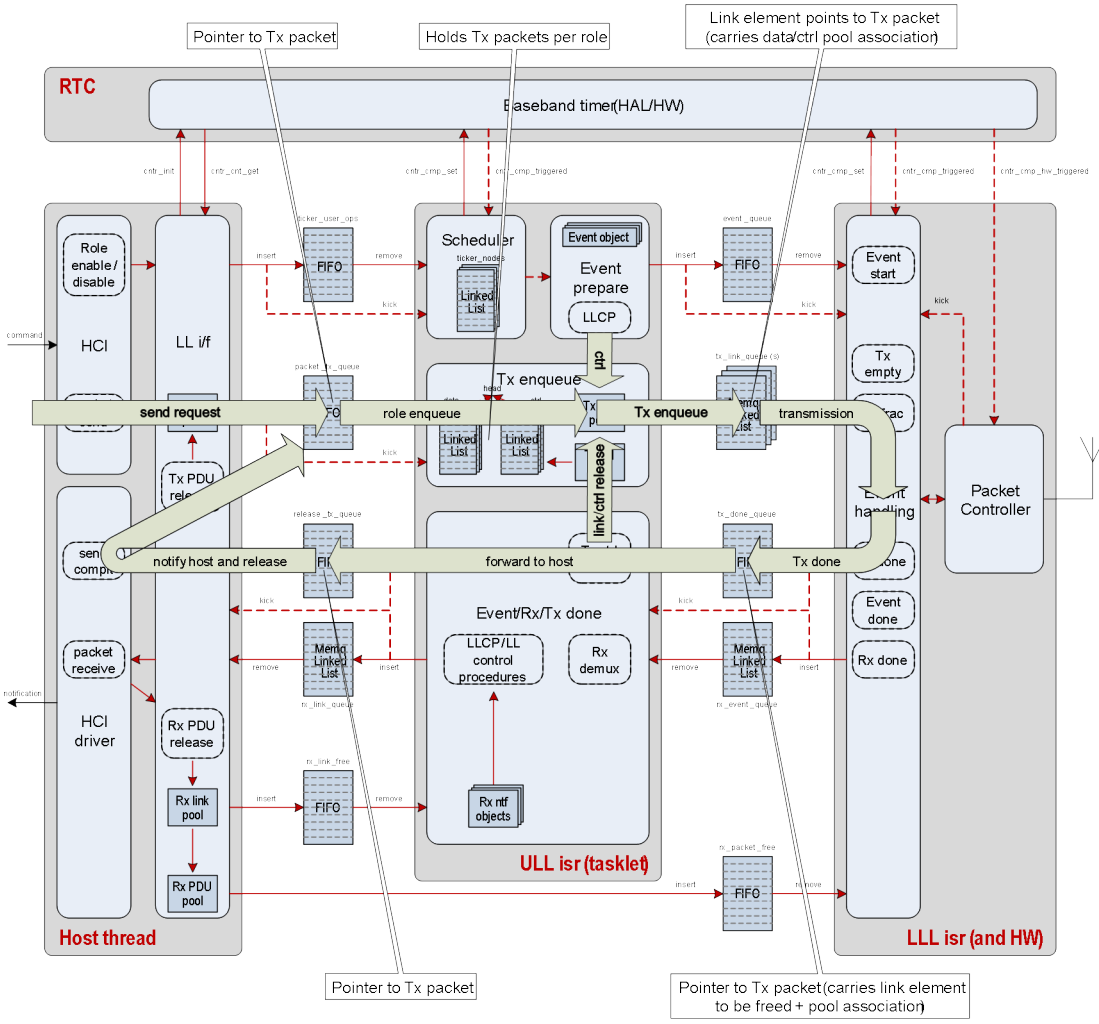


Cancelling Pending Event

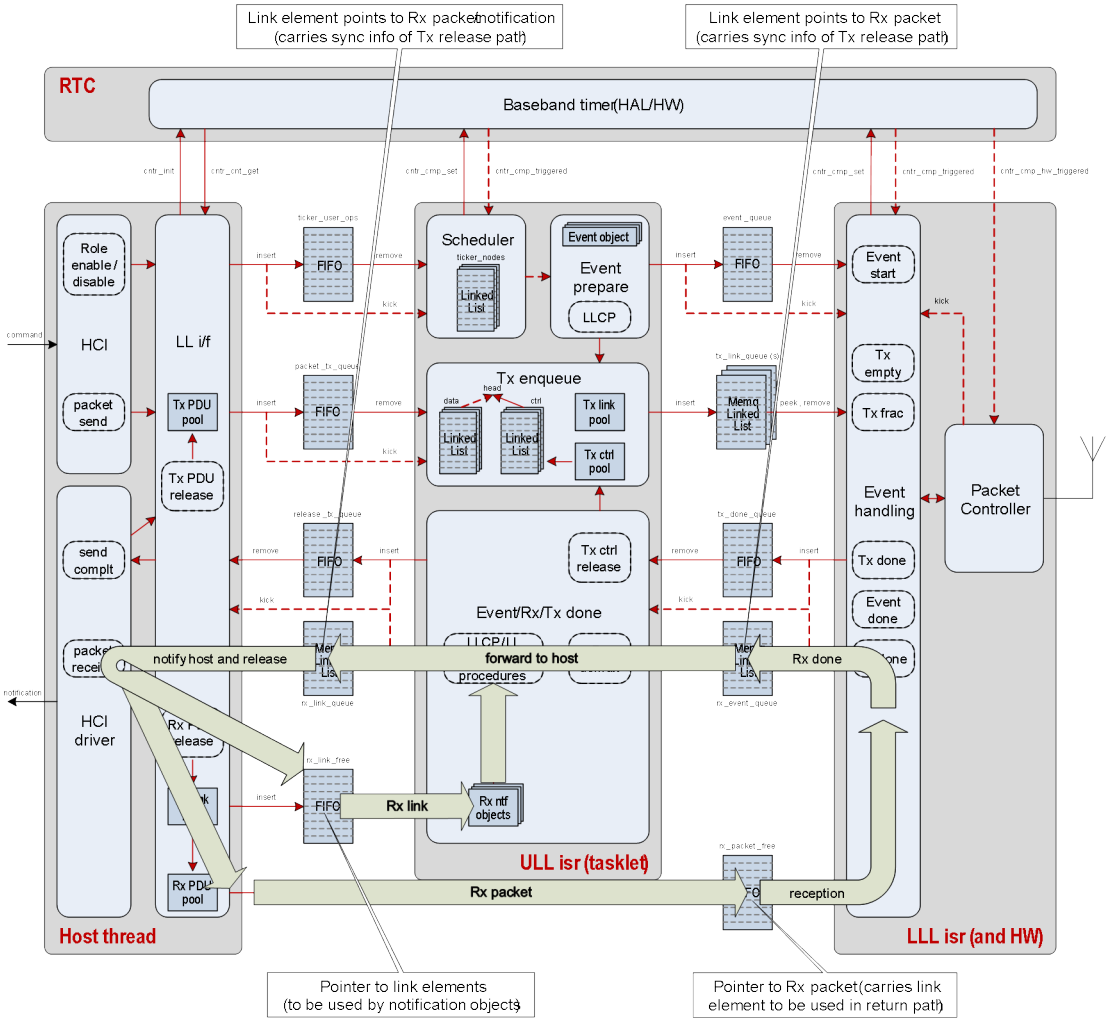


Pre-emption of Active Event

Data Flow

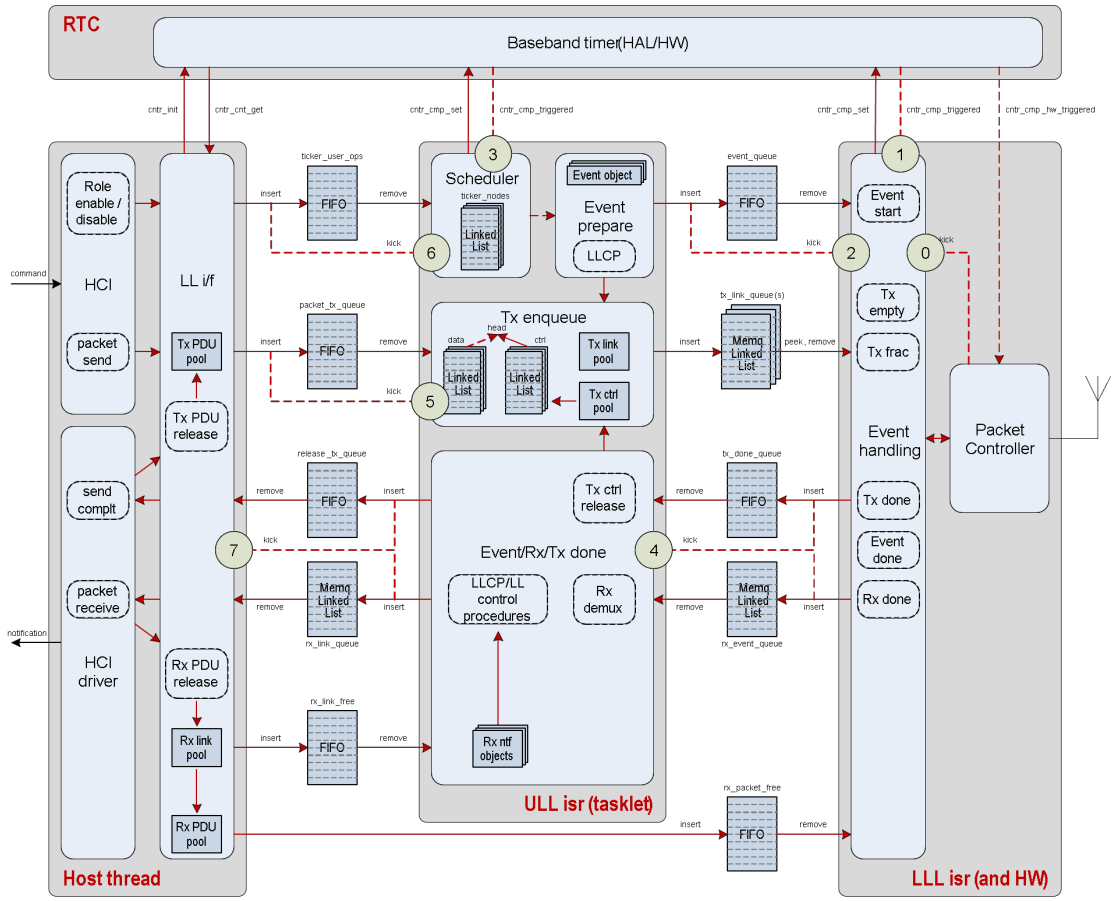


Transmit Data Flow



Receive Data Flow

Execution Priorities



- Event handle (0, 1) < Event preparation (2, 3) < Event/Rx done (4) < Tx request (5) < Role management (6) < Host (7).
- LLL is vendor ISR, ULL is Mayfly ISR concept, Host is kernel thread.

Link Layer Control Procedures

Following is a brief fly in on the main concepts in the implementation of control procedures handling in ULL.

Three main execution contexts

- **HCI/LLCP API**
  - Miscellaneous procedure initiation API
  - From ull_llcp.c::ull_cp_<proc>() for initiating local procedures
  - Interface with running procedures, local and remote
- **lll_prepare context to drive ull_cp_run()**
  - LLCP main state machine entry/tick'er
  - From ull_peripheral.c/ull_central.c::ticker_cb via ull_conn_llcp()
- **rx_demux context to drive ull_cp_tx_ack() and ull_cp_rx()**
  - LLCP tx ack handling and PDU reception
  - From ull_conn.c::ull_conn_rx()

  - Handles passing PDUs into running procedures as well as possibly initiating remote procedures

Data structures and PDU helpers

- **struct llcp_struct**
  - Main LLCP data store
  - Defined in ull_conn_types.h and declared as part of struct ll_conn
  - Holds local and remote procedure request queues as well as conn specific LLCP data
  - Basic conn-level abstraction
- **struct proc_ctx**
  - General procedure context data, contains miscellaneous procedure data and state as well as sys_snode_t for queueing
  - Defined in ull_llcp_internal.h, declared/instantiated through ull_llcp.c::create_procedure()
  - Also holds node references used in tx_ack as well as rx_node retention mechanisms
- **struct llcp_mem_pool**
  - Mem pool used to implement procedure contexts resource - instantiated in both a local and a remote version
  - Used through ull_llcp.c::create_procedure()
- **Miscellaneous pdu gymnastics**
  - Encoding and decoding of control pdus done by ull_llcp_pdu.c::llcp_pdu_encode/decode_<PDU>()
  - Miscellaneous pdu validation handled by ull_llcp.c::pdu_validate_<PDU>() via ull_llcp.c::pdu_is_valid()

LLCP local and remote request/procedure state machines

- **ull_llcp_local.c**
  - State machine handling local initiated procedures
  - Naming concept: lr _<...> => local request machine
  - Local procedure queue handling
  - Local run/rx/tx_ack switch
- **ull_llcp_remote.c**
  - Remote versions of the above
  - Naming concept: rr_<...> => remote request machine
  - Also handling of remote procedure initiation by llcp_rx_new()
  - Miscellaneous procedure collision handling (in rr_st_idle())
- **ull_llcp_common/conn_upd/phy/enc/cc/chmu.c**
  - Individual procedure implementations (ull_llcp_common.c collects the simpler ones)
  - Naming concept: lp_<...> => local initiated procedure, rp_<...> => remote initiated procedure

  - Handling of procedure flow from init (possibly through instant) to completion and host notification if applicable

Miscellaneous concepts

- **Procedure collision handling**
  - See BT spec for explanation
  - Basically some procedures can exist in parallel but some can't - for instance only one instant based at a time
  - Spec states rules for how to handle/resolve collisions when they happen
- **Termination handling**
  - Specific rules apply re. how termination is handled.
  - Since we have resource handling re. procedure contexts and terminate must always be available this is handled as a special case
  - Note also - there are miscellaneous cases where connection termination is triggered on invalid peer behavior
- **New remote procedure handling**
  - Table new_proc_lut[] maps LLCP PDUs to procedures/roles used in llcp_rr_new()
  - Note - for any given connection, there can only ever be ONE remote procedure in the remote procedure queue
- **Miscellaneous minors**
  - pause/resume concepts - there are two (see spec for details)
  - procedure execution can be paused by the encryption procedure
  - data TX can be paused by PHY, DLE and ENC procedure
  - RX node retention - ensures no waiting for allocation of RX node when needed for notification

Miscellaneous unit test concepts

- **Individual ZTEST unit test for each procedure**
  - zephyr/tests/bluetooth/controller/ctrl_<proc>
- **Rx node handling is mocked**
  - Different configs are handled by separate conf files (see ctrl_conn_update for example)
  - ZTEST(periph_rem_no_param_req, test_conn_update_periph_rem_accept_no_param_req)
- **Emulated versions of rx_demux/prepare context used in unit tests - testing ONLY procedure PDU flow**
  - event_prepare()/event_done() helpers emulating LLL prepare/done flow
  - lt_rx()/lt_tx() 'lower tester' emulation of rx/tx
  - ut_rx_node() 'upper tester' emulation of notification flow handling
  - Bunch of helpers to generate and parse PDUs, as well as miscellaneous mocked ull_stuff()

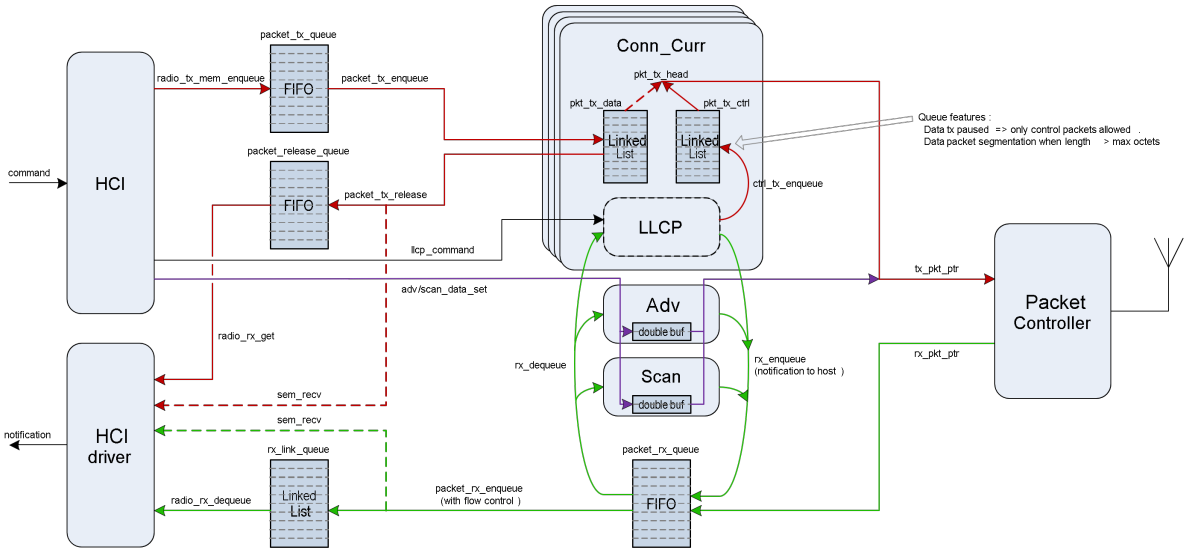
Legacy Controller



Bluetooth Low Energy Controller - Vendor Specific Details

Hardware Requirements

Nordic Semiconductor The Nordic Semiconductor Bluetooth Low Energy Controller implementation requires the following hardware peripherals.

Table 13: SoC Peripheral Use

Resource	nRF Peripheral	# instances	Zephyr Driver Accessible	Description
Clock	NRF_CLOCK	1	Yes	• A Low Frequency Clock (LFCLOCK) or sleep clock, for low power consumption between Bluetooth radio events • A High Frequency Clock (HFCLOCK) or active clock, for high precision packet timing and software based transceiver state switching with inter-frame space (tIFS) timing inside Bluetooth radio events
RTC [a]	NRF_RTC0	1	**No**	• Uses 2 capture/compare registers
Timer	NRF_TIMER0 or NRF_TIMER4 and NRF_TIMER1	2 or 1[Page 1215, 1]	**No**	• 2 instances, one each for packet timing and tIFS software switching, respectively • 7 capture/compare registers (3 mandatory, 1 optional for ISR profiling, 4 for single timer tIFS switching) on first instance • 4 capture/compare registers for second instance, if single tIFS timer is not used.
PPI [b]	NRF_PPI	21 channels (20[2]), and 2 channel groups[3]	Yes[4]	• Used for radio mode switching to achieve tIFS timings, for PA/LNA control
DPPI [c]	NRF_DPPI	20 channels, and 2 channel groups[Page 12]	Yes[Page 1]	• Used for radio mode switching to achieve tIFS timings, for PA/LNA control
SWI [d]	NRF_SWI4 and NRF_SWI5, or NRF_SWI2 and NRF_SWI3[5]	2	**No**	• 2 instances, for Lower Link Layer and Upper Link Layer Low priority execution context
Radio	NRF_RADIO	1	**No**	• 2.4 GHz radio transceiver with multiple radio standards such as 1 Mbps, 2 Mbps and Coded PHY S2/S8 Long Range Bluetooth Low Energy technology
RNG [e]	NRF_RNG	1	Yes	
ECB [f]	NRF_ECB	1	**No**	
CBC-CCM [g]	NRF_CCM	1	**No**	
AAR [h]	NRF_AAR	1	**No**	
GPIO [i]	NRF_GPIO	2 GPIO pins for PA and LNA, 1 each	Yes	• Additionally, 10 Debug GPIO pins (optional)
GPIOTE [j]	NRF_GPIOTE	1	Yes	• Used for PA/LNA
TEMP [k]	NRF_TEMP	1	Yes	• For RC sourced LFCLOCK calibration
UART [l]	NRF_UART0	1	Yes	• For HCI interface in Controller only builds
IPC [m]	NRF_IPC[Page	1	Yes	• For HCI interface in Controller only builds

6.1.8 Application Development

Bluetooth applications are developed using the common infrastructure and approach that is described in the *Application Development* section of the documentation.

Additional information that is only relevant to Bluetooth applications can be found on this page.

- *Thread safety*
- *Hardware setup*
  - *Embedded*
  - *Host on Linux with an external Controller*
  - *Simulated nRF5x with BabbleSim*
- *Initialization*
- *Bluetooth Application Example*
- *More Examples*

Thread safety

Calling into the Bluetooth API is intended to be thread safe, unless otherwise noted in the documentation of the API function. The effort to ensure that this is the case for all API calls is an ongoing one, but the overall goal is formally stated in this paragraph. Bug reports and Pull Requests that move the subsystem in the direction of such goal are welcome.

Hardware setup

This section describes the options you have when building and debugging Bluetooth applications with Zephyr. Depending on the hardware that is available to you, the requirements you have and the type of development you prefer you may pick one or another setup to match your needs.

There are 3 possible setups:

1. *Embedded*
2. *External controller*
   - *QEMU host*
   - *native_sim host*
3. *Simulated nRF5x with BabbleSim*

Embedded This setup relies on all software running directly on the embedded platform(s) that the application is targeting. All the *Configurations* and *Build Types* are supported but you might need to build Zephyr more than once if you are using a dual-chip configuration or if you have multiple cores in your SoC each running a different build type (e.g., one running the Host, the other the Controller).

To start developing using this setup follow the *Getting Started Guide*, choose one (or more if you are using a dual-chip solution) boards that support Bluetooth and then *run the application*).

[1] `CONFIG_BT_CTLR_SW_SWITCH_SINGLE_TIMER=y`
[0] `CONFIG_BT_CTLR_TIFS_HW=n`
[2] When not using pre-defined PPI channels
[3] For software-based tIFS switching
[4] Drivers that use nRFx interfaces
[5] For nRF53x Series

There is a way to access the *HCI* traffic between the Host and Controller, even if there is no physical transport. See *Embedded HCI tracing* for instructions.

Note

This is currently only available on GNU/Linux

Host on Linux with an external Controller This setup relies on a "dual-chip" *configuration* which is comprised of the following devices:

1. A *Host-only* application running in the *QEMU* emulator or the native_sim native port of Zephyr
2. A Controller, which can be one of the following types:
   - A commercially available Controller
   - A *Controller-only* build of Zephyr
   - A *Virtual controller*

Warning

Certain external Controllers are either unable to accept the Host to Controller flow control parameters that Zephyr sets by default (Qualcomm), or do not transmit any data from the Controller to the Host (Realtek). If you see a message similar to:

```
<wrn> bt_hci_core: opcode 0x0c33 status 0x12
```

when booting your sample of choice (make sure you have enabled `CONFIG_LOG` in your `prj.conf` before running the sample), or if there is no data flowing from the Controller to the Host, then you need to disable Host to Controller flow control. To do so, set `CONFIG_BT_HCI_ACL_FLOW_CONTROL=n` in your `prj.conf`.

QEMU You can run the Zephyr Host on the *QEMU emulator* and have it interact with a physical external Bluetooth Controller.

Refer to *Running on QEMU or native_sim* for full instructions on how to build and run an application in this setup.

Note

This is currently only available on GNU/Linux

native_sim The native_sim target builds your Zephyr application with the Zephyr kernel, and some minimal HW emulation as a native Linux executable.

This executable is a normal Linux program, which can be debugged and instrumented like any other, and it communicates with a physical or virtual external Controller. Refer to:

- *Running on QEMU or native_sim* for the physical controller
- *Running on a Virtual Controller and native_sim* for the virtual controller

Note

This is currently only available on GNU/Linux

Simulated nRF5x with BabbleSim The nrf52_bsim and nrf5340bsim boards, are simulated target boards which emulate the necessary peripherals of a nRF52/53 SOC to be able to develop and test Bluetooth LE applications. These boards, use:

- BabbleSim to simulate the nRF5x modem and the radio environment.
- The POSIX arch and native simulator to emulate the processor, and run natively on your host.
- Models of the nrf5x HW

Just like with the native_sim target, the build result is a normal Linux executable. You can find more information on how to run simulations with one or several devices in either of these boards's documentation.

With the nrf52_bsim, typically you do *Combined builds*, but it is also possible to build the controller with one of the bluetooth_hci_uart samples in one simulated device, and the host with the H4 driver instead of the integrated controller in another simulated device.

With the nrf5340bsim, you can build with either, both controller and host on its network core, or, with the network core running only the controller, the application core running the host and your application, and the HCI transport over IPC.

Initialization

The Bluetooth subsystem is initialized using the `bt_enable()` function. The caller should ensure that function succeeds by checking the return code for errors. If a function pointer is passed to `bt_enable()`, the initialization happens asynchronously, and the completion is notified through the given function.

Bluetooth Application Example

A simple Bluetooth beacon application is shown below. The application initializes the Bluetooth Subsystem and enables non-connectable advertising, effectively acting as a Bluetooth Low Energy broadcaster.

```

/*
 * Set Advertisement data. Based on the Eddystone specification:
 * https://github.com/google/eddystone/blob/master/protocol-specification.md
 * https://github.com/google/eddystone/tree/master/eddystone-url
 */
static const struct bt_data ad[] = {
        BT_DATA_BYTES(BT_DATA_FLAGS, BT_LE_AD_NO_BREDR),
        BT_DATA_BYTES(BT_DATA_UUID16_ALL, 0xaa, 0xfe),
        BT_DATA_BYTES(BT_DATA_SVC_DATA16,
                      0xaa, 0xfe, /* Eddystone UUID */
                      0x10, /* Eddystone-URL frame type */
                      0x00, /* Calibrated Tx power at 0m */
                      0x00, /* URL Scheme Prefix http://www. */
                      'z', 'e', 'p', 'h', 'y', 'r',
                      'p', 'r', 'o', 'j', 'e', 'c', 't',
                      0x08) /* .org */
};

```

(continues on next page)

(continued from previous page)

```
/* Set Scan Response data */
static const struct bt_data sd[] = {
        BT_DATA(BT_DATA_NAME_COMPLETE, DEVICE_NAME, DEVICE_NAME_LEN),
};

static void bt_ready(int err)
{
        char addr_s[BT_ADDR_LE_STR_LEN];
        bt_addr_le_t addr = {0};
        size_t count = 1;

        if (err) {
                printk("Bluetooth init failed (err %d)\n", err);
                return;
        }

        printk("Bluetooth initialized\n");

        /* Start advertising */
        err = bt_le_adv_start(BT_LE_ADV_NCONN_IDENTITY, ad, ARRAY_SIZE(ad),
                              sd, ARRAY_SIZE(sd));
        if (err) {
                printk("Advertising failed to start (err %d)\n", err);
                return;
        }

        /* For connectable advertising you would use
         * bt_le_oob_get_local().  For non-connectable non-identity
         * advertising an non-resolvable private address is used;
         * there is no API to retrieve that.
         */

        bt_id_get(&addr, &count);
        bt_addr_le_to_str(&addr, addr_s, sizeof(addr_s));

        printk("Beacon started, advertising as %s\n", addr_s);
}

int main(void)
{
        int err;

        printk("Starting Beacon Demo\n");

        /* Initialize the Bluetooth Subsystem */
        err = bt_enable(bt_ready);
        if (err) {
                printk("Bluetooth init failed (err %d)\n", err);
        }
        return 0;
}
```

The key APIs employed by the beacon sample are `bt_enable()` that's used to initialize Bluetooth and then `bt_le_adv_start()` that's used to start advertising a specific combination of advertising and scan response data.

More Examples

More sample Bluetooth applications are available in `samples/bluetooth/`.

6.1.9 API

Bluetooth Classic Host and profiles

Service Discovery Protocol (SDP)

API Reference

Service Discovery Protocol (SDP)

Bluetooth Logical Link Control and Adaptation Protocol (L2CAP) for BR/EDR L2CAP BR/EDR provides support for Bluetooth Classic L2CAP (Logical Link Control and Adaptation Protocol) features including ECHO request/response and connectionless data channels.

ECHO Request/Response The L2CAP ECHO feature allows testing the connection by sending ECHO requests and receiving ECHO responses. Applications can register callbacks to monitor ECHO packets and send ECHO data. The feature is enabled through the configuration option: `CONFIG_BT_CLASSIC`.

Registering ECHO Callbacks To monitor ECHO request/response packets, register a `bt_l2cap_br_echo_cb` callback structure:

```
static void echo_req_cb(struct bt_conn *conn, uint8_t identifier, struct net_buf␣
↪*buf)
{
    /* Handle ECHO request */
}

static void echo_rsp_cb(struct bt_conn *conn, struct net_buf *buf)
{
    /* Handle ECHO response */
}

static struct bt_l2cap_br_echo_cb echo_cb = {
    .req = echo_req_cb,
    .rsp = echo_rsp_cb,
};

bt_l2cap_br_echo_cb_register(&echo_cb);
```

Sending ECHO Request To send an ECHO request, allocate a buffer with `BT_L2CAP_BR_ECHO_REQ_RESERVE` bytes reserved for the L2CAP header:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_BR_ECHO_REQ_RESERVE);
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_echo_req(conn, buf);
```

Sending ECHO Response To send an ECHO response (typically in response to a received ECHO request), allocate a buffer with `BT_L2CAP_BR_ECHO_RSP_RESERVE` bytes reserved for the L2CAP header:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_BR_ECHO_RSP_RESERVE);
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_echo_rsp(conn, buf);
```

The identifier parameter must match the identifier from the received ECHO request to properly correlate the response with the request.

Connectionless Data Channel The connectionless data channel allows sending and receiving data to/from a specific PSM (Protocol/Service Multiplexer) without establishing a connection-oriented L2CAP channel. The feature is enabled through the configuration option: `CONFIG_BT_L2CAP_CONNLESS`.

Registering Connectionless Callbacks To receive connectionless data, register a `bt_l2cap_br_connless_cb` callback structure:

```
static void connless_recv_cb(struct bt_conn *conn, uint16_t psm, struct net_buf␣
↪*buf)
{
    /* Handle received connectionless data */
}

static struct bt_l2cap_br_connless_cb connless_cb = {
    .psm = MY_PSM,  /* Or 0 to receive all */
    .sec_level = BT_SECURITY_L1,
    .recv = connless_recv_cb,
};

bt_l2cap_br_connless_register(&connless_cb);
```

Sending Connectionless Data To send connectionless data, allocate a buffer with `BT_L2CAP_CONNLESS_RESERVE` bytes reserved:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_CONNLESS_RESERVE);
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_connless_send(conn, psm, buf);
```

Device Address

Defines and Assigned Numbers

Generic Attribute Profile (GATT) The GATT layer manages the service database providing APIs for service registration and attribute declaration.

The GATT Client initiates commands and requests towards the GATT Server, and can receive responses, indications and notifications sent by the server. It is enabled through the configuration option: `CONFIG_BT_GATT_CLIENT`

The GATT Server accepts incoming commands and requests from the GATT Client, and sends responses, indications and notifications to the client.

Services can be registered using the `bt_gatt_service_register()` API which takes the `bt_gatt_service` struct that provides the list of attributes the service contains. The helper macro `BT_GATT_SERVICE()` can be used to declare a service.

Attributes can be declared using the `bt_gatt_attr` struct or using one of the helper macros:

`BT_GATT_PRIMARY_SERVICE`
: Declares a Primary Service.

`BT_GATT_SECONDARY_SERVICE`
: Declares a Secondary Service.

`BT_GATT_INCLUDE_SERVICE`
: Declares a Include Service.

`BT_GATT_CHARACTERISTIC`
: Declares a Characteristic.

`BT_GATT_DESCRIPTOR`
: Declares a Descriptor.

`BT_GATT_ATTRIBUTE`
: Declares an Attribute.

`BT_GATT_CCC`
: Declares a Client Characteristic Configuration.

`BT_GATT_CEP`
: Declares a Characteristic Extended Properties.

`BT_GATT_CUD`
: Declares a Characteristic User Format.

Each attribute contain a `uuid`, which describes their type, a `read` callback, a `write` callback and a set of permission. Both read and write callbacks can be set to NULL if the attribute permission don't allow their respective operations.

Note

32-bit UUIDs are not supported in GATT. All 32-bit UUIDs shall be converted to 128-bit UUIDs when the UUID is contained in an ATT PDU.

Note

Attribute `read` and `write` callbacks are called directly from RX Thread thus it is not recommended to block for long periods of time in them.

Attribute value changes can be notified using `bt_gatt_notify()` API, alternatively there is `bt_gatt_notify_cb()` where it is possible to pass a callback to be called when it is necessary to know the exact instant when the data has been transmitted over the air. Indications are supported by `bt_gatt_indicate()` API.

Discover procedures can be initiated with the use of `bt_gatt_discover()` API which takes the `bt_gatt_discover_params` struct which describes the type of discovery. The parameters also serves as a filter when setting the `uuid` field only attributes which matches will be discovered, in contrast setting it to NULL allows all attributes to be discovered.

Note

Caching discovered attributes is not supported.

Read procedures are supported by `bt_gatt_read()` API which takes the `bt_gatt_read_params` struct as parameters. In the parameters one or more attributes can be set, though setting multiple handles requires the option: `CONFIG_BT_GATT_READ_MULTIPLE`

Write procedures are supported by `bt_gatt_write()` API and takes `bt_gatt_write_params` struct as parameters. In case the write operation don't require a response

`bt_gatt_write_without_response()` or `bt_gatt_write_without_response_cb()` APIs can be used, with the later working similarly to `bt_gatt_notify_cb()`.

Subscriptions to notification and indication can be initiated with use of `bt_gatt_subscribe()` API which takes `bt_gatt_subscribe_params` as parameters. Multiple subscriptions to the same attribute are supported so there could be multiple `notify` callback being triggered for the same attribute. Subscriptions can be removed with use of `bt_gatt_unsubscribe()` API.

Note

When subscriptions are removed `notify` callback is called with the data set to NULL.

Bluetooth Mesh

Bluetooth Mesh Profile The Bluetooth Mesh profile adds secure wireless multi-hop communication for Bluetooth Low Energy. This module implements the Bluetooth Mesh Protocol Specification v1.1.1.

Read more about Bluetooth Mesh on the Bluetooth SIG Website.

Core The core provides functionality for managing the general Bluetooth Mesh state.

Low Power Node The Low Power Node (LPN) role allows battery powered devices to participate in a mesh network as a leaf node. An LPN interacts with the mesh network through a Friend node, which is responsible for relaying any messages directed to the LPN. The LPN saves power by keeping its radio turned off, and only wakes up to either send messages or poll the Friend node for any incoming messages.

The radio control and polling is managed automatically by the mesh stack, but the LPN API allows the application to trigger the polling at any time through `bt_mesh_lpn_poll()`. The LPN operation parameters, including poll interval, poll event timing and Friend requirements is controlled through the `CONFIG_BT_MESH_LOW_POWER` option and related configuration options.

When using the LPN feature with logging, it is strongly recommended to only use the `CONFIG_LOG_MODE_DEFERRED` option. Log modes other than the deferred may cause unintended delays during processing of log messages. This in turns will affect scheduling of the receive delay and receive window. The same limitation applies for the `CONFIG_BT_MESH_FRIEND` option.

Replay Protection List The Replay Protection List (RPL) is used to hold recently received sequence numbers from elements within the mesh network to perform protection against replay attacks.

To keep a node protected against replay attacks after reboot, it needs to store the entire RPL in the persistent storage before it is powered off. Depending on the amount of traffic in a mesh network, storing recently seen sequence numbers can make flash wear out sooner or later. To mitigate this, `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` can be used. This option postpones storing of RPL entries in the persistent storage.

This option, however, doesn't completely solve the issue as the node may get powered off before the timer to store the RPL is fired. To ensure that messages can not be replayed, the node can initiate storage of the pending RPL entry (or entries) at any time (or sufficiently before power loss) by calling `bt_mesh_rpl_pending_store()`. This is up to the node to decide, which RPL entries are to be stored in this case.

Setting `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` to -1 allows to completely switch off the timer, which can help to significantly reduce flash wear out. This moves the responsibility of storing RPL to the user application and requires that sufficient power backup is available from the time this API is called until all RPL entries are written to the flash.

Finding the right balance between `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` and calling `bt_mesh_rpl_pending_store()` may reduce a risk of security vulnerability and flash wear out.

Persistent storage The mesh stack uses the *Settings Subsystem* for storing the device configuration persistently. When the stack configuration changes and the change needs to be stored persistently, the stack schedules a work item. The delay between scheduling the work item and submitting it to the workqueue is defined by the `CONFIG_BT_MESH_STORE_TIMEOUT` option. Once storing of data is scheduled, it can not be rescheduled until the work item is processed. Exceptions are made in certain cases as described below.

When IV index, Sequence Number or CDB configuration have to be stored, the work item is submitted to the workqueue without the delay. If the work item was previously scheduled, it will be rescheduled without the delay.

The Replay Protection List uses the same work item to store RPL entries. If storing of RPL entries is requested and no other configuration is pending to be stored, the delay is set to `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`. If other stack configuration has to be stored, the delay defined by the `CONFIG_BT_MESH_STORE_TIMEOUT` option is less than `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`, and the work item was scheduled by the Replay Protection List, the work item will be rescheduled.

When the work item is running, the stack will store all pending configuration, including the RPL entries.

Work item execution context The `CONFIG_BT_MESH_SETTINGS_WORKQ` option configures the context from which the work item is executed. This option is enabled by default, and results in stack using a dedicated cooperative thread to process the work item. This allows the stack to process other incoming and outgoing messages, as well as other work items submitted to the system workqueue, while the stack configuration is being stored.

When this option is disabled, the work item is submitted to the system workqueue. This means that the system workqueue is blocked for the time it takes to store the stack's configuration. It is not recommended to disable this option as this will make the device non-responsive for a noticeable amount of time.

Advertisement identity All mesh stack bearers advertise data with the `BT_ID_DEFAULT` local identity. The value is preset in the mesh stack implementation. When Bluetooth® Low Energy (LE) and Bluetooth Mesh coexist on the same device, the application should allocate and configure another local identity for Bluetooth LE purposes before starting the communication.

Access layer The access layer is the application's interface to the Bluetooth Mesh network. The access layer provides mechanisms for compartmentalizing the node behavior into elements and models, which are implemented by the application.

Mesh models The functionality of a mesh node is represented by models. A model implements a single behavior the node supports, like being a light, a sensor or a thermostat. The mesh models are grouped into *elements*. Each element is assigned its own unicast address, and may only contain one of each type of model. Conventionally, each element represents a single aspect of the mesh node behavior. For instance, a node that contains a sensor, two lights and a power outlet would spread this functionality across four elements, with each element instantiating all the models required for a single aspect of the supported behavior.

The node's element and model structure is specified in the node composition data, which is passed to `bt_mesh_init()` during initialization. The Bluetooth SIG have defined a set of foundation models (see *Mesh models*) and a set of models for implementing common behavior in the Bluetooth Mesh Model Specification. All models not specified by the Bluetooth SIG are vendor models, and must be tied to a Company ID.

Mesh models have several parameters that can be configured either through initialization of the mesh stack or with the *Configuration Server*:

Opcode list The opcode list contains all message opcodes the model can receive, as well as the minimum acceptable payload length and the callback to pass them to. Models can support any number of opcodes, but each opcode can only be listed by one model in each element.

The full opcode list must be passed to the model structure in the composition data, and cannot be changed at runtime. The end of the opcode list is determined by the special `BT_MESH_MODEL_OP_END` entry. This entry must always be present in the opcode list, unless the list is empty. In that case, `BT_MESH_MODEL_NO_OPS` should be used in place of a proper opcode list definition.

AppKey list The AppKey list contains all the application keys the model can receive messages on. Only messages encrypted with application keys in the AppKey list will be passed to the model.

The maximum number of supported application keys each model can hold is configured with the `CONFIG_BT_MESH_MODEL_KEY_COUNT` configuration option. The contents of the AppKey list is managed by the *Configuration Server*.

Subscription list A model will process all messages addressed to the unicast address of their element (given that the utilized application key is present in the AppKey list). Additionally, the model will process packets addressed to any group or virtual address in its subscription list. This allows nodes to address multiple nodes throughout the mesh network with a single message.

The maximum number of supported addresses in the Subscription list each model can hold is configured with the `CONFIG_BT_MESH_MODEL_GROUP_COUNT` configuration option. The contents of the subscription list is managed by the *Configuration Server*.

Model publication The models may send messages in two ways:

- By specifying a set of message parameters in a `bt_mesh_msg_ctx`, and calling `bt_mesh_model_send()`.
- By setting up a `bt_mesh_model_pub` structure and calling `bt_mesh_model_publish()`.

When publishing messages with `bt_mesh_model_publish()`, the model will use the publication parameters configured by the *Configuration Server*. This is the recommended way to send unprompted model messages, as it passes the responsibility of selecting message parameters to the network administrator, which likely knows more about the mesh network than the individual nodes will.

To support publishing with the publication parameters, the model must allocate a packet buffer for publishing, and pass it to `bt_mesh_model_pub.msg`. The Config Server may also set up period publication for the publication message. To support this, the model must populate the `bt_mesh_model_pub.update` callback. The `bt_mesh_model_pub.update` callback will be called right before the message is published, allowing the model to change the payload to reflect its current state.

By setting `bt_mesh_model_pub.retr_update` to 1, the model can configure the `bt_mesh_model_pub.update` callback to be triggered on every retransmission. This can, for example, be used by models that make use of a Delay parameter, which can be adjusted for every retransmission. The `bt_mesh_model_pub_is_retransmission()` function can be used to differentiate a first publication and a retransmission. The `BT_MESH_PUB_MSG_TOTAL` and

BT_MESH_PUB_MSG_NUM macros can be used to return total number of transmissions and the retransmission number within one publication interval.

Extended models The Bluetooth Mesh specification allows the mesh models to extend each other. When a model extends another, it inherits that model's functionality, and extension can be used to construct complex models out of simple ones, leveraging the existing model functionality to avoid defining new opcodes. Models may extend any number of models, from any element. When one model extends another in the same element, the two models will share subscription lists. The mesh stack implements this by merging the subscription lists of the two models into one, combining the number of subscriptions the models can have in total. Models may extend models that extend others, creating an "extension tree". All models in an extension tree share a single subscription list per element it spans.

Model extensions are done by calling bt_mesh_model_extend() during initialization. A model can only be extended by one other model, and extensions cannot be circular. Note that binding of node states and other relationships between the models must be defined by the model implementations.

The model extension concept adds some overhead in the access layer packet processing, and must be explicitly enabled with CONFIG_BT_MESH_MODEL_EXTENSIONS to have any effect.

Model data storage Mesh models may have data associated with each model instance that needs to be stored persistently. The access API provides a mechanism for storing this data, leveraging the internal model instance encoding scheme. Models can store one user defined data entry per instance by calling bt_mesh_model_data_store(). To be able to read out the data the next time the device reboots, the model's bt_mesh_model_cb.settings_set callback must be populated. This callback gets called when model specific data is found in the persistent storage. The model can retrieve the data by calling the read_cb passed as a parameter to the callback. See the *Settings* module documentation for details.

When model data changes frequently, storing it on every change may lead to increased wear of flash. To reduce the wear, the model can postpone storing of data by calling bt_mesh_model_data_store_schedule(). The stack will schedule a work item with delay defined by the CONFIG_BT_MESH_STORE_TIMEOUT option. When the work item is running, the stack will call the bt_mesh_model_cb.pending_store callback for every model that has requested storing of data. The model can then call bt_mesh_model_data_store() to store the data.

If CONFIG_BT_MESH_SETTINGS_WORKQ is enabled, the bt_mesh_model_cb.pending_store callback is called from a dedicated thread. This allows the stack to process other incoming and outgoing messages while model data is being stored. It is recommended to use this option and the bt_mesh_model_data_store_schedule() function when large amount of data needs to be stored.

Composition Data The Composition Data provides information about a mesh device. A device's Composition Data holds information about the elements on the device, the models that it supports, and other features. The Composition Data is split into different pages, where each page contains specific feature information about the device. In order to access this information, the user may use the *Configuration Server* model or, if supported, the *Large Composition Data Server* model.

Composition Data Page 0 Composition Data Page 0 provides the fundamental information about a device, and is mandatory for all mesh devices. It contains the element and model composition, the supported features, and manufacturer information.

Composition Data Page 1 Composition Data Page 1 provides information about the relationships between models, and is mandatory for all mesh devices. A model may extend and/or correspond to one or more models. A model can extend another model by calling bt_mesh_model_extend(), or correspond to another model by calling bt_mesh_model_correspond(). CONFIG_BT_MESH_MODEL_EXTENSION_LIST_SIZE specifies how

many model relations can be stored in the composition on a device, and this number should reflect the number of `bt_mesh_model_extend()` and `bt_mesh_model_correspond()` calls.

Composition Data Page 2 Composition Data Page 2 provides information for supported mesh profiles. Mesh profile specifications define product requirements for devices that want to support a specific Bluetooth SIG defined profile. Currently supported profiles can be found in section 3.12 in Bluetooth SIG Assigned Numbers. Composition Data Page 2 is only mandatory for devices that claim support for one or more mesh profile(s).

Composition Data Pages 128, 129 and 130 Composition Data Pages 128, 129 and 130 mirror Composition Data Pages 0, 1 and 2 respectively. They are used to represent the new content of the mirrored pages when the Composition Data will change after a firmware update. See *Composition Data and Models Metadata* for details.

Delayable messages The delayable message functionality is enabled with Kconfig option `CONFIG_BT_MESH_ACCESS_DELAYABLE_MSG`. This is an optional functionality that implements specification recommendations for messages that are transmitted by a model in a response to a received message, also called response messages.

Response messages should be sent with the following random delays:

- Between 20 and 50 milliseconds if the received message was sent to a unicast address
- Between 20 and 500 milliseconds if the received message was sent to a group or virtual address

The delayable message functionality is triggered if the `bt_mesh_msg_ctx.rnd_delay` flag is set. The delayable message functionality stores messages in the local memory while they are waiting for the random delay expiration.

If the transport layer doesn't have sufficient memory to send a message at the moment the random delay expires, the message is postponed for another 10 milliseconds. If the transport layer cannot send a message for any other reason, the delayable message functionality raises the `bt_mesh_send_cb.start` callback with a transport layer error code.

If the delayable message functionality cannot find enough free memory to store an incoming message, it will send messages with delay close to expiration to free memory.

When the mesh stack is suspended or reset, messages not yet sent are removed and the `bt_mesh_send_cb.start` callback is raised with an error code.

Note

When a model sends several messages in a row, it may happen that the messages are not sent in the order they were passed to the access layer. This is because some messages can be delayed for a longer time than the others.

Disable the randomization by setting the `bt_mesh_msg_ctx.rnd_delay` to `false`, when a set of messages originated by the same model needs to be sent in a certain order.

Delayable publications The delayable publication functionality implements the specification recommendations for message publication delays in the following cases:

- Between 20 to 500 milliseconds when the Bluetooth Mesh stack starts or when the publication is triggered by the `bt_mesh_model_publish()` function
- Between 20 to 50 milliseconds for periodically published messages

This feature is optional and enabled with the `CONFIG_BT_MESH_DELAYABLE_PUBLICATION` Kconfig option. When enabled, each model can enable or disable the delayable publication by setting the

`bt_mesh_model_pub.delayable` bit field to `1` or `0` correspondingly. This bit field can be changed at any time.

Access layer

Mesh models

Foundation models The Bluetooth Mesh specification defines foundation models that can be used by network administrators to configure and diagnose mesh nodes.

Bridge Configuration Client The Bridge Configuration Client is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_BRG_CFG_CLI` option.

The Bridge Configuration Client model provides functionality for configuring the subnet bridge functionality of another Mesh node containing the *Bridge Configuration Server*. The device key of the node containing the target Bridge Configuration Server is used for access layer security.

If present, the Bridge Configuration Client model must only be instantiated on the primary element.

API reference
Bridge Configuration Client Model

Bridge Configuration Server The Bridge Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_BRG_CFG_SRV` configuration option. This model extends the *Configuration Server* model.

The Bridge Configuration Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used for supporting and configuring the Subnet Bridge feature.

The Bridge Configuration Server model relies on a *Bridge Configuration Client* to configure it. The Bridge Configuration Server model only accepts messages encrypted with the node's device key.

If present, the Bridge Configuration Server model must be instantiated on the primary element.

The Bridge Configuration Server model provides access to the following three states:

- Subnet Bridge
- Bridging Table
- Bridging Table Size

For more information about the states, see *Subnet Bridge states*.

API reference
Bridge Configuration Server Model

Configuration Client The Configuration Client model is a foundation model defined by the Bluetooth Mesh specification. It provides functionality for configuring most parameters of a mesh node, including encryption keys, model configuration and feature enabling.

The Configuration Client model communicates with a *Configuration Server* model using the device key of the target node. The Configuration Client model may communicate with servers on other nodes or self-configure through the local Configuration Server model.

All configuration functions in the Configuration Client API have `net_idx` and `addr` as their first parameters. These should be set to the network index and primary unicast address that the target node was provisioned with.

The Configuration Client model is optional, and it must only be instantiated on the primary element if present in the Composition Data.

API reference
Configuration Client Model

Configuration Server The Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. The Configuration Server model controls most parameters of the mesh node. It does not have an API of its own, but relies on a *Configuration Client* to control it.

The Configuration Server model is mandatory on all Bluetooth Mesh nodes, and must only be instantiated on the primary element.

API reference
Configuration Server Model

Health Client The Health Client model interacts with a Health Server model to read out diagnostics and control the node's attention state.

All message passing functions in the Health Client API have `cli` as their first parameter. This is a pointer to the client model instance to be used in this function call. The second parameter is the `ctx` or message context. Message context contains netkey index, appkey index and unicast address that the target node uses.

The Health Client model is optional, and may be instantiated on any element. However, if a Health Client model is instantiated on an element other than the primary, an instance must also be present on the primary element.

See *Health faults* for a list of specification defined fault values.

API reference
Health Client Model

Health Server The Health Server model provides attention callbacks and node diagnostics for *Health Client* models. It is primarily used to report faults in the mesh node and map the mesh nodes to their physical location.

If present, the Health Server model must be instantiated on the primary element.

Faults The Health Server model may report a list of faults that have occurred in the device's lifetime. Typically, the faults are events or conditions that may alter the behavior of the node, like power outages or faulty peripherals. Faults are split into warnings and errors. Warnings indicate conditions that are close to the limits of what the node is designed to withstand, but not necessarily damaging to the device. Errors indicate conditions that are outside of the node's design limits, and may have caused invalid behavior or permanent damage to the device.

Fault values `0x01` to `0x7f` are reserved for the Bluetooth Mesh specification, and the full list of specification defined faults are available in *Health faults*. Fault values `0x80` to `0xff` are vendor specific. The list of faults are always reported with a company ID to help interpreting the vendor specific faults.

Attention state The attention state is used to make the device call attention to itself through some physical behavior like blinking, playing a sound or vibrating. The attention state may be used during provisioning to let the user know which device they're provisioning, as well as through the Health models at runtime.

The attention state is always assigned a timeout in the range of one to 255 seconds when enabled. The Health Server API provides two callbacks for the application to run their attention calling behavior: `bt_mesh_health_srv_cb.attn_on` is called at the beginning of the attention period, `bt_mesh_health_srv_cb.attn_off` is called at the end.

The remaining time for the attention period may be queried through `bt_mesh_health_srv.attn_timer`.

API reference
Health Server Model

Health faults Fault values defined by the Bluetooth Mesh specification.

Health faults

Large Composition Data Client The Large Composition Data Client model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_CLI` option.

The Large Composition Data Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the functionality of reading pages of Composition Data that do not fit in a Config Composition Data Status message and reading the metadata of the model instances on a node that supports the *Large Composition Data Server* model.

The Large Composition Data Client model communicates with a Large Composition Data Server model using the device key of the node containing the target Large Composition Data Server model instance.

If present, the Large Composition Data Client model must only be instantiated on the primary element.

API reference
Large Composition Data Client model

Large Composition Data Server The Large Composition Data Server model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_SRV` option.

The Large Composition Data Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of exposing pages of Composition Data that do not fit in a Config Composition Data Status message and to expose metadata of the model instances.

The Large Composition Data Server does not have an API of its own and relies on a *Large Composition Data Client* to control it. The model only accepts messages encrypted with the node's device key.

If present, the Large Composition Data Server model must only be instantiated on the primary element.

Models metadata The Large Composition Data Server model allows each model to have a list of model's specific metadata that can be read by the Large Composition Data Client model. The metadata list can be associated with the `bt_mesh_model` through the `bt_mesh_model.metadata` field. The metadata list consists of one or more entries defined

by the bt_mesh_models_metadata_entry structure. Each entry contains the length and ID of the metadata, and a pointer to the raw data. Entries can be created using the BT_MESH_MODELS_METADATA_ENTRY macro. The BT_MESH_MODELS_METADATA_END macro marks the end of the metadata list and must always be present. If the model has no metadata, the helper macro BT_MESH_MODELS_METADATA_NONE can be used instead.

API reference
Large Composition Data Server model

On-Demand Private Proxy Client The On-Demand Private Proxy Client model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled with the CONFIG_BT_MESH_OD_PRIV_PROXY_CLI option.

The On-Demand Private Proxy Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to set and retrieve the On-Demand Private GATT Proxy state. The state defines how long a node will advertise Mesh Proxy Service with Private Network Identity type after it receives a Solicitation PDU.

The On-Demand Private Proxy Client model communicates with an On-Demand Private Proxy Server model using the device key of the node containing the target On-Demand Private Proxy Server model instance.

If present, the On-Demand Private Proxy Client model must only be instantiated on the primary element.

Configurations The On-Demand Private Proxy Client model behavior can be configured with the transmission timeout option CONFIG_BT_MESH_OD_PRIV_PROXY_CLI_TIMEOUT. The CONFIG_BT_MESH_OD_PRIV_PROXY_CLI_TIMEOUT controls how long the Client waits for a state response message to arrive in milliseconds. This value can be changed at runtime using bt_mesh_od_priv_proxy_cli_timeout_set().

API reference
Bluetooth Mesh On-Demand Private GATT Proxy Client

On-Demand Private Proxy Server The On-Demand Private Proxy Server model is a foundation model defined by the Bluetooth Mesh specification. It is enabled with the CONFIG_BT_MESH_OD_PRIV_PROXY_SRV option.

The On-Demand Private Proxy Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the configuration of advertising with Private Network Identity type of a node that is a recipient of Solicitation PDUs by managing its On-Demand Private GATT Proxy state.

When enabled, the *Solicitation PDU RPL Configuration Server* is also enabled. The On-Demand Private Proxy Server is dependent on the *Private Beacon Server* to be present on the node.

The On-Demand Private Proxy Server does not have an API of its own, and relies on a *On-Demand Private Proxy Client* to control it. The On-Demand Private Proxy Server model only accepts messages encrypted with the node's device key.

If present, the On-Demand Private Proxy Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh On-Demand Private GATT Proxy Server

Opcodes Aggregator Client The Opcodes Aggregator Client model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_OP_AGG_CLI` option.

The Opcodes Aggregator Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of dispatching a sequence of access layer messages to nodes supporting the *Opcodes Aggregator Server* model.

The Opcodes Aggregator Client model communicates with an Opcodes Aggregator Server model using the device key of the target node or the application keys configured by the Configuration Client.

If present, the Opcodes Aggregator Client model must only be instantiated on the primary element.

The Opcodes Aggregator Client model is implicitly bound to the device key on initialization. It should be bound to the same application keys as the client models that are used to produce the sequence of messages.

To be able to aggregate a message from a client model, it should support an asynchronous API, for example through callbacks.

API reference
Opcodes Aggregator Client model

Opcodes Aggregator Server The Opcodes Aggregator Server model is a foundation model defined by the Bluetooth mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_OP_AGG_SRV` option.

The Opcodes Aggregator Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of processing a sequence of access layer messages.

The Opcodes Aggregator Server model accepts messages encrypted with the node's device key or the application keys.

If present, the Opcodes Aggregator Server model must only be instantiated on the primary element.

The targeted server models should be bound to the same application key that is used to encrypt the sequence of access layer messages sent to the Opcodes Aggregator Server.

The Opcodes Aggregator Server handles aggregated messages and dispatches them to the respective models and their message handlers. Current implementation assumes that responses are sent from the same execution context as the received message and doesn't allow to send a postponed response, for example from a work queue.

API reference
Opcodes Aggregator Server model

Private Beacon Client The Private Beacon Client model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_PRIV_BEACON_CLI` option.

The Private Beacon Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and provides functionality for configuring the *Private Beacon Server* models.

The Private Beacons feature adds privacy to the different Bluetooth Mesh beacons by periodically randomizing the beacon input data. This protects the mesh node from being tracked by devices outside the mesh network, and hides the network's IV index, IV update and the Key Refresh state.

The Private Beacon Client model communicates with a *Private Beacon Server* model using the device key of the target node. The Private Beacon Client model may communicate with servers on other nodes or self-configure through the local Private Beacon Server model.

All configuration functions in the Private Beacon Client API have `net_idx` and `addr` as their first parameters. These should be set to the network index and the primary unicast address the target node was provisioned with.

If present, the Private Beacon Client model must only be instantiated on the primary element.

API reference
Bluetooth Mesh Private Beacon Client

Private Beacon Server The Private Beacon Server model is a foundation model defined by the Bluetooth mesh specification. It is enabled with `CONFIG_BT_MESH_PRIV_BEACON_SRV` option.

The Private Beacon Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and controls the mesh node's Private Beacon state, Private GATT Proxy state and Private Node Identity state.

The Private Beacons feature adds privacy to the different Bluetooth Mesh beacons by periodically randomizing the beacon input data. This protects the mesh node from being tracked by devices outside the mesh network, and hides the network's IV index, IV update and the Key Refresh state. The Private Beacon Server must be instantiated for the device to support sending of the private beacons, but the node will process received private beacons without it.

The Private Beacon Server does not have an API of its own, but relies on a *Private Beacon Client* to control it. The Private Beacon Server model only accepts messages encrypted with the node's device key.

The application can configure the initial parameters of the Private Beacon Server model through the `bt_mesh_priv_beacon_srv` instance passed to `BT_MESH_MODEL_PRIV_BEACON_SRV`. Note that if the mesh node stored changes to this configuration in the settings subsystem, the initial values may be overwritten upon loading.

If present, the Private Beacon Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh Private Beacon Server

Remote Provisioning Client The Remote Provisioning Client model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_RPR_CLI` option.

The Remote Provisioning Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1. This model provides functionality to remotely provision devices into a mesh network, and perform Node Provisioning Protocol Interface procedures by interacting with mesh nodes that support the *Remote Provisioning Server* model.

The Remote Provisioning Client model communicates with a Remote Provisioning Server model using the device key of the node containing the target Remote Provisioning Server model instance.

If present, the Remote Provisioning Client model must be instantiated on the primary element.

Scanning The scanning procedure is used to scan for unprovisioned devices located nearby the Remote Provisioning Server. The Remote Provisioning Client starts a scan procedure by using the `bt_mesh_rpr_scan_start()` call:

```
static void rpr_scan_report(struct bt_mesh_rpr_cli *cli,
            const struct bt_mesh_rpr_node *srv,
            struct bt_mesh_rpr_unprov *unprov,
            struct net_buf_simple *adv_data)
{
```

(continues on next page)

(continued from previous page)

```
}

struct bt_mesh_rpr_cli rpr_cli = {
   .scan_report = rpr_scan_report,
};

const struct bt_mesh_rpr_node srv = {
   .addr = 0x0004,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

struct bt_mesh_rpr_scan_status status;
uint8_t *uuid = NULL;
uint8_t timeout = 10;
uint8_t max_devs = 3;

bt_mesh_rpr_scan_start(&rpr_cli, &srv, uuid, timeout, max_devs, &status);
```

The above example shows pseudo code for starting a scan procedure on the target Remote Provisioning Server node. This procedure will start a ten-second, multiple-device scanning where the generated scan report will contain a maximum of three unprovisioned devices. If the UUID argument was specified, the same procedure would only scan for the device with the corresponding UUID. After the procedure completes, the server sends the scan report that will be handled in the client's `bt_mesh_rpr_cli.scan_report` callback.

Additionally, the Remote Provisioning Client model also supports extended scanning with the `bt_mesh_rpr_scan_start_ext()` call. Extended scanning supplements regular scanning by allowing the Remote Provisioning Server to report additional data for a specific device. The Remote Provisioning Server will use active scanning to request a scan response from the unprovisioned device if it is supported by the unprovisioned device.

Provisioning The Remote Provisioning Client starts a provisioning procedure by using the `bt_mesh_provision_remote()` call:

```
struct bt_mesh_rpr_cli rpr_cli;

const struct bt_mesh_rpr_node srv = {
   .addr = 0x0004,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

uint8_t uuid[16] = { 0xaa };
uint16_t addr = 0x0006;
uint16_t net_idx = 0;

bt_mesh_provision_remote(&rpr_cli, &srv, uuid, net_idx, addr);
```

The above example shows pseudo code for remotely provisioning a device through a Remote Provisioning Server node. This procedure will attempt to provision the device with the corresponding UUID, and assign the address 0x0006 to its primary element using the network key located at index zero.

Note

During the remote provisioning, the same `bt_mesh_prov` callbacks are triggered as for ordinary provisioning. See section *Provisioning* for further details.

Re-provisioning In addition to scanning and provisioning functionality, the Remote Provisioning Client also provides means to reconfigure node addresses, device keys and Composition Data on devices that support the *Remote Provisioning Server* model. This is provided through the Node Provisioning Protocol Interface (NPPI) which supports the following three procedures:

- Device Key Refresh procedure: Used to change the device key of the Target node without a need to reconfigure the node.
- Node Address Refresh procedure: Used to change the node's device key and unicast address.
- Node Composition Refresh procedure: Used to change the device key of the node, and to add or delete models or features of the node.

The three NPPI procedures can be initiated with the `bt_mesh_reprovision_remote()` call:

```
struct bt_mesh_rpr_cli rpr_cli;
struct bt_mesh_rpr_node srv = {
   .addr = 0x0006,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

bool composition_changed = false;
uint16_t new_addr = 0x0009;

bt_mesh_reprovision_remote(&rpr_cli, &srv, new_addr, composition_changed);
```

The above example shows pseudo code for triggering a Node Address Refresh procedure on the Target node. The specific procedure is not chosen directly, but rather through the other parameters that are inputted. In the example we can see that the current unicast address of the Target is 0x0006, while the new address is set to 0x0009. If the two addresses were the same, and the `composition_changed` flag was set to true, this code would instead trigger a Node Composition Refresh procedure. If the two addresses were the same, and the `composition_changed` flag was set to false, this code would trigger a Device Key Refresh procedure.

API reference

Remote Provisioning Client model

Remote Provisioning Server The Remote Provisioning Server model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_RPR_SRV` option.

The Remote Provisioning Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of remotely provisioning devices into a mesh network.

The Remote Provisioning Server does not have an API of its own, but relies on a *Remote Provisioning Client* to control it. The Remote Provisioning Server model only accepts messages encrypted with the node's device key.

If present, the Remote Provisioning Server model must be instantiated on the primary element.

Note that after refreshing the device key, node address or Composition Data through a Node Provisioning Protocol Interface (NPPI) procedure, the `bt_mesh_prov.reprovisioned` callback is triggered. See section *Remote Provisioning Client* for further details.

Limitations The following limitations apply to Remote Provisioning Server model:

- Provisioning of unprovisioned device using PB-GATT is not supported.
- All Node Provisioning Protocol Interface (NPPI) procedures are supported. However, if the composition data of a device gets changed after device firmware update (see *firmware effect*), it is not possible for the device to remain provisioned. The device should be unprovisioned if its composition data is expected to change.

API reference
Remote provisioning server

SAR Configuration Client The SAR Configuration Client model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_SAR_CFG_CLI` configuration option.

The SAR Configuration Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and it supports the configuration of the lower transport layer behavior of a node that supports the *SAR Configuration Server* model.

The model can send messages to query or change the states supported by the SAR Configuration Server (SAR Transmitter and SAR Receiver) using SAR Configuration messages.

The SAR Transmitter procedure is used to determine and configure the SAR Transmitter state of a SAR Configuration Server. Function calls `bt_mesh_sar_cfg_cli_transmitter_get()` and `bt_mesh_sar_cfg_cli_transmitter_set()` are used to get and set the SAR Transmitter state of the Target node respectively.

The SAR Receiver procedure is used to determine and configure the SAR Receiver state of a SAR Configuration Server. Function calls `bt_mesh_sar_cfg_cli_receiver_get()` and `bt_mesh_sar_cfg_cli_receiver_set()` are used to get and set the SAR Receiver state of the Target node respectively.

For more information about the two states, see *SAR states*.

An element can send any SAR Configuration Client message at any time to query or change the states supported by the SAR Configuration Server model of a peer node. The SAR Configuration Client model only accepts messages encrypted with the device key of the node supporting the SAR Configuration Server model.

If present, the SAR Configuration Client model must only be instantiated on the primary element.

API reference
Bluetooth Mesh SAR Configuration Client Model

SAR Configuration Server The SAR Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_SAR_CFG_SRV` configuration option.

The SAR Configuration Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and it supports the configuration of the *segmentation and reassembly (SAR)* behavior of a Bluetooth Mesh node. The model defines a set of states and messages for the SAR configuration.

The SAR Configuration Server model defines two states, SAR Transmitter state and SAR Receiver state. For more information about the two states, see *SAR states*.

The model also supports the SAR Transmitter and SAR Receiver get and set messages.

The SAR Configuration Server model does not have an API of its own, but relies on a *SAR Configuration Client* to control it. The SAR Configuration Server model only accepts messages encrypted with the node's device key.

If present, the SAR Configuration Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh SAR Configuration Server Model

Solicitation PDU RPL Configuration Client The Solicitation PDU RPL Configuration Client model is a foundation model defined by the Bluetooth mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_SOL_PDU_RPL_CLI` option.

The Solicitation PDU RPL Configuration Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the functionality of removing addresses from the solicitation replay protection list (SRPL) of a node that supports the *Solicitation PDU RPL Configuration Server* model.

The Solicitation PDU RPL Configuration Client model communicates with a Solicitation PDU RPL Configuration Server model using the application keys configured by the Configuration Client.

If present, the Solicitation PDU RPL Configuration Client model must only be instantiated on the primary element.

Configurations The Solicitation PDU RPL Configuration Client model behavior can be configured with the transmission timeout option `CONFIG_BT_MESH_SOL_PDU_RPL_CLI_TIMEOUT`. The `CONFIG_BT_MESH_SOL_PDU_RPL_CLI_TIMEOUT` controls how long the Solicitation PDU RPL Configuration Client waits for a response message to arrive in milliseconds. This value can be changed at runtime using `bt_mesh_sol_pdu_rpl_cli_timeout_set()`.

API reference
Bluetooth Mesh Solicitation PDU RPL Client

Solicitation PDU RPL Configuration Server The Solicitation PDU RPL Configuration Server model is a foundation model defined by the Bluetooth mesh specification. The model is enabled if the node has the *On-Demand Private Proxy Server* enabled.

The Solicitation PDU RPL Configuration Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and manages the Solicitation Replay Protection List (SRPL) saved on the device. The SRPL is used to reject Solicitation PDUs that are already processed by a node. When a valid Solicitation PDU message is successfully processed by a node, the SSRC field and SSEQ field of the message are stored in the node's SRPL.

The Solicitation PDU RPL Configuration Server does not have an API of its own, and relies on a *Solicitation PDU RPL Configuration Client* to control it. The model only accepts messages encrypted with an application key as configured by the Configuration Client.

If present, the Solicitation PDU RPL Configuration Server model must only be instantiated on the primary element.

Configurations For the Solicitation PDU RPL Configuration Server model, the `CONFIG_BT_MESH_PROXY_SRPL_SIZE` option can be configured to set the size of the SRPL.

API reference
Bluetooth Mesh Solicitation PDU RPL Server

Model specification models In addition to the foundation models defined in the Bluetooth Mesh specification, the Bluetooth Mesh Model Specification defines several models, some of which are implemented in Zephyr:

BLOB Transfer models The Binary Large Object (BLOB) Transfer models implement the Bluetooth Mesh Binary Large Object Transfer Model specification version 1.0 and provide functionality for sending large binary objects from a single source to many Target nodes over the Bluetooth Mesh network. It is the underlying transport method for the *Device Firmware Update (DFU)*, but may be used for other object transfer purposes. The implementation is in experimental state.

The BLOB Transfer models support transfers of continuous binary objects of up to 4 GB (2^{32} bytes). The BLOB transfer protocol has built-in recovery procedures for packet losses, and sets up checkpoints to ensure that all targets have received all the data before moving on. Data transfer order is not guaranteed.

BLOB transfers are constrained by the transfer speed and reliability of the underlying mesh network. Under ideal conditions, the BLOBs can be transferred at a rate of up to 1 kbps, allowing a 100 kB BLOB to be transferred in 10-15 minutes. However, network conditions, transfer capabilities and other limiting factors can easily degrade the data rate by several orders of magnitude. Tuning the parameters of the transfer according to the application and network configuration, as well as scheduling it to periods with low network traffic, will offer significant improvements on the speed and reliability of the protocol. However, achieving transfer rates close to the ideal rate is unlikely in actual deployments.

There are two BLOB Transfer models:

BLOB Transfer Server The Binary Large Object (BLOB) Transfer Server model implements reliable receiving of large binary objects. It serves as the backend of the *Firmware Update Server*, but can also be used for receiving other binary images.

BLOBs As described in *BLOB Transfer models*, the binary objects transferred by the BLOB Transfer models are divided into blocks, which are divided into chunks. As the transfer is controlled by the BLOB Transfer Client model, the BLOB Transfer Server must allow blocks to come in any order. The chunks within a block may also come in any order, but all chunks in a block must be received before the next block is started.

The BLOB Transfer Server keeps track of the received blocks and chunks, and will process each block and chunk only once. The BLOB Transfer Server also ensures that any missing chunks are resent by the BLOB Transfer Client.

Usage The BLOB Transfer Server is instantiated on an element with a set of event handler callbacks:

```
static const struct bt_mesh_blob_srv_cb blob_cb = {
    /* Callbacks */
};

static struct bt_mesh_blob_srv blob_srv = {
    .cb = &blob_cb,
};

static const struct bt_mesh_model models[] = {
    BT_MESH_MODEL_BLOB_SRV(&blob_srv),
};
```

A BLOB Transfer Server is capable of receiving a single BLOB transfer at a time. Before the BLOB Transfer Server can receive a transfer, it must be prepared by the user. The transfer ID must be passed to the BLOB Transfer Server through the `bt_mesh_blob_srv_recv()` function before the transfer is started by the BLOB Transfer Client. The ID must be shared between the BLOB Transfer Client and the BLOB Transfer Server through some higher level procedure, like a vendor specific transfer management model.

Once the transfer has been set up on the BLOB Transfer Server, it's ready for receiving the BLOB. The application is notified of the transfer progress through the event handler callbacks, and the BLOB data is sent to the BLOB stream.

The interaction between the BLOB Transfer Server, BLOB stream and application is shown below:

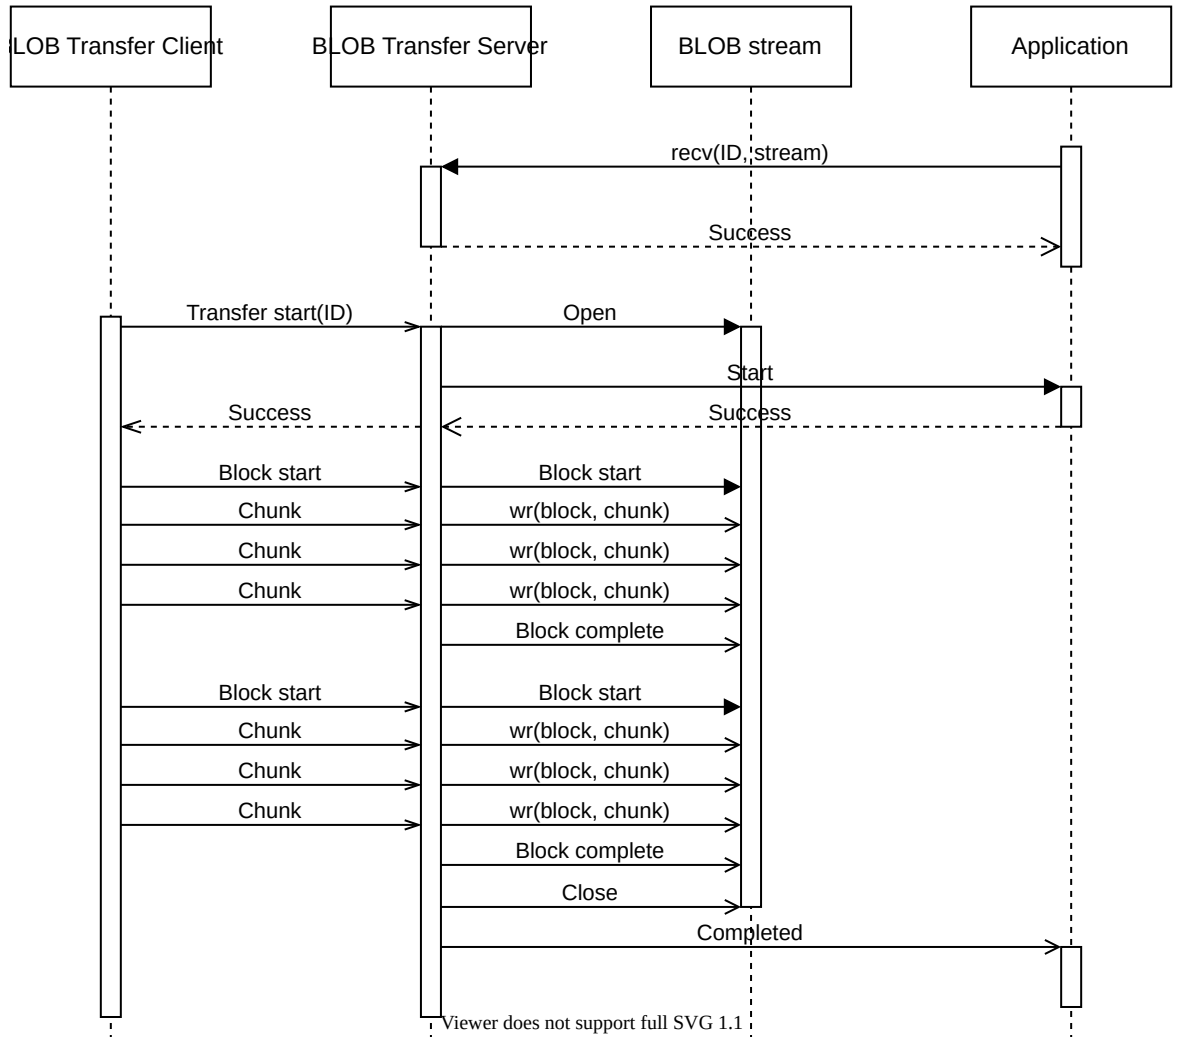

Fig. 8: BLOB Transfer Server model interaction

Transfer suspension The BLOB Transfer Server keeps a running timer during the transfer, that is reset on every received message. If the BLOB Transfer Client does not send a message before the transfer timer expires, the transfer is suspended by the BLOB Transfer Server.

The BLOB Transfer Server notifies the user of the suspension by calling the `suspended` callback. If the BLOB Transfer Server is in the middle of receiving a block, this block is discarded.

The BLOB Transfer Client may resume a suspended transfer by starting a new block transfer. The BLOB Transfer Server notifies the user by calling the `resume` callback.

Transfer recovery The state of the BLOB transfer is stored persistently. If a reboot occurs, the BLOB Transfer Server will attempt to recover the transfer. When the Bluetooth Mesh subsystem is started (for instance by calling `bt_mesh_init()`), the BLOB Transfer Server will check for aborted transfers, and call the `recover` callback if there is any. In the recover callback, the user must provide a BLOB stream to use for the rest of the transfer. If the recover callback doesn't return successfully or does not provide a BLOB stream, the transfer is abandoned. If no recover callback is implemented, transfers are always abandoned after a reboot.

After a transfer is successfully recovered, the BLOB Transfer Server enters the suspended state. It will stay suspended until the BLOB Transfer Client resumes the transfer, or the user cancels it.

Note

The BLOB Transfer Client sending the transfer must support transfer recovery for the transfer to complete. If the BLOB Transfer Client has already given up the transfer, the BLOB Transfer Server will stay suspended until the application calls `bt_mesh_blob_srv_cancel()`.

API reference

Bluetooth Mesh BLOB Transfer Server model API

BLOB Transfer Client The Binary Large Object (BLOB) Transfer Client is the sender of the BLOB transfer. It supports sending BLOBs of any size to any number of Target nodes, in both Push BLOB Transfer Mode and Pull BLOB Transfer Mode.

Usage

Initialization The BLOB Transfer Client is instantiated on an element with a set of event handler callbacks:

```
static const struct bt_mesh_blob_cli_cb blob_cb = {
      /* Callbacks */
};

static struct bt_mesh_blob_cli blob_cli = {
      .cb = &blob_cb,
};

static const struct bt_mesh_model models[] = {
      BT_MESH_MODEL_BLOB_CLI(&blob_cli),
};
```

Transfer context Both the transfer capabilities retrieval procedure and the BLOB transfer uses an instance of a `bt_mesh_blob_cli_inputs` to determine how to perform the transfer. The BLOB Transfer Client Inputs structure must at least be initialized with a list of targets, an application key and a time to live (TTL) value before it is used in a procedure:

```
static struct bt_mesh_blob_target targets[3] = {
        { .addr = 0x0001 },
        { .addr = 0x0002 },
        { .addr = 0x0003 },
};
static struct bt_mesh_blob_cli_inputs inputs = {
        .app_idx = MY_APP_IDX,
        .ttl = BT_MESH_TTL_DEFAULT,
};

sys_slist_init(&inputs.targets);
sys_slist_append(&inputs.targets, &targets[0].n);
sys_slist_append(&inputs.targets, &targets[1].n);
sys_slist_append(&inputs.targets, &targets[2].n);
```

Note that all BLOB Transfer Servers in the transfer must be bound to the chosen application key.

Group address The application may additionally specify a group address in the context structure. If the group is not `BT_MESH_ADDR_UNASSIGNED`, the messages in the transfer will be sent to the group address, instead of being sent individually to each Target node. Mesh Manager must ensure that all Target nodes having the BLOB Transfer Server model subscribe to this group address.

Using group addresses for transferring the BLOBs can generally increase the transfer speed, as the BLOB Transfer Client sends each message to all Target nodes at the same time. However, sending large, segmented messages to group addresses in Bluetooth Mesh is generally less reliable than sending them to unicast addresses, as there is no transport layer acknowledgment mechanism for groups. This can lead to longer recovery periods at the end of each block, and increases the risk of losing Target nodes. Using group addresses for BLOB transfers will generally only pay off if the list of Target nodes is extensive, and the effectiveness of each addressing strategy will vary heavily between different deployments and the size of the chunks.

Transfer timeout If a Target node fails to respond to an acknowledged message within the BLOB Transfer Client's time limit, the Target node is dropped from the transfer. The application can reduce the chances of this by giving the BLOB Transfer Client extra time through the context structure. The extra time may be set in 10-second increments, up to 182 hours, in addition to the base time of 20 seconds. The wait time scales automatically with the transfer TTL.

Note that the BLOB Transfer Client only moves forward with the transfer in following cases:

- All Target nodes have responded.
- A node has been removed from the list of Target nodes.
- The BLOB Transfer Client times out.

Increasing the wait time will increase this delay.

BLOB transfer capabilities retrieval It is generally recommended to retrieve BLOB transfer capabilities before starting a transfer. The procedure populates the transfer capabilities from all Target nodes with the most liberal set of parameters that allows all Target nodes to participate in the transfer. Any Target nodes that fail to respond, or respond with incompatible transfer parameters, will be dropped.

Target nodes are prioritized according to their order in the list of Target nodes. If a Target node is found to be incompatible with any of the previous Target nodes, for instance by reporting a non-overlapping block size range, it will be dropped. Lost Target nodes will be reported through the `lost_target` callback.

The end of the procedure is signalled through the `caps` callback, and the resulting capabilities can be used to determine the block and chunk sizes required for the BLOB transfer.

BLOB transfer The BLOB transfer is started by calling `bt_mesh_blob_cli_send()` function, which (in addition to the aforementioned transfer inputs) requires a set of transfer parameters and a BLOB stream instance. The transfer parameters include the 64-bit BLOB ID, the BLOB size, the transfer mode, the block size in logarithmic representation and the chunk size. The BLOB ID is application defined, but must match the BLOB ID the BLOB Transfer Servers have been started with.

The transfer runs until it either completes successfully for at least one Target node, or it is cancelled. The end of the transfer is communicated to the application through the `end` callback. Lost Target nodes will be reported through the `lost_target` callback.

API reference

Bluetooth Mesh BLOB Transfer Client model API

The BLOB Transfer Client is instantiated on the sender node, and the BLOB Transfer Server is instantiated on the receiver nodes.

Concepts The BLOB transfer protocol introduces several new concepts to implement the BLOB transfer.

BLOBs BLOBs are binary objects up to 4 GB in size, that can contain any data the application would like to transfer through the mesh network. The BLOBs are continuous data objects, divided into blocks and chunks to make the transfers reliable and easy to process. No limitations are put on the contents or structure of the BLOB, and applications are free to define any encoding or compression they'd like on the data itself.

The BLOB transfer protocol does not provide any built-in integrity checks, encryption or authentication of the BLOB data. However, the underlying encryption of the Bluetooth Mesh protocol provides data integrity checks and protects the contents of the BLOB from third parties using network and application level encryption.

Blocks The binary objects are divided into blocks, typically from a few hundred to several thousand bytes in size. Each block is transmitted separately, and the BLOB Transfer Client ensures that all BLOB Transfer Servers have received the full block before moving on to the next. The block size is determined by the transfer's `block_size_log` parameter, and is the same for all blocks in the transfer except the last, which may be smaller. For a BLOB stored in flash memory, the block size is typically a multiple of the flash page size of the Target devices.

Chunks Each block is divided into chunks. A chunk is the smallest data unit in the BLOB transfer, and must fit inside a single Bluetooth Mesh access message excluding the opcode (379 bytes or less). The mechanism for transferring chunks depends on the transfer mode.

When operating in Push BLOB Transfer Mode, the chunks are sent as unacknowledged packets from the BLOB Transfer Client to all targeted BLOB Transfer Servers. Once all chunks in a block have been sent, the BLOB Transfer Client asks each BLOB Transfer Server if they're missing any chunks, and resends them. This is repeated until all BLOB Transfer Servers have received all chunks, or the BLOB Transfer Client gives up.

When operating in Pull BLOB Transfer Mode, the BLOB Transfer Server will request a small number of chunks from the BLOB Transfer Client at a time, and wait for the BLOB Transfer Client to send them before requesting more chunks. This repeats until all chunks have been transferred, or the BLOB Transfer Server gives up.

Read more about the transfer modes in *Transfer modes* section.

BLOB streams In the BLOB Transfer models' APIs, the BLOB data handling is separated from the high-level transfer handling. This split allows reuse of different BLOB storage and transfer strategies for different applications. While the high level transfer is controlled directly by the application, the BLOB data itself is accessed through a *BLOB stream*.

The BLOB stream is comparable to a standard library file stream. Through opening, closing, reading and writing, the BLOB Transfer model gets full access to the BLOB data, whether it's kept in flash, RAM, or on a peripheral. The BLOB stream is opened with an access mode (read or write) before it's used, and the BLOB Transfer models will move around inside the BLOB's data in blocks and chunks, using the BLOB stream as an interface.

Interaction Before the BLOB is read or written, the stream is opened by calling its `open` callback. When used with a BLOB Transfer Server, the BLOB stream is always opened in write mode, and when used with a BLOB Transfer Client, it's always opened in read mode.

For each block in the BLOB, the BLOB Transfer model starts by calling `block_start`. Then, depending on the access mode, the BLOB stream's `wr` or `rd` callback is called repeatedly to move data to or from the BLOB. When the model is done processing the block, it calls `block_end`. When the transfer is complete, the BLOB stream is closed by calling `close`.

Implementations The application may implement their own BLOB stream, or use the implementations provided by Zephyr:

BLOB Flash The BLOB Flash Readers and Writers implement BLOB reading to and writing from flash partitions defined in the *flash map*.

BLOB Flash Reader The BLOB Flash Reader interacts with the BLOB Transfer Client to read BLOB data directly from flash. It must be initialized by calling `bt_mesh_blob_flash_rd_init()` before being passed to the BLOB Transfer Client. Each BLOB Flash Reader only supports one transfer at the time.

BLOB Flash Writer The BLOB Flash Writer interacts with the BLOB Transfer Server to write BLOB data directly to flash. It must be initialized by calling `bt_mesh_blob_flash_rd_init()` before being passed to the BLOB Transfer Server. Each BLOB Flash Writer only supports one transfer at the time, and requires a block size that is a multiple of the flash page size. If a transfer is started with a block size lower than the flash page size, the transfer will be rejected.

The BLOB Flash Writer copies chunk data into a buffer to accommodate chunks that are unaligned with the flash write block size. The buffer data is padded with `0xff` if either the start or length of the chunk is unaligned.

API Reference
Bluetooth Mesh BLOB flash stream

Transfer capabilities Each BLOB Transfer Server may have different transfer capabilities. The transfer capabilities of each device are controlled through the following configuration options:

- `CONFIG_BT_MESH_BLOB_SIZE_MAX`
- `CONFIG_BT_MESH_BLOB_BLOCK_SIZE_MIN`
- `CONFIG_BT_MESH_BLOB_BLOCK_SIZE_MAX`
- `CONFIG_BT_MESH_BLOB_CHUNK_COUNT_MAX`

The `CONFIG_BT_MESH_BLOB_CHUNK_COUNT_MAX` option is also used by the BLOB Transfer Client and affects memory consumption by the BLOB Transfer Client model structure.

To ensure that the transfer can be received by as many servers as possible, the BLOB Transfer Client can retrieve the capabilities of each BLOB Transfer Server before starting the transfer. The client will transfer the BLOB with the highest possible block and chunk size.

Transfer modes BLOBs can be transferred using two transfer modes, Push BLOB Transfer Mode and Pull BLOB Transfer Mode. In most cases, the transfer should be conducted in Push BLOB Transfer Mode.

In Push BLOB Transfer Mode, the send rate is controlled by the BLOB Transfer Client, which will push all the chunks of each block without any high level flow control. Push BLOB Transfer Mode supports any number of Target nodes, and should be the default transfer mode.

In Pull BLOB Transfer Mode, the BLOB Transfer Server will "pull" the chunks from the BLOB Transfer Client at its own rate. Pull BLOB Transfer Mode can be conducted with multiple Target nodes, and is intended for transferring BLOBs to Target nodes acting as *Low Power Node*. When operating in Pull BLOB Transfer Mode, the BLOB Transfer Server will request chunks from the BLOB Transfer Client in small batches, and wait for them all to arrive before requesting more chunks. This process is repeated until the BLOB Transfer Server has received all chunks in a block. Then, the BLOB Transfer Client starts the next block, and the BLOB Transfer Server requests all chunks of that block.

Transfer timeout The timeout of the BLOB transfer is based on a Timeout Base value. Both client and server use the same Timeout Base value, but they calculate timeout differently.

The BLOB Transfer Server uses the following formula to calculate the BLOB transfer timeout:

```
10 * (Timeout Base + 1) seconds
```

For the BLOB Transfer Client, the following formula is used:

```
(10000 * (Timeout Base + 2)) + (100 * TTL) milliseconds
```

where TTL is time to live value set in the transfer.

API reference This section contains types and defines common to the BLOB Transfer models.

Bluetooth Mesh BLOB model API

Device Firmware Update (DFU) Bluetooth Mesh supports the distribution of firmware images across a mesh network. The Bluetooth mesh DFU subsystem implements the Bluetooth Mesh Device Firmware Update Model specification version 1.0.

Bluetooth Mesh DFU implements a distribution mechanism for firmware images, and does not put any restrictions on the size, format or usage of the images. The primary design goal of the subsystem is to provide the qualifiable parts of the Bluetooth Mesh DFU specification, and leave the usage, firmware validation and deployment to the application.

The DFU specification is implemented in the Zephyr Bluetooth Mesh DFU subsystem as three separate models:

Firmware Update Server The Firmware Update Server model implements the Target node functionality of the *Device Firmware Update (DFU)* subsystem. It extends the *BLOB Transfer Server*, which it uses to receive the firmware image binary from the Distributor node.

Together with the extended BLOB Transfer Server model, the Firmware Update Server model implements all the required functionality for receiving firmware updates over the mesh network, but does not provide any functionality for storing, applying or verifying the images.

Firmware images The Firmware Update Server holds a list of all the updatable firmware images on the device. The full list shall be passed to the server through the `_imgs` parameter in `BT_MESH_DFU_SRV_INIT`, and must be populated before the Bluetooth Mesh subsystem is started. Each firmware image in the image list must be independently updatable, and should have its own firmware ID.

For instance, a device with an upgradable bootloader, an application and a peripheral chip with firmware update capabilities could have three entries in the firmware image list, each with their own separate firmware ID.

Receiving transfers The Firmware Update Server model uses a BLOB Transfer Server model on the same element to transfer the binary image. The interaction between the Firmware Update Server, BLOB Transfer Server and application is described below:

Transfer check The transfer check is an optional pre-transfer check the application can perform on incoming firmware image metadata. The Firmware Update Server performs the transfer check by calling the `check` callback.

The result of the transfer check is a pass/fail status return and the expected `bt_mesh_dfu_effect`. The DFU effect return parameter will be communicated back to the Distributor, and should indicate what effect the firmware update will have on the mesh state of the device.

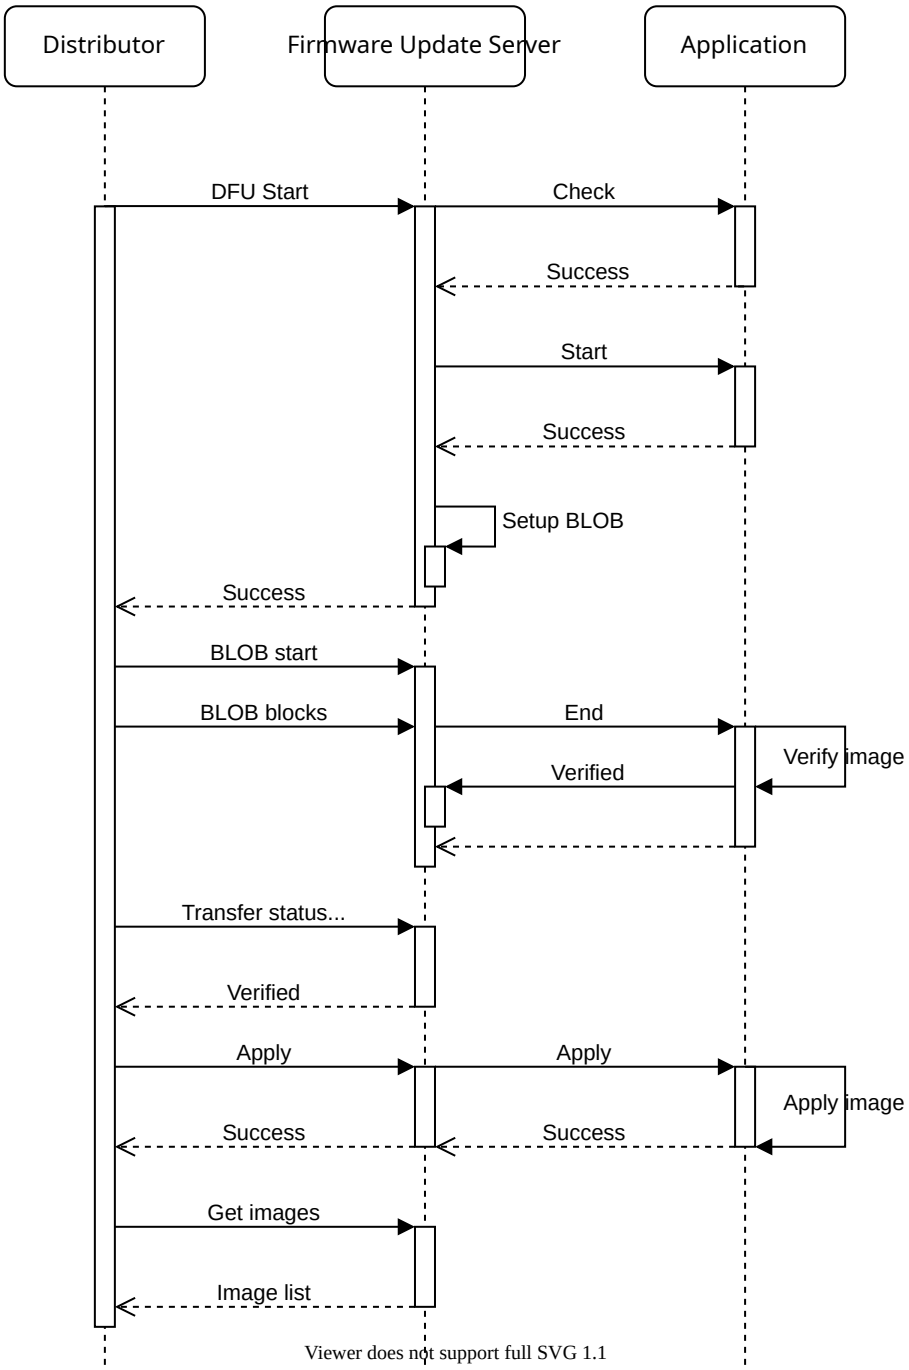

Fig. 9: Bluetooth Mesh Firmware Update Server transfer

Composition Data and Models Metadata If the transfer will cause the device to change its Composition Data or become unprovisioned, this should be communicated through the effect parameter of the metadata check.

When the transfer will cause the Composition Data to change, and the *Remote Provisioning Server* is supported, the Composition Data of the new firmware image will be represented by Composition Data Pages 128, 129, and 130. The Models Metadata of the new firmware image will be represented by Models Metadata Page 128. Composition Data Pages 0, 1 and 2, and Models Metadata Page 0, will represent the Composition Data and the Models Metadata of the old firmware image until the device is reprovisioned with Node Provisioning Protocol Interface (NPPI) procedures using the *Remote Provisioning Client*.

The application must call functions `bt_mesh_comp_change_prepare()` and `bt_mesh_models_metadata_change_prepare()` to store the existing Composition Data and Models Metadata pages before booting into the firmware with the updated Composition Data and Models Metadata. The old Composition Data will then be loaded into Composition Data Pages 0, 1 and 2, while the Composition Data in the new firmware will be loaded into Composition Data Pages 128, 129 and 130. The Models Metadata for the old image will be loaded into Models Metadata Page 0, and the Models Metadata for the new image will be loaded into Models Metadata Page 128.

Limitation:

- It is not possible to change the Composition Data of the device and keep the device provisioned and working with the old firmware after the new firmware image is applied.

Start The Start procedure prepares the application for the incoming transfer. It'll contain information about which image is being updated, as well as the update metadata.

The Firmware Update Server `start` callback must return a pointer to the BLOB Writer the BLOB Transfer Server will send the BLOB to.

BLOB transfer After the setup stage, the Firmware Update Server prepares the BLOB Transfer Server for the incoming transfer. The entire firmware image is transferred to the BLOB Transfer Server, which passes the image to its assigned BLOB Writer.

At the end of the BLOB transfer, the Firmware Update Server calls its `end` callback.

Image verification After the BLOB transfer has finished, the application should verify the image in any way it can to ensure that it is ready for being applied. Once the image has been verified, the application calls `bt_mesh_dfu_srv_verified()`.

If the image can't be verified, the application calls `bt_mesh_dfu_srv_rejected()`.

Applying the image Finally, if the image was verified, the Distributor may instruct the Firmware Update Server to apply the transfer. This is communicated to the application through the `apply` callback. The application should swap the image and start running with the new firmware. The firmware image table should be updated to reflect the new firmware ID of the updated image.

When the transfer applies to the mesh application itself, the device might have to reboot as part of the swap. This restart can be performed from inside the apply callback, or done asynchronously. After booting up with the new firmware, the firmware image table should be updated before the Bluetooth Mesh subsystem is started.

The Distributor will read out the firmware image table to confirm that the transfer was successfully applied. If the metadata check indicated that the device would become unprovisioned, the Target node is not required to respond to this check.

API reference
Firmware Update Server model

Firmware Update Client The Firmware Update Client is responsible for distributing firmware updates through the mesh network. The Firmware Update Client uses the *BLOB Transfer Client* as a transport for its transfers.

API reference
Firmware Uppdate Client model

Firmware Distribution Server The Firmware Distribution Server model implements the Distributor role for the *Device Firmware Update (DFU)* subsystem. It extends the *BLOB Transfer Server*, which it uses to receive the firmware image binary from the Initiator node. It also instantiates a *Firmware Update Client*, which it uses to distribute firmware updates throughout the mesh network.

> **Note**
>
> Currently, the Firmware Distribution Server supports out-of-band (OOB) retrieval of firmware images over SMP service only.

The Firmware Distribution Server does not have an API of its own, but relies on a Firmware Distribution Client model on a different device to give it information and trigger image distribution and upload.

Firmware slots The Firmware Distribution Server is capable of storing multiple firmware images for distribution. Each slot contains a separate firmware image with metadata, and can be distributed to other mesh nodes in the network in any order. The contents, format and size of the firmware images are vendor specific, and may contain data from other vendors. The application should never attempt to execute or modify them.

The slots are managed remotely by a Firmware Distribution Client, which can both upload new slots and delete old ones. The application is notified of changes to the slots through the Firmware Distribution Server's callbacks (`bt_mesh_fd_srv_cb`). While the metadata for each firmware slot is stored internally, the application must provide a *BLOB streams* for reading and writing the firmware image.

API reference
Firmware Distribution Server model

Overview

DFU roles The Bluetooth Mesh DFU subsystem defines three different roles the mesh nodes have to assume in the distribution of firmware images:

Target node
: Target node is the receiver and user of the transferred firmware images. All its functionality is implemented by the *Firmware Update Server* model. A transfer may be targeting any number of Target nodes, and they will all be updated concurrently.

Distributor
: The Distributor role serves two purposes in the DFU process. First, it's acting as the Target node in the Upload Firmware procedure, then it distributes the uploaded image to other Target nodes as the Distributor. The Distributor does not select the parameters of the transfer, but relies on an Initiator to give it a list of Target nodes and transfer parameters. The Distributor functionality is implemented in two models, *Firmware Distribution Server* and *Firmware Update Client*. The *Firmware Distribution Server* is responsible for communicating with the Initiator, and the *Firmware Update Client* is responsible for distributing the image to the Target nodes.

Initiator
: The Initiator role is typically implemented by the same device that implements the Bluetooth Mesh *Provisioner* and *Configurator* roles. The Initiator needs a full overview of the potential Target nodes and their firmware, and will control (and initiate) all firmware updates. The Initiator role is not implemented in the Zephyr Bluetooth Mesh DFU subsystem.

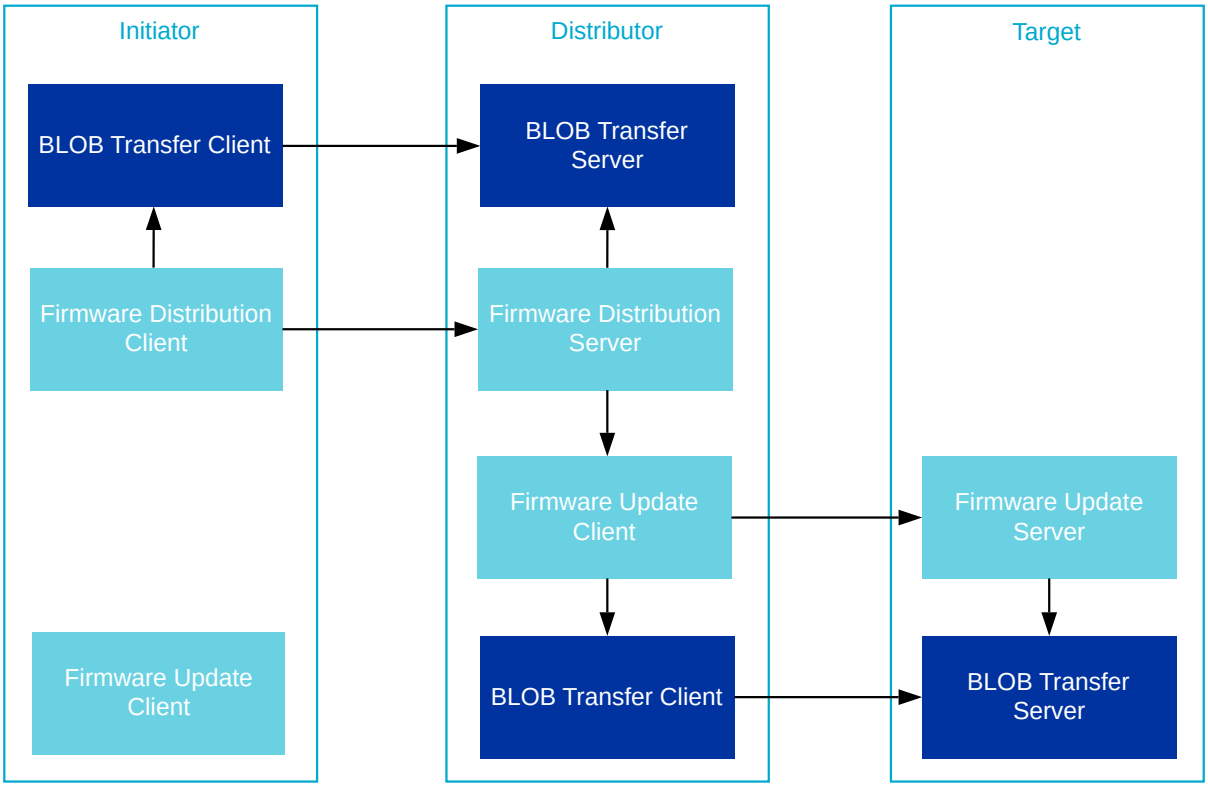

Fig. 10: DFU roles and the associated Bluetooth Mesh models

Bluetooth Mesh applications may combine the DFU roles in any way they'd like, and even take on multiple instances of the same role by instantiating the models on separate elements. For instance, the Distributor and Initiator role can be combined by instantiating the *Firmware Update Client* on the Initiator node and calling its API directly.

It's also possible to combine the Initiator and Distributor devices into a single device, and replace the Firmware Distribution Server model with a proprietary mechanism that will access the Firmware Update Client model directly, e.g. over a serial protocol.

Note

All DFU models instantiate one or more *BLOB Transfer models*, and may need to be spread over multiple elements for certain role combinations.

Stages The Bluetooth Mesh DFU process is designed to act in three stages:

Upload stage
: First, the image is uploaded to a Distributor in a mesh network by an external entity, such as a phone or gateway (the Initiator). During the Upload stage, the Initiator transfers the firmware image and all its metadata to the Distributor node inside the mesh network. The Distributor stores the firmware image and its metadata persistently, and awaits further instructions from the Initiator. The time required to complete the upload process depends on the size of the image. After the upload completes, the Initiator can disconnect from the network during the much more time-consuming Distribution stage. Once the firmware

has been uploaded to the Distributor, the Initiator may trigger the Distribution stage at any time.

Firmware Capability Check stage (optional)
Before starting the Distribution stage, the Initiator may optionally check if Target nodes can accept the new firmware. Nodes that do not respond, or respond that they can't receive the new firmware, are excluded from the firmware distribution process.

Distribution stage
Before the firmware image can be distributed, the Initiator transfers the list of Target nodes and their designated firmware image index to the Distributor. Next, it tells the Distributor to start the firmware distributon process, which runs in the background while the Initiator and the mesh network perform other duties. Once the firmware image has been transferred to the Target nodes, the Distributor may ask them to apply the firmware image immediately and report back with their status and new firmware IDs.

Firmware images All updatable parts of a mesh node's firmware should be represented as a firmware image. Each Target node holds a list of firmware images, each of which should be independently updatable and identifiable.

Firmware images are represented as a BLOB (the firmware itself) with the following additional information attached to it:

Firmware ID
The firmware ID is used to identify a firmware image. The Initiator node may ask the Target nodes for a list of its current firmware IDs to determine whether a newer version of the firmware is available. The format of the firmware ID is vendor specific, but generally, it should include enough information for an Initiator node with knowledge of the format to determine the type of image as well as its version. The firmware ID is optional, and its max length is determined by `CONFIG_BT_MESH_DFU_FWID_MAXLEN`.

Firmware metadata
The firmware metadata is used by the Target node to determine whether it should accept an incoming firmware update, and what the effect of the update would be. The metadata format is vendor specific, and should contain all information the Target node needs to verify the image, as well as any preparation the Target node has to make before the image is applied. Typical metadata information can be image signatures, changes to the node's Composition Data and the format of the BLOB. The Target node may perform a metadata check before accepting incoming transfers to determine whether the transfer should be started. The firmware metadata can be discarded by the Target node after the metadata check, as other nodes will never request the metadata from the Target node. The firmware metadata is optional, and its maximum length is determined by `CONFIG_BT_MESH_DFU_METADATA_MAXLEN`.

The Bluetooth Mesh DFU subsystem in Zephyr provides its own metadata format (`bt_mesh_dfu_metadata`) together with a set of related functions that can be used by an end product. The support for it is enabled using the `CONFIG_BT_MESH_DFU_METADATA` option. The format of the metadata is presented in the table below.

Field	Size (Bytes)	Description
New firmware version	8 B	1 B: Major version 1 B: Minor version 2 B: Revision 4 B: Build number
New firmware size	3 B	Size in bytes for a new firmware
New firmware core type	1 B	Bit field: Bit 0: Application core Bit 1: Network core Bit 2: Applications specific BLOB. Other bits: RFU
Hash of incoming composition data	4 B (Optional)	Lower 4 octets of AES-CMAC (app-specific-key, composition data). This field is present, if Bit 0 is set in the New firmware core type field.
New number of elements	2 B (Optional)	Number of elements on the node after firmware is applied. This field is present, if Bit 0 is set in the New firmware core type field.
Application-specific data for new firmware	<variable> (Optional)	Application-specific data to allow application to execute some vendor-specific behaviors using this data before it can respond with a status message.

> **Note**
>
> The AES-CMAC algorithm serves as a hashing function with a fixed key and is not used for encryption in Bluetooth Mesh DFU metadata. The resulting hash is not secure since the key is known.

Firmware URI

The firmware URI gives the Initiator information about where firmware updates for the image can be found. The URI points to an online resource the Initiator can interact with to get new versions of the firmware. This allows Initiators to perform updates for any node in the mesh network by interacting with the web server pointed to in the URI. The URI must point to a resource using the `http` or `https` schemes, and the targeted web server must behave according to the Firmware Check Over HTTPS procedure defined by the specification. The firmware URI is optional, and its max length is determined by `CONFIG_BT_MESH_DFU_URI_MAXLEN`.

> **Note**
>
> The out-of-band distribution mechanism is not supported.

Firmware effect A new image may have the Composition Data Page 0 different from the one allocated on a Target node. This may have an effect on the provisioning data of the node and how the Distributor finalizes the DFU. Depending on the availability of the Remote Provisioning Server model on the old and new image, the device may either boot up unprovisioned after applying the new firmware or require to be re-provisioned. The complete list of available options is defined in `bt_mesh_dfu_effect`:

`BT_MESH_DFU_EFFECT_NONE`
: The device stays provisioned after the new firmware is programmed. This effect is chosen if the composition data of the new firmware doesn't change.

`BT_MESH_DFU_EFFECT_COMP_CHANGE_NO_RPR`
: This effect is chosen when the composition data changes and the device doesn't support the remote provisioning. The new composition data takes place only after re-provisioning.

`BT_MESH_DFU_EFFECT_COMP_CHANGE`
: This effect is chosen when the composition data changes and the device supports the remote

provisioning. In this case, the device stays provisioned and the new composition data takes place after re-provisioning using the Remote Provisioning models.

`BT_MESH_DFU_EFFECT_UNPROV`
: This effect is chosen if the composition data in the new firmware changes, the device does not support the remote provisioning, and the new composition data takes effect after applying the firmware. The effect can also be chosen, if it is necessary to unprovision the device for application-specific reasons.

When the Target node receives the Firmware Update Firmware Metadata Check message, the Firmware Update Server model calls the `bt_mesh_dfu_srv_cb.check` callback, the application can then process the metadata and provide the effect value. If the effect is `BT_MESH_DFU_EFFECT_COMP_CHANGE`, the application must call functions `bt_mesh_comp_change_prepare()` and `bt_mesh_models_metadata_change_prepare()` to prepare the Composition Data Page and Models Metadata Page contents before applying the new firmware image. See *Composition Data and Models Metadata* for more information.

DFU procedures The DFU protocol is implemented as a set of procedures that must be performed in a certain order.

The Initiator controls the Upload stage of the DFU protocol, and all Distributor side handling of the upload subprocedures is implemented in the *Firmware Distribution Server*.

The Distribution stage is controlled by the Distributor, as implemented by the *Firmware Update Client*. The Target node implements all handling of these procedures in the *Firmware Update Server*, and notifies the application through a set of callbacks.

Uploading the firmware The Upload Firmware procedure uses the *BLOB Transfer models* to transfer the firmware image from the Initiator to the Distributor. The Upload Firmware procedure works in two steps:

1. The Initiator generates a BLOB ID, and sends it to the Distributor's Firmware Distribution Server along with the firmware information and other input parameters of the BLOB transfer. The Firmware Distribution Server stores the information, and prepares its BLOB Transfer Server for the incoming transfer before it responds with a status message to the Initiator.
2. The Initiator's BLOB Transfer Client model transfers the firmware image to the Distributor's BLOB Transfer Server, which stores the image in a predetermined flash partition.

When the BLOB transfer finishes, the firmware image is ready for distribution. The Initiator may upload several firmware images to the Distributor, and ask it to distribute them in any order or at any time. Additional procedures are available for querying and deleting firmware images from the Distributor.

The following Distributor's capabilities related to firmware images can be configured using the configuration options:

- `CONFIG_BT_MESH_DFU_SLOT_CNT`: Amount of image slots available on the device.
- `CONFIG_BT_MESH_DFD_SRV_SLOT_MAX_SIZE`: Maximum allowed size for each image.
- `CONFIG_BT_MESH_DFD_SRV_SLOT_SPACE`: Available space for all images.

Populating the Distributor's receivers list Before the Distributor can start distributing the firmware image, it needs a list of Target nodes to send the image to. The Initiator gets the full list of Target nodes either by querying the potential targets directly, or through some external authority. The Initiator uses this information to populate the Distributor's receivers list with the address and relevant firmware image index of each Target node. The Initiator may send one or more Firmware Distribution Receivers Add messages to build the Distributor's receivers list, and a Firmware Distribution Receivers Delete All message to clear it.

The maximum number of receivers that can be added to the Distributor is configured through the `CONFIG_BT_MESH_DFD_SRV_TARGETS_MAX` configuration option.

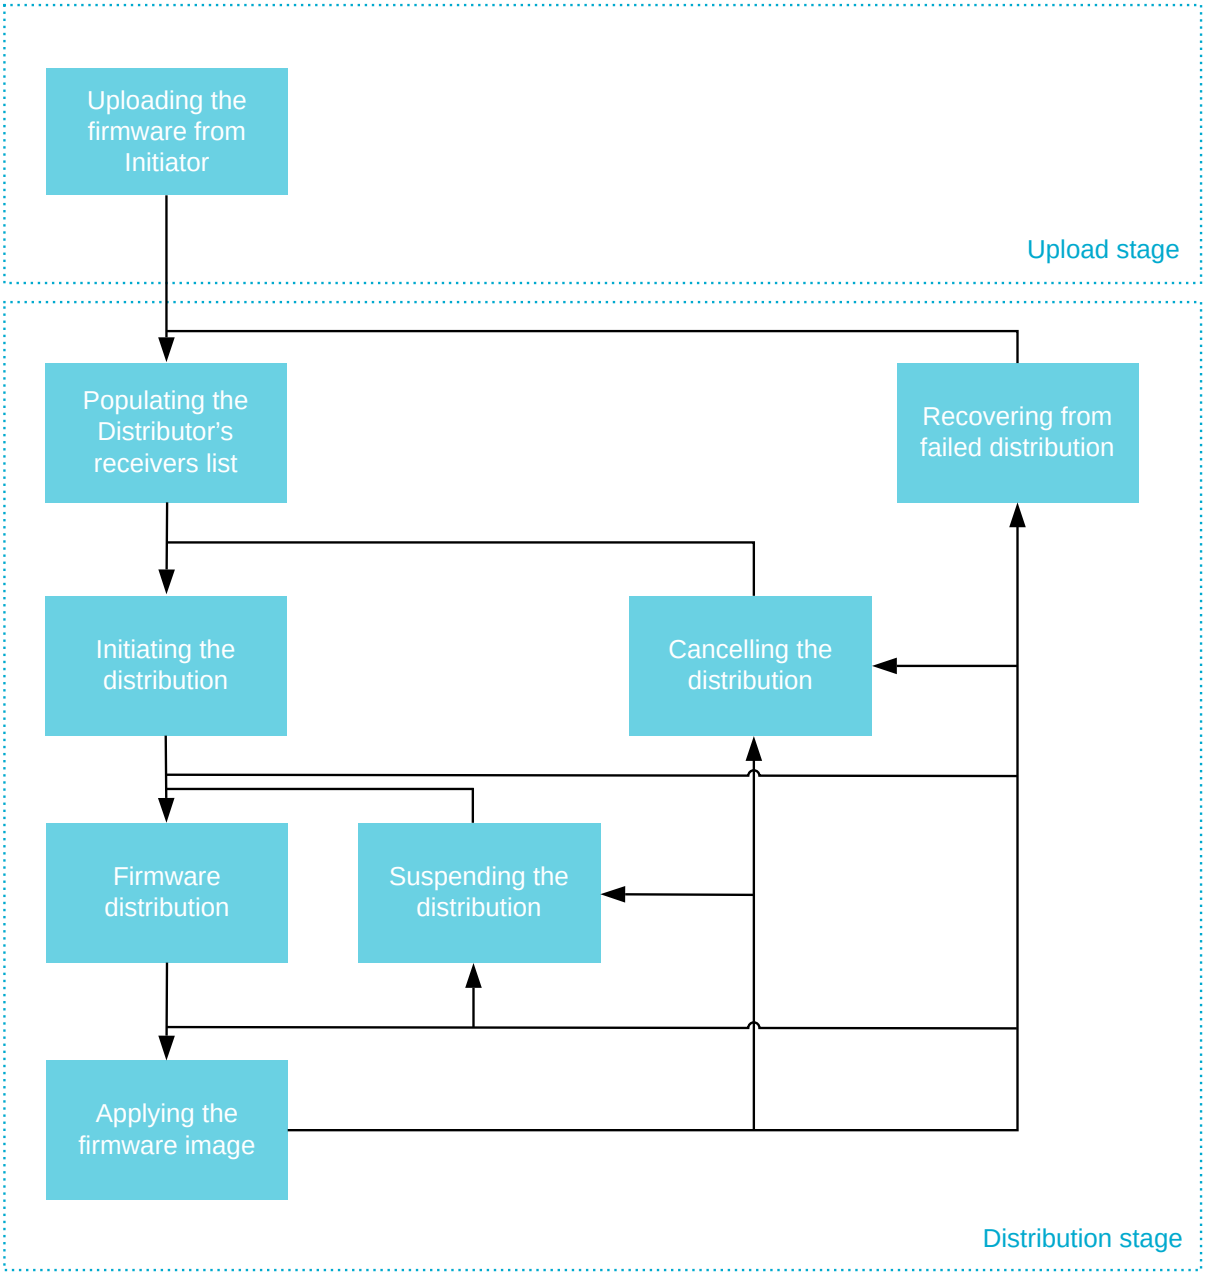

Fig. 11: DFU stages and procedures as seen from the Distributor

Initiating the distribution Once the Distributor has stored a firmware image and received a list of Target nodes, the Initiator may initiate the distribution procedure. The BLOB transfer parameters for the distribution are passed to the Distributor along with an update policy. The update policy decides whether the Distributor should request that the firmware is applied on the Target nodes or not. The Distributor stores the transfer parameters and starts distributing the firmware image to its list of Target nodes.

Firmware distribution The Distributor's Firmware Update Client model uses its BLOB Transfer Client model's broadcast subsystem to communicate with all Target nodes. The firmware distribution is performed with the following steps:

1. The Distributor's Firmware Update Client model generates a BLOB ID and sends it to each Target node's Firmware Update Server model, along with the other BLOB transfer parameters, the Target node firmware image index and the firmware image metadata. Each Target node performs a metadata check and prepares their BLOB Transfer Server model for the transfer, before sending a status response to the Firmware Update Client, indicating if the firmware update will have any effect on the Bluetooth Mesh state of the node.
2. The Distributor's BLOB Transfer Client model transfers the firmware image to all Target nodes.
3. Once the BLOB transfer has been received, the Target nodes' applications verify that the firmware is valid by performing checks such as signature verification or image checksums against the image metadata.
4. The Distributor's Firmware Update Client model queries all Target nodes to ensure that they've all verified the firmware image.

If the distribution procedure completed with at least one Target node reporting that the image has been received and verified, the distribution procedure is considered successful.

> **Note**
>
> The firmware distribution procedure only fails if *all* Target nodes are lost. It is up to the Initiator to request a list of failed Target nodes from the Distributor and initiate additional attempts to update the lost Target nodes after the current attempt is finished.

Suspending the distribution The Initiator can also request the Distributor to suspend the firmware distribution. In this case, the Distributor will stop sending any messages to Target nodes. When the firmware distribution is resumed, the Distributor will continue sending the firmware from the last successfully transferred block.

Applying the firmware image If the Initiator requested it, the Distributor can initiate the Apply Firmware on Target Node procedure on all Target nodes that successfully received and verified the firmware image. The Apply Firmware on Target Node procedure takes no parameters, and to avoid ambiguity, it should be performed before a new transfer is initiated. The Apply Firmware on Target Node procedure consists of the following steps:

1. The Distributor's Firmware Update Client model instructs all Target nodes that have verified the firmware image to apply it. The Target nodes' Firmware Update Server models respond with a status message before calling their application's `apply` callback.
2. The Target node's application performs any preparations needed before applying the transfer, such as storing a snapshot of the Composition Data or clearing its configuration.
3. The Target node's application swaps the current firmware with the new image and updates its firmware image list with the new firmware ID.

4. The Distributor's Firmware Update Client model requests the full list of firmware images from each Target node, and scans through the list to make sure that the new firmware ID has replaced the old.

> **Note**
>
> During the metadata check in the distribution procedure, the Target node may have reported that it will become unprovisioned after the firmware image is applied. In this case, the Distributor's Firmware Update Client model will send a request for the full firmware image list, and expect no response.

Cancelling the distribution The firmware distribution can be cancelled at any time by the Initiator. In this case, the Distributor starts the cancelling procedure by sending a cancelling message to all Target nodes. The Distributor waits for the response from all Target nodes. Once all Target nodes have replied, or the request has timed out, the distribution procedure is cancelled. After this the distribution procedure can be started again from the `Firmware distribution` section.

API reference This section lists the types common to the Device Firmware Update mesh models.

Firmware Distribution models

Bluetooth Mesh Device Firmware Update

Bluetooth Mesh Device Firmware Update (DFU) metadata

Message The Bluetooth Mesh message provides set of structures, macros and functions used for preparing message buffers, managing message and acknowledged message contexts.

API reference
Message

Segmentation and reassembly (SAR) Segmentation and reassembly (SAR) provides a way of handling larger upper transport layer messages in a mesh network, with a purpose of enhancing the Bluetooth Mesh throughput. The segmentation and reassembly mechanism is used by the lower transport layer.

The lower transport layer defines how the upper transport layer PDUs are segmented and reassembled into multiple Lower Transport PDUs, and sends them to the lower transport layer on a peer device. If the Upper Transport PDU fits, it is sent in a single Lower Transport PDU. For longer packets, which do not fit into a single Lower Transport PDU, the lower transport layer performs segmentation, splitting the Upper Transport PDU into multiple segments.

The lower transport layer on the receiving device reassembles the segments into a single Upper Transport PDU before passing it up the stack. Delivery of a segmented message is acknowledged by the lower transport layer of the receiving node, while an unsegmented message delivery is not acknowledged. However, an Upper Transport PDU that fits into one Lower Transport PDU can also be sent as a single-segment segmented message when acknowledgment by the lower transport layer is required. Set the `send rel` flag (see `bt_mesh_msg_ctx`) to use the reliable message transmission and acknowledge single-segment segmented messages.

The transport layer is able to transport up to 32 segments with its SAR mechanism, with a maximum message (PDU) size of 384 octets. To configure message size for the Bluetooth Mesh stack, use the following Kconfig options:

- `CONFIG_BT_MESH_RX_SEG_MAX` to set the maximum number of segments in an incoming message.

- `CONFIG_BT_MESH_TX_SEG_MAX` to set the maximum number of segments in an outgoing message.

The Kconfig options `CONFIG_BT_MESH_TX_SEG_MSG_COUNT` and `CONFIG_BT_MESH_RX_SEG_MSG_COUNT` define how many outgoing and incoming segmented messages can be processed simultaneously. When more than one segmented message is sent to the same destination, the messages are queued and sent one at a time.

Incoming and outgoing segmented messages share the same pool for allocation of their segments. This pool size is configured through the `CONFIG_BT_MESH_SEG_BUFS` Kconfig option. Both incoming and outgoing messages allocate segments at the start of the transaction. The outgoing segmented message releases its segments one by one as soon as they are acknowledged by the receiver, while the incoming message releases the segments first after the message is fully received. Keep this in mind when defining the size of the buffers.

SAR does not impose extra overhead on the access layer payload per segment.

Segmentation and reassembly (SAR) Configuration models With Bluetooth Mesh Protocol Specification version 1.1, it became possible to configure SAR behavior, such as intervals, timers and retransmission counters, over a mesh network using SAR Configuration models:

- *SAR Configuration Client*
- *SAR Configuration Server*

The following SAR behavior applies regardless of the presence of a SAR Configuration Server on a node.

Transmission of segments is separated by a segment transmission interval (see the *SAR Segment Interval Step* state). Other configurable time intervals and delays available for the segmentation and reassembly are:

- Interval between unicast retransmissions (see the states *SAR Unicast Retransmissions Interval Step* and *SAR Unicast Retransmissions Interval Increment*).
- Interval between multicast retransmissions (see the *SAR Multicast Retransmissions Interval Step* state).
- Segment reception interval (see the *SAR Receiver Segment Interval Step* state).
- Acknowledgment delay increment (see the *SAR Acknowledgment Delay Increment* state).

When the last segment marked as unacknowledged is transmitted, the lower transport layer starts a retransmissions timer. The initial value of the SAR Unicast Retransmissions timer depends on the value of the TTL field of the message. If the TTL field value is greater than `0`, the initial value for the timer is set according to the following formula:

$$unicast\ retransmissions\ interval\ step + unicast\ retransmissions\ interval\ increment \times (TTL - 1)$$

If the TTL field value is `0`, the initial value of the timer is set to the unicast retransmissions interval step.

The initial value of the SAR Multicast Retransmissions timer is set to the multicast retransmissions interval.

When the lower transport layer receives a message segment, it starts a SAR Discard timer. The discard timer tells how long the lower transport layer waits before discarding the segmented message the segment belongs to. The initial value of the SAR Discard timer is the discard timeout value indicated by the *SAR Discard Timeout* state.

SAR Acknowledgment timer holds the time before a Segment Acknowledgment message is sent for a received segment. The initial value of the SAR Acknowledgment timer is calculated using the following formula:

$$min(SegN + 0.5, acknowledgment\ delay\ increment) \times segment\ reception\ interval$$

The SegN field value identifies the total number of segments the Upper Transport PDU is segmented into.

Four counters are related to SAR behavior:

- Two unicast retransmissions counts (see *SAR Unicast Retransmissions Count* state and *SAR Unicast Retransmissions Without Progress Count* state)
- Multicast retransmissions count (see *SAR Multicast Retransmissions Count* state)
- Acknowledgment retransmissions count (see *SAR Acknowledgment Retransmissions Count* state)

If the number of segments in the transmission is higher than the value of the *SAR Segments Threshold* state, Segment Acknowledgment messages are retransmitted using the value of the *SAR Acknowledgment Retransmissions Count* state.

SAR states There are two states defined related to segmentation and reassembly:

- SAR Transmitter state
- SAR Receiver state

The SAR Transmitter state is a composite state that controls the number and timing of transmissions of segmented messages. It includes the following states:

- SAR Segment Interval Step
- SAR Unicast Retransmissions Count
- SAR Unicast Retransmissions Without Progress Count
- SAR Unicast Retransmissions Interval Step
- SAR Unicast Retransmissions Interval Increment
- SAR Multicast Retransmissions Count
- SAR Multicast Retransmissions Interval Step

The SAR Receiver state is a composite state that controls the number and timing of Segment Acknowledgment transmissions and the discarding of reassembly of a segmented message. It includes the following states:

- SAR Segments Threshold
- SAR Discard Timeout
- SAR Acknowledgment Delay Increment
- SAR Acknowledgment Retransmissions Count
- SAR Receiver Segment Interval Step

SAR Segment Interval Step SAR Segment Interval Step state holds a value that controls the interval between transmissions of segments of a segmented message. The interval is measured in milliseconds.

Use the CONFIG_BT_MESH_SAR_TX_SEG_INT_STEP Kconfig option to set the default value. Segment transmission interval is then calculated using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_SEG_INT_STEP} + 1) \times 10 \text{ ms}$$

SAR Unicast Retransmissions Count SAR Unicast Retransmissions Count holds a value that defines the maximum number of retransmissions of a segmented message to a unicast destination. Use the CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_COUNT Kconfig option to set the default value for this state.

SAR Unicast Retransmissions Without Progress Count This state holds a value that defines the maximum number of retransmissions of a segmented message to a unicast address that will be sent if no acknowledgment was received during the timeout, or if an acknowledgment with already confirmed segments was received. Use the Kconfig option CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_WITHOUT_PROG_COUNT to set the maximum number of retransmissions.

SAR Unicast Retransmissions Interval Step The value of this state controls the interval step used for delaying the retransmissions of unacknowledged segments of a segmented message to a unicast address. The interval step is measured in milliseconds.

Use the CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_STEP Kconfig option to set the default value. This value is then used to calculate the interval step using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_STEP} + 1) \times 25 \text{ ms}$$

SAR Unicast Retransmissions Interval Increment SAR Unicast Retransmissions Interval Increment holds a value that controls the interval increment used for delaying the retransmissions of unacknowledged segments of a segmented message to a unicast address. The increment is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_INC to set the default value. The Kconfig option value is used to calculate the increment using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_INC} + 1) \times 25 \text{ ms}$$

SAR Multicast Retransmissions Count The state holds a value that controls the total number of retransmissions of a segmented message to a multicast address. Use the Kconfig option CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_COUNT to set the total number of retransmissions.

SAR Multicast Retransmissions Interval Step This state holds a value that controls the interval between retransmissions of all segments in a segmented message to a multicast address. The interval is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_INT to set the default value that is used to calculate the interval using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_INT} + 1) \times 25 \text{ ms}$$

SAR Discard Timeout The value of this state defines the time in seconds that the lower transport layer waits after receiving segments of a segmented message before discarding that segmented message. Use the Kconfig option CONFIG_BT_MESH_SAR_RX_DISCARD_TIMEOUT to set the default value. The discard timeout will be calculated using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_RX_DISCARD_TIMEOUT} + 1) \times 5 \text{ seconds}$$

SAR Acknowledgment Delay Increment This state holds a value that controls the delay increment of an interval used for delaying the transmission of an acknowledgment message after receiving a new segment. The increment is measured in segments.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_ACK_DELAY_INC to set the default value. The increment value is calculated to be CONFIG_BT_MESH_SAR_RX_ACK_DELAY_INC + 1.5.

SAR Segments Threshold SAR Segments Threshold state holds a value that defines a threshold in number of segments of a segmented message for acknowledgment retransmissions. Use the Kconfig option CONFIG_BT_MESH_SAR_RX_SEG_THRESHOLD to set the threshold.

When the number of segments of a segmented message is above this threshold, the stack will additionally retransmit every acknowledgment message the number of times given by the value of CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT.

SAR Acknowledgment Retransmissions Count The SAR Acknowledgment Retransmissions Count state controls the number of retransmissions of Segment Acknowledgment messages sent by the lower transport layer. It gives the total number of retranmissions of an acknowledgment message that the stack will additionally send when the size of segments in a segmented message is above the CONFIG_BT_MESH_SAR_RX_SEG_THRESHOLD value.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT to set the default value for this state. The maximum number of transmissions of a Segment Acknowledgment message is CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT + 1.

SAR Receiver Segment Interval Step The SAR Receiver Segment Interval Step defines the segments reception interval step used for delaying the transmission of an acknowledgment message after receiving a new segment. The interval is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_SEG_INT_STEP to set the default value and calculate the interval using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_RX_SEG_INT_STEP} + 1) \times 10 \text{ ms}$$

Provisioning Provisioning is the process of adding devices to a mesh network. It requires two devices operating in the following roles:

- The *provisioner* represents the network owner, and is responsible for adding new nodes to the mesh network.
- The *provisionee* is the device that gets added to the network through the Provisioning process. Before the provisioning process starts, the provisionee is an *unprovisioned device*.

The Provisioning module in the Zephyr Bluetooth Mesh stack supports both the Advertising and GATT Provisioning bearers for the provisionee role, as well as the Advertising Provisioning bearer for the provisioner role.

The Provisioning process All Bluetooth Mesh nodes must be provisioned before they can participate in a Bluetooth Mesh network. The Provisioning API provides all the functionality necessary for a device to become a provisioned mesh node. Provisioning is a five-step process, involving the following steps:

- Beaconing
- Invitation
- Public key exchange
- Authentication
- Provisioning data transfer

Beaconing To start the provisioning process, the unprovisioned device must first start broadcasting the Unprovisioned Beacon. This makes it visible to nearby provisioners, which can initiate the provisioning. To indicate that the device needs to be provisioned, call bt_mesh_prov_enable(). The device starts broadcasting the Unprovisioned Beacon with the device UUID and the OOB information field, as specified in the prov parameter passed to bt_mesh_init(). Additionally, a Uniform Resource Identifier (URI) may be specified, which can

point the provisioner to the location of some Out Of Band information, such as the device's public key or an authentication value database. The URI is advertised in a separate beacon, with a URI hash included in the unprovisioned beacon, to tie the two together.

Uniform Resource Identifier The Uniform Resource Identifier shall follow the format specified in the Bluetooth Core Specification Supplement. The URI must start with a URI scheme, encoded as a single utf-8 data point, or the special `none` scheme, encoded as `0x01`. The available schemes are listed on the Bluetooth website.

Examples of encoded URIs:

Table 14: URI encoding examples

URI	Encoded
`http://example.com`	`\x16//example.com`
`https://www.zephyrproject.org/`	`\x17//www.zephyrproject.org/`
`just a string`	`\x01just a string`

Provisioning invitation The provisioner initiates the Provisioning process by sending a Provisioning invitation. The invitations prompts the provisionee to call attention to itself using the Health Server *Attention state*, if available.

The Unprovisioned device automatically responds to the invite by presenting a list of its capabilities, including the supported Out of Band Authentication methods and algorithms.

Public key exchange Before the provisioning process can begin, the provisioner and the unprovisioned device exchange public keys, either in-band or Out of Band (OOB).

In-band public key exchange is a part of the provisioning process and always supported by the unprovisioned device and provisioner.

If the application wants to support public key exchange via OOB, it needs to provide public and private keys to the mesh stack. The unprovisioned device will reflect this in its capabilities. The provisioner obtains the public key via any available OOB mechanism (e.g. the device may advertise a packet containing the public key or it can be encoded in a QR code printed on the device packaging). Note that even if the unprovisioned device has specified the public key for the Out of Band exchange, the provisioner may choose to exchange the public key in-band if it can't retrieve the public key via OOB mechanism. In this case, a new key pair will be generated by the mesh stack for each Provisioning process.

To enable support of OOB public key on the unprovisioned device side, `CONFIG_BT_MESH_PROV_OOB_PUBLIC_KEY` needs to be enabled. The application must provide public and private keys before the Provisioning process is started by initializing pointers to `bt_mesh_prov.public_key_be` and `bt_mesh_prov.private_key_be`. The keys needs to be provided in big-endian bytes order.

To provide the device's public key obtained via OOB, call `bt_mesh_prov_remote_pub_key_set()` on the provisioner side.

Authentication After the initial exchange, the provisioner selects an Out of Band (OOB) Authentication method. This allows the user to confirm that the device the provisioner connected to is actually the device they intended, and not a malicious third party.

The Provisioning API supports the following authentication methods for the provisionee:

- **Static OOB:** An authentication value is assigned to the device in production, which the provisioner can query in some application specific way. For secure provisioning with the BTM_ECDH_P256_HMAC_SHA256_AES_CCM algorithm, the Static OOB value should contain more than 128 bits of entropy to provide adequate security against attacks.

- **Input OOB:** The user inputs the authentication value. The available input actions are listed in `bt_mesh_input_action_t`.
- **Output OOB:** Show the user the authentication value. The available output actions are listed in `bt_mesh_output_action_t`.

The application must provide callbacks for the supported authentication methods in `bt_mesh_prov`, as well as enabling the supported actions in `bt_mesh_prov.output_actions` and `bt_mesh_prov.input_actions`.

When an Output OOB action is selected, the authentication value should be presented to the user when the output callback is called, and remain until the `bt_mesh_prov.input_complete` or `bt_mesh_prov.complete` callback is called. If the action is `blink`, `beep` or `vibrate`, the sequence should be repeated after a delay of three seconds or more.

When an Input OOB action is selected, the user should be prompted when the application receives the `bt_mesh_prov.input` callback. The user response should be fed back to the Provisioning API through `bt_mesh_input_string()` or `bt_mesh_input_numeric()`. If no user response is recorded within 60 seconds, the Provisioning process is aborted.

If Provisionee wants to mandate OOB authentication, it is mandatory to use the BT_MESH_ECDH_P256_HMAC_SHA256_AES_CCM algorithm.

Data transfer After the device has been successfully authenticated, the provisioner transfers the Provisioning data:

- Unicast address
- A network key
- IV index
- Network flags
  - Key refresh
  - IV update

Additionally, a device key is generated for the node. All this data is stored by the mesh stack, and the provisioning `bt_mesh_prov.complete` callback gets called.

Provisioning security Depending on the choice of public key exchange mechanism and authentication method, the provisioning process can be secure or insecure.

On May 24th 2021, ANSSI disclosed a set of vulnerabilities in the Bluetooth Mesh provisioning protocol that showcased how the low entropy provided by the Blink, Vibrate, Push, Twist and Input/Output numeric OOB methods could be exploited in impersonation and MITM attacks. In response, the Bluetooth SIG has reclassified these OOB methods as insecure in the Bluetooth Mesh Profile Specification v1.0.1 erratum 16350, as AuthValue may be brute forced in real time. To ensure secure provisioning, applications should use a static OOB value and OOB public key transfer.

API reference

Provisioning

Proxy The Proxy feature allows legacy devices like phones to access the Bluetooth Mesh network through GATT. The Proxy feature is only compiled in if the `CONFIG_BT_MESH_GATT_PROXY` option is set. The Proxy feature state is controlled by the *Configuration Server*, and the initial value can be set with `bt_mesh_cfg_srv.gatt_proxy`.

Nodes with the Proxy feature enabled can advertise with Network Identity and Node Identity, which is controlled by the *Configuration Client*.

The GATT Proxy state indicates if the Proxy feature is supported.

Private Proxy A node supporting the Proxy feature and the *Private Beacon Server* model can advertise with Private Network Identity and Private Node Identity types, which is controlled by the *Private Beacon Client*. By advertising with this set of identification types, the node allows the legacy device to connect to the network over GATT while maintaining the privacy of the network.

The Private GATT Proxy state indicates whether the Private Proxy functionality is supported.

Proxy Solicitation In the case where both GATT Proxy and Private GATT Proxy states are disabled on a node, a legacy device cannot connect to it. A node supporting the *On-Demand Private Proxy Server* may however be solicited to advertise connectable advertising events without enabling the Private GATT Proxy state. To solicit the node, the legacy device can send a Solicitation PDU by calling the `bt_mesh_proxy_solicit()` function. To enable this feature, the device must to be compiled with the `CONFIG_BT_MESH_PROXY_SOLICITATION` option set.

Solicitation PDUs are non-mesh, non-connectable, undirected advertising messages containing Proxy Solicitation UUID, encrypted with the network key of the subnet that the legacy device wants to connect to. The PDU contains the source address of the legacy device and a sequence number. The sequence number is maintained by the legacy device and is incremented for every new Solicitation PDU sent.

Each node supporting the Solicitation PDU reception holds its own Solicitation Replay Protection List (SRPL). The SRPL protects the solicitation mechanism from replay attacks by storing solicitation sequence number (SSEQ) and solicitation source (SSRC) pairs of valid Solicitation PDUs processed by the node. The delay between updating the SRPL and storing the change to the persistent storage is defined by `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`.

The Solicitation PDU RPL Configuration models, *Solicitation PDU RPL Configuration Client* and *Solicitation PDU RPL Configuration Server*, provide the functionality of saving and clearing SRPL entries. A node that supports the Solicitation PDU RPL Configuration Client model can clear a section of the SRPL on the target by calling the `bt_mesh_sol_pdu_rpl_clear()` function. Communication between the Solicitation PDU RPL Configuration Client and Server is encrypted using the application key, therefore, the Solicitation PDU RPL Configuration Client can be instantiated on any device in the network.

When the node receives the Solicitation PDU and successfully authenticates it, it will start advertising connectable advertisements with the Private Network Identity type. The duration of the advertisement can be configured by the On-Demand Private Proxy Client model.

Proxy

Heartbeat The Heartbeat feature provides functionality for monitoring Bluetooth Mesh nodes and determining the distance between nodes.

The Heartbeat feature is configured through the *Configuration Server* model.

Heartbeat messages Heartbeat messages are sent as transport control packets through the network, and are only encrypted with a network key. Heartbeat messages contain the original Time To Live (TTL) value used to send the message and a bitfield of the active features on the node. Through this, a receiving node can determine how many relays the message had to go through to arrive at the receiver, and what features the node supports.

Available Heartbeat feature flags:

- `BT_MESH_FEAT_RELAY`
- `BT_MESH_FEAT_PROXY`
- `BT_MESH_FEAT_FRIEND`
- `BT_MESH_FEAT_LOW_POWER`

Heartbeat publication Heartbeat publication is controlled through the Configuration models, and can be triggered in two ways:

Periodic publication
: The node publishes a new Heartbeat message at regular intervals. The publication can be configured to stop after a certain number of messages, or continue indefinitely.

Triggered publication
: The node publishes a new Heartbeat message every time a feature changes. The set of features that can trigger the publication is configurable.

The two publication types can be combined.

Heartbeat subscription A node can be configured to subscribe to Heartbeat messages from one node at the time. To receive a Heartbeat message, both the source and destination must match the configured subscription parameters.

Heartbeat subscription is always time limited, and throughout the subscription period, the node keeps track of the number of received Heartbeats as well as the minimum and maximum received hop count.

All Heartbeats received with the configured subscription parameters are passed to the `bt_mesh_hb_cb::recv` event handler.

When the Heartbeat subscription period ends, the `bt_mesh_hb_cb::sub_end` callback gets called.

Heartbeat

Runtime Configuration The runtime configuration API allows applications to change their runtime configuration directly, without going through the Configuration models.

Bluetooth Mesh nodes should generally be configured by a central network configurator device with a *Configuration Client* model. Each mesh node instantiates a *Configuration Server* model that the Configuration Client can communicate with to change the node configuration. In some cases, the mesh node can't rely on the Configuration Client to detect or determine local constraints, such as low battery power or changes in topology. For these scenarios, this API can be used to change the configuration locally.

Note

Runtime configuration changes before the node is provisioned will not be stored in the *persistent storage*.

API reference
Runtime Configuration

Frame statistic The frame statistic API allows monitoring the number of received frames over different interfaces, and the number of planned and succeeded transmission and relaying attempts.

The API helps the user to estimate the efficiency of the advertiser configuration parameters and the scanning ability of the device. The number of the monitored parameters can be easily extended by customer values.

An application can read out and clean up statistics at any time.

Statistic

Bluetooth Mesh Shell The Bluetooth Mesh shell subsystem provides a set of Bluetooth Mesh shell commands for the *Shell* module. It allows for testing and exploring the Bluetooth Mesh API through an interactive interface, without having to write an application.

The Bluetooth Mesh shell interface provides access to most Bluetooth Mesh features, including provisioning, configuration, and message sending.

Prerequisites The Bluetooth Mesh shell subsystem depends on the application to create the composition data and do the mesh initialization.

Application The Bluetooth Mesh shell subsystem is most easily used through the Bluetooth Mesh shell application under `tests/bluetooth/mesh_shell`. See *Shell* for information on how to connect and interact with the Bluetooth Mesh shell application.

Basic usage The Bluetooth Mesh shell subsystem adds a single `mesh` command, which holds a set of sub-commands. Every time the device boots up, make sure to call `mesh init` before any of the other Bluetooth Mesh shell commands can be called:

```
uart:~$ mesh init
```

This is done to ensure that all available log will be printed to the shell output.

Provisioning The mesh node must be provisioned to become part of the network. This is only necessary the first time the device boots up, as the device will remember its provisioning data between reboots.

The simplest way to provision the device is through self-provisioning. To do this the user must provision the device with the default network key and address `0x0001`, execute:

```
uart:~$ mesh prov local 0 0x0001
```

Since all mesh nodes use the same values for the default network key, this can be done on multiple devices, as long as they're assigned non-overlapping unicast addresses. Alternatively, to provision the device into an existing network, the unprovisioned beacon can be enabled with `mesh prov pb-adv on` or `mesh prov pb-gatt on`. The beacons can be picked up by an external provisioner, which can provision the node into its network.

Once the mesh node is part of a network, its transmission parameters can be controlled by the general configuration commands:

- To set the destination address, call `mesh target dst <Addr>`.
- To set the network key index, call `mesh target net <NetKeyIdx>`.
- To set the application key index, call `mesh target app <AppKeyIdx>`.

By default, the transmission parameters are set to send messages to the provisioned address and network key.

Configuration By setting the destination address to the local unicast address (`0x0001` in the `mesh prov local` command above), we can perform self-configuration through any of the *Models* commands.

A good first step is to read out the node's own composition data:

```
uart:~$ mesh models cfg get-comp
```

This prints a list of the composition data of the node, including a list of its model IDs.

Next, since the device has no application keys by default, it's a good idea to add one:

```
uart:~$ mesh models cfg appkey add 0 0
```

Message sending With an application key added (see above), the mesh node's transition parameters are all valid, and the Bluetooth Mesh shell can send raw mesh messages through the network.

For example, to send a Generic OnOff Set message, call:

```
uart:~$ mesh test net-send 82020100
```

Note

All multibyte fields model messages are in little endian, except the opcode.

The message will be sent to the current destination address, using the current network and application key indexes. As the destination address points to the local unicast address by default, the device will only send packets to itself. To change the destination address to the All Nodes broadcast address, call:

```
uart:~$ mesh target dst 0xffff
```

With the destination address set to `0xffff`, any other mesh nodes in the network with the configured network and application keys will receive and process the messages we send.

Note

To change the configuration of the device, the destination address must be set back to the local unicast address before issuing any configuration commands.

Sending raw mesh packets is a good way to test model message handler implementations during development, as it can be done without having to implement the sending model. By default, only the reception of the model messages can be tested this way, as the Bluetooth Mesh shell only includes the foundation models. To receive a packet in the mesh node, you have to add a model with a valid opcode handler list to the composition data in `subsys/bluetooth/mesh/shell.c`, and print the incoming message to the shell in the handler callback.

Parameter formats The Bluetooth Mesh shell commands are parsed with a variety of formats:

Table 15: Parameter formats

Type	Description	Example
Integers	The default format unless something else is specified. Can be either decimal or hexadecimal.	`1234`, `0xabcd01234`
Hexstrings	For raw byte arrays, like UUIDs, key values and message payloads, the parameters should be formatted as an unbroken string of hexadecimal values without any prefix.	`deadbeef01234`
Booleans	Boolean values are denoted in the API documentation as `<val(off, on)>`.	`on`, `off`, `enabled`, `disabled`, `1`, `0`

Commands The Bluetooth Mesh shell implements a large set of commands. Some of the commands accept parameters, which are mentioned in brackets after the command name. For example, `mesh lpn set <value: off, on>`. Mandatory parameters are marked with angle brackets (e.g. `<NetKeyIdx>`), and optional parameters are marked with square brackets (e.g. `[DstAddr]`).

The Bluetooth Mesh shell commands are divided into the following groups:

- *General configuration*
- *Target*
- *Low Power Node*
- *Testing*
- *Provisioning*
- *Proxy*
- *Models*
- *Configuration database*
- *Frame statistic*

Note

Some commands depend on specific features being enabled in the compile time configuration of the application. Not all features are enabled by default. The list of available Bluetooth mesh shell commands can be shown in the shell by calling `mesh` without any arguments.

General configuration

`mesh init`

Initialize the mesh shell. This command must be run before any other mesh command.

`mesh reset-local`

Reset the local mesh node to its initial unprovisioned state. This command will also clear the Configuration Database (CDB) if present.

Target The target commands enables the user to monitor and set the target destination address, network index and application index for the shell. These parameters are used by several commands, like provisioning, Configuration Client, etc.

`mesh target dst [DstAddr]`

Get or set the message destination address. The destination address determines where mesh packets are sent with the shell, but has no effect on modules outside the shell's control.

- `DstAddr`: If present, sets the new 16-bit mesh destination address. If omitted, the current destination address is printed.

`mesh target net [NetKeyIdx]`

Get or set the message network index. The network index determines which network key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell's control. The network key must already be added to the device, either through provisioning or by a Configuration Client.

- `NetKeyIdx`: If present, sets the new network index. If omitted, the current network index is printed.

`mesh target app [AppKeyIdx]`

Get or set the message application index. The application index determines which application key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell's control. The application key must already be added to the device by a Configuration Client, and must be bound to the current network index.

- `AppKeyIdx`: If present, sets the new application index. If omitted, the current application index is printed.

Low Power Node

`mesh lpn set <Val(off, on)>`

Enable or disable Low Power operation. Once enabled, the device will turn off its radio and start polling for friend nodes.

- `Val`: Sets whether Low Power operation is enabled.

`mesh lpn poll`

Perform a poll to the friend node, to receive any pending messages. Only available when LPN is enabled.

Testing

`mesh test net-send <HexString>`

Send a raw mesh message with the current destination address, network and application index. The message opcode must be encoded manually.

- `HexString` Raw hexadecimal representation of the message to send.

`mesh test iv-update`

Force an IV update.

`mesh test iv-update-test <Val(off, on)>`

Set the IV update test mode. In test mode, the IV update timing requirements are bypassed.

- `Val`: Enable or disable the IV update test mode.

`mesh test rpl-clear`

Clear the replay protection list, forcing the node to forget all received messages.

Warning

Clearing the replay protection list breaks the security mechanisms of the mesh node, making it susceptible to message replay attacks. This should never be performed in a real deployment.

Health Server Test

`mesh test health-srv add-fault <FaultID>`

Register a new Health Server Fault for the Linux Foundation Company ID.

- `FaultID`: ID of the fault to register (`0x0001` to `0xFFFF`)

`mesh test health-srv del-fault [FaultID]`

Remove registered Health Server faults for the Linux Foundation Company ID.

- `FaultID`: If present, the given fault ID will be deleted. If omitted, all registered faults will be cleared.

Provisioning To allow a device to broadcast connectable unprovisioned beacons, the `CONFIG_BT_MESH_PROVISIONEE` configuration option must be enabled, along with the `CONFIG_BT_MESH_PB_GATT` option.

`mesh prov pb-gatt <Val(off, on)>`

Start or stop advertising a connectable unprovisioned beacon. The connectable unprovisioned beacon allows the mesh node to be discovered by nearby GATT based provisioners, and provisioned through the GATT bearer.

- `Val`: Enable or disable provisioning with GATT

To allow a device to broadcast unprovisioned beacons, the `CONFIG_BT_MESH_PROVISIONEE` configuration option must be enabled, along with the `CONFIG_BT_MESH_PB_ADV` option.

`mesh prov pb-adv <Val(off, on)>`

Start or stop advertising the unprovisioned beacon. The unprovisioned beacon allows the mesh node to be discovered by nearby advertising-based provisioners, and provisioned through the advertising bearer.

- `Val`: Enable or disable provisioning with advertiser

To allow a device to provision devices, the `CONFIG_BT_MESH_PROVISIONER` and `CONFIG_BT_MESH_PB_ADV` configuration options must be enabled.

`mesh prov remote-adv <UUID(1-16 hex)> <NetKeyIdx> <Addr> <AttDur(s)>`

Provision a nearby device into the mesh. The mesh node starts scanning for unprovisioned beacons with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by `NetKeyIdx`.

- `UUID`: UUID of the unprovisioned device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Index of the network key to pass to the device.

- `Addr`: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- `AttDur`: The duration in seconds the unprovisioned device will identify itself for, if supported. See *Attention state* for details.

To allow a device to provision devices over GATT, the `CONFIG_BT_MESH_PROVISIONER` and `CONFIG_BT_MESH_PB_GATT_CLIENT` configuration options must be enabled.

`mesh prov remote-gatt <UUID(1-16 hex)> <NetKeyIdx> <Addr> <AttDur(s)>`

Provision a nearby device into the mesh. The mesh node starts scanning for connectable advertising for PB-GATT with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by `NetKeyIdx`.

- `UUID`: UUID of the unprovisioned device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Index of the network key to pass to the device.
- `Addr`: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- `AttDur`: The duration in seconds the unprovisioned device will identify itself for, if supported. See *Attention state* for details.

`mesh prov uuid [UUID(1-16 hex)]`

Get or set the mesh node's UUID, used in the unprovisioned beacons.

- `UUID`: If present, new 128-bit UUID value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the current UUID will be printed. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

`mesh prov input-num <Number>`

Input a numeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input number must match the number presented by the other participant in the provisioning.

- `Number`: Decimal authentication number.

`mesh prov input-str <String>`

Input an alphanumeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input string must match the string presented by the other participant in the provisioning.

- `String`: Unquoted alphanumeric authentication string.

`mesh prov static-oob [Val(1-32 hex)]`

Set or clear the static OOB authentication value. The static OOB authentication value must be set before provisioning starts to have any effect. The static OOB value must be same on both participants in the provisioning. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

- `Val`: If present, indicates the new hexadecimal value of the static OOB. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the static OOB value is cleared.

`mesh prov local <NetKeyIdx> <Addr> [IVI]`

Provision the mesh node itself. If the Configuration database is enabled, the network key must be created. Otherwise, the default key value is used.

- `NetKeyIdx`: Index of the network key to provision.
- `Addr`: First unicast address to assign to the device. The device will occupy as many addresses as it has elements, and all must be available.
- `IVI`: Indicates the current network IV index. Defaults to 0 if omitted.

`mesh prov beacon-listen <Val(off, on)>`

Enable or disable printing of incoming unprovisioned beacons. Allows a provisioner device to detect nearby unprovisioned devices and provision them. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

- `Val`: Whether to enable the unprovisioned beacon printing.

`mesh prov remote-pub-key <PubKey>`

Provide Device public key.

- `PubKey` - Device public key in big-endian.

`mesh prov auth-method input <Action> <Size>`

From the provisioner device, instruct the unprovisioned device to use the specified Input OOB authentication action.

- `Action` - Input action. Allowed values:
  - `0` - No input action.
  - `1` - Push action set.
  - `2` - Twist action set.
  - `4` - Enter number action set.
  - `8` - Enter String action set.
- `Size` - Authentication size.

`mesh prov auth-method output <Action> <Size>`

From the provisioner device, instruct the unprovisioned device to use the specified Output OOB authentication action.

- `Action` - Output action. Allowed values:
  - `0` - No output action.
  - `1` - Blink action set.
  - `2` - Vibrate action set.
  - `4` - Display number action set.
  - `8` - Display String action set.
- `Size` - Authentication size.

`mesh prov auth-method static <Val(1-16 hex)>`

From the provisioner device, instruct the unprovisioned device to use static OOB authentication, and use the given static authentication value when provisioning.

- `Val` - Static OOB value. Providing a hex-string shorter than 32 bytes will populate the N most significant bytes of the array and zero-pad the rest.

`mesh prov auth-method none`

From the provisioner device, don't use any authentication when provisioning new devices. This is the default behavior.

Proxy The Proxy Server module is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_GATT_PROXY` configuration option.

`mesh proxy identity-enable`

Enable the Proxy Node Identity beacon, allowing Proxy devices to connect explicitly to this device. The beacon will run for 60 seconds before the node returns to normal Proxy beacons.

The Proxy Client module is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_PROXY_CLIENT` configuration option.

`mesh proxy connect <NetKeyIdx>`

Auto-Connect a nearby proxy server into the mesh.

- `NetKeyIdx`: Index of the network key to connect.

`mesh proxy disconnect <NetKeyIdx>`

Disconnect the existing proxy connection.

- `NetKeyIdx`: Index of the network key to disconnect.

`mesh proxy solicit <NetKeyIdx>`

Begin Proxy Solicitation of a subnet. Support of this feature can be enabled through the `CONFIG_BT_MESH_PROXY_SOLICITATION` configuration option.

- `NetKeyIdx`: Index of the network key to send Solicitation PDUs to.

Models

Configuration Client The Configuration Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_CFG_CLI` configuration option. This is implemented as a separate module (`mesh models cfg`) inside the `mesh models` subcommand list. This module will work on any instance of the Configuration Client model if the mentioned shell configuration options is enabled, and as long as the Configuration Client model is present in the model composition of the application. This shell module can be used for configuring itself and other nodes in the mesh network.

The Configuration Client uses general message parameters set by `mesh target dst` and `mesh target net` to target specific nodes. When the Bluetooth Mesh shell node is provisioned, given that the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option is enabled with the shell provisioning context initialized, the Configuration Client model targets itself by default. Similarly, when another node has been provisioned by the Bluetooth Mesh shell, the Configuration Client model targets the new node. In most common use-cases, the Configuration Client is depending on the provisioning features and the Configuration database to be fully functional. The Configuration

Client always sends messages using the Device key bound to the destination address, so it will only be able to configure itself and the mesh nodes it provisioned. The following steps are an example of how you can set up a device to start using the Configuration Client commands:

- Initialize the client node (`mesh init`).
- Create the CDB (`mesh cdb create`).
- Provision the local device (`mesh prov local`).
- The shell module should now target itself.
- Monitor the composition data of the local node (`mesh models cfg get-comp`).
- Configure the local node as desired with the Configuration Client commands.
- Provision other devices (`mesh prov beacon-listen`) (`mesh prov remote-adv`) (`mesh prov remote-gatt`).
- The shell module should now target the newly added node.
- Monitor the newly provisioned nodes and their addresses (`mesh cdb show`).
- Monitor the composition data of the target device (`mesh models cfg get-comp`).
- Configure the node as desired with the Configuration Client commands.

`mesh models cfg target get`

Get the target Configuration server for the Configuration Client model.

`mesh models cfg help`

Print information for the Configuration Client shell module.

`mesh models cfg reset`

Reset the target device.

`mesh models cfg timeout [Timeout(s)]`

Get and set the Config Client model timeout used during message sending.

- `Timeout`: If present, set the Config Client model timeout in seconds. If omitted, the current timeout is printed.

`mesh models cfg get-comp [Page]`

Read a composition data page. The full composition data page will be printed. If the target does not have the given page, it will return the last page before it.

- `Page`: The composition data page to request. Defaults to 0 if omitted.

`mesh models cfg beacon [Val(off, on)]`

Get or set the network beacon transmission.

- `Val`: If present, enables or disables sending of the network beacon. If omitted, the current network beacon state is printed.

`mesh models cfg ttl [TTL]`

Get or set the default TTL value.

- `TTL`: If present, sets the new default TTL value. Legal TTL values are 0x00 and 0x02-0x7f. If omitted, the current default TTL value is printed.

`mesh models cfg friend [Val(off, on)]`

Get or set the Friend feature.

- `Val`: If present, enables or disables the Friend feature. If omitted, the current Friend feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.

`mesh models cfg gatt-proxy [Val(off, on)]`

Get or set the GATT Proxy feature.

- `Val`: If present, enables or disables the GATT Proxy feature. If omitted, the current GATT Proxy feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.

`mesh models cfg relay [<Val(off, on)> [<Count> [Int(ms)]]]`

Get or set the Relay feature and its parameters.

- `Val`: If present, enables or disables the Relay feature. If omitted, the current Relay feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.
- `Count`: Sets the new relay retransmit count if `val` is `on`. Ignored if `val` is `off`. Legal retransmit count is 0-7. Defaults to `2` if omitted.
- `Int`: Sets the new relay retransmit interval in milliseconds if `val` is `on`. Legal interval range is 10-320 milliseconds. Ignored if `val` is `off`. Defaults to `20` if omitted.

`mesh models cfg node-id <NetKeyIdx> [Identity]`

Get or Set of current Node Identity state of a subnet.

- `NetKeyIdx`: The network key index to Get/Set.
- `Identity`: If present, sets the identity of Node Identity state.

`mesh models cfg polltimeout-get <LPNAddr>`

Get current value of the PollTimeout timer of the LPN within a Friend node.

- `LPNAddr` Address of Low Power node.

`mesh models cfg net-transmit-param [<Count> <Int(ms)>]`

Get or set the network transmit parameters.

- `Count`: Sets the number of additional network transmits for every sent message. Legal retransmit count is 0-7.
- `Int`: Sets the new network retransmit interval in milliseconds. Legal interval range is 10-320 milliseconds.

`mesh models cfg netkey add <NetKeyIdx> [Key(1-16 hex)]`

Add a network key to the target node. Adds the key to the Configuration Database if enabled.

- `NetKeyIdx`: The network key index to add.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

`mesh models cfg netkey upd <NetKeyIdx> [Key(1-16 hex)]`

Update a network key to the target node.

- `NetKeyIdx`: The network key index to updated.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the default key value is used.

`mesh models cfg netkey get`

Get a list of known network key indexes.

`mesh models cfg netkey del <NetKeyIdx>`

Delete a network key from the target node.

- `NetKeyIdx`: The network key index to delete.

`mesh models cfg appkey add <NetKeyIdx> <AppKeyIdx> [Key(1-16 hex)]`

Add an application key to the target node. Adds the key to the Configuration Database if enabled.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to add.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

`mesh models cfg appkey upd <NetKeyIdx> <AppKeyIdx> [Key(1-16 hex)]`

Update an application key to the target node.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to update.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the default key value is used.

`mesh models cfg appkey get <NetKeyIdx>`

Get a list of known application key indexes bound to the given network key index.

- `NetKeyIdx`: Network key indexes to get a list of application key indexes from.

`mesh models cfg appkey del <NetKeyIdx> <AppKeyIdx>`

Delete an application key from the target node.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to delete.

`mesh models cfg model app-bind <Addr> <AppKeyIdx> <MID> [CID]`

Bind an application key to a model. Models can only encrypt and decrypt messages sent with application keys they are bound to.

- `Addr`: Address of the element the model is on.
- `AppKeyIdx`: The application key to bind to the model.
- `MID`: The model ID of the model to bind the key to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model app-unbind <Addr> <AppKeyIdx> <MID> [CID]`

Unbind an application key from a model.

- `Addr`: Address of the element the model is on.
- `AppKeyIdx`: The application key to unbind from the model.
- `MID`: The model ID of the model to unbind the key from.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model app-get <ElemAddr> <MID> [CID]`

Get a list of application keys bound to a model.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model pub <Addr> <MID> [CID] [<PubAddr> <AppKeyIdx> <Cred(off, on)> <TTL> <PerRes> <PerSteps> <Count> <Int(ms)>]`

Get or set the publication parameters of a model. If all publication parameters are included, they become the new publication parameters of the model. If all publication parameters are omitted, print the current publication parameters of the model.

- `Addr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

Publication parameters:

- `PubAddr`: The destination address to publish to.
- `AppKeyIdx`: The application key index to publish with.
- `Cred`: Whether to publish with Friendship credentials when acting as a Low Power Node.

- `TTL`: TTL value to publish with (`0x00` to `0x7f`).
- `PerRes`: Resolution of the publication period steps:
  - `0x00`: The Step Resolution is 100 milliseconds
  - `0x01`: The Step Resolution is 1 second
  - `0x02`: The Step Resolution is 10 seconds
  - `0x03`: The Step Resolution is 10 minutes
- `PerSteps`: Number of publication period steps, or 0 to disable periodic publication.
- `Count`: Number of retransmission for each published message (`0` to 7).
- `Int` The interval between each retransmission, in milliseconds. Must be a multiple of 50.

`mesh models cfg model pub-va <Addr> <UUID(1-16 hex)> <AppKeyIdx> <Cred(off, on)> <TTL> <PerRes> <PerSteps> <Count> <Int(ms)> <MID> [CID]`

Set the publication parameters of a model.

- `Addr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

Publication parameters:

- `UUID`: The destination virtual address to publish to. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `AppKeyIdx`: The application key index to publish with.
- `Cred`: Whether to publish with Friendship credentials when acting as a Low Power Node.
- `TTL`: TTL value to publish with (`0x00` to `0x7f`).
- `PerRes`: Resolution of the publication period steps:
  - `0x00`: The Step Resolution is 100 milliseconds
  - `0x01`: The Step Resolution is 1 second
  - `0x02`: The Step Resolution is 10 seconds
  - `0x03`: The Step Resolution is 10 minutes
- `PerSteps`: Number of publication period steps, or 0 to disable periodic publication.
- `Count`: Number of retransmission for each published message (`0` to 7).
- `Int` The interval between each retransmission, in milliseconds. Must be a multiple of 50.

`mesh models cfg model sub-add <ElemAddr> <SubAddr> <MID> [CID]`

Subscription the model to a group address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- `ElemAddr`: Address of the element the model is on.

- SubAddr: 16-bit group address the model should subscribe to (0xc000 to 0xFEFF).
- MID: The model ID of the model to add the subscription to.
- CID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del <ElemAddr> <SubAddr> <MID> [CID]`

Unsubscribe a model from a group address.

- ElemAddr: Address of the element the model is on.
- SubAddr: 16-bit group address the model should remove from its subscription list (0xc000 to 0xFEFF).
- MID: The model ID of the model to add the subscription to.
- CID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-add-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Subscribe the model to a virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- ElemAddr: Address of the element the model is on.
- LabelUUID: 128-bit label UUID of the virtual address to subscribe to. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- MID: The model ID of the model to add the subscription to.
- CID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Unsubscribe a model from a virtual address.

- ElemAddr: Address of the element the model is on.
- LabelUUID: 128-bit label UUID of the virtual address to remove the subscription of. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- MID: The model ID of the model to add the subscription to.
- CID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-ow <ElemAddr> <SubAddr> <MID> [CID]`

Overwrite all model subscriptions with a single new group address.

- ElemAddr: Address of the element the model is on.
- SubAddr: 16-bit group address the model should added to the subscription list (0xc000 to 0xFEFF).
- MID: The model ID of the model to add the subscription to.
- CID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-ow-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Overwrite all model subscriptions with a single new virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- `ElemAddr`: Address of the element the model is on.
- `LabelUUID`: 128-bit label UUID of the virtual address as the new Address to be added to the subscription list. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del-all <ElemAddr> <MID> [CID]`

Remove all group and virtual address subscriptions from of a model.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to Unsubscribe all.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-get <ElemAddr> <MID> [CID]`

Get a list of addresses the model subscribes to.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the subscription list of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg krp <NetKeyIdx> [Phase]`

Get or set the key refresh phase of a subnet.

- `NetKeyIdx`: The identified network key used to Get/Set the current Key Refresh Phase state.
- `Phase`: New Key Refresh Phase. Valid phases are:
  - `0x00`: Normal operation; Key Refresh procedure is not active
  - `0x01`: First phase of Key Refresh procedure
  - `0x02`: Second phase of Key Refresh procedure

`mesh models cfg hb-sub [<Src> <Dst> <Per>]`

Get or set the Heartbeat subscription parameters. A node only receives Heartbeat messages matching the Heartbeat subscription parameters. Sets the Heartbeat subscription parameters if present, or prints the current Heartbeat subscription parameters if called with no parameters.

- `Src`: Unicast source address to receive Heartbeat messages from.
- `Dst`: Destination address to receive Heartbeat messages on.
- `Per`: Logarithmic representation of the Heartbeat subscription period:
  - `0`: Heartbeat subscription will be disabled.

  - 1 to 17: The node will subscribe to Heartbeat messages for $2^{(period - 1)}$ seconds.

`mesh models cfg hb-pub [<Dst> <Count> <Per> <TTL> <Features> <NetKeyIdx>]`

Get or set the Heartbeat publication parameters. Sets the Heartbeat publication parameters if present, or prints the current Heartbeat publication parameters if called with no parameters.

- `Dst`: Destination address to publish Heartbeat messages to.
- `Count`: Logarithmic representation of the number of Heartbeat messages to publish periodically:
  - `0`: Heartbeat messages are not published periodically.
  - 1 to 17: The node will periodically publish $2^{(count - 1)}$ Heartbeat messages.
  - `255`: Heartbeat messages will be published periodically indefinitely.
- `Per`: Logarithmic representation of the Heartbeat publication period:
  - `0`: Heartbeat messages are not published periodically.
  - 1 to 17: The node will publish Heartbeat messages every $2^{(period - 1)}$ seconds.
- `TTL`: The TTL value to publish Heartbeat messages with (`0x00` to `0x7f`).
- `Features`: Bitfield of features that should trigger a Heartbeat publication when changed:
  - `Bit 0`: Relay feature.
  - `Bit 1`: Proxy feature.
  - `Bit 2`: Friend feature.
  - `Bit 3`: Low Power feature.
- `NetKeyIdx`: Index of the network key to publish Heartbeat messages with.

Health Client The Health Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_HEALTH_CLI` configuration option. This is implemented as a separate module (`mesh models health`) inside the `mesh models` subcommand list. This module will work on any instance of the Health Client model if the mentioned shell configuration options is enabled, and as long as one or more Health Client model(s) is present in the model composition of the application. This shell module can be used to trigger interaction between Health Clients and Servers on devices in a Mesh network.

By default, the module will choose the first Health Client instance in the model composition when using the Health Client commands. To choose a specific Health Client instance the user can utilize the commands `mesh models health instance set` and `mesh models health instance get-all`.

The Health Client may use the general messages parameters set by `mesh target dst`, `mesh target net` and `mesh target app` to target specific nodes. If the shell target destination address is set to zero, the targeted Health Client will attempt to publish messages using its configured publication parameters.

`mesh models health instance set <ElemIdx>`

Set the Health Client model instance to use.

- `ElemIdx`: Element index of Health Client model.

`mesh models health instance get-all`

Prints all available Health Client model instances on the device.

`mesh models health fault-get <CID>`

Get a list of registered faults for a Company ID.

- `CID`: Company ID to get faults for.

`mesh models health fault-clear <CID>`

Clear the list of faults for a Company ID.

- `CID`: Company ID to clear the faults for.

`mesh models health fault-clear-unack <CID>`

Clear the list of faults for a Company ID without requesting a response.

- `CID`: Company ID to clear the faults for.

`mesh models health fault-test <CID> <TestID>`

Invoke a self-test procedure, and show a list of triggered faults.

- `CID`: Company ID to perform self-tests for.
- `TestID`: Test to perform.

`mesh models health fault-test-unack <CID> <TestID>`

Invoke a self-test procedure without requesting a response.

- `CID`: Company ID to perform self-tests for.
- `TestID`: Test to perform.

`mesh models health period-get`

Get the current Health Server publish period divisor.

`mesh models health period-set <Divisor>`

Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / 2^{divisor}.

- `Divisor`: The new Health Server publish period divisor.

`mesh models health period-set-unack <Divisor>`

Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / 2^{divisor}.

- `Divisor`: The new Health Server publish period divisor.

`mesh models health attention-get`

Get the current Health Server attention state.

`mesh models health attention-set <Time(s)>`

Enable the Health Server attention state for some time.

- `Time`: Duration of the attention state, in seconds (`0` to `255`)

`mesh models health attention-set-unack <Time(s)>`

Enable the Health Server attention state for some time without requesting a response.

- `Time`: Duration of the attention state, in seconds (`0` to `255`)

Binary Large Object (BLOB) Transfer Client model The *BLOB Transfer Client* can be added to the mesh shell by enabling the `CONFIG_BT_MESH_BLOB_CLI` option, and disabling the `CONFIG_BT_MESH_DFU_CLI` option.

`mesh models blob cli target <Addr>`

Add a Target node for the next BLOB transfer.

- `Addr`: Unicast address of the Target node's BLOB Transfer Server model.

`mesh models blob cli caps [<Group> [<TimeoutBase>]]`

Retrieve transfer capabilities for Target nodes.

- `Group`: Optional group address to use when communicating with Target nodes. If omitted, the BLOB Transfer Client will address each Target node individually.
- `TimeoutBase`: Optional time to wait for responses from Target nodes, in 10-second increments.

`mesh models blob cli tx <Id> <Size> <BlockSizeLog> <ChunkSize> [<Group> [<Mode(push, pull)>]]`

Perform a BLOB transfer to Target nodes. The BLOB Transfer Client will send a dummy BLOB to all Target nodes, then post a message when the transfer is completed. Note that all Target nodes must first be configured to receive the transfer using the `mesh models blob srv rx` command.

- `Id`: 64-bit BLOB transfer ID.
- `Size`: Size of the BLOB in bytes.
- `BlockSizeLog`: Logarithmic representation of the BLOB's block size. The final block size will be `1 << block size log` bytes.
- `ChunkSize`: Chunk size in bytes.
- `Group`: Optional group address to use when communicating with Target nodes. If omitted or set to 0, the BLOB Transfer Client will address each Target node individually.
- `Mode`: BLOB transfer mode to use. Must be either `push` (Push BLOB Transfer Mode) or `pull` (Pull BLOB Transfer Mode). If omitted, `push` will be used by default.

`mesh models blob cli tx-cancel`

Cancel an ongoing BLOB transfer.

`mesh models blob cli tx-get [Group]`

Determine the progress of a previously running BLOB transfer. Can be used when not performing a BLOB transfer.

- `Group`: Optional group address to use when communicating with Target nodes. If omitted or set to 0, the BLOB Transfer Client will address each Target node individually.

`mesh models blob cli tx-suspend`

Suspend the ongoing BLOB transfer.

`mesh models blob cli tx-resume`

Resume the suspended BLOB transfer.

`mesh models blob cli instance-set <ElemIdx>`

Use the BLOB Transfer Client model instance on the specified element when using the other BLOB Transfer Client model commands.

- `ElemIdx`: The element on which to find the BLOB Transfer Client model instance to use.

`mesh models blob cli instance-get-all`

Get a list of all BLOB Transfer Client model instances on the node.

BLOB Transfer Server model The *BLOB Transfer Server* can be added to the mesh shell by enabling the `CONFIG_BT_MESH_BLOB_SRV` option. The BLOB Transfer Server model is capable of receiving any BLOB data, but the implementation in the mesh shell will discard the incoming data.

`mesh models blob srv rx <ID> [<TimeoutBase(10s steps)>]`

Prepare to receive a BLOB transfer.

- `ID`: 64-bit BLOB transfer ID to receive.
- `TimeoutBase`: Optional additional time to wait for client messages, in 10-second increments.

`mesh models blob srv rx-cancel`

Cancel an ongoing BLOB transfer.

`mesh models blob srv instance-set <ElemIdx>`

Use the BLOB Transfer Server model instance on the specified element when using the other BLOB Transfer Server model commands.

- `ElemIdx`: The element on which to find the BLOB Transfer Server model instance to use.

`mesh models blob srv instance-get-all`

Get a list of all BLOB Transfer Server model instances on the node.

Binary Large Object (BLOB) Transfer flash stream BLOB flash stream configuration can be added to the mesh shell by enabling the `CONFIG_BT_MESH_SHELL_BLOB_IO_FLASH` option. By default, the shell uses a dummy BLOB stream. This option allows the user to specify which area in the flash to use. See *Flash map* for information on how to obtain related parameters.

`mesh models blob flash-stream-set <AreaID> [<Offset>]`

Set the BLOB stream to a specified area.

- `AreaID`: Flash area ID to write/read the BLOB to/from.
- `Offset`: Optional offset into the flash area to place the BLOB at (in bytes).

`mesh models blob flash-stream-unset`

Set the BLOB stream back to the dummy stream.

Firmware Update Client model The Firmware Update Client model can be added to the mesh shell by enabling configuration options `CONFIG_BT_MESH_BLOB_CLI` and `CONFIG_BT_MESH_DFU_CLI`. The Firmware Update Client demonstrates the firmware update Distributor role by transferring a dummy firmware update to a set of Target nodes.

`mesh models dfu slot add <Size> <FwID> [<Metadata>]`

Add a virtual DFU image slot that can be transferred as a DFU image. The image slot will be assigned an image slot index, which is printed as a response, and can be used to reference the slot in other commands. To update the image slot, remove it using the `mesh models dfu slot del` shell command and then add it again.

- `Size`: DFU image slot size in bytes.
- `FwID`: Firmware ID, formatted as a hexstring.
- `Metadata`: Optional firmware metadata, formatted as a hexstring.

`mesh models dfu slot del <SlotIdx>`

Delete the DFU image slot at the given index.

- `SlotIdx`: Index of the slot to delete.

`mesh models dfu slot get <SlotIdx>`

Get all available information about a DFU image slot.

- `SlotIdx`: Index of the slot to get.

`mesh models dfu cli target <Addr> <ImgIdx>`

Add a Target node.

- `Addr`: Unicast address of the Target node.
- `ImgIdx`: Image index to address on the Target node.

`mesh models dfu cli target-state`

Check the DFU Target state of the device at the configured destination address.

`mesh models dfu cli target-imgs [<MaxCount>]`

Get a list of DFU images on the device at the configured destination address.

- `MaxCount`: Optional maximum number of images to return. If omitted, there's no limit on the number of returned images.

`mesh models dfu cli target-check <SlotIdx> <TargetImgIdx>`

Check whether the device at the configured destination address will accept a DFU transfer from the given DFU image slot to the Target node's DFU image at the given index, and what the effect would be.

- `SlotIdx`: Index of the local DFU image slot to check.
- `TargetImgIdx`: Index of the Target node's DFU image to check.

`mesh models dfu cli send <SlotIdx> [<Group>]`

Start a DFU transfer to all added Target nodes.

- `SlotIdx`: Index of the local DFU image slot to send.
- `Group`: Optional group address to use when communicating with the Target nodes. If omitted, the Firmware Update Client will address each Target node individually.

`mesh models dfu cli cancel [<Addr>]`

Cancel the DFU procedure at any state on a specific Target node or on all Target nodes. When a Target node address is provided, the Firmware Update Client model will try to cancel the DFU procedure on the provided Target node. Otherwise, the Firmware Update Client model will try to cancel the ongoing DFU procedure on all Target nodes.

- `Addr`: Optional unicast address of a Target node on which to cancel the DFU procedure.

`mesh models dfu cli apply`

Apply the most recent DFU transfer on all Target nodes. Can only be called after a DFU transfer is completed.

`mesh models dfu cli confirm`

Confirm that the most recent DFU transfer was successfully applied on all Target nodes. Can only be called after a DFU transfer is completed and applied.

`mesh models dfu cli suspend`

Suspend the ongoing DFU transfer.

`mesh models dfu cli resume`

Resume the suspended DFU transfer.

`mesh models dfu cli progress`

Check the progress of the current transfer.

`mesh models dfu cli instance-set <ElemIdx>`

Use the Firmware Update Client model instance on the specified element when using the other Firmware Update Client model commands.

- `ElemIdx`: The element on which to find the Firmware Update Client model instance to use.

`mesh models dfu cli instance-get-all`

Get a list of all Firmware Update Client model instances on the node.

Firmware Update Server model The Firmware Update Server model can be added to the mesh shell by enabling configuration options `CONFIG_BT_MESH_BLOB_SRV` and `CONFIG_BT_MESH_DFU_SRV`. The Firmware Update Server demonstrates the firmware update Target role by accepting any firmware update. The mesh shell Firmware Update Server will discard the incoming firmware data, but otherwise behave as a proper firmware update Target node.

`mesh models dfu srv applied`

Mark the most recent DFU transfer as applied. Can only be called after a DFU transfer is completed, and the Distributor has requested that the transfer is applied.

As the mesh shell Firmware Update Server doesn't actually apply the incoming firmware image, this command can be used to emulate an applied status, to notify the Distributor that the transfer was successful.

`mesh models dfu srv progress`

Check the progress of the current transfer.

`mesh models dfu srv rx-cancel`

Cancel incoming DFU transfer.

`mesh models dfu srv instance-set <ElemIdx>`

Use the Firmware Update Server model instance on the specified element when using the other Firmware Update Server model commands.

- `ElemIdx`: The element on which to find the Firmware Update Server model instance to use.

`mesh models dfu srv instance-get-all`

Get a list of all Firmware Update Server model instances on the node.

Firmware Distribution Server model The Firmware Distribution Server model commands can be added to the mesh shell by enabling the `CONFIG_BT_MESH_DFD_SRV` configuration option. The shell commands for this model mirror the messages sent to the server by a Firmware Distribution Client model. To use these commands, a Firmware Distribution Server must be instantiated by the application.

`mesh models dfd receivers-add <Addr>,<FwIdx>[;<Addr>,<FwIdx>]...`

Add receivers to the Firmware Distribution Server. Supply receivers as a list of comma-separated addr,fw_idx pairs, separated by semicolons, for example, `0x0001,0;0x0002,0;0x0004,1`. Do not use spaces in the receiver list. Repeated calls to this command will continue populating the receivers list until `mesh models dfd receivers-delete-all` is called.

- `Addr`: Address of the receiving node(s).
- `FwIdx`: Index of the firmware slot to send to `Addr`.

`mesh models dfd receivers-delete-all`

Delete all receivers from the server.

`mesh models dfd receivers-get <First> <Count>`

Get a list of info about firmware receivers.

- `First`: Index of the first receiver to get from the receiver list.
- `Count`: The number of receivers for which to get info.

`mesh models dfd capabilities-get`

Get the capabilities of the server.

`mesh models dfd get`

Get information about the current distribution state, phase and the transfer parameters.

`mesh models dfd start <AppKeyIdx> <SlotIdx> [<Group> [<PolicyApply> [<TTL> [<TimeoutBase> [<XferMode>]]]]]`

Start the firmware distribution.

- `AppKeyIdx`: Application index to use for sending. The common application key should be bound to the Firmware Update and BLOB Transfer models on the Distributor and Target nodes.
- `SlotIdx`: Index of the local image slot to send.
- `Group`: Optional group address to use when communicating with the Target nodes. If omitted, the Firmware Distribution Server will address each Target node individually. To keep addressing each Target node individually while changing other arguments, set this argument value to 0.
- `PolicyApply`: Optional field that corresponds to the update policy. Setting this to `true` will make the Firmware Distribution Server apply the image immediately after the transfer is completed.
- `TTL`: Optional. TTL value to use when sending. Defaults to configured default TTL.
- `TimeoutBase`: Optional additional value used to calculate timeout values in the firmware distribution process, in 10-second increments.. See *Transfer timeout* for information about how `timeout_base` is used to calculate the transfer timeout. Defaults to 0.
- `XferMode`: Optional BLOB transfer mode. 1 = Push mode (Push BLOB Transfer Mode), 2 = Pull mode (Pull BLOB Transfer Mode). Defaults to Push mode.

`mesh models dfd suspend`

Suspends the ongoing distribution.

`mesh models dfd cancel`

Cancel the ongoing distribution.

`mesh models dfd apply`

Apply the distributed firmware.

`mesh models dfd fw-get <FwID>`

Get information about the firmware image uploaded to the server.

- `FwID`: Firmware ID of the image to get.

`mesh models dfd fw-get-by-idx <Idx>`

Get information about the firmware image uploaded to the server in a specific slot.

- `Idx`: Index of the slot to get the image from.

`mesh models dfd fw-delete <FwID>`

Delete a firmware image from the server.

- `FwID`: Firmware ID of the image to delete.

`mesh models dfd fw-delete-all`

Delete all firmware images from the server.

`mesh models dfd instance-set <ElemIdx>`

Use the Firmware Distribution Server model instance on the specified element when using the other Firmware Distribution Server model commands.

- `ElemIdx`: The element on which to find the Firmware Distribution Server model instance to use.

`mesh models dfd instance-get-all`

Get a list of all Firmware Distribution Server model instances on the node.

DFU metadata The DFU metadata shell commands allow generating metadata that can be used by a Target node to check the firmware before accepting it. The commands are enabled through the `CONFIG_BT_MESH_SHELL_DFU_METADATA` configuration option.

`mesh models dfu metadata comp-clear`

Clear the stored composition data to be used for the Target node.

`mesh models dfu metadata comp-add <CID> <ProductID> <VendorID> <Crpl> <Features>`

Create a header of the Composition Data Page 0.

- `CID`: Company identifier assigned by Bluetooth SIG.
- `ProductID`: Vendor-assigned product identifier.
- `VendorID`: Vendor-assigned version identifier.
- `Crpl`: The size of the replay protection list.
- `Features`: Features supported by the node in bit field format:
  - `0`: Relay.
  - `1`: Proxy.
  - `2`: Friend.

- 3: Low Power.

`mesh models dfu metadata comp-elem-add <Loc> <NumS> <NumV> {<SigMID>|<VndCID> <VndMID>}...`

Add element description of the Target node.

- `Loc`: Element location.
- `NumS`: Number of SIG models instantiated on the element.
- `NumV`: Number of vendor models instantiated on the element.
- `SigMID`: SIG Model ID.
- `VndCID`: Vendor model company identifier.
- `VndMID`: Vendor model identifier.

`mesh models dfu metadata comp-hash-get [<Key(16 hex)>]`

Generate a hash of the stored Composition Data to be used in metadata.

- `Key`: Optional 128-bit key to be used to generate the hash. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.

`mesh models dfu metadata encode <Major> <Minor> <Rev> <BuildNum> <Size> <CoreType> <Hash> <Elems> [<UserData>]`

Encode metadata for the DFU.

- `Major`: Major version of the firmware.
- `Minor`: Minor version of the firmware.
- `Rev`: Revision number of the firmware.
- `BuildNum`: Build number.
- `Size`: Size of the signed bin file.
- `CoreType`: New firmware core type:
  - 1: Application core.
  - 2: Network core.
  - 4: Applications specific BLOB.
- `Hash`: Hash of the composition data generated using `mesh models dfu metadata comp-hash-get` command.
- `Elems`: Number of elements on the new firmware.
- `UserData`: User data supplied with the metadata.

Segmentation and Reassembly (SAR) Configuration Client The SAR Configuration client is an optional mesh model that can be enabled through the `CONFIG_BT_MESH_SAR_CFG_CLI` configuration option. The SAR Configuration Client model is used to support the functionality of configuring the behavior of the lower transport layer of a node that supports the SAR Configuration Server model.

`mesh models sar tx-get`

Send SAR Configuration Transmitter Get message.

`mesh models sar tx-set <SegIntStep> <UniRetransCnt> <UniRetransWithoutProgCnt> <UniRetransIntStep> <UniRetransIntInc> <MultiRetransCnt> <MultiRetransInt>`

Send SAR Configuration Transmitter Set message.

- `SegIntStep`: SAR Segment Interval Step state.
- `UniRetransCnt`: SAR Unicast Retransmissions Count state.
- `UniRetransWithoutProgCnt`: SAR Unicast Retransmissions Without Progress Count state.
- `UniRetransIntStep`: SAR Unicast Retransmissions Interval Step state.
- `UniRetransIntInc`: SAR Unicast Retransmissions Interval Increment state.
- `MultiRetransCnt`: SAR Multicast Retransmissions Count state.
- `MultiRetransInt`: SAR Multicast Retransmissions Interval state.

`mesh models sar rx-get`

Send SAR Configuration Receiver Get message.

`mesh models sar rx-set <SegThresh> <AckDelayInc> <DiscardTimeout> <RxSegIntStep> <AckRetransCount>`

Send SAR Configuration Receiver Set message.

- `SegThresh`: SAR Segments Threshold state.
- `AckDelayInc`: SAR Acknowledgment Delay Increment state.
- `DiscardTimeout`: SAR Discard Timeout state.
- `RxSegIntStep`: SAR Receiver Segment Interval Step state.
- `AckRetransCount`: SAR Acknowledgment Retransmissions Count state.

Private Beacon Client The Private Beacon Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_PRIV_BEACON_CLI` configuration option.

`mesh models prb priv-beacon-get`

Get the target's Private Beacon state. Possible values:

- `0x00`: The node doesn't broadcast Private beacons.
- `0x01`: The node broadcasts Private beacons.

`mesh models prb priv-beacon-set <Val(off, on)> <RandInt(10s steps)>`

Set the target's Private Beacon state.

- `Val`: Control Private Beacon state.
- `RandInt`: Random refresh interval (in 10-second steps), or 0 to keep current value.

`mesh models prb priv-gatt-proxy-get`

Get the target's Private GATT Proxy state. Possible values:

- `0x00`: The Private Proxy functionality is supported, but disabled.
- `0x01`: The Private Proxy functionality is enabled.
- `0x02`: The Private Proxy functionality is not supported.

`mesh models prb priv-gatt-proxy-set <Val(off, on)>`

Set the target's Private GATT Proxy state.

- `Val`: New Private GATT Proxy value:
  - `0x00`: Disable the Private Proxy functionality.
  - `0x01`: Enable the Private Proxy functionality.

`mesh models prb priv-node-id-get <NetKeyIdx>`

Get the target's Private Node Identity state. Possible values:

- `0x00`: The node does not adverstise with the Private Node Identity.
- `0x01`: The node advertises with the Private Node Identity.
- `0x02`: The node doesn't support advertising with the Private Node Identity.
- `NetKeyIdx`: Network index to get the Private Node Identity state of.

`mesh models prb priv-node-id-set <NetKeyIdx> <State>`

Set the target's Private Node Identity state.

- `NetKeyIdx`: Network index to set the Private Node Identity state of.
- `State`: New Private Node Identity value:
  - `0x00`: Stop advertising with the Private Node Identity.
  - `0x01`: Start advertising with the Private Node Identity.

Opcodes Aggregator Client The Opcodes Aggregator client is an optional Bluetooth Mesh model that can be enabled through the `CONFIG_BT_MESH_OP_AGG_CLI` configuration option. The Opcodes Aggregator Client model is used to support the functionality of dispatching a sequence of access layer messages to nodes supporting the Opcodes Aggregator Server model.

`mesh models opagg seq-start <ElemAddr>`

Start the Opcodes Aggregator Sequence message. This command initiates the context for aggregating messages and sets the destination address for next shell commands to `elem_addr`.

- `ElemAddr`: Element address that will process the aggregated opcodes.

`mesh models opagg seq-send`

Send the Opcodes Aggregator Sequence message. This command completes the procedure, sends the aggregated sequence message to the target node and clears the context.

`mesh models opagg seq-abort`

Abort the Opcodes Aggregator Sequence message. This command clears the Opcodes Aggregator Client context.

Remote Provisioning Client The Remote Provisioning Client is an optional Bluetooth Mesh model enabled through the `CONFIG_BT_MESH_RPR_CLI` configuration option. The Remote Provisioning Client model provides support for remote provisioning of devices into a mesh network by using the Remote Provisioning Server model.

This shell module can be used to trigger interaction between Remote Provisioning Clients and Remote Provisioning Servers on devices in a mesh network.

`mesh models rpr scan <Timeout(s)> [<UUID(1-16 hex)>]`

Start scanning for unprovisioned devices.

- `Timeout`: Scan timeout in seconds. Must be at least 1 second.
- `UUID`: Device UUID to scan for. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, all devices will be reported.

`mesh models rpr scan-ext <Timeout(s)> <UUID(1-16 hex)> [<ADType> ... ]`

Start the extended scanning for unprovisioned devices.

- `Timeout`: Scan timeout in seconds. Valid values from `BT_MESH_RPR_EXT_SCAN_TIME_MIN` to `BT_MESH_RPR_EXT_SCAN_TIME_MAX`.
- `UUID`: Device UUID to start extended scanning for. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `ADType`: List of AD types to include in the scan report. Must contain 1 to `CONFIG_BT_MESH_RPR_AD_TYPES_MAX` entries.

`mesh models rpr scan-srv [<ADType> ... ]`

Start the extended scanning for the Remote Provisioning Server.

- `ADType`: List of AD types to include in the scan report. Must contain 1 to `CONFIG_BT_MESH_RPR_AD_TYPES_MAX` entries.

`mesh models rpr scan-caps`

Get the scanning capabilities of the Remote Provisioning Server.

`mesh models rpr scan-get`

Get the current scanning state of the Remote Provisioning Server.

`mesh models rpr scan-stop`

Stop any ongoing scanning on the Remote Provisioning Server.

`mesh models rpr link-get`

Get the current link status of the Remote Provisioning Server.

`mesh models rpr link-close`

Close any open links on the Remote Provisioning Server.

`mesh models rpr provision-remote <UUID(1-16 hex)> <NetKeyIdx> <Addr>`

Provision a mesh node using the PB-Remote provisioning bearer.

- `UUID`: UUID of the unprovisioned node. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Network Key Index to give to the unprovisioned node.
- `Addr`: Address to assign to remote device. If `addr` is 0, the lowest available address will be chosen.

`mesh models rpr reprovision-remote <Addr> [<CompChanged(false, true)>]`

Reprovision a mesh node using the PB-Remote provisioning bearer.

- `Addr`: Address to assign to remote device. If `addr` is 0, the lowest available address will be chosen.
- `CompChanged`: The Target node has indicated that its Composition Data has changed. Defaults to false.

`mesh models rpr instance-set <ElemIdx>`

Use the Remote Provisioning Client model instance on the specified element when using the other Remote Provisioning Client model commands.

- `ElemIdx`: The element on which to find the Remote Provisioning Client model instance to use.

`mesh models rpr instance-get-all`

Get a list of all Remote Provisioning Client model instances on the node.

Large Composition Data Client The Large Composition Data Client is an optional Bluetooth Mesh model enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_CLI` configuration option. The Large Composition Data Client model is used to support the functionality of reading pages of Composition Data that do not fit in a Config Composition Data Status message, and reading the metadata of the model instances.

`mesh models lcd large-comp-data-get <Page> <Offset>`

Send the Large Composition Data Get message to query a portion of the Composition Data state of a node.

- `Page`: Page number of the Composition Data.
- `Offset`: Offset within the page.

`mesh models lcd models-metadata-get <Page> <Offset>`

Send the Models Metadata Get message to query a portion of a page of the Models Metadata state.

- `Page`: Page number of the Models Metadata.
- `Offset`: Offset within the page.

Bridge Configuration Client The Bridge Configuration Client model is an optional Bluetooth Mesh model that can be enabled through the `CONFIG_BT_MESH_BRG_CFG_CLI` configuration option. The model provides functionality for configuring the subnet bridge functionality of a mesh node.

`mesh models brg get`

Get the current Subnet Bridge state.

`mesh models brg set <State(disable, enable)>`

Set the Subnet Bridge state.

- `State`: Disable or enable the Subnet Bridge functionality.

`mesh models brg table-size-get`

Get the current size of the Bridging Table.

`mesh models brg table-add <Directions> <NetIdx1> <NetIdx2> <Addr1> <Addr2>`

Add an entry to the Bridging Table.

- `Directions`: Allowed directions for the bridged traffic. Valid values are:
  - `0x01`: Bridging is allowed only for messages with `Addr1` as the source address and `Addr2` as the destination address.
  - `0x02`: Bridging is allowed in both directions.
- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `Addr1`: Address of the node in the first subnet.
- `Addr2`: Address of the node in the second subnet.

`mesh models brg table-remove <NetIdx1> <NetIdx2> <Addr1> <Addr2>`

Remove an entry from the Bridging Table.

- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `Addr1`: Address of the node in the first subnet.
- `Addr2`: Address of the node in the second subnet.

`mesh models brg subnets-get <Filter> <NetIdx> <StartIdx>`

Get a filtered set of NetKey index pairs extracted from the Bridging Table.

- `Filter`: Filter to be applied when reporting pairs of NetKey indexes extracted from the Bridging Table. Allowed values:
  - `0x00`: Report all pairs.
  - `0x01`: Report pairs in which the NetKey index of the first subnet matches `NetIdx`.
  - `0x02`: Report pairs in which the NetKey index of the second subnet matches `NetIdx`.
  - `0x03`: Report pairs in which one of the NetKey indexes matches `NetIdx`.
- `NetIdx`: NetKey index of any of the subnets.
- `StartIdx`: Start offset in units of pairs of NetKey indexes to read.

`mesh models brg table-get <NetIdx1> <NetIdx2> <StartIdx>`

Get a list of addresses and allowed traffic directions of the Bridging Table entries.

- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `StartIdx`: Start offset to read in units of Bridging Table state entries.

Configuration database The Configuration database is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_CDB` configuration option. The Configuration database is only available on provisioner devices, and allows them to store all information about the mesh network. To avoid conflicts, there should only be one mesh node in the network with the Configuration database enabled. This node is the Configurator, and is responsible for adding new nodes to the network and configuring them.

`mesh cdb create [NetKey(1-16 hex)]`

Create a Configuration database.

- `NetKey`: Optional network key value of the primary network key (NetKeyIndex=0). Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Defaults to the default key value if omitted.

`mesh cdb clear`

Clear all data from the Configuration database.

`mesh cdb show`

Show all data in the Configuration database.

`mesh cdb node-add <UUID(1-16 hex)> <Addr> <ElemCnt> <NetKeyIdx> [DevKey(1-16 hex)]`

Manually add a mesh node to the configuration database. Note that devices provisioned with `mesh provision` and `mesh provision-adv` will be added automatically if the Configuration Database is enabled and created.

- `UUID`: 128-bit hexadecimal UUID of the node. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `Addr`: Unicast address of the node, or 0 to automatically choose the lowest available address.
- `ElemCnt`: Number of elements on the node.
- `NetKeyIdx`: The network key the node was provisioned with.
- `DevKey`: Optional 128-bit device key value for the device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb node-del <Addr>`

Delete a mesh node from the Configuration database. If possible, the node should be reset with `mesh reset` before it is deleted from the Configuration database, to avoid unexpected behavior and uncontrolled access to the network.

- `Addr` Address of the node to delete.

`mesh cdb subnet-add <NetKeyIdx> [<NetKey(1-16 hex)>]`

Add a network key to the Configuration database. The network key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known network keys.

- `NetKeyIdx`: Key index of the network key to add.

- NetKey: Optional 128-bit network key value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb subnet-del <NetKeyIdx>`

Delete a network key from the Configuration database.

- NetKeyIdx: Key index of the network key to delete.

`mesh cdb app-key-add <NetKeyIdx> <AppKeyIdx> [<AppKey(1-16 hex)>]`

Add an application key to the Configuration database. The application key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known application keys.

- NetKeyIdx: Network key index the application key is bound to.
- AppKeyIdx: Key index of the application key to add.
- AppKey: Optional 128-bit application key value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb app-key-del <AppKeyIdx>`

Delete an application key from the Configuration database.

- AppKeyIdx: Key index of the application key to delete.

On-Demand Private GATT Proxy Client The On-Demand Private GATT Proxy Client model is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_OD_PRIV_PROXY_CLI configuration option.

`mesh models od_priv_proxy od-priv-gatt-proxy [Dur(s)]`

Set the On-Demand Private GATT Proxy state on active target, or fetch the value of this state from it.

- Dur: If given, set the state of On-Demand Private GATT Proxy to this value in seconds. Fetch this value otherwise.

Solicitation PDU RPL Client The Solicitation PDU RPL Client model is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_SOL_PDU_RPL_CLI configuration option.

`mesh models sol_pdu_rpl sol-pdu-rpl-clear <RngStart> <Ackd> [RngLen]`

Clear active target's solicitation replay protection list (SRPL) in given range of solicitation source (SSRC) addresses.

- RngStart: Start address of the SSRC range.
- Ackd: This argument decides on whether an acknowledged or unacknowledged message will be sent.
- RngLen: Range length for the SSRC addresses to be cleared from the solicitiation RPL list. This parameter is optional; if absent, only a single SSRC address will be cleared.

Frame statistic

`mesh stat get`

Get the frame statistic. The command prints numbers of received frames, as well as numbers of planned and succeeded transmission attempts.

`mesh stat clear`

Clear all statistics collected before.

Subnet Bridge With Bluetooth Mesh Protocol Specification version 1.1, the Bluetooth Mesh Subnet Bridge feature was introduced. This feature allows mesh networks to use subnets for area isolation, but to also allow communication between specific devices in different, adjacent subnets without compromising security.

The Bluetooth Mesh Subnet Bridge feature makes it possible for selected nodes in the network to act as Subnet Bridges, allowing controlled communication by relaying messages between nodes in adjacent subnets.

The Subnet Bridge feature includes two models:

- *Bridge Configuration Server*
- *Bridge Configuration Client*

The Bridge Configuration Server model is mandatory for supporting the Subnet Bridge feature. The Bridge Configuration Client model is optional and allows nodes to configure the Subnet Bridge on other nodes. These models define the necessary states, messages, and behaviors for configuring and managing the Subnet Bridge feature.

The configuration and management of the Subnet Bridge feature are handled using the Bridge Configuration Server and Client models. A node implementing the Bridge Configuration Client model can act as a *Configuration Manager* for the Subnet Bridge feature.

Concepts To get a better understanding of the Subnet Bridge feature and its capabilities, an overview of a few concepts is needed.

Subnet A subnet is a group of nodes within a mesh network that share a common network key, enabling them to communicate securely at the network layer. Each subnet operates independently, with nodes exchanging messages exclusively within that group. A node may belong to multiple subnets at the same time.

Subnet Bridge node A Subnet Bridge node is a node in a Bluetooth Mesh network that belongs to multiple subnets and has a Subnet Bridge functionality enabled. Subnet bridging can be performed only by such a node. The Subnet Bridge node connects the subnets, and allows communication between them by relaying messages across the subnet groups.

The Subnet Bridge node has a primary subnet, based on the primary NetKey, which handles the IV Update procedure and propagates updates to other subnets. The secondary subnets, on which messages are relayed, are referred to as *bridged subnets*.

Bridging Table The Bridging Table contains the entries for the subnets that are bridged by the node, and is managed by the Bridge Configuration Server model.

The maximum number of entries in the bridging table is defined by the `CONFIG_BT_MESH_BRG_TABLE_ITEMS_MAX` option, which defaults to the minimum value of 16, with a maximum possible size of 255.

Enabling or disabling the Subnet Bridge feature The Bridge Configuration Client (or Configuration Manager) can enable or disable the Subnet Bridge feature on a node by sending a **Subnet Bridge Set** message to the Bridge Configuration Server model on the target node, using the `bt_mesh_brg_cfg_cli_set()` function.

Adding or removing subnets The Bridge Configuration Client can add or remove an entry from the Bridging Table by sending a **Bridging Table Add** or **Bridging Table Remove** message to the Bridge Configuration Server model on the target node, calling the `bt_mesh_brg_cfg_cli_table_add()` or `bt_mesh_brg_cfg_cli_table_remove()` functions.

Subnet Bridge states The Subnet Bridge has the following states:

- *Subnet Bridge*: This state indicates whether the Subnet Bridge feature is enabled or disabled on the node. The Bridge Configuration Client can retrieve this information by sending a **Subnet Bridge Get** message to the Bridge Configuration Server using the `bt_mesh_brg_cfg_cli_get()` function.
- *Bridging Table*: This state holds the bridging table. The Client can request a list of entries from a Bridging Table by sending a **Bridging Table Get** message to the target node using the `bt_mesh_brg_cfg_cli_table_get()` function.

  The Client can get a list of subnets currently bridged by a Subnet Bridge by sending a **Bridged Subnets Get** message to the target Server by calling the `bt_mesh_brg_cfg_cli_subnets_get()` function.
- *Bridging Table Size*: This state reports the maximum number of entries the Bridging Table can store. The Client can retrieve this information by sending a **Bridging Table Size Get** message using the `bt_mesh_brg_cfg_cli_table_size_get()` function. This is a read-only state.

Subnet bridging and replay protection The Subnet Bridge feature enables message relaying between subnets and requires effective replay protection to ensure network security. Key considerations to take into account are described below.

Relay buffer considerations When a message is relayed between subnets by a Subnet Bridge, it is allocated from the relay buffer pool. The number of relay buffers are configurable using the `CONFIG_BT_MESH_RELAY_BUF_COUNT` Kconfig option.

When `CONFIG_BT_MESH_ADV_EXT` is enabled, messages will be transmitted using the relay advertising sets. The number of advertising sets are configurable using the `CONFIG_BT_MESH_RELAY_ADV_SETS` Kconfig option.

Both the relay buffer pool and advertising sets can be used even if the relay feature `CONFIG_BT_MESH_RELAY` is disabled.

Replay protection and Bridging Table A Subnet Bridge node must implement replay protection for all Access and Transport Control messages sent to bridged subnets.

The Replay Protection List (RPL) works with the Bridging Table to ensure security:

- The Subnet Bridge stores the latest IVISeq for each source address authorized to send messages to bridged subnets.
- Messages with an IVISeq less than or equal to the stored value are discarded, while valid messages update the stored IVISeq before being relayed.

To ensure proper operation, it is important that the RPL and Bridging Table are synchronized, as every bridged message must pass through the replay protection mechanism before being relayed.

Note

The RPL size should scale with the Bridging Table. As the number of bridged subnets grows, more source addresses and IVISeq values must be tracked, requiring a larger RPL to maintain effective replay protection.

Subnet Bridge and Directed Forwarding Bluetooth Mesh Directed Forwarding (MDF) enables efficient routing between nodes across subnets by optimizing relay paths. While MDF can enhance Subnet Bridging by handling path discovery and forwarding, the current implementation does not support this feature.

API reference This section contains types and defines common to the Bridge Configuration models.

Overview The Configuration Database (CDB) is the subsystem for Bluetooth® Mesh provisioner devices. It stores and manages information about the mesh network, including provisioned nodes, network keys, and application keys. The CDB enables a provisioner to track the network topology, assign addresses, and configure nodes systematically.

Note

The CDB implementation has proprietary design and does not follow the Bluetooth SIG specification.

The CDB is enabled with the `CONFIG_BT_MESH_CDB` configuration option and is typically used only on the provisioner device in the network. There should be only one device in the mesh network with CDB enabled to avoid conflicts.

Key features

- **Persistent Storage**: All CDB data is stored persistently when `CONFIG_BT_SETTINGS` is enabled, allowing the provisioner to recover network state across reboots.
- **Address Management**: Automatic allocation and tracking of unicast addresses for provisioned nodes.
- **Key Management**: Storage and synchronization of network keys and application keys.
- **Node Tracking**: Maintains information about each provisioned node including UUID, address, element count, device key, and configuration status.
- **IV Index Management**: Tracks the network's IV Index and IV Update state.

Configuration options The following Kconfig options control the CDB capacity:

- `CONFIG_BT_MESH_CDB_NODE_COUNT` - Maximum number of nodes the CDB can handle.
- `CONFIG_BT_MESH_CDB_SUBNET_COUNT` - Maximum number of subnets the CDB can handle.
- `CONFIG_BT_MESH_CDB_APP_KEY_COUNT` - Maximum number of application keys the CDB can handle.

Additional options:

- `CONFIG_BT_MESH_CDB_KEY_SYNC` - Enables automatic synchronization between mesh keys on the provisioner node and the CDB keys. If option is enabled then operations with keys performed through the *Configuration Server* are automatically mirrored to the CDB.

Data Structures The CDB was designed to handle data collected in several data structures. The structures represent nodes, subnets, application keys, and the overall database state.

Node structure

```
struct bt_mesh_cdb_node {
        /** Node UUID */
        uint8_t  uuid[16];
        /** Primary element address */
        uint16_t addr;
        /** Network key index used during provisioning */
        uint16_t net_idx;
        /** Number of elements */
        uint8_t  num_elem;
        /** Device key */
        struct bt_mesh_key dev_key;
        /** Node flags */
        ATOMIC_DEFINE(flags, BT_MESH_CDB_NODE_FLAG_COUNT);
};
```

Node flags:

- BT_MESH_CDB_NODE_CONFIGURED - Set when the node has been configured with keys and bindings.

Subnet structure

```
struct bt_mesh_cdb_subnet {
        /** Network key index */
        uint16_t net_idx;
        /** Key Refresh phase */
        uint8_t kr_phase;
        /** Old and new keys for Key Refresh */
        struct {
                struct bt_mesh_key net_key;
        } keys[2];
};
```

Application Key structure

```
struct bt_mesh_cdb_app_key {
        /** Bound network key index */
        uint16_t net_idx;
        /** Application key index */
        uint16_t app_idx;
        /** Old and new keys for Key Refresh */
        struct {
                struct bt_mesh_key app_key;
        } keys[2];
};
```

Main CDB structure

```
struct bt_mesh_cdb {
        /** Network IV Index */
        uint32_t iv_index;
        /** Lowest available unicast address for provisioning */
        uint16_t lowest_avail_addr;
        /** Flags for CDB state (private) */
        ATOMIC_DEFINE(flags, BT_MESH_CDB_FLAG_COUNT);
        /** Nodes in the mesh network */
        struct bt_mesh_cdb_node nodes[NODE_COUNT];
        /** Subnets in the mesh network */
        struct bt_mesh_cdb_subnet subnets[SUBNET_COUNT];
        /** Application keys in the mesh network */
        struct bt_mesh_cdb_app_key app_keys[APP_KEY_COUNT];
};

/** The global CDB instance is accessible through this variable. */
extern struct bt_mesh_cdb bt_mesh_cdb;
```

Usage scenarios The following patterns demonstrate common CDB usage scenarios:

- *Provisioner initialization* - Creating and initializing the CDB
- *Provisioning and node allocation* - Managing node provisioning and addresses
- *Subnet and key management* - Managing network keys and subnets
- *Subnet lookup and removal* - Finding and removing subnets
- *Setting up application keys* - Adding application keys to the CDB

- *Application keys lookup and removal* - Finding and removing application keys
- *Node configuration* - Configuring provisioned nodes
- *Iterating over nodes* - Processing nodes with callbacks
- *Node lookup and removal* - Finding and removing nodes
- *IV Index management* - Managing IV Index updates
- *Working with device keys* - Importing/exporting device keys
- *Clearing the CDB* - Resetting the database

Note

The provided below source code of scenarios should be treated as conceptual patterns rather than exact implementations. They require adaptation to fit into an application context and testing. Please read the CDB API description for correct usage.

Provisioner initialization On the embedded provisioner node, the CDB must be initialized before the mesh stack is provisioned and the application can use it for key storage, node tracking, and configuration. This step establishes the primary network key, the initial subnet, and the starting IV Index and address space, so that all later CDB operations work on a well-defined network context and can be persisted across reboots.

A typical provisioner initializes the CDB during startup:

```
#include <zephyr/bluetooth/mesh.h>

static int provisioner_init(void)
{
    uint8_t net_key[16];
    int err;

    /* Initialize Bluetooth Mesh */
    err = bt_mesh_init(&prov, &comp);
    if (err) {
        return err;
    }

    /* Load settings if persistent storage is enabled */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        settings_load();
    }

    /* Generate or use predefined network key */
    bt_rand(net_key, 16);

    /* Create CDB with primary network key */
    err = bt_mesh_cdb_create(net_key);
    if (err == -EALREADY) {
        printk("Using stored CDB\n");
    } else if (err) {
        printk("Failed to create CDB (err %d)\n", err);
        return err;
    } else {
        printk("Created new CDB\n");
    }
```

(continues on next page)

(continued from previous page)

```
    return 0;
}
```

Key points:

- Call the `bt_mesh_cdb_create()` function with the primary network key.
- Returns error code if CDB already exists (loaded from persistent storage).
- The function automatically creates a subnet with `NetIdx = 0`.
- Sets the IV Index to `0` and lowest available address to `1`.

Provisioning and node allocation When you add new devices to the mesh, their addresses, device keys, and basic metadata must be recorded consistently in the provisioner's database. Automatic node allocation during PB-ADV/PB-GATT provisioning keeps CDB and the actual network in sync. When provisioning a new device, the CDB automatically allocates the node during the provisioning process.

However, you can also manually allocate nodes or check allocation. Manual node allocation is useful for advanced scenarios such as importing nodes from an external source, pre-allocating address ranges, or recovering a network from known information.

```
/* Provisioning callback - node is automatically added to CDB */
static void node_added(uint16_t idx, uint8_t uuid[16], uint16_t addr,
                       uint8_t num_elem)
{
    printk("Node added: addr=0x%04x, elements=%d\n", addr, num_elem);
    /* The CDB node is created automatically by the provisioning subsystem */
}

static const struct bt_mesh_prov prov = {
    .uuid = dev_uuid,
    .node_added = node_added,
    /* ... other callbacks ... */
};

/* Manual node allocation (if needed) */
static struct bt_mesh_cdb_node *allocate_node(const uint8_t uuid[16],
                                              uint8_t num_elem)
{
    struct bt_mesh_cdb_node *node;
    uint16_t addr;

    /* Get free address or specify one (0 = auto-allocate) */
    addr = bt_mesh_cdb_free_addr_get(num_elem);
    if (addr == BT_MESH_ADDR_UNASSIGNED) {
        printk("No free addresses available\n");
        return NULL;
    }

    /* Allocate node in CDB */
    node = bt_mesh_cdb_node_alloc(uuid, addr, num_elem, net_idx);
    if (node == NULL) {
        printk("Failed to allocate node\n");
        return NULL;
    }
```

(continues on next page)

(continued from previous page)

```
    return node;
}
```

Key points:

- During normal PB-ADV/PB-GATT provisioning, nodes are automatically added to the CDB.
- The `bt_mesh_cdb_node_alloc()` function creates a CDB entry with the specified parameters.
- Pass `BT_MESH_ADDR_UNASSIGNED` as the address to let the CDB auto-assign the lowest available address.
- The `bt_mesh_cdb_free_addr_get()` function finds a free address range for a given element count.
- Address allocation checks for conflicts and ensures the unicast address validity.

Subnet and key management Large or segmented mesh networks often use multiple subnets to separate traffic domains, enable secure migration, or support the Key Refresh procedure. Managing subnets and their network keys in the CDB allows the provisioner to create new subnets, rotate keys, and derive the correct flags and IV Index when provisioning and configuring nodes.

Manage network keys and subnets in the CDB:

```
/* Add a new subnet */
static int add_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t net_key[16];
    int err;

    /* Allocate subnet in CDB */
    sub = bt_mesh_cdb_subnet_alloc(net_idx);
    if (sub == NULL) {
        printk("Failed to allocate subnet\n");
        return -ENOMEM;
    }

    /* Generate network key */
    bt_rand(net_key, 16);

    /* Import key value */
    err = bt_mesh_cdb_subnet_key_import(sub, 0, net_key);
    if (err) {
        bt_mesh_cdb_subnet_del(sub, false);
        return err;
    }

    /* Store subnet */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_subnet_store(sub);
    }

    return 0;
}

/* Get subnet for provisioning */
```

(continues on next page)

(continued from previous page)

```
static int get_subnet_flags(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t flags;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        return -ENOENT;
    }

    flags = bt_mesh_cdb_subnet_flags(sub);
    printk("Subnet flags: KR=%d IVU=%d\n",
           !!(flags & BT_MESH_NET_FLAG_KR),
           !!(flags & BT_MESH_NET_FLAG_IVU));

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_subnet_alloc()` function allocates a subnet by NetIdx.
- The `bt_mesh_cdb_subnet_key_import()` function sets the actual key value.
- The `bt_mesh_cdb_subnet_flags()` function returns flags needed for provisioning data.
- The flags include Key Refresh and IV Update state from the CDB.

Subnet lookup and removal At some point you may need to inspect an existing subnet (for diagnostics or tooling) or remove it entirely (for example when decommissioning a segment, rotating to a new subnet, or cleaning up after experimentation). The CDB provides lookup and deletion helpers so that the provisioner can keep its view of active subnets consistent with what nodes actually use.

Find and manage subnets in the CDB:

```
/* Get subnet by NetIdx */
static void lookup_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        printk("Subnet 0x%03x not found\n", net_idx);
        return;
    }

    printk("Subnet 0x%03x: kr_phase=%d\n", net_idx, sub->kr_phase);
}

/* Remove a subnet from the CDB */
static void remove_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        printk("Subnet not found\n");
```

(continues on next page)

(continued from previous page)

```
        return;
    }

    /* First, remove the subnet from all nodes in the network */
    /* ... send NetKey Delete to all nodes using Config Client ... */

    /* Delete subnet from CDB */
    bt_mesh_cdb_subnet_del(sub, true);

    printk("Subnet 0x%03x removed\n", net_idx);
}

/* Export subnet key for external use */
static int export_subnet_key(uint16_t net_idx, int key_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t net_key[16];
    int err;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        return -ENOENT;
    }

    err = bt_mesh_cdb_subnet_key_export(sub, key_idx, net_key);
    if (err) {
        printk("Failed to export subnet key (err %d)\n", err);
        return err;
    }

    printk("NetKey[%d] for subnet 0x%03x: ", key_idx, net_idx);
    for (int i = 0; i < 16; i++) {
        printk("%02x", net_key[i]);
    }
    printk("\n");

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_subnet_get()` function retrieves a subnet by its NetKeyIndex.
- Pass `true` to the `bt_mesh_cdb_subnet_del()` function to clear persistent storage.
- Always remove the subnet from all nodes before deleting it from the CDB.
- Use the `bt_mesh_cdb_subnet_key_export()` function to retrieve key material securely.
- The `key_idx` parameter (`0` or `1`) selects between old and new keys during the Key Refresh procedure.

Setting up application keys Application keys define which application traffic can be encrypted and where it can be bound. After the CDB is initialized, the provisioner must create one or more application keys so that it can bind models on nodes and enable real application-level communication (for example, lighting or sensor data).

After creating the CDB, add application keys for node configuration:

```
static void setup_cdb_keys(void)
{
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    int err;

    /* Allocate application key in CDB */
    key = bt_mesh_cdb_app_key_alloc(net_idx, app_idx);
    if (key == NULL) {
        printk("Failed to allocate app-key\n");
        return;
    }

    /* Generate random key value */
    bt_rand(app_key, 16);

    /* Import the key into CDB */
    err = bt_mesh_cdb_app_key_import(key, 0, app_key);
    if (err) {
        printk("Failed to import appkey (err %d)\n", err);
        return;
    }

    /* Store to persistent storage */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_app_key_store(key);
    }
}
```

Key points:

- The `bt_mesh_cdb_app_key_alloc()` function allocates a slot in the CDB.
- The `bt_mesh_cdb_app_key_import()` function sets the actual key value.
- The second parameter to import (`0`) is the key index for the Key Refresh procedure (`0` = current key).
- Always store keys after creation when using persistent storage.

Application keys lookup and removal Over time, you may need to inspect which network key an application key is bound to, rotate or revoke application keys, or clean up keys that are no longer used. Proper lookup and removal through the CDB helps avoid dangling bindings and ensures that nodes and the provisioner share the same view of usable application keys.

Find and manage application keys in the CDB:

```
/* Get application key by AppIdx */
static void lookup_app_key(uint16_t app_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        printk("AppKey 0x%03x not found\n", app_idx);
        return;
    }

    printk("AppKey 0x%03x: bound to NetIdx 0x%03x\n",
```

(continues on next page)

(continued from previous page)

```
            app_idx, key->net_idx);
}

/* Remove an application key from the CDB */
static void remove_app_key(uint16_t app_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        printk("AppKey not found\n");
        return;
    }

    /* First, remove the app key from all nodes in the network */
    /* ... send AppKey Delete to all nodes using Config Client ... */

    /* Delete app key from CDB */
    bt_mesh_cdb_app_key_del(key, true);

    printk("AppKey 0x%03x removed\n", app_idx);
}

/* Export application key for external use */
static int export_app_key(uint16_t app_idx, int key_idx)
{
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    int err;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        return -ENOENT;
    }

    err = bt_mesh_cdb_app_key_export(key, key_idx, app_key);
    if (err) {
        printk("Failed to export app key (err %d)\n", err);
        return err;
    }

    printk("AppKey[%d] 0x%03x: ", key_idx, app_idx);
    for (int i = 0; i < 16; i++) {
        printk("%02x", app_key[i]);
    }
    printk("\n");

    return 0;
}

/* Update application key binding */
static int update_app_key_binding(uint16_t app_idx, uint16_t new_net_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
```

(continues on next page)

(continued from previous page)

```
    if (key == NULL) {
        return -ENOENT;
    }

    /* Verify the new subnet exists */
    if (bt_mesh_cdb_subnet_get(new_net_idx) == NULL) {
        printk("Target subnet 0x%03x not found\n", new_net_idx);
        return -ENOENT;
    }

    key->net_idx = new_net_idx;

    /* Store updated binding */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_app_key_store(key);
    }

    printk("AppKey 0x%03x rebound to NetIdx 0x%03x\n",
           app_idx, new_net_idx);

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_app_key_get()` function retrieves an application key by its AppKeyIndex.
- Pass `true` to the `bt_mesh_cdb_app_key_del()` function to clear persistent storage.
- Always remove the app key from all nodes before deleting it from the CDB.
- Use the `bt_mesh_cdb_app_key_export()` function to retrieve key material securely.
- The `key_idx` parameter (`0` or `1`) selects between old and new keys during the Key Refresh procedure.
- Application keys are bound to a network key through the `net_idx` field.

Node configuration Provisioning only adds a node to the network; it does not make it participate in your application. After provisioning, you must configure nodes—add network/app keys, bind models, and set subscriptions/publications. The CDB stores the keys and configuration status so the provisioner can resume configuration after a reboot and avoid re-configuring already finished nodes.

After provisioning, configure the node by adding keys and binding models:

```
static void configure_node(struct bt_mesh_cdb_node *node)
{
    NET_BUF_SIMPLE_DEFINE(buf, BT_MESH_RX_SDU_MAX);
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    uint8_t status;
    int err;

    printk("Configuring node 0x%04x\n", node->addr);

    /* Get application key from CDB */
    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
```

(continues on next page)

(continued from previous page)

```
        printk("App-key not found\n");
        return;
    }

    /* Export key value from CDB */
    err = bt_mesh_cdb_app_key_export(key, 0, app_key);
    if (err) {
        printk("Failed to export key (err %d)\n", err);
        return;
    }

    /* Add application key to the node */
    err = bt_mesh_cfg_cli_app_key_add(net_idx, node->addr,
                                      net_idx, app_idx,
                                      app_key, &status);
    if (err || status) {
        printk("Failed to add app-key (err %d, status %d)\n",
               err, status);
        return;
    }

    /* Get composition data and bind models */
    err = bt_mesh_cfg_cli_comp_data_get(net_idx, node->addr, 0,
                                        &status, &buf);
    if (err || status) {
        printk("Failed to get composition data\n");
        return;
    }

    /* Parse composition and bind models to app key */
    /* ... model binding code ... */

    /* Mark node as configured */
    atomic_set_bit(node->flags, BT_MESH_CDB_NODE_CONFIGURED);

    /* Persist configuration status */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_node_store(node);
    }
}
```

Key points:

- Use the `bt_mesh_cdb_app_key_get()` and the `bt_mesh_cdb_app_key_export()` functions to retrieve keys.
- The Configuration Client model is used to configure remote nodes.
- Set the `BT_MESH_CDB_NODE_CONFIGURED` flag after successful configuration.
- Always call the `bt_mesh_cdb_node_store()` function to persist the configured state.

Iterating over nodes Many management tasks involve acting on all (or a filtered subset of) nodes: checking which ones still need configuration, generating statistics, or performing bulk operations. The CDB iterator lets the provisioner traverse all known nodes in a safe, abstract way without relying on internal storage details.

The CDB provides an iterator to process all allocated nodes:

```
/* Check for unconfigured nodes */
static uint8_t check_unconfigured(struct bt_mesh_cdb_node *node,
                                  void *user_data)
{
    if (!atomic_test_bit(node->flags, BT_MESH_CDB_NODE_CONFIGURED)) {
        printk("Node 0x%04x needs configuration\n", node->addr);
        configure_node(node);
    }

    return BT_MESH_CDB_ITER_CONTINUE;
}

static void process_nodes(void)
{
    bt_mesh_cdb_node_foreach(check_unconfigured, NULL);
}

/* Example: Count nodes on a specific subnet */
static uint8_t count_subnet_nodes(struct bt_mesh_cdb_node *node,
                                  void *user_data)
{
    uint16_t *net_idx = user_data;
    static int count = 0;

    if (node->net_idx == *net_idx) {
        count++;
    }

    return BT_MESH_CDB_ITER_CONTINUE;
}
```

Key points:

- The `bt_mesh_cdb_node_foreach()` function calls the callback for each allocated node.
- Return `BT_MESH_CDB_ITER_CONTINUE` to continue iteration.
- Return `BT_MESH_CDB_ITER_STOP` to stop iteration early.
- The callback is only called for nodes with `addr != BT_MESH_ADDR_UNASSIGNED`.

Node lookup and removal Sometimes a single node must be inspected (for example, when debugging) or removed from the network (for example, when it is physically decommissioned or replaced). Using CDB node lookup and deletion keeps the logical view of the mesh consistent with the actual devices and prevents address reuse conflicts.

Find and manage nodes in the CDB:

```
/* Get node by address */
static void lookup_node(uint16_t addr)
{
    struct bt_mesh_cdb_node *node;

    node = bt_mesh_cdb_node_get(addr);
    if (node == NULL) {
        printk("Node 0x%04x not found\n", addr);
        return;
    }
```

(continues on next page)

(continued from previous page)

```
    printk("Node 0x%04x: %d elements, net_idx=0x%03x\n",
           node->addr, node->num_elem, node->net_idx);
}

/* Remove a node from the network */
static void remove_node(uint16_t addr)
{
    struct bt_mesh_cdb_node *node;

    node = bt_mesh_cdb_node_get(addr);
    if (node == NULL) {
        printk("Node not found\n");
        return;
    }

    /* First, send Node Reset to the device (recommended) */
    /* ... send reset command using Config Client ... */

    /* Delete node from CDB */
    bt_mesh_cdb_node_del(node, true);

    printk("Node 0x%04x removed\n", addr);
}
```

Key points:

- The `bt_mesh_cdb_node_get()` function searches by element address (works for any element address).
- Always send a `Node Reset` command before removing a node to avoid orphaned devices.
- Pass `true` to the `bt_mesh_cdb_node_del()` function to clear persistent storage.
- Deleting a node might update the `lowest_avail_addr` if appropriate (please read CDB API for details).

IV Index management The IV Index is a core part of Bluetooth Mesh security and replay protection. When IV Update procedures occur, the provisioner must update its stored IV Index so that future provisioning and configuration use the correct value and address space. Storing this in the CDB keeps the network state coherent across reboots and between provisioning actions.

Update the network's IV Index:

```
/* Update IV Index when IV Update procedure occurs */
static void handle_iv_update(uint32_t iv_index, bool iv_update)
{
    bt_mesh_cdb_iv_update(iv_index, iv_update);

    printk("IV Index updated: %u (IV Update: %s)\n",
           iv_index, iv_update ? "in progress" : "normal");
}

/* The IV Index is automatically used during provisioning */
static void provision_with_current_iv(void)
{
    /* The provisioner automatically uses bt_mesh_cdb.iv_index
     * and bt_mesh_cdb_subnet_flags() when sending provisioning data
     */
}
```

Key points:

- The `bt_mesh_cdb_iv_update()` function updates both the IV Index and IV Update flag.
- The CDB automatically resets `lowest_avail_addr` during IV Index updates.
- The provisioner subsystem automatically uses CDB's IV Index for new nodes.

Working with device keys Device keys are sensitive information and often handled through secure key storage (for example, PSA crypto). The CDB's key import/export APIs abstract how keys are stored, allowing the application to use device keys when needed (for configuration or external tooling) without breaking the security model or relying on direct pointers into key storage.

Import and export device keys using the key management API:

```
/* Import a known device key */
static int import_dev_key(struct bt_mesh_cdb_node *node,
                          const uint8_t dev_key[16])
{
    int err;

    err = bt_mesh_cdb_node_key_import(node, dev_key);
    if (err) {
        printk("Failed to import device key (err %d)\n", err);
        return err;
    }

    /* Store updated node */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_node_store(node);
    }

    return 0;
}

/* Export device key for external use */
static int export_dev_key(struct bt_mesh_cdb_node *node)
{
    uint8_t dev_key[16];
    int err;

    err = bt_mesh_cdb_node_key_export(node, dev_key);
    if (err) {
        printk("Failed to export device key (err %d)\n", err);
        return err;
    }

    /* Use the exported key */
    printk("Device key: ");
    for (int i = 0; i < 16; i++) {
        printk("%02x", dev_key[i]);
    }
    printk("\n");

    return 0;
}
```

Key points:

- Always use import/export functions when working with keys (required for PSA crypto).

- Keys are stored securely and are not be directly accessible through pointers.
- The provisioner automatically generates and imports device keys during provisioning.

Clearing the CDB For factory reset, testing, or starting a completely new network, you may need to wipe all provisioning and configuration data. Clearing the CDB resets the logical network state so you can safely recreate it from scratch, while avoiding inconsistencies with stale keys or node entries.

Reset the entire configuration database:

```
static void reset_network(void)
{
    printk("Clearing CDB...\n");

    /* Clear all CDB data */
    bt_mesh_cdb_clear();

    printk("CDB cleared\n");
}
```

Key points:

- The `bt_mesh_cdb_clear()` function removes all nodes, subnets, and app keys.
- Clears persistent storage if the `CONFIG_BT_SETTINGS` Kconfig option is enabled.
- Marks the CDB as invalid (must call the `bt_mesh_cdb_create()` function to use again).

Best practices

- **Error handling** - Check return values from all CDB functions, especially allocation functions which can fail when capacity is reached.
- **Address management** - Let the CDB manage address allocation by passing `0` to the `bt_mesh_cdb_node_alloc()` function unless you have specific addressing requirements.
- **Configuration tracking** - Always set the `BT_MESH_CDB_NODE_CONFIGURED` flag and store the node after successful configuration to avoid reconfiguring nodes unnecessarily.
- **Key security** - Never log or expose keys in production code. Use import/export functions to handle key material securely.
- **Iteration safety** - Do not modify the CDB (add/remove nodes) during `bt_mesh_cdb_node_foreach()` iteration. Collect addresses first, then modify.

Common pitfalls

CDB synchronization among multiple provisioners
: If there are multiple provisioners in the network, ensure they synchronize their CDBs to avoid conflicts. Use application-level mechanisms to share CDB among multiple provisioners. There is no built-in mechanism for CDB synchronization.

Forgetting to store
: CDB modifications are not automatically persisted. Always call the appropriate `_store()` function after making changes when using persistent storage.

Incorrect key index
: When importing/exporting keys, the key index parameter (`0` or `1`) refers to the position in the Key Refresh key array, not the NetIdx or AppIdx.

Address conflicts
: If manually specifying addresses, ensure they do not conflict with existing nodes. Use the `bt_mesh_cdb_free_addr_get()` function to find available addresses.

Over-capacity
: CDB has fixed capacity defined by Kconfig. Exceeding capacity causes allocation failures. Monitor CDB usage and increase capacity if needed.

Accessing invalid nodes
: Always check if returned pointers from `_get()` or `_alloc()` functions are `NULL` before dereferencing.

Core Host and drivers

Logical Link Control and Adaptation Protocol (L2CAP) L2CAP layer enables connection-oriented channels which can be enabled with the configuration option: `CONFIG_BT_L2CAP_DYNAMIC_CHANNEL`. These channels support segmentation and reassembly transparently, they also support credit based flow control making it suitable for data streams.

Channels instances are represented by the `bt_l2cap_chan` struct which contains the callbacks in the `bt_l2cap_chan_ops` struct to inform when the channel has been connected, disconnected or when the encryption has changed. In addition to that it also contains the `recv` callback which is called whenever an incoming data has been received. Data received this way can be marked as processed by returning 0 or using `bt_l2cap_chan_recv_complete()` API if processing is asynchronous.

Note

The `recv` callback is called directly from RX Thread thus it is not recommended to block for long periods of time.

For sending data the `bt_l2cap_chan_send()` API can be used noting that it may block if no credits are available, and resuming as soon as more credits are available.

Servers can be registered using `bt_l2cap_server_register()` API passing the `bt_l2cap_server` struct which informs what `psm` it should listen to, the required security level `sec_level`, and the callback `accept` which is called to authorize incoming connection requests and allocate channel instances.

```
#define PSM 0x29 /* example PSM */

static int l2cap_recv(struct bt_l2cap_chan *chan, struct net_buf *buf);
static void l2cap_connected(struct bt_l2cap_chan *chan);
static void l2cap_disconnected(struct bt_l2cap_chan *chan);

/* ops used for every channel instance */
static struct bt_l2cap_chan_ops l2cap_ops = {
        .recv       = l2cap_recv,
        .connected  = l2cap_connected,
```

(continues on next page)

(continued from previous page)

```
        .disconnected = l2cap_disconnected,
};

/* Fixed array of channel instances, one per possible connection */
static struct bt_l2cap_chan l2cap_chans[CONFIG_BT_MAX_CONN];

static int accept_cb(struct bt_conn *conn, struct bt_l2cap_server *server,
                     struct bt_l2cap_chan **chan)
{
        uint8_t conn_index = bt_conn_index(conn);

        /* initialize the chosen entry */
        l2cap_chans[conn_index] = (struct bt_l2cap_chan){
                .ops = &l2cap_ops,
        };

        *chan = &l2cap_chans[conn_index];

        printk("L2CAP channel accepted, assigned chan[%d]\n", conn_index);

        return 0; /* accept */
}

static struct bt_l2cap_server server = {
        .psm = PSM,
        .sec_level = BT_SECURITY_L1,
        .accept = accept_cb,
};
```

A complete working example demonstrating L2CAP dynamic channels is available in the acceptor (server) sample: bluetooth_l2cap_coc_acceptor

Fixed Channels The user can also define fixed channels using the BT_L2CAP_FIXED_CHANNEL_DEFINE macro. Fixed channels are initialized upon connection, and do not support segmentation. An example of how to define a fixed channel is shown below.

```
static struct bt_l2cap_chan fixed_chan[CONFIG_BT_MAX_CONN];

/* Callbacks are assumed to be defined prior. */
static struct bt_l2cap_chan_ops ops = {
    .recv = recv_cb,
    .sent = sent_cb,
    .connected = connected_cb,
    .disconnected = disconnected_cb,
};

static int l2cap_fixed_accept(struct bt_conn *conn, struct bt_l2cap_chan **chan)
{
    uint8_t conn_index = bt_conn_index(conn);

    *chan = &fixed_chan[conn_index];

    **chan = (struct bt_l2cap_chan){
        .ops = &ops,
    };
```

(continues on next page)

(continued from previous page)

```
    return 0;
}

BT_L2CAP_FIXED_CHANNEL_DEFINE(fixed_channel) = {
    .cid = 0x0010,
    .accept = l2cap_fixed_accept,
};
```

Client Channels Client channels can be initiated with use of `bt_l2cap_chan_connect()` API and can be disconnected with the `bt_l2cap_chan_disconnect()` API. Note that the latter can also disconnect channel instances created by servers.

See the initiator (client) sample for a complete example: bluetooth_l2cap_coc_initiator

Connection Management The Zephyr Bluetooth stack uses an abstraction called `bt_conn` to represent connections to other devices. The internals of this struct are not exposed to the application, but a limited amount of information (such as the remote address) can be acquired using the `bt_conn_get_info()` API. Connection objects are reference counted, and the application is expected to use the `bt_conn_ref()` API whenever storing a connection pointer for a longer period of time, since this ensures that the object remains valid (even if the connection would get disconnected). Similarly the `bt_conn_unref()` API is to be used when releasing a reference to a connection.

A common mistake is to forget unreleasing a reference to a connection object created by functions `bt_conn_le_create()` and `bt_conn_le_create_synced()`. To protect against this, use the `CONFIG_BT_CONN_CHECK_NULL_BEFORE_CREATE` Kconfig option, which forces these functions return an error if the connection pointer passed to them is not NULL. This helps to spot such issues and avoid sporadic bugs caused by not releasing the connection object.

An application may track connections by registering a `bt_conn_cb` struct using the `bt_conn_cb_register()` or `BT_CONN_CB_DEFINE` APIs. This struct lets the application define callbacks for connection & disconnection events, as well as other events related to a connection such as a change in the security level or the connection parameters. When acting as a central the application will also get hold of the connection object through the return value of the `bt_conn_le_create()` API.

6.1.10 Tools

This page lists and describes tools that can be used to assist during Bluetooth stack or application development in order to help, simplify and speed up the development process.

- *Mobile applications*
- *Using BlueZ with Zephyr*
- *Running on QEMU or native_sim*
  - *Using the Host System Bluetooth Controller*
  - *Using a Zephyr-based Bluetooth Controller*
  - *HCI Tracing*
- *Running on a Virtual Controller and native_sim*
  - *Android Emulator*
- *Using Zephyr-based Controllers with BlueZ*

Mobile applications

It is often useful to make use of existing mobile applications to interact with hardware running Zephyr, to test functionality without having to write any additional code or requiring extra hardware.

The recommended mobile applications for interacting with Zephyr are:

- Android:
  - nRF Connect for Android
  - nRF Mesh for Android
  - LightBlue for Android
- iOS:
  - nRF Connect for iOS
  - nRF Mesh for iOS
  - LightBlue for iOS

Using BlueZ with Zephyr

The Linux Bluetooth Protocol Stack, BlueZ, comes with a very useful set of tools that can be used to debug and interact with Zephyr's Bluetooth Host and Controller. In order to benefit from these tools you will need to make sure that you are running a recent version of the Linux Kernel and BlueZ:

- Linux Kernel 4.10+
- BlueZ 4.45+

Additionally, some of the BlueZ tools might not be bundled by default by your Linux distribution. If you need to build BlueZ from scratch to update to a recent version or to obtain all of its tools you can follow the steps below:

```
git clone git://git.kernel.org/pub/scm/bluetooth/bluez.git
cd bluez
./bootstrap-configure --disable-android --disable-midi
make
```

You can then find `btattach`, `btmgt` and `btproxy` in the `tools/` folder and `btmon` in the `monitor/` folder.

You'll need to enable BlueZ's experimental features so you can access its most recent Bluetooth functionality. Do this by editing the file `/lib/systemd/system/bluetooth.service` and making sure to include the `-E` option in the daemon's execution start line:

```
ExecStart=/usr/libexec/bluetooth/bluetoothd -E
```

Finally, reload and restart the daemon:

```
sudo systemctl daemon-reload
sudo systemctl restart bluetooth
```

Running on QEMU or native_sim

It's possible to run Bluetooth applications using either the *QEMU emulator* or native_sim.

In either case, a Bluetooth controller needs to be exported from the host OS (Linux) to the emulator. For this purpose you will need some tools described in the *Using BlueZ with Zephyr* section.

Using the Host System Bluetooth Controller The host OS's Bluetooth controller is connected in the following manner:

- To the second QEMU serial line using a UNIX socket. This socket gets used with the help of the QEMU option `-serial unix:/tmp/bt-server-bredr`. This option gets passed to QEMU through `QEMU_EXTRA_FLAGS` automatically whenever an application has enabled Bluetooth support.
- To native_sim's BT User Channel driver through the use of a command-line option passed to the native_sim executable: `--bt-dev=hci0`

On the host side, BlueZ allows you to export its Bluetooth controller through a so-called user channel for QEMU and native_sim to use.

Note

You only need to run `btproxy` when using QEMU. native_sim handles the UNIX socket proxying automatically

If you are using QEMU, in order to make the Controller available you will need one additional step using `btproxy`:

1. Make sure that the Bluetooth controller is down
2. Use the btproxy tool to open the listening UNIX socket, type:

   ```
   sudo tools/btproxy -u -i 0
   Listening on /tmp/bt-server-bredr
   ```

   You might need to replace `-i 0` with the index of the Controller you wish to proxy.

   If you see `Received unknown host packet type 0x00` when running QEMU, then add `-z` to the `btproxy` command line to ignore any null bytes transmitted at startup.

Once the hardware is connected and ready to use, you can then proceed to building and running a sample:

- Choose one of the Bluetooth sample applications located in `samples/bluetooth`.
- To run a Bluetooth application in QEMU, type:

  ```
  west build -b qemu_x86 samples/bluetooth/<sample>
  west build -t run
  ```

  Running QEMU now results in a connection with the second serial line to the `bt-server-bredr` UNIX socket, letting the application access the Bluetooth controller.
- To run a Bluetooth application in native_sim, first build it:

  ```
  west build -b native_sim samples/bluetooth/<sample>
  ```

  And then run it with:

  ```
  $ sudo ./build/zephyr/zephyr.exe --bt-dev=hci0
  ```

Using a Zephyr-based Bluetooth Controller Depending on which hardware you have available, you can choose between two transports when building a single-mode, Zephyr-based Bluetooth Controller:

- UART: Use the bluetooth_hci_uart sample and follow the instructions in bluetooth-hci-uart-qemu-posix.
- USB: Use the bluetooth_hci_usb sample and then treat it as a Host System Bluetooth Controller (see previous section)

HCI Tracing When running the Host on a computer connected to an external Controller, it is very useful to be able to see the full log of exchanges between the two, in the format of a *Host Controller Interface* log. In order to see those logs, you can use the built-in `btmon` tool from BlueZ:

```
$ btmon
```

The output looks like this:

```
= New Index: 00:00:00:00:00:00 (Primary,Virtual,Control)                 ␣
↪0.274200
= Open Index: 00:00:00:00:00:00                                          ␣
↪0.274500
< HCI Command: Reset (0x03|0x0003) plen 0                               #1␣
↪0.274600
> HCI Event: Command Complete (0x0e) plen 4                             #2␣
↪0.274700
```

(continues on next page)

(continued from previous page)

```
      Reset (0x03|0x0003) ncmd 1
      Status: Success (0x00)
< HCI Command: Read Local Supported Features (0x04|0x0003) plen 0         #3␣
↪0.274800
> HCI Event: Command Complete (0x0e) plen 12                              #4␣
↪0.274900
      Read Local Supported Features (0x04|0x0003) ncmd 1
      Status: Success (0x00)
      Features: 0x00 0x00 0x00 0x00 0x60 0x00 0x00 0x00
         BR/EDR Not Supported
         LE Supported (Controller)
```

Embedded HCI tracing When running both Host and Controller in actual Integrated Circuits, you will only see normal log messages on the console by default, without any way of accessing the HCI traffic between the Host and the Controller. However, there is a special Bluetooth logging mode that converts the console to use a binary protocol that interleaves both normal log messages as well as the HCI traffic.

Set the following Kconfig options to enable this protocol before building your application:

```
CONFIG_BT_DEBUG_MONITOR_UART=y
CONFIG_UART_CONSOLE=n
```

- Setting `CONFIG_BT_DEBUG_MONITOR_UART` activates the formatting
- Clearing `CONFIG_UART_CONSOLE` makes the UART unavailable for the system console. E.g. for `printk` and the `boot banner`

To decode the binary protocol that will now be sent to the console UART you need to use the btmon tool from *BlueZ*:

```
$ btmon --tty <console TTY> --tty-speed 115200
```

If UART is not available (or you still want non-binary logs), you can set `CONFIG_BT_DEBUG_MONITOR_RTT` instead, which will use Segger RTT. For example, if trying to connect to a nRF52840DK with S/N 683578642:

```
$ btmon --jlink nRF52840_xxAA,683578642
```

Running on a Virtual Controller and native_sim

An alternative to a Bluetooth physical controller is the use of a virtual controller. This controller can be connected over an HCI TCP server. This TCP server must support the HCI H4 protocol. In comparison to the physical controller variant, the virtual controller allows to test a Zephyr application running on the native boards without a physical Bluetooth controller.

The main use case for a virtual controller is to do Bluetooth connectivity tests without the need of Bluetooth hardware. This allows to automate Bluetooth integration tests with external applications such as a Bluetooth gateway or a mobile application.

To demonstrate this functionality an example is given to interact with a virtual controller. For this purpose, the experimental python module Bumble from Google is used as it allows to create a TCP Bluetooth virtual controller and connect with the Zephyr Bluetooth host. To install bumble follow the Bumble Getting Started Guide.

Note

If your Zephyr application requires the use of the HCI LE Set extended commands, install the branch `controller-extended-advertising` from Bumble.

Android Emulator You can test the virtual controller by connecting a Bluetooth Zephyr application to the Android Emulator.

To connect your application to the Android Emulator follow the next steps:

1. Build your Zephyr application and disable the HCI ACL flow control (i.e. `CONFIG_BT_HCI_ACL_FLOW_CONTROL=n`) as the virtual controller from android does not support it at the moment.
2. Install Android Emulator version >= 33.1.4.0. The easiest way to do this is by installing the latest Android Studio Preview version.
3. Create a new Android Virtual Device (AVD) with the Android Device Manager. The AVD should use at least SDK API 34.
4. Run the Android Emulator via terminal as follows:

   ```
   emulator avd YOUR_AVD -packet-streamer-endpoint default
   ```

5. Create a Bluetooth bridge between the Zephyr application and the virtual controller from Android Emulator with the Bumble utility `hci-bridge`.

   ```
   bumble-hci-bridge tcp-server:_:1234 android-netsim
   ```

   This command will create a TCP server bridge on the local host IP address `127.0.0.1` and port number `1234`.

6. Run the Zephyr application and connect to the TCP server created in the last step.

   ```
   ./zephyr.exe --bt-dev=127.0.0.1:1234
   ```

After following these steps the Zephyr application will be available to the Android Emulator over the virtual Bluetooth controller that was bridged with Bumble. You can verify that the Zephyr application can communicate over Bluetooth by opening the Bluetooth settings in your AVD and scanning for your Zephyr application device. To test this you can build the Bluetooth peripheral samples such as ble_peripheral_hr or ble_peripheral_dis.

Using Zephyr-based Controllers with BlueZ

If you want to test a Zephyr-powered Bluetooth Controller using BlueZ's Bluetooth Host, you will need a few tools described in the *Using BlueZ with Zephyr* section. Once you have installed the tools you can then use them to interact with your Zephyr-based controller:

```
sudo tools/btmgmt --index 0
[hci0]# auto-power
[hci0]# find -l
```

You might need to replace `--index 0` with the index of the Controller you wish to manage. Additional information about `btmgmt` can be found in its manual pages.

6.1.11 Shell

The Bluetooth Shell is an application based on the *Shell* module. It offer a collection of commands made to easily interact with the Bluetooth stack.

For specific Bluetooth functionality see also the following shell documentation

Bluetooth: Basic Audio Profile Shell

This document describes how to run Basic Audio Profile functionality which includes:

- Capabilities and Endpoint discovery
- Audio Stream Endpoint procedures

Commands

```

Table 16: State Machine Transitions

Command	Depends	Allowed States	Next States
init	none	any	none
discover	init	any	any
config	discover	idle/codec-configured/qos-configured	codec-configured
qos	config	codec-configured/qos-configured	qos-configured
enable	qos	qos-configured	enabling
connect	qos/enable	qos-configured/enabling	qos-configured/enabling
[start]	enable/connect	enabling	streaming
disable	enable	enabling/streaming	disabling
[stop]	disable	disabling	qos-configure/idle
release	config	any	releasing/codec-configure/idle
list	none	any	none
select_unicast	none	any	none
send	enable	streaming	none

Example Central Connect and establish a sink stream:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ bap discover sink
uart:~$ bap config sink 0
uart:~$ bap qos
uart:~$ bap enable
uart:~$ bap connect
```

Connect and establish a source stream:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ bap discover source
uart:~$ bap config source 0
uart:~$ bap qos
uart:~$ bap enable
uart:~$ bap connect
uart:~$ bap start
```

Disconnect and release:

```
uart:~$ bap disable
uart:~$ bap release
```

Example Peripheral Listen:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt advertise on
```

Server initiated disable and release:

```
uart:~$ bap disable
uart:~$ bap release
```

Example Broadcast Source Create and establish a broadcast source stream:

```
uart:~$ bap init
uart:~$ bap create_broadcast
uart:~$ bap start_broadcast
```

Stop and release a broadcast source stream:

```
uart:~$ bap stop_broadcast
uart:~$ bap delete_broadcast
```

Example Broadcast Sink Scan for and establish a broadcast sink stream. The command bap `create_broadcast_sink` will either use existing periodic advertising sync (if exist) or start scanning and sync to the periodic advertising with the provided broadcast ID before syncing to the BIG.

```
uart:~$ bap init
uart:~$ bap create_broadcast_sink 0xEF6716
No PA sync available, starting scanning for broadcast_id
Found broadcaster with ID 0xEF6716 and addr 03:47:95:75:C0:08 (random) and sid 0x00
Attempting to PA sync to the broadcaster
PA synced to broadcast with broadcast ID 0xEF6716
Attempting to sync to the BIG

uart:~$ bap sync_broadcast 0x01
```

Scan for and establish a broadcast sink stream by broadcast name The command `bap create_sink_by_name` will start scanning and sync to the periodic advertising with the provided broadcast name before syncing to the BIG.

```
uart:~$ bap init
uart:~$ bap create_sink_by_name "Test Broadcast"
Starting scanning for broadcast_name
Found matched broadcast name 'Test Broadcast' with address 03:47:95:75:C0:08␣
↪(random)
Found broadcaster with ID 0xEF6716 and addr 03:47:95:75:C0:08 (random) and sid 0x00
Attempting to PA sync to the broadcaster
PA synced to broadcast with broadcast ID 0xEF6716
Attempting to create the sink

Sink 0x20019110 is ready to sync without encryption
uart:~$ bap sync_broadcast 0x01
```

Syncing to encrypted broadcast If the broadcast is encrypted, the broadcast code can be entered with the `bap sync_broadcast` command as such:

```
Sink 0x20019110 is ready to sync with encryption
uart:~$ bap sync_broadcast 0x01 bcode 0102030405060708090a0b0c0d0e0f
```

The broadcast code can be 1-16 values, either as a string or a hexadecimal value.

```
Sink 0x20019110 is ready to sync with encryption
uart:~$ bap sync_broadcast 0x01 bcode_str thisismycode
```

Stop and release a broadcast sink stream:

```
uart:~$ bap stop_broadcast_sink
uart:~$ bap term_broadcast_sink
```

Init The `init` command register local PAC records which are necessary to be able to configure stream and properly manage capabilities in use.

Table 17: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap init
```

Discover PAC(s) and ASE(s) Once connected the `discover` command discover PAC records and ASE characteristics representing remote endpoints.

Table 18: State Machine Transitions

Depends	Allowed States	Next States
init	any	any

Note

Use command `gatt exchange-mtu` to make sure the MTU is configured properly.

```
uart:~$ gatt exchange-mtu
Exchange pending
Exchange successful
uart:~$ bap discover [type: sink, source]
uart:~$ bap discover sink

Configure Codec The `config` command attempts to configure a stream for the given direction using a preset codec configuration which can either be passed directly or in case it is omitted the default preset is used.

Table 19: State Machine Transitions

Depends	Allowed States	Next States
discover	idle/codec-configured/qos-configured	codec-configured

```
uart:~$ bap config <direction: sink, source> <index> [loc <loc_bits>] [preset
↪<preset_name>]
uart:~$ bap config sink 0
Setting location to 0x00000000
ASE config: preset 16_2_1
stream 0x2000df70 config operation rsp_code 0 reason 0
```

Configure Stream QoS The `stream_qos` Sets a new stream QoS.

```
uart:~$ bap stream_qos <interval> [framing] [latency] [pd] [sdu] [phy] [rtn]
uart:~$ bap stream_qos 10
```

Configure QoS The `qos` command attempts to configure the stream QoS using the preset configuration, each individual QoS parameter can be set with use optional parameters.

Table 20: State Machine Transitions

Depends	Allowed States	Next States
config	qos-configured/codec-configured	qos-configured

```
uart:~$ bap qos
```

Enable The `enable` command attempts to enable the stream previously configured.

Table 21: State Machine Transitions

Depends	Allowed States	Next States
qos	qos-configured	enabling

```
uart:~$ bap enable [context]
uart:~$ bap enable Media
```

Connect The `connect` command attempts to connect the stream previously configured. Sink streams will have to be started by the unicast server, and source streams will have to be started by the unicast client.

Table 22: State Machine Transitions

Depends	Allowed States	Next States
qos/enable	qos-configured/enabling	qos-configured/enabling

```
uart:~$ bap connect
```

Start The `start` command is only necessary when starting a source stream.

Table 23: State Machine Transitions

Depends	Allowed States	Next States
enable/connect	enabling	streaming

```
uart:~$ bap start
```

Disable The `disable` command attempts to disable the stream previously enabled, if the remote peer accepts then the ISO disconnection procedure is also initiated.

Table 24: State Machine Transitions

Depends	Allowed States	Next States
enable	enabling/streaming	disabling

```
uart:~$ bap disable
```

Stop The `stop` command is only necessary when acting as a sink as it indicates to the source the stack is ready to stop receiving data.

Table 25: State Machine Transitions

Depends	Allowed States	Next States
disable	disabling	qos-configure/idle

```
uart:~$ bap stop
```

Release The `release` command releases the current stream and its configuration.

Table 26: State Machine Transitions

Depends	Allowed States	Next States
config	any	releasing/codec-configure/idle

```
uart:~$ bap release
```

List The `list` command list the available streams.

Table 27: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap list
*0: ase 0x01 dir 0x01 state 0x01
```

Select Unicast The `select_unicast` command set a unicast stream as default.

Table 28: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap select <ase>
uart:~$ bap select 0x01
Default stream: 1
```

To select a broadcast stream:

```
uart:~$ bap select 0x01 broadcast
Default stream: 1 (broadcast)
```

Send The send command sends data over BAP Stream.

Table 29: State Machine Transitions

Depends	Allowed States	Next States
enable	streaming	none

```
uart:~$ bap send [count]
uart:~$ bap send
Audio sending...
```

Bluetooth: Basic Audio Profile: Broadcast Assistant Shell

This document describes how to run the BAP Broadcast Assistant functionality. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

The Broadcast Assistant is responsible for offloading scan for a resource restricted device, such that scanning does not drain the battery. The Broadcast Assistant shall support scanning for periodic advertisements and may optionally support the periodic advertisements synchronization transfer (PAST) protocol.

The Broadcast Assistant will typically be phones or laptops. The Broadcast Assistant scans for periodic advertisements and transfer information to the server.

It is necessary to have `CONFIG_BT_BAP_BROADCAST_ASSISTANT_LOG_LEVEL_DBG` enabled for using the Broadcast Assistant interactively.

When the Bluetooth stack has been initialized (`bt init`), and a device has been connected, the Broadcast Assistant can discover BASS on the connected device calling `bap_broadcast_assistant discover`, which will start a discovery for the BASS UUIDs and store the handles, and subscribe to all notifications.

```
uart:~$ bap_broadcast_assistant --help
bap_broadcast_assistant - Bluetooth BAP broadcast assistant client shell
                          commands
Subcommands:
discover           : Discover BASS on the server
scan_start         : Start scanning for broadcasters
scan_stop          : Stop scanning for BISs
add_src            : Add a source <address: XX:XX:XX:XX:XX:XX> <type:
                      public/random> <adv_sid> <sync_pa> <broadcast_id>
                      [<pa_interval>] [<sync_bis>] [<metadata>]
add_broadcast_id   : Add a source by broadcast ID <broadcast_id> <sync_pa>
                      [<sync_bis>] [<metadata>]
add_broadcast_name: Add a source by broadcast name <broadcast_name> <sync_pa>
                      [<sync_bis>] [<metadata>]
add_pa_sync        : Add a PA sync as a source <sync_pa> <broadcast_id>
                      [bis_index [bis_index [bix_index [...]]]]>
mod_src            : Set sync <src_id> <sync_pa> [<pa_interval> | "unknown"]␣
↪[<sync_bis>]
                      [<metadata>]
broadcast_code     : Send a string-based broadcast code of up to 16 bytes
                      <src_id> <broadcast code>
rem_src            : Remove a source <src_id>
read_state         : Remove a source <index>
```

Example usage

Setup

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect xx:xx:xx:xx:xx:xx public
```

When connected

> **Note**
>
> The Broadcast Assistant will not actually start scanning for periodic advertisements, as that feature is still, at the time of writing, not implemented.

Start scanning for periodic advertisements for a server:

```
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ bap_broadcast_assistant scan_start true
BASS scan start successful
Found broadcaster with ID 0x05BD38 and addr 1E:4D:0A:AA:6E:49 (random) and sid 0x00
```

Adding a source to the receive state with add_src:

```
uart:~$ bap_broadcast_assistant add_src 11:22:33:44:55:66 public 5 1 1
BASS recv state: src_id 0, addr 11:22:33:44:55:66 (public), sid 5, sync_state 1,␣
↪encrypt_state 00000000000000000000000000000000
    [0]: BIS sync 0, metadata_len 0
```

Adding a source to the receive state with add_broadcast_id (recommended):

```
uart:~$ bap_broadcast_assistant add_broadcast_id 0x05BD38 true
[DEVICE]: 1E:4D:0A:AA:6E:49 (random), AD evt type 5, RSSI -28 Broadcast Audio␣
↪Source C:0 S:0 D:0 SR:0 E:1 Prim: LE 1M, Secn: LE 2M, Interval: 0x03c0 (1200000␣
↪us), SID: 0x0
Found BAP broadcast source with address 1E:4D:0A:AA:6E:49 (random) and ID 0x05BD38
BASS recv state: src_id 0, addr 1E:4D:0A:AA:6E:49 (random), sid 0, sync_state 0,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 0
BASS add source successful
BASS recv state: src_id 0, addr 1E:4D:0A:AA:6E:49 (random), sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 0
BASS recv state: src_id 0, addr 1E:4D:0A:AA:6E:49 (random), sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 4
              Metadata length 2, type 2, data: 0100
```

Modifying a receive state:

```
uart:~$ bap_broadcast_assistant mod_src 0 true 0x03c0 0x02
BASS modify source successful
BASS recv state: src_id 0, addr 1E:4D:0A:AA:6E:49 (random), sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0001, metadata_len 4
              Metadata length 2, type 2, data: 0100
```

Supplying a broadcast code:

```
uart:~$ bap_broadcast_assistant broadcast_code 0 secretCode
Sending broadcast code:
00000000: 73 65 63 72 65 74 43 6f 64 65 00 00 00 00 00 00 |secretCo de....|
uart:~$ BASS broadcast code successful
```

Bluetooth: Basic Audio Profile: Scan Delegator Shell

This document describes how to run the Scan Delegator functionality, Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

The Scan Delegator may optionally support the periodic advertisements synchronization transfer (PAST) protocol.

The Scan Delegator server typically resides on devices that have inputs or outputs.

It is necessary to have `CONFIG_BT_BAP_SCAN_DELEGATOR_LOG_LEVEL_DBG` enabled for using the Scan Delegator interactively.

The Scan Delegator can currently only set the sync state of a receive state, but does not actually support syncing with periodic advertisements yet.

```
bap_scan_delegator --help
bap_scan_delegator - Bluetooth BAP Scan Delegator shell commands
Subcommands:
  init                : Initialize the service and register callbacks
  set_past_pref       : Set PAST preference <true || false>
  sync_pa             : Sync to PA <src_id>
  term_pa             : Terminate PA sync <src_id>
  add_src             : Add a PA as source <addr> <sid> <broadcast_id>
                        <enc_state> [bis_sync [metadata]]
  add_src_by_pa_sync  : Add a PA as source <broadcast_id> <enc_state> [bis_sync
                        [metadata]]
  mod_src             : Modify source <src_id> <broadcast_id> <enc_state>
                        [bis_sync [metadata]]
  rem_src             : Remove source <src_id>
  synced              : Set server scan state <src_id> <bis_syncs>
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ bap_scan_delegator init
uart:~$ bt advertise on
Advertising started
```

Adding a source

```
uart:~$ bap_scan_delegator add_src 11:22:33:44:55:66 public 0 1234 0
Receive state with ID 0 updated
```

Adding a source from a PA sync

```
uart:~$ bt scan on
Found broadcaster with ID 0x681A22 and addr 2C:44:05:82:EB:82 (random) and sid␣
↪0x00 (looking for 0x1000000)
uart:~$ bt scan off
uart:~$ bt per-adv-sync-create 2C:44:05:82:EB:82 (random) 0
PA 0x2003e9b0 synced
uart:~$ bap_scan_delegator add_src_by_pa_sync 0x681A22 0
Receive state with ID 0 updated
```

When connected Set sync state for a source:

```
uart:~$ bap_scan_delegator synced 0 1 3 0
```

Bluetooth: Common Audio Profile Shell

This document describes how to run the Common Audio Profile functionality.

CAP Acceptor The Acceptor will typically be a resource-constrained device, such as a headset, earbud or hearing aid. The Acceptor can initialize a Coordinated Set Identification Service instance, if it is in a pair with one or more other CAP Acceptors.

Using the CAP Acceptor When the Bluetooth stack has been initialized (`bt init`), the Acceptor can be registered by calling `cap_acceptor init`, which will register the CAS and CSIS services, as well as register callbacks.

```
cap_acceptor --help
cap_acceptor - Bluetooth CAP acceptor shell commands
Subcommands:
  init          :Initialize the service and register callbacks [size <int>]
                 [rank <int>] [not-lockable] [sirk <data>]
  lock          :Lock the set
  release       :Release the set [force]
  sirk          :Set the currently used SIRK <sirk>
  get_info      :Get CSIS info
  sirk_rsp      :Set the response used in SIRK requests <accept, accept_enc,
                 reject, oob>
```

Besides initializing the CAS and the CSIS, there are also commands to lock and release the CSIS instance, as well as printing and modifying access to the SIRK of the CSIS.

Setting a new SIRK This command can modify the currently used SIRK. To get the new RSI to advertise on air, `bt adv-data` or `bt advertise` must be called again to set the new advertising data. If `CONFIG_BT_CSIP_SET_MEMBER_SIRK_NOTIFIABLE` is enabled, this will also notify connected clients.

```
uart:~$ cap_acceptor sirk 00112233445566778899aabbccddeeff
SIRK updated
```

Getting the current SIRK This command can get the currently used SIRK.

```
uart:~$ cap_acceptor get_info
Info for 0x2003b0c8
        SIRK
00000000: 20 37 0a 00 95 c4 04 20  00 00 00 00 f1 79 09 00 | 7.....  .....y..|
        Set size: 2
        Rank: 1
        Lockable: true
        Locked: false
```

CAP Initiator The Initiator will typically be a resource-rich device, such as a phone or PC. The Initiator can discover CAP Acceptors's CAS and optional CSIS services. The CSIS service can be read to provide information about other CAP Acceptors in the same Coordinated Set. The Initiator can execute stream control procedures on sets of devices, either ad-hoc or Coordinated, and thus provides an easy way to setup multiple streams on multiple devices at once.

Using the CAP Initiator When the Bluetooth stack has been initialized (`bt init`), the Initiator can discover CAS and the optionally included CSIS instance by calling (`cap_initiator discover`). The CAP initiator also supports broadcast audio as a source.

```
uart:~$ cap_initiator --help
cap_initiator - Bluetooth CAP initiator shell commands
Subcommands:
  discover          : Discover CAS
  unicast_start     : Unicast Start [csip] [sinks <cnt> (default 1)] [sources
                      <cnt> (default 1)] [conns (<cnt> | all) (default 1)]
  unicast_list      : Unicast list streams
  unicast_update    : Unicast Update <all | stream [stream [stream...]]>
  unicast_stop      : Unicast stop streams [stream [stream [stream...]]] (all by␣
↪default)
  unicast_cancel    : Unicast cancel current procedure
  ac_1              : Unicast audio configuration 1
  ac_2              : Unicast audio configuration 2
  ac_3              : Unicast audio configuration 3
  ac_4              : Unicast audio configuration 4
  ac_5              : Unicast audio configuration 5
  ac_6_i            : Unicast audio configuration 6(i)
  ac_6_ii           : Unicast audio configuration 6(ii)
  ac_7_i            : Unicast audio configuration 7(i)
  ac_7_ii           : Unicast audio configuration 7(ii)
  ac_8_i            : Unicast audio configuration 8(i)
  ac_8_ii           : Unicast audio configuration 8(ii)
  ac_9_i            : Unicast audio configuration 9(i)
  ac_9_ii           : Unicast audio configuration 9(ii)
  ac_10             : Unicast audio configuration 10
  ac_11_i           : Unicast audio configuration 11(i)
  ac_11_ii          : Unicast audio configuration 11(ii)
  broadcast_start   :
  broadcast_update  : <meta>
  broadcast_stop    :
  broadcast_delete  :
  ac_12             : Broadcast audio configuration 12
  ac_13             : Broadcast audio configuration 13
  ac_14             : Broadcast audio configuration 14
```

Before being able to perform any stream operation, the device must also perform the `bap discover` operation to discover the ASEs and PAC records. The `bap init` command also needs to be called.

When connected Discovering CAS and CSIS on a device:

```
uart:~$ cap_initiator discover
discovery completed with CSIS
```

Discovering ASEs and PAC records on a device:

```
uart:~$ bap discover
conn 0x81cc260: #0: codec 0x81d5b28 dir 0x01

dir 2 loc 1
snk ctx 6 src ctx 6
Conn: 0x81cc260, Source #0: ep 0x81e5c88
Conn: 0x81cc260, Source #1: ep 0x81e60e8
Discover complete: err 0
```

Both of the above commands should be done for each device that you want to use in the set. To use multiple devices, simply connect to more and then use `bt select` the device to execute the commands on.

Once all devices have been connected and the respective discovery commands have been called, the `cap_initiator unicast_start` command can be used to put one or more streams into the streaming state.

```
uart:~$ cap_initiator unicast_start sinks 1 sources 0 conns all
Setting up 1 sinks and 0 sources on each (2) conn
Starting 1 streams
Unicast start completed
```

To stop all the streams that has been started, the `cap_initiator unicast_stop` command can be used.

```
uart:~$ cap_initiator unicast_stop all
Unicast stop completed
```

When doing broadcast To start a broadcast as the CAP initiator there are a few steps to be done:

1. Create and configure an extended advertising set with periodic advertising
2. Create and configure a broadcast source
3. Setup extended and periodic advertising data

The following commands will setup a CAP broadcast source using the 16_2_1 preset (defined by BAP):

```
bt init
bap init
```

(continues on next page)

(continued from previous page)

```
bt adv-create nconn-nscan ext-adv
bt per-adv-param
bap preset broadcast 16_2_1
cap_initiator ac_12
bt adv-data dev-name discov
bt per-adv-data
cap_initiator broadcast_start
bt adv-start
bt per-adv on
```

The broadcast source is created by the `cap_initiator ac_12`, `cap_initiator ac_13`, and `cap_initiator ac_14` commands, configuring the broadcast source for the defined audio configurations from BAP. The broadcast source can then be stopped with `cap_initiator broadcast_stop` or deleted with `cap_initiator broadcast_delete`.

The metadata of the broadcast source can be updated at any time, including when it is already streaming. To update the metadata the `cap_initiator broadcast_update` command can be used. The command takes an array of data, and the only requirement (besides having valid data) is that the streaming context shall be set. For example to set the streaming context to media, the command can be used as

```
cap_initiator broadcast_update 03020400
CAP Broadcast source updated with new metadata. Update the advertised base via `bt␣
↪per-adv-data`
bt per-adv-data
```

The `bt per-adv-data` command should be used afterwards to update the data is the advertised BASE. The data must be little-endian, so in the above example the metadata `03020400` is setting the metadata entry with `03` as the length, `02` as the type (streaming context) and `0400` as the value `BT_AUDIO_CONTEXT_TYPE_MEDIA` (which has the numeric value of 0x).

CAP Commander The Commander will typically be a either co-located with a CAP Initiator or be on a separate resource-rich mobile device, such as a phone or smartwatch. The Commander can discover CAP Acceptors's CAS and optional CSIS services. The CSIS service can be read to provide information about other CAP Acceptors in the same Coordinated Set. The Commander can provide information about broadcast sources to CAP Acceptors or coordinate capture and rendering information such as mute or volume states.

Using the CAP Commander When the Bluetooth stack has been initialized (`bt init`), the Commander can discover CAS and the optionally included CSIS instance by calling (`cap_commander discover`).

```
cap_commander --help
cap_commander - Bluetooth CAP commander shell commands
Subcommands:
  discover                  :Discover CAS
  cancel                    :CAP commander cancel current procedure
  change_volume             :Change volume on all connections <volume>
  change_volume_mute        :Change volume mute state on all connections <mute>
  change_volume_offset      :Change volume offset per connection <volume_offset
                             [volume_offset [...]]>
  change_microphone_mute    :Change microphone mute state on all connections <mute>
  change_microphone_gain    :Change microphone gain per connection <gain
                             [gain [...]]>
  broadcast_reception_start : Start broadcast reception with
                              source <address: XX:XX:XX:XX:XX:XX>
```

(continues on next page)

(continued from previous page)

```
                              <type: public/random> <adv_sid> <broadcast_id>
                              [<pa_interval>] [<sync_bis>] [<metadata>]
  broadcast_reception_stop  : Stop broadcast reception <src_id [...]>
  distribute_broadcast_code : Distribute broadcast code <src_id [...]>
↪<broadcast_code>
```

Before being able to perform any stream operation, the device must also perform the `bap discover` operation to discover the ASEs and PAC records. The `bap init` command also needs to be called.

When connected

Discovering CAS and CSIS on a device

```
uart:~$ cap_commander discover
discovery completed with CSIS
```

Setting the volume on all connected devices

```
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$ cap_commander change_volume 15
uart:~$ cap_commander change_volume 15
Setting volume to 15 on 2 connections
VCP volume 15, mute 0
VCP vol_set done
VCP volume 15, mute 0
VCP flags 0x01
VCP vol_set done
Volume change completed
```

Setting the volume offset on one or more devices The offsets are set by connection index, so connection index 0 gets the first offset, and index 1 gets the second offset, etc.:

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_volume_offset 10
Setting volume offset on 1 connections
VOCS inst 0x200140a4 offset 10
Offset set for inst 0x200140a4
Volume offset change completed
uart:~$
uart:~$ cap_commander change_volume_offset 10 15
```

(continues on next page)

(continued from previous page)

```
Setting volume offset on 2 connections
Offset set for inst 0x200140a4
VOCS inst 0x20014188 offset 15
Offset set for inst 0x20014188
Volume offset change completed
```

Setting the volume mute on all connected devices

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_volume_mute 1
Setting volume mute to 1 on 2 connections
VCP volume 100, mute 1
VCP mute done
VCP volume 100, mute 1
VCP mute done
Volume mute change completed
uart:~$ cap_commander change_volume_mute 0
Setting volume mute to 0 on 2 connections
VCP volume 100, mute 0
VCP unmute done
VCP volume 100, mute 0
VCP unmute done
Volume mute change completed
```

Setting the microphone mute on all connected devices

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_microphone_mute 1
Setting microphone mute to 1 on 2 connections
MICP microphone 100, mute 1
```

(continues on next page)

(continued from previous page)

```
MICP mute done
MICP microphone 100, mute 1
MICP mute done
Microphone mute change completed
uart:~$ cap_commander change_microphone_mute 0
Setting microphone mute to 0 on 2 connections
MICP microphone 100, mute 0
MICP unmute done
MICP microphone 100, mute 0
MICP unmute done
Microphone mute change completed
```

Setting the microphone gain on one or more devices The gains are set by connection index, so connection index 0 gets the first offset, and index 1 gets the second offset, etc.:

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 AICS
uart:~$
uart:~$ cap_commander change_microphone_gain 10
Setting microphone gain on 1 connections
AICS inst 0x200140a4 state gain 10, mute 0, mode 0
Gain set for inst 0x200140a4
Microphone gain change completed
uart:~$
uart:~$ cap_commander change_microphone_gain 10 15
Setting microphone gain on 2 connections
Gain set for inst 0x200140a4
AICS inst 0x20014188 state gain 15, mute 0, mode 0
Gain set for inst 0x20014188
Microphone gain change completed
```

Starting and stopping broadcast reception

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ bap_init
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ cap_commander broadcast_reception_start <device B> 0 4
Starting broadcast reception on 1 connection(s)
Broadcast reception start completed
uart:~$ cap_commander broadcast_reception_stop 0
```

(continues on next page)

(continued from previous page)

```
Stopping broadcast reception on 1 connection(s)
Broadcast reception stop completed
```

Distributing the broadcast code

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ bap_init
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ cap_commander broadcast_reception_start <device B> 0 4
Starting broadcast reception on 1 connection(s)
Broadcast reception start completed
uart:~$ cap_commander distribute_broadcast_code 0 "BroadcastCode"
Distribute broadcast code completed
```

Bluetooth: Call Control Profile Shell

Call Control Server The Call Control Server is a role that typically resides on devices that can make calls, including calls from apps such as Skype, e.g. (smart)phones and PCs, which are typically GAP Central devices.

Using the Call Control Server The Server can be controlled locally, or by a remote device (when in a call). For example a remote device may initiate a call to the server, or the Server may initiate a call to remote device, without a client.

For all commands that take an optional `index`, if the index is not supplied then it defaults to `0` which is the GTBS bearer.

```
ccp_call_control_server --help
ccp_call_control_server - Bluetooth CCP Call Control Server shell commands
Subcommands:
  init             : Initialize CCP Call Control Server
  set_bearer_name  : Set bearer name [index] <name>
  get_bearer_name  : Get bearer name [index]
  get_bearer_uci   : Get bearer UCI [index]
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ ccp_call_control_server init
Registered GTBS bearer
Registered bearer[1]
uart:~$ bt connect xx:xx:xx:xx:xx:xx public
```

Setting and getting the bearer name

```
uart:~$ ccp_call_control_server get_bearer_name
Bearer[0] name: Generic TBS
uart:~$ ccp_call_control_server set_bearer_name "New name"
Bearer[0] name: New name
```

(continues on next page)

(continued from previous page)

```
uart:~$ ccp_call_control_server get_bearer_name
Bearer[0] name: New name
uart:~$ ccp_call_control_server get_bearer_name 1
Bearer[1] name: Telephone Bearer #1
uart:~$ ccp_call_control_server set_bearer_name 1 "New TBS name"
Bearer[1] name: New TBS name
uart:~$ ccp_call_control_server get_bearer_name 1
Bearer[1] name: New TBS name
```

Getting the bearer UCI

```
uart:~$ ccp_call_control_server get_bearer_uci
Bearer[0] UCI: un999
uart:~$ ccp_call_control_server get_bearer_uci 1
Bearer[1] UCI: skype
```

Call Control Client The Call Control Client is a role that typically resides on resource constrained devices such as earbuds or headsets.

Using the Call Control Client The Client can control a remote CCP server device. For example a remote device may have an incoming call that can be accepted by the Client.

```
uart:~$ ccp_call_control_client --help
ccp_call_control_client - Bluetooth CCP Call Control Client shell commands
Subcommands:
  discover  : Discover GTBS and TBS on remote device
```

Example Usage when connected

```
uart:~$ ccp_call_control_client discover
Discovery completed with GTBS and 1 TBS bearers
```

```
uart:~$ ccp_call_control_client read_bearer_name
Bearer 0x20046254 name: Generic TBS
uart:~$ ccp_call_control_client read_bearer_name 1
Bearer 0x20046256 name: Telephone Bearer #1
```

Bluetooth: Coordinated Set Identification Profile Shell

This document describes how to run the coordinated set identification functionality, both as a client and as a server. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

Set Coordinator (Client) The client will typically be a resource-rich device, such as a smartphone or a laptop. The client is able to lock and release members of a coordinated set. While the coordinated set is locked, no other clients may lock the set.

To lock a set, the client must connect to each of the set members it wants to lock. This implementation will always try to connect to all the members of the set, and at the same time. Thus if the set size is 3, then `BT_MAX_CONN` shall be at least 3.

If the locks on set members shall persists through disconnects, it is necessary to bond with the set members. If you need to bond with multiple set members, make sure that `BT_MAX_PAIRED` is correctly configured.

Using the Set Coordinator When the Bluetooth stack has been initialized (`bt init`), and a set member device has been connected, the call control client can be initialized by calling `csip_set_coordinator init`, which will start a discovery for the TBS uuids and store the handles, and optionally subscribe to all notifications (default is to subscribe to all).

Once the client has connected and discovered the handles, then it can read the set information, which is needed to identify other set members. The client can then scan for and connect to the remaining set members, and once all the members has been connected to, it can lock and release the set.

It is necessary to enable `CONFIG_BT_CSIP_SET_COORDINATOR_LOG_LEVEL_DBG` to properly use the set coordinator.

```
csip_set_coordinator --help
csip_set_coordinator - Bluetooth CSIP_SET_COORDINATOR shell commands
Subcommands:
   init              :Initialize CSIP_SET_COORDINATOR
   discover          :Run discover for CSIS on peer device [member_index]
   discover_members  :Scan for set members <set_pointer>
   lock_set          :Lock set
   release_set       :Release set
   lock              :Lock specific member [member_index]
   release           :Release specific member [member_index]
   lock_get          :Get the lock value of the specific member and instance
                      [member_index [inst_idx]]
```

Example usage

Setup

```
uart:~$ init
uart:~$ bt connect xx:xx:xx:xx:xx:xx public
```

When connected Discovering sets on a device:

```
uart:~$ csip_set_coordinator init
<dbg> bt_csip_set_coordinator.primary_discover_func: [ATTRIBUTE] handle 0x0048
<dbg> bt_csip_set_coordinator.primary_discover_func: Discover complete, found 1␣
↪instances
<dbg> bt_csip_set_coordinator.discover_func: Setup complete for 1 / 1
Found 1 sets on device
uart:~$ csip_set_coordinator discover_sets

Coordinated Set Member (Server) The server on devices that are part of a set, consisting of at least two devices, e.g. a pair of earbuds.

Using the Set Member

```
csip_set_member --help
csip_set_member - Bluetooth CSIP set member shell commands
   Subcommands:
   register           : Initialize the service and register callbacks [size
                        <int>] [rank <int>] [not-lockable] [sirk <data>]
   lock               : Lock the set
   release            : Release the set [force]
   sirk               : Set the currently used SIRK <sirk>
   set_size_and_rank  : Set the currently used size and rank <size> <rank>
   get_info           : Get service info
```

(continues on next page)

(continued from previous page)

```
   sirk_rsp           : Set the response used in SIRK requests <accept,
                        accept_enc, reject, oob>
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ csip_set_member register
```

Setting a new SIRK This command can modify the currently used SIRK. To get the new RSI to advertise on air, `bt adv-data` or `bt advertise` must be called again to set the new advertising data. If `CONFIG_BT_CSIP_SET_MEMBER_SIRK_NOTIFIABLE` is enabled, this will also notify connected clients.

```
uart:~$ csip_set_member sirk 00112233445566778899aabbccddeeff
SIRK updated
```

Setting a new set size and rank This command can modify the set size and rank of a service instance. This shall be done for all device in the set at the same time, and all devices shall have the same set size. The rank will be ignored if the set is not lockable, else the rank shall be <= the set size, and shall be unique for this device in the set.

```
uart:~$ csip_set_member set_size_and_rank 1 1
Set size and rank updated to 1 and 1
```

Getting the current info This command can get the currently used set info.

```
uart:~$ csip_set_member get_info
Info for 0x2003b0c8
        SIRK
00000000: 20 37 0a 00 95 c4 04 20  00 00 00 00 f1 79 09 00 | 7.....  .....y..|
        Set size: 2
        Rank: 1
        Lockable: true
        Locked: false
```

Bluetooth: Gaming Audio Profile Shell

This document describes how to run the Gaming Audio Profile shell functionality. Unlike most other low-layer profiles, GMAP is a profile that exists and has a service (GMAS) on all devices. Thus both the initiator and acceptor (or central and peripheral) should do a discovery of the remote device's GMAS to see what GMAP roles and features they support.

Using the GMAP Shell When the Bluetooth stack has been initialized (`bt init`), the GMAS can be registered by by calling `gmap init`. It is also strongly suggested to enable BAP via `bap init`.

```
uart:~$ gmap --help
gmap - Bluetooth GMAP shell commands
Subcommands:
  init      : [none]
  set_role  : [ugt | ugg | bgr | bgs]
  discover  : [none]
```

(continues on next page)

(continued from previous page)

```
  ac_1      : Unicast audio configuration 1
  ac_2      : Unicast audio configuration 2
  ac_3      : Unicast audio configuration 3
  ac_4      : Unicast audio configuration 4
  ac_5      : Unicast audio configuration 5
  ac_6_i    : Unicast audio configuration 6(i)
  ac_6_ii   : Unicast audio configuration 6(ii)
  ac_7_ii   : Unicast audio configuration 7(ii)
  ac_8_i    : Unicast audio configuration 8(i)
  ac_8_ii   : Unicast audio configuration 8(ii)
  ac_11_i   : Unicast audio configuration 11(i)
  ac_11_ii  : Unicast audio configuration 11(ii)
  ac_12     : Broadcast audio configuration 12
  ac_13     : Broadcast audio configuration 13
  ac_14     : Broadcast audio configuration 14
```

The `set_role` command can be used to change the role at runtime, assuming that the device supports the role (the GMAP roles depend on some BAP configurations).

Example Central with GMAP UGT role Connect and establish Gaming Audio streams using Audio Configuration (AC) 3 (some logging has been omitted for clarity):

```
uart:~$ bt init
uart:~$ bap init
uart:~$ gmap init
uart:~$ bt connect <address>

Bluetooth: Media Control Profile Shell

This document describes how to run the media control functionality, using the shell, both as a client and as a server.

The media control server consists of to parts. There is a media player (mpl) that contains the logic to handle media, and there is a media control service (mcs) that serves as a GATT-based interface to the player. The media control client consists of one part, the GATT based client (mcc).

The media control server may include an object transfer service (ots) and the media control client may include an object transfer client (otc). When these are included, a richer set of functionality is available.

The media control server and client both implement the Generic Media Control Service (only), and do not use any underlying Media Control Services.

Note that in the examples below, in many cases the debug output has been removed and long outputs may have been shortened to make the examples shorter and clearer.

Also note that this documentation does not list all shell commands, it just shows examples of some of them. The set of commands is explorable from the mcc shell and the mpl shell, by typing `mcc` or `mpl` and pressing TAB. A help text for each command can be found by doing `mcc <command> help` or `mpl <command> help`.

Overview A media player has a *name* and an *icon* that allows identification of the player for the user.

The content of the media player is structured into tracks and groups. A media player has a number of groups. A group contains tracks and other groups. (In this implementation, a group only contains tracks, not other groups.) Tracks can be divided into segments.

An active player will have a *current track*. This is the track that is playing now (if the player is playing). The current track has a *title*, a *duration* (given in hundredths of a second) and a *position* - the current position of the player within the track.

There is also a *current group* (the group of the current track), a *parent group* (the parent group of the current group) and a *next track*.

The media player is in a *state*, which will be one of playing, paused, seeking or inactive. When playing, playback happens at a given *playback speed*, and the tracks are played according to the *playing order*, which is one of the *playing orders supported*. Track changes are signalled as notifications of the *track changed* characteristic. When seeking (fast forward or fast rewind), the track position is moved according to the *seeking speed*.

The *opcodes supported* tells which operations are supported by the player by writing to the *media control point*. There is also a *search control point* that allows to search for groups and tracks according to various criteria, with the result returned in the *search results*.

Finally, the *content control ID* is used to associate the media player with an audio stream.

Media Control Client (MCP) The media control client is used to control, and to get information from, a media control server. Control is done by writing to one of the two control points, or by writing to other writable characteristics. Getting information is done by reading characteristics, or by configuring the server to send notifications.

Using the media control client Before use, the media control client must be initialized by the command `mcc init`.

To achieve a connection to the peer, the `bt` commands must be used - `bt init` followed by `bt advertise on` (or `bt connect` if the server is advertising).

When the media control client is connected to a media control server, the client can discover the server's Generic Media Control Service, by giving the command `mcc discover_mcs`. This will store the handles of the service, and (optionally, but default) subscribe to all notifications.

After discovery, the media control client can read and write characteristics, including the media control point and the search control point.

Example usage

Setup

```
uart:~$ bt init
Bluetooth initialized

uart:~$ mcc init
MCC init complete

uart:~$ bt advertise on
Advertising started
Connected: F6:58:DC:27:F3:57 (random)
```

When connected Service discovery (GMCS and included OTS):

```
uart:~$ mcc discover_mcs
<dbg> bt_mcc.bt_mcc_discover_mcs: start discovery of MCS primary service
<dbg> bt_mcc.discover_primary_func: [ATTRIBUTE] handle 0x00ae

<dbg> bt_mcc.discover_mcs_char_func: Setup complete for MCS
<dbg> bt_mcc.discover_mcs_char_func: Start discovery of included services
<dbg> bt_mcc.discover_include_func: [ATTRIBUTE] handle 0x00af
<dbg> bt_mcc.discover_include_func: Include UUID 1825
<dbg> bt_mcc.discover_include_func: Discover include complete for MCS: OTS
<dbg> bt_mcc.discover_include_func: Start discovery of OTS characteristics
<dbg> bt_mcc.discover_otc_char_func: [ATTRIBUTE] handle 0x009c
<dbg> bt_mcc.discover_otc_char_func: OTS Features
[...]
<dbg> bt_mcc.discover_otc_char_func: [ATTRIBUTE] handle 0x00ac
<dbg> bt_mcc.discover_otc_char_func: Object Size
Discovery complete
```

(continues on next page)

(continued from previous page)

```
<dbg> bt_otc.bt_otc_register: 0
<dbg> bt_otc.bt_otc_register: L2CAP psm 0x  25 sec_level 1 registered
<dbg> bt_mcc.discover_otc_char_func: Setup complete for OTS 1 / 1
uart:~$
```

Reading characteristics - the player name and the track duration as examples:

```
uart:~$ mcc read_player_name
Player name: My media player
4d 79 20 6d 65 64 69 61  20 70 6c 61 79 65 72    |My media  player

uart:~$ mcc read_track_duration
Track duration: 6300
```

Note that the value of some characteristics may be truncated due to being too long to fit in the ATT packet. Increasing the ATT MTU may help:

```
uart:~$ mcc read_track_title
Track title: Interlude #1 (Song for

uart:~$ gatt exchange-mtu
Exchange pending
Exchange successful

uart:~$ mcc read_track_title
Track title: Interlude #1 (Song for Alison)
```

Writing characteristics - track position as an example:

The track position is where the player “is” in the current track. Read the track position, change it by writing to it, confirm by reading it again.

```
uart:~$ mcc read_track_position
Track Position: 0

uart:~$ mcc set_track_position 500
Track Position: 500

uart:~$ mcc read_track_position
Track Position: 500
```

Controlling the player via the control point:

Writing to the control point allows the client to request the server to do operations like play, pause, fast forward, change track, change group and so on. Some operations (e.g. goto track) take an argument. Currently, raw opcode values are used as input to the control point shell command. These opcode values can be found in the mpl.h header file.

Send the play command (opcode “1”), the command to go to track (opcode “52”) number three, and the pause command (opcode “2”):

```
uart:~$ mcc set_cp 1
Media State: 1
Operation: 1, result: 1
Operation: 1, param: 0

uart:~$ mcc set_cp 52 3
Track changed
Track title: Interlude #3 (Levanto Seventy)
```

(continues on next page)

(continued from previous page)

```
Track duration: 7800
Track Position: 0
Current Track Object ID: 0x000000000104
Next Track Object ID: 0x000000000105
Operation: 52, result: 1
Operation: 52, param: 3

uart:~$ mcc set_cp 2
Media State: 2
Operation: 2, result: 1
Operation: 2, param: 0
```

Using the included object transfer client When object transfer is supported by both the client and the server, a larger set of characteristics is available. These include object IDs for the various track and group objects. These IDs can be used to select and download the corresponding objects from the server's object transfer service.

Read the object ID of the current group object:

```
uart:~$ mcc read_current_group_obj_id
Current Group Object ID: 0x000000000107
```

Select the object with that ID:

```
uart:~$ mcc ots_select 0x107
Selecting object succeeded
```

Read the object's metadata:

```
uart:~$ mcc ots_read_metadata
Reading object metadata succeeded
<inf> bt_mcc: Object's meta data:
<inf> bt_mcc:        Current size    :35
<inf> bt_otc: --- Displaying 1 metadata records ---
<inf> bt_otc: Object ID: 0x000000000107
<inf> bt_otc: Object name: Joe Pass - Guitar Inte
<inf> bt_otc: Object Current Size: 35
<inf> bt_otc: Object Allocate Size: 35
<inf> bt_otc: Type: Group Obj Type
<inf> bt_otc: Properties:0x4
<inf> bt_otc:  - read permitted
```

Read the object itself:

The object received is a group object. It consists of a series of records consisting of a type (track or group) and an object ID.

```
uart:~$ mcc ots_read_current_group_object
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000102
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000103
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000104
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000105
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000106
```

Search The search control point takes as its input a sequence of search control items, each consisting of length, type (e.g. track name or artist name) and parameter (the track name or artist name to search for). If the result is successful, the search results are stored in an object in the

object transfer service. The ID of the search results ID object can be read from the search results object ID characteristic. The search result object can then be downloaded as for the current group object above. (Note that the search results object ID is empty until a search has been done.)

This implementation has a working implementation of the search functionality interface and the server-side search control point parameter parsing. But the **actual searching is faked**, the same results are returned no matter what is searched for.

There are two commands for search, one (`mcc set_scp_raw`) allows to input the search control point parameter (the sequence of search control items) as a string. The other (`mcc set_scp_ioptest`) does preset IOP test searches and takes the round number of the IOP search control point test as a parameter.

Before the search, the search results object ID is empty

```
uart:~$ mcc read_search_results_obj_id
Search Results Object ID: 0x000000000000
<dbg> bt_mcc.mcc_read_search_results_obj_id_cb: Zero-length Search Results Object␣
↪ID
```

Run the search corresponding to the fourth round of the IOP test:

The search control point parameter generated by this command and parameter has one search control item. The length field (first octet) is 16 (0x10). (The length of the length field itself is not included.) The type field (second octet) is 0x04 (search for a group name). The parameter (the group name to search for) is “TSPX_Group_Name”.

```
uart:~$ mcc set_scp_ioptest 4
Search string:
00000000: 10 04 54 53 50 58 5f 47  72 6f 75 70 5f 4e 61 6d |..TSPX_G roup_Nam|
00000010: 65                                              |e                |
Search control point notification result code: 1
Search Results Object ID: 0x000000000107
Search Control Point set
```

After the successful search, the search results object ID has a value:

```
uart:~$ mcc read_search_results_obj_id
Search Results Object ID: 0x000000000107
```

Media Control Service (MCS) The media control service (mcs) and the associated media player (mpl) typically reside on devices that can provide access to, and serve, media content, like PCs and smartphones.

As mentioned above, the media player (mpl) has the player logic, while the media control service (mcs) has the GATT-based interface. This separation is done so that the media player can also be used without the GATT-based interface.

Using the media control service and the media player The media control service and the media player are in general controlled remotely, from the media control client.

Before use, the media control client must be initialized by the command `mpl init`.

As for the client, the `bt` commands are used for connecting - `bt init` followed by `bt connect <address> <address type>` (or `bt advertise on` if the server is advertising).

Example Usage

Setup

```
uart:~$ bt init
Bluetooth initialized

uart:~$ mpl init
[Large amounts of debug output]

uart:~$ bt connect F9:33:3B:67:D2:A7 (random)
Connection pending
Connected: F9:33:3B:67:D2:A7 (random)
```

When connected Control is done from the client.

The server will give debug output related to the various operations performed by the client.

Example: Debug output by the server when the client gives the "next track" command:

```
[00:13:29.932,373] <dbg> bt_mcs.control_point_write: Opcode: 49
[00:13:29.932,403] <dbg> bt_mpl.mpl_operation_set: opcode: 49, param: 536880068
[00:13:29.932,403] <dbg> bt_mpl.paused_state_operation_handler: Operation opcode:␣
↪49
[00:13:29.932,495] <dbg> bt_mpl.do_next_track: Track ID before: 0x000000000104
[00:13:29.932,586] <dbg> bt_mpl.do_next_track: Track ID after: 0x000000000105
[00:13:29.932,617] <dbg> bt_mcs.mpl_track_changed_cb: Notifying track change
[00:13:29.932,708] <dbg> bt_mcs.mpl_track_title_cb: Notifying track title:␣
↪Interlude #4 (Vesper Dreams)
[00:13:29.932,800] <dbg> bt_mcs.mpl_track_duration_cb: Notifying track duration:␣
↪13500
[00:13:29.932,861] <dbg> bt_mcs.mpl_track_position_cb: Notifying track position: 0
[00:13:29.933,044] <dbg> bt_mcs.mpl_current_track_id_cb: Notifying current track␣
↪ID: 0x000000000105
[00:13:29.933,258] <dbg> bt_mcs.mpl_next_track_id_cb: Notifying next track ID:␣
↪0x000000000106
[00:13:29.933,380] <dbg> bt_mcs.mpl_operation_cb: Notifying control point -␣
↪opcode: 49, result: 1
```

Some server commands are available. These commands force notifications of the various characteristics, for testing that the client receives notifications. The values sent in the notifications caused by these testing commands are independent of the media player, so they do not correspond the actual values of the characteristics nor to the actual state of the media player.

Example: Force (fake value) notification of the track duration:

```
uart:~$ mpl duration_changed_cb
[00:15:17.491,058] <dbg> bt_mcs.mpl_track_duration_cb: Notifying track duration:␣
↪12000
```

Bluetooth: Telephone Bearer Service Shell

This document describes how to run the call control functionality, both as a client and as a (telephone bearer service (TBS)) server. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

Telephone Bearer Service Client The telephone bearer service client will typically exist on a resource restricted device, such as headphones, but may also exist on e.g. phones or laptops. The call control client will also thus typically be the advertiser. The client can control the states of calls on a server using the call control point.

It is necessary to have `CONFIG_BT_TBS_CLIENT_LOG_LEVEL_DBG` enabled for using the client interactively.

Using the telephone bearer service client When the Bluetooth stack has been initialized (`bt init`), and a device has been connected, the telephone bearer service client can discover TBS on the connected device calling `tbs_client discover`, which will start a discovery for the TBS UUIDs and store the handles, and optionally subscribe to all notifications (default is to subscribe to all).

Since a server may have multiple TBS instances, most of the tbs_client commands will take an index (starting from 0) as input. Joining calls require at least 2 call IDs, and all call indexes shall be on the same TBS instance.

A server will also have a GTBS instance, which is an abstraction layer for all the telephone bearers on the server. If the server has both GTBS and TBS, the client may subscribe and use either when sending requests if `BT_TBS_CLIENT_GTBS` is enabled.

```
tbs_client --help
tbs_client - Bluetooth TBS_CLIENT shell commands
Subcommands:
   discover                        :Discover TBS [subscribe]
   set_signal_reporting_interval   :Set the signal reporting interval
                                    [<{instance_index, gtbs}>] <interval>
   originate                       :Originate a call [<{instance_index, gtbs}>]
                                    <uri>
   terminate                       :terminate a call [<{instance_index, gtbs}>]
                                    <id>
   accept                          :Accept a call [<{instance_index, gtbs}>] <id>
   hold                            :Place a call on hold [<{instance_index,
                                    gtbs}>] <id>
   retrieve                        :Retrieve a held call [<{instance_index,
                                    gtbs}>] <id>
   read_provider_name              :Read the bearer name [<{instance_index,
                                    gtbs}>]
   read_bearer_uci                 :Read the bearer UCI [<{instance_index, gtbs}>]
   read_technology                 :Read the bearer technology [<{instance_index,
                                    gtbs}>]
   read_uri_list                   :Read the bearer's supported URI list
                                    [<{instance_index, gtbs}>]
   read_signal_strength            :Read the bearer signal strength
                                    [<{instance_index, gtbs}>]
   read_signal_interval            :Read the bearer signal strength reporting
                                    interval [<{instance_index, gtbs}>]
   read_current_calls              :Read the current calls [<{instance_index,
                                    gtbs}>]
   read_ccid                       :Read the CCID [<{instance_index, gtbs}>]
   read_status_flags               :Read the in feature and status value
                                    [<{instance_index, gtbs}>]
   read_uri                        :Read the incoming call target URI
                                    [<{instance_index, gtbs}>]
   read_call_state                 :Read the call state [<{instance_index, gtbs}>]
   read_remote_uri                 :Read the incoming remote URI
                                    [<{instance_index, gtbs}>]
   read_friendly_name              :Read the friendly name of an incoming call
                                    [<{instance_index, gtbs}>]
   read_optional_opcodes           :Read the optional opcodes [<{instance_index,
                                    gtbs}>]
```

In the following examples, notifications from GTBS are ignored, unless otherwise specified.

Example usage

Setup

```
uart:~$ bt init
uart:~$ bt advertise on
Advertising started
```

When connected Placing a call:

```
uart:~$ tbs_client discover
<dbg> bt_tbs_client.primary_discover_func: Discover complete, found 1 instances␣
↪(GTBS found)
<dbg> bt_tbs_client.discover_func: Setup complete for 1 / 1 TBS
<dbg> bt_tbs_client.discover_func: Setup complete GTBS
uart:~$ tbs_client originate 0 tel:123
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the dialing␣
↪state with URI tel:123
<dbg> bt_tbs_client.call_cp_notify_handler: Status: success for the originate␣
↪opcode for call 0x00
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the alerting␣
↪state with URI tel:123
<call answered by peer device, and status notified by TBS server>
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the active state␣
↪with URI tel:123
```

Placing a call on GTBS:

```
uart:~$ tbs_client originate 0 tel:123
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the dialing␣
↪state with URI tel:123
<dbg> bt_tbs_client.call_cp_notify_handler: Status: success for the originate␣
↪opcode for call 0x00
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the alerting␣
↪state with URI tel:123
<call answered by peer device, and status notified by TBS server>
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the active state␣
↪with URI tel:123
```

It is necessary to set an outgoing caller ID before placing a call.

Accepting incoming call from peer device:

```
<dbg> bt_tbs_client.incoming_uri_notify_handler: tel:123
<dbg> bt_tbs_client.in_call_notify_handler: tel:456
<dbg> bt_tbs_client.friendly_name_notify_handler: Peter
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x05 is in the incoming␣
↪state with URI tel:456
uart:~$ tbs_client accept 0 5
<dbg> bt_tbs_client.call_cp_callback_handler: Status: success for the accept␣
↪opcode for call 0x05
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x05 is in the active state␣
↪with URI tel
```

Terminate call:

```
uart:~$ tbs_client terminate 0 5
<dbg> bt_tbs_client.termination_reason_notify_handler: ID 0x05, reason 0x06
<dbg> bt_tbs_client.call_cp_notify_handler: Status: success for the terminate␣
↪opcode for call 0x05
<dbg> bt_tbs_client.current_calls_notify_handler:
```

Telephone Bearer Service (TBS) The telephone bearer service is a service that typically resides on devices that can make calls, including calls from apps such as Skype, e.g. (smart)phones and PCs.

It is necessary to have `CONFIG_BT_TBS_LOG_LEVEL_DBG` enabled for using the TBS server interactively.

Using the telephone bearer service TBS can be controlled locally, or by a remote device (when in a call). For example a remote device may initiate a call to the device with the TBS server, or the TBS server may initiate a call to remote device, without a TBS_CLIENT client. The TBS implementation is capable of fully controlling any call. Omitting an index for commands where a `<instance_index>` can be supplied, defaults to the GTBS bearer.

```
tbs --help
tbs - Bluetooth TBS shell commands
Subcommands:
   init                        :Initialize TBS
   authorize                   :Authorize the current connection
   accept                      :Accept call <call_index>
   terminate                   :Terminate call <call_index>
   hold                        :Hold call <call_index>
   retrieve                    :Retrieve call <call_index>
   originate                   :Originate call [<instance_index>] <uri>
   join                        :Join calls <id> <id> [<id> [<id> [...]]]
   incoming                    :Simulate incoming remote call [<{instance_index,
                                gtbs}>] <local_uri> <remote_uri>
                                <remote_friendly_name>
   remote_answer               :Simulate remote answer outgoing call <call_index>
   remote_retrieve             :Simulate remote retrieve <call_index>
   remote_terminate            :Simulate remote terminate <call_index>
   remote_hold                 :Simulate remote hold <call_index>
   set_bearer_provider_name    :Set the bearer provider name [<{instance_index,
                                gtbs}>] <name>
   set_bearer_technology       :Set the bearer technology [<{instance_index,
                                gtbs}>] <technology>
   set_bearer_signal_strength  :Set the bearer signal strength [<{instance_index,
                                gtbs}>] <strength>
   set_status_flags            :Set the bearer feature and status value
                                [<{instance_index, gtbs}>] <feature_and_status>
   set_uri_scheme              :Set the URI prefix list <bearer_idx>
↪<uri1[,uri2[,uri3[,...]]]>
   print_calls                 :Output all calls in the debug log
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ bt connect xx:xx:xx:xx:xx:xx public
```

When connected Answering a call for a peer device originated by a client:

```
<dbg> bt_tbs.write_call_cp: Index 0: Processing the originate opcode
<dbg> bt_tbs.originate_call: New call with call index 1
<dbg> bt_tbs.write_call_cp: Index 0: Processed the originate opcode with status␣
↪success for call index 1
uart:~$ tbs remote_answer 1
TBS succeeded for call_id: 1
```

Incoming call from a peer device, accepted by client:

```
uart:~$ tbs incoming 0 tel:123 tel:456 Peter
TBS succeeded for call_id: 4
<dbg> bt_tbs.bt_tbs_remote_incoming: New call with call index 4
<dbg> bt_tbs.write_call_cp: Index 0: Processed the accept opcode with status␣
↪success for call index 4
```

Bluetooth: Telephone and Media Audio Profile Shell

This document describes how to run the Telephone and Media Audio Profile functionality. Unlike most other low-layer profiles, TMAP is a profile that exists and has a service (TMAS) on all devices. Thus both the initiator and acceptor (or central and peripheral) should do a discovery of the remote device's TMAS to see what TMAP roles they support.

Using the TMAP Shell When the Bluetooth stack has been initialized (`bt init`), the TMAS can be registered by calling `tmap init`.

```
tmap --help
tmap - Bluetooth TMAP shell commands
Subcommands:
  init          :Initialize and register the TMAS
  discover      :Discover TMAS on remote device
```

Bluetooth: Public Broadcast Profile Shell

This document describes how to run the Public Broadcast Profile functionality. PBP does not have an associated service. Its purpose is to enable a faster, more efficient discovery of Broadcast Sources that are transmitting audio with commonly used codec configurations.

Using the PBP Shell When the Bluetooth stack has been initialized (`bt init`), the Public Broadcast Profile is ready to run. To set the Public Broadcast Announcement features call `pbp set_features`.

```
pbp --help
pbp - Bluetooth PBP shell commands
Subcommands:
  set_features    :Set the Public Broadcast Announcement features
```

Bluetooth: A2DP Shell

The `a2dp` command exposes parts of the A2DP API.

The following examples assume that you have two devices already connected.

A2DP Connection Demonstrate the flow of creating an A2DP connection:

- Both sides register A2DP callbacks using `a2dp register_cb`.
- Either side establishes an A2DP connection, which will create the AVDTP Signaling channel, using `a2dp connect`.
- Either side can get the ACL connection using `a2dp get_conn`.
- Either side can disconnect the A2DP connection using `a2dp disconnect`.

Device A (initiator)

```
uart:~$ a2dp register_cb
success
uart:~$ a2dp connect
Bonded with XX:XX:XX:XX:XX:XX
Security changed: XX:XX:XX:XX:XX:XX level 2
a2dp connected
uart:~$ a2dp get_conn
a2dp conn is: 0xXXXXXXXX
uart:~$ a2dp disconnect
a2dp disconnected
```

Device B (acceptor)

```
uart:~$ a2dp register_cb
success
<input `a2dp connect` in initiator side>
Connected: XX:XX:XX:XX:XX:XX
Bonded with XX:XX:XX:XX:XX:XX
Security changed: XX:XX:XX:XX:XX:XX level 2
a2dp connected
<input `a2dp disconnect` in initiator side>
a2dp disconnected
```

Basic A2DP Operations Demonstrate the flow of basic A2DP operations:

- Source and Sink sides register stream endpoints using `a2dp register_ep source sbc` and `a2dp register_ep sink sbc`.
- Create an A2DP connection based on *a2dp connection*.
- Initiator discovers remote device's stream endpoints using `a2dp discover_peer_eps 0x0104`.
- Initiator configures the stream to create the stream after discovering remote endpoints using `a2dp configure`.
- Initiator establishes the stream using `a2dp establish`.
- Sink sends delay report using `a2dp send_delay_report`.
- Initiator starts the media using `a2dp start`.
- Source tests media sending using `a2dp send_media` to send one test packet data.
- Initiator suspends the media using `a2dp suspend`.
- Initiator releases the media using `a2dp release`.

Note

The initiator is the A2DP source role and the acceptor is the A2DP sink role in the following logs. The delay report can only be sent by the sink role. The media data can only be sent by the source role.

Device A (initiator)

```
uart:~$ a2dp register_ep source sbc
SBC source endpoint is registered
uart:~$ a2dp discover_peer_eps 0x0104
endpoint id: 1, (sink), (idle):
  codec type: SBC
  sample frequency:
          44100
          48000
  channel mode:
          Mono
          Stereo
          Joint-Stereo
  Block Length:
          16
  Subbands:
          8
  Allocation Method:
          Loudness
  Bitpool Range: 18 - 35
uart:~$ a2dp configure
success to configure
stream configured
uart:~$ a2dp establish
success to establish
stream established
<input `a2dp send_delay_report` in sink side>
receive delay report and accept
received delay report: 1 1/10ms
uart:~$ a2dp start
success to start
stream started
uart:~$ a2dp send_media
frames num: 1, data length: 160
data: 1, 2, 3, 4, 5, 6 ......
uart:~$ a2dp suspend
success to suspend
stream suspended
uart:~$ a2dp release
success to release
stream released
```

Device B (acceptor)

```
uart:~$ a2dp register_ep sink sbc
SBC sink endpoint is registered
<input `a2dp configure` in initiator side>
receive requesting config and accept
sample rate 44100Hz
stream configured
<input `a2dp establish` in initiator side>
receive requesting establishment and accept
```

(continues on next page)

(continued from previous page)

```
stream established
uart:~$ a2dp send_delay_report
success to send report delay
<input `a2dp start` in initiator side>
receive requesting start and accept
stream started
<input `a2dp send_media` in source side>
received, num of frames: 1, data length: 160
data: 1, 2, 3, 4, 5, 6 ......
<input `a2dp suspend` in initiator side>
receive requesting suspend and accept
stream suspended
<input `a2dp release` in initiator side>
receive requesting release and accept
stream released
```

Abort Operation Demonstrate the abort operation:

- Establish an A2DP stream based on *basic a2dp operations*.
- Initiator aborts the stream using `a2dp abort`.

Device A (initiator)

```
uart:~$ a2dp abort
success to abort
stream released
```

Device B (acceptor)

```
<input `a2dp abort` in initiator side>
receive requesting abort and accept
stream released
```

Get Configuration and Reconfigure Operation Demonstrate the get configuration and reconfigure operations:

- Establish an A2DP stream based on *basic a2dp operations*.
- Initiator gets configuration using `a2dp get_config`.
- Initiator reconfigures the stream using `a2dp reconfigure`.

Device A (initiator)

```
uart:~$ a2dp get_config
get config result: 0
sample rate 44100Hz
uart:~$ a2dp reconfigure
success to configure
stream configured
```

Device B (acceptor)

```
<input `a2dp get_config` in initiator side>
receive get config request and accept
<input `a2dp reconfigure` in initiator side>
receive requesting reconfig and accept
```

(continues on next page)

(continued from previous page)

```
sample rate 44100Hz
stream configured
```

Bluetooth: Classic: AVRCP Shell

This document describes how to use the Bluetooth Classic AVRCP (Audio/Video Remote Control Profile) functionality via shell commands. The `avrcp` command exposes both Controller (CT) and Target (TG) roles for exercising AVRCP control and browsing features.

There are two sub-commands: `avrcp ct` and `avrcp tg`. The `avrcp ct` sub-command provides **Controller (CT)** functionality, and `avrcp tg` sub-command provides **Target (TG)** functionality.

Prerequisites Before running the `avrcp` shell, make sure your build enables Bluetooth Classic and the shell. An ACL BR/EDR connection to the peer device must be established first (typically via the general `bt` shell commands) before AVRCP control or browsing connections can be created.

Commands All commands can only be used after the ACL connection has been established except `avrcp ct register_cb` and `avrcp tg register_cb`.

The `avrcp` commands:

```
uart:~$ avrcp
avrcp - Bluetooth AVRCP shell commands
Subcommands:
  connect               : connect AVRCP
  disconnect            : disconnect AVRCP
  browsing_connect      : connect browsing AVRCP
  browsing_disconnect   : disconnect browsing AVRCP
  ct                    : AVRCP CT shell commands
  tg                    : AVRCP TG shell commands
```

The `avrcp ct` commands:

```
uart:~$ avrcp ct
ct - AVRCP CT shell commands
Subcommands:
  register_cb                : register avrcp ct callbacks
  get_unit                   : get unit info
  get_subunit                : get subunit info
  get_caps                   : get capabilities <cap_id: company or events>
  play                       : request a play at the remote player
  pause                      : request a pause at the remote player
  register_notification      : register notify <event_id> [playback_interval]
  set_browsed_player         : set browsed player <player_id>
  get_folder_items           : [none]
  change_path                : [none]
  get_item_attrs             : get item attrs [scope]
  get_total_number_of_items  : get total number of items [scope]
  search                     : search [search_string]
  list_app_attrs             : [none]
  list_app_vals              : List App vals <attr_id>
  get_app_curr               : Get curr player app setting val [attr1] [attr2] ...
  set_app_val                : Set app setting Val <attr1> <val1> [<attr2>
↪<val2>] ...
  get_app_attr_text          : Get app setting attrs text <attr1> [attr2] ...
```

(continues on next page)

(continued from previous page)

```
  get_app_val_text            : Get setting vals Text <attr_id> <val1> [val2] ...
  inform_displayable_char     : Inform Displayable Character Set <charset_id1>␣
↪[charset_id2] ...
  inform_batt                 : Inform Battery Status Of CT <Battery status>
  set_absolute_volume         : set absolute volume <volume>
  get_element_attrs           : get element attrs [identifier] [attr1] [attr2] ...
  get_play_status             : [none]
  set_addressed_player        : set addressed player <player_id>
  play_item                   : PlayItem <scope> <uid_hex> <uid_counter>
  add_to_now_playing          : AddToNowPlaying <scope> <uid_hex> <uid_counter>
```

The `avrcp tg` commands:

```
uart:~$ avrcp tg
tg - AVRCP TG shell commands
Subcommands:
  register_cb                               : register avrcp tg callbacks
  send_unit_rsp                             : send unit info response
  send_subunit_rsp                          : [none]
  send_get_caps_rsp                         : send get capabilities response␣
↪[status]
  send_notification_rsp                     : send notify rsp <event_id> <type>␣
↪[value...]
  send_browsed_player_rsp                   : Send SetBrowsedPlayer response
  send_get_folder_items_rsp                 : send get folder items [status]
  send_change_path_rsp                      : send change path [status]
  send_get_item_attrs_rsp                   : send get item attrs [status]
  send_get_total_number_of_items_rsp        : send get total number of items␣
↪[status]
  send_search_rsp                           : search [status]
  send_browsing_general_reject              : send browsing general reject␣
↪[reason]
  send_passthrough_rsp                      : send_passthrough_rsp <op/opvu>
↪<opid> <state>
  send_list_player_app_setting_attrs_rsp    : send attrs rsp <num> [attr_id...]
  send_list_player_app_setting_vals_rsp     : send vals rsp <num> [val_id...]
  send_get_curr_player_app_setting_val_rsp  : send current vals rsp <num_pairs>␣
↪[attr val]...
  send_set_player_app_setting_val_rsp       : set app setting val rsp [status]
  send_get_player_app_setting_attr_text_rsp : send get player app setting attr␣
↪text rsp [status]
  send_get_player_app_setting_val_text_rsp  : send get player app setting val␣
↪text rsp [status]
  send_inform_displayable_char_rsp          : send displayable char rsp [status]
  send_inform_batt_status_of_ct_rsp         : send inform batt rsp [status]
  send_get_element_attrs_rsp                : send get element attrs␣
↪response<large: 1>
  send_absolute_volume_rsp                  : send absolute volume rsp <volume>
  send_get_play_status_rsp                  : send get play status [status]
  send_set_addressed_player_rsp             : send set addressed player rsp␣
↪[status]
  send_play_item_rsp                        : send play item rsp [status]
  send_add_to_now_playing_rsp               : send add to now playing rsp [status]
```

Basic AVRCP Operations

Demonstrate the flow of basic AVRCP operations:

- Both sides register AVRCP callbacks using `avrcp ct register_cb` and `avrcp tg register_cb`.
- Create an AVRCP connection using `avrcp connect`.
- CT gets capabilities from TG using `avrcp ct get_caps events`.
- CT registers for notifications using `avrcp ct register_notification 0x01`.
- CT requests playback control using `avrcp ct play`.
- CT gets current play status using `avrcp ct get_play_status`.
- CT gets element attributes (metadata) using `avrcp ct get_element_attrs`.
- CT sets volume using `avrcp ct set_absolute_volume 50`.
- CT pauses playback using `avrcp ct pause`.

Note

CT (Controller) sends commands and TG (Target) responds. For notification-capable events, TG typically sends an **INTERIM** response immediately after registration to indicate the current value, and later a **CHANGED** response when the value actually changes.

Device A (CT - Controller)

```
uart:~$ avrcp ct register_cb
AVRCP CT callbacks registered
uart:~$ avrcp connect
AVRCP CT connected
uart:~$ avrcp ct get_caps events
GetCapabilities : status=0x04
Remote supported EventID = 0x01
Remote supported EventID = 0x02
Remote supported EventID = 0x0d
uart:~$ avrcp ct register_notification 0x01
Get capabilities command sent successfully: cap_id=events
Sent register notification event_id=0x01
AVRCP notification rsp: tid=0x01, status=0x04, event_id=0x01
 Notification type: INTERIM
 PLAYBACK_STATUS_CHANGED: status=0x00
uart:~$ avrcp ct play
Passthrough PRESSED command sent successfully: opid=0x44
Passthrough RELEASED command sent successfully: opid=0x44
<input `avrcp tg send_passthrough_rsp op play pressed` in TG side>
AVRCP passthough command accepted, operation id = 0x44, state = 0
<input `avrcp tg send_passthrough_rsp op play released` in TG side>
AVRCP passthough command accepted, operation id = 0x44, state = 1
<input `avrcp tg send_notification_rsp 0x01 changed 1` in TG side>
AVRCP notification rsp: tid=0x01, status=0x04, event_id=0x01
 Notification type: CHANGED
 PLAYBACK_STATUS_CHANGED: status=0x01
uart:~$ avrcp ct get_play_status
AVRCP GetPlayStatus
getplaystatus : status=0x04
GetPlayStatus: len=180000 ms, pos=30000 ms, status=0x01
 status: PLAYING
uart:~$ avrcp ct get_element_attrs
Requesting element attributes: identifier=0x0000000000000000, num_attrs=0
```

(continues on next page)

(continued from previous page)

```
AVRCP CT get element attrs command sent
GetElementAttributes : status=0x04
AVRCP GetElementAttributes response received, tid=0x05, num_attrs=7
 Attr[0]: ID=0x00000001 (TITLE), charset=0x006a, len=11
   Value: "Test Title"
 Attr[1]: ID=0x00000002 (ARTIST), charset=0x006a, len=11
   Value: "Test Artist"
uart:~$ avrcp ct set_absolute_volume 50
set absolute volume absolute_volume=0x32
AVRCP set absolute volume rsp: tid=0x02, status=0x04, volume=0x32
uart:~$ avrcp ct pause
Passthrough PRESSED command sent successfully: opid=0x46
Passthrough RELEASED command sent successfully: opid=0x46
<input `avrcp tg send_passthrough_rsp op pause pressed` in TG side>
AVRCP passthough command accepted, operation id = 0x46, state = 0
<input `avrcp tg send_passthrough_rsp op pause released` in TG side>
AVRCP passthough command accepted, operation id = 0x46, state = 1
```

Device B (TG - Target)

```
uart:~$ avrcp tg register_cb
AVRCP TG callbacks registered
<input `avrcp connect` in CT side>
AVRCP TG connected
<input `avrcp ct get_caps events` in CT side>
AVRCP get capabilities command received: cap_id 0x03 (EVENTS_SUPPORTED)
uart:~$ avrcp tg send_get_caps_rsp
Get capabilities response sent successfully
<input `avrcp ct register_notification 0x01` in CT side>
receive register notification request event_id=0x01
uart:~$ avrcp tg send_notification_rsp 0x01 interim 0
Sent notification rsp event_id=0x01 type=interim
<input `avrcp ct play` in CT side>
receive passthrough command: op_id=0x44 (PLAY)
uart:~$ avrcp tg send_passthrough_rsp op play pressed
Passthrough opid=0x44 (STANDARD), state=pressed sent successfully
uart:~$ avrcp tg send_passthrough_rsp op play released
Passthrough opid=0x44 (STANDARD), state=released sent successfully
uart:~$ avrcp tg send_notification_rsp 0x01 changed 1
Sent notification rsp event_id=0x01 type=changed
<input `avrcp ct get_play_status` in CT side>
receive get play status request
uart:~$ avrcp tg send_get_play_status_rsp
GetPlayStatus rsp sent
<input `avrcp ct get_element_attrs` in CT side>
AVRCP GetElementAttributes command received
uart:~$ avrcp tg send_get_element_attrs_rsp 0
Sending standard GetElementAttributes response (7 attrs)
GetElementAttributes response sent successfully
<input `avrcp ct set_absolute_volume 50` in CT side>
AVRCP set_absolute_volume_req: tid=0x06, absolute_volume=0x32
uart:~$ avrcp tg send_absolute_volume_rsp 50
Set absolute volume response sent successfully
<input `avrcp ct pause` in CT side>
AVRCP passthrough command received: opid = 0x46
uart:~$ avrcp tg send_passthrough_rsp op pause pressed
```

(continues on next page)

(continued from previous page)

```
send passthrough response
uart:~$ avrcp tg send_passthrough_rsp op pause released
send passthrough response
```

AVRCP Connection The AVRCP profile supports both control and browsing connections. The control connection is used for basic remote control functionality, while the browsing connection allows browsing of media content.

Control Connection Establish AVRCP control connection:

1. Register callbacks (CT side):

```
uart:~$ avrcp ct register_cb
AVRCP CT callbacks registered
```

2. Register callbacks (TG side):

```
uart:~$ avrcp tg register_cb
AVRCP TG callbacks registered
```

3. Connect AVRCP:

```
uart:~$ avrcp connect
AVRCP CT connected
AVRCP TG connected
```

4. Disconnect AVRCP:

```
uart:~$ avrcp disconnect
AVRCP CT disconnected
AVRCP TG disconnected
```

Browsing Connection After control connection is established, browsing connection can be initiated:

1. Connect browsing:

```
uart:~$ avrcp browsing_connect
AVRCP browsing connect request sent
AVRCP CT browsing connected
AVRCP TG browsing connected
```

2. Disconnect browsing:

```
uart:~$ avrcp browsing_disconnect
AVRCP browsing disconnect request sent
AVRCP CT browsing disconnected
AVRCP TG browsing disconnected
```

Basic Playback Control Control playback from CT side:

Play Command

```
uart:~$ avrcp ct play
Passthrough PRESSED command sent successfully: opid=0x44
Passthrough RELEASED command sent successfully: opid=0x44
```

Pause Command

```
uart:~$ avrcp ct pause
Passthrough PRESSED command sent successfully: opid=0x46
Passthrough RELEASED command sent successfully: opid=0x46
```

Get Capabilities Query supported capabilities:

Company ID

```
uart:~$ avrcp ct get_caps company
Get capabilities command sent successfully: cap_id=company
GetCapabilities : status=0x04
Remote CompanyID = 0x001958
```

Events Supported

```
uart:~$ avrcp ct get_caps events
Get capabilities command sent successfully: cap_id=events
GetCapabilities : status=0x04
Remote supported EventID = 0x01
Remote supported EventID = 0x02
Remote supported EventID = 0x03
Remote supported EventID = 0x04
Remote supported EventID = 0x0d
```

TG Response

```
uart:~$ avrcp tg send_get_caps_rsp
Sending company ID capability rsp: 0x001958
```

Media Metadata Operations

Get Element Attributes Retrieve metadata for the currently playing media:

CT Request

```
uart:~$ avrcp ct get_element_attrs
Requesting element attributes: identifier=0x0000000000000000, num_attrs=0
AVRCP CT get element attrs command sent
GetElementAttributes : status=0x04
AVRCP GetElementAttributes response received, tid=0x00, num_attrs=7
 Attr[0]: ID=0x00000001 (TITLE), charset=0x006a, len=11
   Value: "Test Title"
 Attr[1]: ID=0x00000002 (ARTIST), charset=0x006a, len=11
   Value: "Test Artist"
 Attr[2]: ID=0x00000003 (ALBUM), charset=0x006a, len=10
   Value: "Test Album"
 Attr[3]: ID=0x00000004 (TRACK_NUMBER), charset=0x006a, len=1
   Value: "1"
 Attr[4]: ID=0x00000005 (TOTAL_TRACKS), charset=0x006a, len=2
   Value: "10"
 Attr[5]: ID=0x00000006 (GENRE), charset=0x006a, len=4
   Value: "Rock"
 Attr[6]: ID=0x00000007 (PLAYING_TIME), charset=0x006a, len=6
   Value: "240000"
```

TG Response

```
uart:~$ avrcp tg send_get_element_attrs_rsp 0
Sending standard GetElementAttributes response (7 attrs)
GetElementAttributes response sent successfully
```

Play Status Get current playback status:

CT Request

```
uart:~$ avrcp ct get_play_status
AVRCP GetPlayStatus
getplaystatus : status=0x04
GetPlayStatus: len=180000 ms, pos=30000 ms, status=0x01
 status: PLAYING
```

TG Response

```
uart:~$ avrcp tg send_get_play_status_rsp
GetPlayStatus rsp sent
```

Volume Control Set absolute volume:

CT Set Volume

```
uart:~$ avrcp ct set_absolute_volume 50
set absolute volume absolute_volume=0x32
AVRCP set absolute volume rsp: tid=0x01, status=0x04, volume=0x32
```

TG Response

```
uart:~$ avrcp tg send_absolute_volume_rsp 50
Set absolute volume response sent successfully
```

Event Notifications Register for notifications and handle events:

Register for Volume Change Notification CT Register

```
uart:~$ avrcp ct register_notification 0x0d
Sent register notification event_id=0x0d
AVRCP notification rsp: tid=0x02, status=0x04, event_id=0x0d
 Notification type: INTERIM
 VOLUME_CHANGED: absolute_volume=0x0a
AVRCP notify_changed_cb received: event_id=0x0d
 Notification type: CHANGED
 VOLUME_CHANGED: absolute_volume=0x14
```

TG Send Notification

```
uart:~$ avrcp tg send_notification_rsp 0x0d interim 10
Sent notification rsp event_id=0x0d type=interim

uart:~$ avrcp tg send_notification_rsp 0x0d changed 20
Sent notification rsp event_id=0x0d type=changed
```

Browsing Operations

Set Browsed Player CT Request

```
uart:~$ avrcp ct set_browsed_player 1
AVRCP send set browsed player req
AVRCP set browsed player success, tid = 0
  UID Counter: 1
  Number of Items: 100
  Charset ID: 0x006A
  Folder Depth: 1
  charset_id  : 0x006A
  Get folder Name (hex)  :
00000000: 4d 75 73 69 63                                  |Music            |
```

TG Response

```
uart:~$ avrcp tg send_browsed_player_rsp
Send set browsed player response, status = 0x04
```

Get Folder Items CT Request

```
uart:~$ avrcp ct get_folder_items
Sent GetFolderItems command
AVRCP get folder items success, tid = 1
  UID Counter: 1
  Number of Items: 1
Media Player Item:
  item_len   : 28
  player_id   : 1
  major_type  : 0x01
  sub_type    : 0x00000000
  play_status : 0x00
  charset_id  : 0x006A
  name_len    : 4
  charset_id  : 0x006A
  Name (hex)  :
00000000: 44:65:6d:6f                                     |Demo
```

TG Response

```
uart:~$ avrcp tg send_get_folder_items_rsp
TG: Sent GetFolderItems response
```

Player Application Settings List and get configure player application settings:

List Available Settings CT Request

```
uart:~$ avrcp ct list_app_attrs
Sent list player app setting attrs
list player app setting attrs : status=0x04
attr =0x01 (EQUALIZER)
attr =0x02 (REPEAT_MODE)
```

TG Response

```
uart:~$ avrcp tg send_list_player_app_setting_attrs_rsp 2 0x01 0x02
TG: Sent list player app setting attrs response
```

Get Current Settings CT Request

```
uart:~$ avrcp ct get_app_curr 1 2
Sent get_curr_player_app_setting_val num=2
get curr player app setting val : status=0x04
attr_id :1 val 1
attr_id :2 val 1
```

TG Response

```
uart:~$ avrcp tg send_get_curr_player_app_setting_val_rsp 2 0x01 0x01 0x02 0x02
TG: Send get curr player app setting val rsp (num=2)
```

Bluetooth: Classic: GOEP Shell

This document describes how to run the Bluetooth Classic GOEP functionality. The goep command exposes the Bluetooth Classic GOEP Shell commands.

Commands The goep commands:

```
uart:~$ goep
goep - Bluetooth GOEP shell commands
Subcommands:
  register-rfcomm    : <channel>
  connect-rfcomm     : <channel>
  disconnect-rfcomm  :
  register-l2cap     : <psm>
  connect-l2cap      : <psm>
  disconnect-l2cap   :
  alloc-buf          : Alloc tx buffer
  release-buf        : Free allocated tx buffer
  add-header         : Adding header sets
  client             : Client sets
  server             : Server sets
```

The `goep client` commands:

```
uart:~$ goep client
client - Client sets
Subcommands:
  conn     : <mopl>
  disconn  :
  put      : <final: true, false>
  get      : <final: true, false>
  abort    :
  setpath  : [parent] [create]
  action   : <final: true, false>
```

The `goep server` commands:

```
uart:~$ goep server
server - Server sets
Subcommands:
  reg      : [UUID 128]
  unreg    :
  conn     : <rsp: continue, success, error> <mopl> [rsp_code]
  disconn  : <rsp: continue, success, error> [rsp_code]
  put      : <rsp: continue, success, error> [rsp_code]
```

(continues on next page)

(continued from previous page)

```
  get      : <rsp: continue, success, error> [rsp_code]
  abort    : <rsp: continue, success, error> [rsp_code]
  setpath  : <rsp: continue, success, error> [rsp_code]
  action   : <rsp: continue, success, error> [rsp_code]
```

Connect GOEP Transport The ACL connection should be established before creating the GOEP transport connection.

The transport is based on L2CAP Channel:

L2CAP Server

```
uart:~$ goep register-l2cap 0
L2CAP server (psm 1001) is registered
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

L2CAP Client

```
uart:~$ goep connect-l2cap 1001
GOEP L2CAP connection pending
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

The transport is based on RFCOMM Channel:

RFCOMM Server

```
uart:~$ goep register-rfcomm 0
RFCOMM server (channel 06) is registered
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

RFCOMM Client

```
uart:~$ goep connect-rfcomm 6
GOEP RFCOMM connection pending
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

Disconnect GOEP transport The transport is based on L2CAP Channel:

One Side

```
GOEP 0x20005600 transport disconnected
uart:~$
```

Another Side

```
uart:~$ goep disconnect-l2cap
GOEP L2CAP disconnection pending
GOEP 0x20005600 transport disconnected
uart:~$
```

The transport is based on RFCOMM Channel:

One Side

```
GOEP 0x20005600 transport disconnected
uart:~$
```

Another Side

```
uart:~$ goep disconnect-rfcomm
GOEP RFCOMM disconnection pending
GOEP 0x20005600 transport disconnected
uart:~$
```

Connect to OBEX Server OBEX Server

```
uart:~$ goep server reg
uart:~$
OBEX server 0x20005850 conn req, version 10, mopl 00ff
uart:~$ goep server conn success 255
uart:~$
```

OBEX Client

```
uart:~$ goep client conn 255
OBEX client 0x20005818 conn rsp, rsp_code Success, version 10, mopl 00ff
uart:~$
```

Disconnect from OBEX Server OBEX Server

```
OBEX server 0x20005850 disconn req
uart:~$ goep server disconn success
uart:~$
```

OBEX Client

```
uart:~$ goep client disconn
OBEX client 0x20005818 disconn rsp, rsp_code Success
uart:~$
```

OBEX Put Operation OBEX Server

```
uart:~$
OBEX server 0x20005850 put req, final false, data len 12

uart:~$
```

Bluetooth: Classic: HFP Shell

This document describes how to run the Bluetooth Classic HFP functionality. The `hfp` command exposes the Bluetooth Classic HFP Shell commands.

There are two sub-commands, `hfp hf` and `hfp ag`.

The `hfp hf` is for Hands-Free Profile (HF) functionality, and the `hfp ag` is for Audio Gateway (AG) functionality.

Commands All commands can only be used after the ACL connection has been established except `hfp hf reg` and `hfp ag reg`.

The `hfp` commands:

```
uart:~$ hfp
hfp - Bluetooth HFP shell commands
Subcommands:
  hf  : HFP HF shell commands
  ag  : HFP AG shell commands
```

The `hfp hf` commands:

```
uart:~$ hfp hf
hf - HFP HF shell commands
Subcommands:
  reg                          : [none]
  connect                      : <channel>
  disconnect                   : [none]
  sco_disconnect               : [none]
  cli                          : <enable/disable>
  vgm                          : <gain>
  vgs                          : <gain>
  operator                     : [none]
  audio_connect                : [none]
  auto_select_codec            : <enable/disable>
  select_codec                 : Codec ID
  set_codecs                   : Codec ID Map
  accept                       : <call index>
  reject                       : <call index>
  terminate                    : <call index>
  hold_incoming                : <call index>
  query_respond_hold_status    : [none]
  number_call                  : <phone number>
  memory_dial                  : <memory location>
  redial                       : [none]
  turn_off_ecnr                : [none]
  call_waiting_notify          : <enable/disable>
  release_all_held             : [none]
  set_udub                     : [none]
  release_active_accept_other  : [none]
  hold_active_accept_other     : [none]
  join_conversation            : [none]
  explicit_call_transfer       : [none]
  release_specified_call       : <call index>
  private_consultation_mode    : <call index>
  voice_recognition            : <activate/deactivate>
  ready_to_accept_audio        : [none]
  request_phone_number         : [none]
  transmit_dtmf_code           : <call index> <code(set 0-9, #,*,A-D)>
  query_subscriber             : [none]
  indicator_status             : <Activate/deactivate AG indicators bitmap>
  enhanced_safety              : <enable/disable>
  battery                      : <level>
```

The `hfp ag` commands:

```
uart:~$ hfp ag
ag - HFP AG shell commands
Subcommands:
  reg                     : [none]
  connect                 : <channel>
  disconnect              : [none]
  sco_disconnect          : [none]
  ongoing_calls           : <yes or no>
  set_ongoing_calls       : <number> <type> <status> <dir> [all]

  hf_indicator            : <indicator> <enable/disable>
```

HFP AG SLC The `hfp ag` subcommand provides functionality for HFP AG in Bluetooth Classic.

1. Register HFP AG:

```
uart:~$ hfp ag reg
```

2. Connect to HFP HF:

```
uart:~$ hfp ag connect 1
```

3. Connection is established with the HF device:

```
Security changed: XX:XX:XX:XX:XX:XX level 2
AG received codec id bit map 2
AG connected
AG received vgm 0
AG received vgs 0
```

4. Disconnect from HFP HF:

```
uart:~$ hfp ag disconnect
```

5. Connection is broken:

```
AG disconnected
```

HFP HF SLC The `hfp hf` subcommand provides functionality for HFP HF in Bluetooth Classic.

1. Register HFP HF:

```
uart:~$ hfp hf reg
```

2. Connect to HFP AG:

```
uart:~$ hfp hf connect 2
```

3. Connection is established with the AG device:

```
Security changed: XX:XX:XX:XX:XX:XX level 2
HF service 0
HF signal 0
HF roam 0
HF battery 0
HF ring: in-band
HF connected
```

4. Disconnect from HFP HF:

```
uart:~$ hfp hf disconnect
```

5. Connection is broken:

```
HF disconnected
```

Call outgoing Place a call with the Phone number supplied by the AG:

Outgoing Call Sequence on AG side

```
uart:~$ hfp ag outgoing 123456
AG outgoing call 0x20007690, number 123456
AG SCO connected 0x20005248
AG SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
uart:~$ hfp ag remote_ringing 0
AG call 0x20007690 start ringing mode 1
uart:~$ hfp ag remote_accept 0
AG call 0x20007690 accept
```

Outgoing Call Sequence on HF side

```
uart:~$ hfp hf auto_select_codec enable
HF call 0x20007408 outgoing
codec negotiation: 1
codec auto selected: id 1
HF SCO connected 0x20005248
HF SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
HF remote call 0x20007408 start ringing
HF call 0x20007408 accepted
```

Place a call with the Phone number supplied by the HF:

Outgoing Call Sequence on AG side

```
uart:~$
AG number call
AG outgoing call 0x20007690, number 123456789
AG SCO connected 0x20005248
AG SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
uart:~$ hfp ag remote_ringing 0
AG call 0x20007690 start ringing mode 1
uart:~$ hfp ag remote_accept 0
AG call 0x20007690 accept
```

Outgoing Call Sequence on HF side

```
uart:~$ hfp hf auto_select_codec enable
uart:~$ hfp hf number_call 123456789
HF start dialing call: err 0
HF call 0x20007408 outgoing
codec negotiation: 1
codec auto selected: id 1
HF SCO connected 0x20005248
HF SCO info:

HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
uart:~$ hfp hf accept 0
```

(continues on next page)

(continued from previous page)

```
HF call 0x20007408 accepted
```

Call termination After the call (outgoing or incoming) is accepted, it can be terminated from either the AG (Audio Gateway) or HF (Hands-Free) side.

Terminate a call process from the AG:

Call termination on AG side

```
uart:~$ hfp ag terminate 0
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Terminate a call process from the HF:

Call termination on AG side

```
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
uart:~$ hfp hf terminate 0
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Terminate a call process from the remote:

Call termination on AG side

```
uart:~$ hfp ag remote_terminate 0
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Bluetooth: Classic: L2CAP Shell

This document describes how to run the Bluetooth Classic L2CAP functionality. The `br l2cap` command exposes the Bluetooth Classic L2CAP Shell commands.

Commands The `br l2cap` commands:

```
uart:~$ br l2cap
l2cap - [none]
Subcommands:
  register    : <psm> <mode: none, ret, fc, eret, stream> [hold_credit]
                [mode_optional] [extended_control]
  connect     : <psm> <mode: none, ret, fc, eret, stream> [hold_credit]
                [mode_optional] [extended_control]
```

(continues on next page)

(continued from previous page)

```
  disconnect  : [none]
  send        : [number of packets] [length of packet(s)]
  credits     : [none]
  echo        : L2CAP BR ECHO commands
  connless    : L2CAP connectionless commands
```

The `br l2cap echo` commands:

```
uart:~$ br l2cap echo
echo - L2CAP BR ECHO commands
Subcommands:
  register    : [none]
  unregister  : [none]
  req         : <length of data>
  rsp         : <identifier> <length of data>
```

The `br l2cap connless` commands:

```
uart:~$ br l2cap connless
connless - L2CAP connectionless commands
Subcommands:
  register    : <psm> [sec level]
  unregister  : [none]
  send        : <psm> <length of data>
```

Connection-oriented L2CAP

1. [Server] Register L2CAP Server:

When the Bluetooth stack has been initialized (`bt init`), the L2CAP server can be registered by calling `br l2cap register`.

```
uart:~$ br l2cap register 1001 none
L2CAP psm 4097 registered
```

2. [Client] Create L2CAP connection:

The command can only be used after the ACL connection has been established.

```
uart:~$ br l2cap connect 1001 none
L2CAP connection pending
```

3. L2CAP connection is established:

```
uart:~$
Security changed: XX:XX:XX:XX:XX:XX level 2
Incoming BR/EDR conn 0x20004848
Channel 0x20000b18 connected
It is basic mode
```

3. Send L2CAP data to remote:

```
uart:~$ br l2cap send
Rem 0
```

4. L2CAP data is received:

```
uart:~$
Incoming data channel 0x20000b18 len 200
00000000: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000010: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000020: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000030: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000040: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000050: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000060: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000070: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000080: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000090: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000A0: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000B0: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000C0: 00 00 00 00 00 00 00 00                         |........         |
```

5. Disconnect L2CAP connection:

```
uart:~$ br l2cap disconnect
```

6. L2CAP connection is broken:

```
Channel 0x20000b18 disconnected
```

L2CAP echo The echo subcommand provides functionality for L2CAP echo requests and responses in Bluetooth Classic.

The commands can only be used after the ACL connection has been established.

1. Listen for L2CAP echo request an L2CAP echo response:

```
uart:~$ br l2cap echo register
```

2. Stop listening for L2CAP echo request an L2CAP echo response:

```
uart:~$ br l2cap echo unregister
```

3. Send L2CAP echo request:

```
uart:~$ br l2cap echo req 1
```

4. Echo request is received:

```
Incoming ECHO REQ data identifier 4 len 1
00000000: 00                                              |.                |
```

5. Send L2CAP echo response:

```
uart:~$ br l2cap echo rsp 4 1
```

6. Echo response is received:

```
uart:~$
Incoming ECHO RSP data len 1
00000000: 00                                              |.                |
```

Connectionless L2CAP The connless subcommand provides functionality for connectionless L2CAP communication in Bluetooth Classic, allowing packet transmission without establishing a L2CAP connection.

The subcommand is controlled by CONFIG_BT_L2CAP_CONNLESS.

The commands can only be used after the ACL connection has been established.

1. Listen for connectionless L2CAP packets:

```
uart:~$ br l2cap connless register 1001
Register connectionless callbacks with PSM 0x1001
```

2. Send data

```
uart:~$ br l2cap connless send 1001 1
Sending connectionless data with PSM 0x1001
```

3. Connectionless data is received:

```
Incoming connectionless data psm 0x1001 len 1
00000000: 00                                              |.               |
```

Bluetooth: Classic: RFCOMM Shell

This document describes how to run the Bluetooth Classic RFCOMM functionality. The rfcomm command exposes the Bluetooth Classic RFCOMM Shell commands.

Commands The rfcomm commands:

```
uart:~$ rfcomm
rfcomm - Bluetooth RFCOMM shell commands
Subcommands:
  register    : [none]
  connect     : <channel>
  disconnect  : [none]
  send        : <number of packets>
  rpn         : Send RPN command with default settings
```

Connect The ACL connection should be established before creating the RFCOMM connection.

Non-initializing device

```
uart:~$ rfcomm  register
RFCOMM channel 5 registered
Security changed: XX:XX:XX:XX:XX:XX level 2
Incoming RFCOMM conn 0x20004dc8
Dlc 0x20000d20 connected
```

Initializing device

```
uart:~$ rfcomm connect 5
RFCOMM connection pending
Security changed: XX:XX:XX:XX:XX:XX level 2
Dlc 0x20000d20 connected
```

Send Data Non-initializing device

```
Incoming data dlc 0x20000d20 len 30
uart:~$ rfcomm send 1
uart:~$
```

Initializing device

```
uart:~$ rfcomm send 1
Incoming data dlc 0x20000d20 len 30
```

Disconnect Create disconnect request from non-initializing device:

Non-initializing device

```
uart:~$ rfcomm disconnect
Dlc 0x20000d20 disconnected
uart:~$
```

Initializing device

```
Dlc 0x20000d20 disconnected
uart:~$
```

Create disconnect request from initializing device:

Non-initializing device

```
Dlc 0x20000d20 disconnected
uart:~$
```

Initializing device

```
uart:~$ rfcomm disconnect
Dlc 0x20000d20 disconnected
uart:~$
```

Bluetooth: GAP Shell

The GAP shell is the "main" shell of Bluetooth and handles connection management, scanning, advertising, and more.

Identities Identities are a Zephyr host concept, allowing a single physical device to behave like multiple logical Bluetooth devices.

The shell allows the creation of multiple identities, to a maximum that is set by the Kconfig symbol `CONFIG_BT_ID_MAX`. To create a new identity, use `bt id-create` command. You can then use it by selecting it with its ID `bt id-select <id>`. Finally, you can list all the available identities with `id-show`.

Scan for devices Start scanning by using the `bt scan on` command. Depending on the environment you're in, you may see a lot of lines printed on the shell. To stop the scan, run `bt scan off`, the scrolling should stop.

Here is an example of what you can expect:

```
uart:~$ bt scan on
Bluetooth active scan enabled
[DEVICE]: CB:01:1A:2D:6E:AE (random), AD evt type 0, RSSI -78  C:1 S:1 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: 20:C2:EE:59:85:5B (random), AD evt type 3, RSSI -62  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: E3:72:76:87:2F:E8 (random), AD evt type 3, RSSI -74  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: 1E:19:25:8A:CB:84 (random), AD evt type 3, RSSI -67  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
```

(continues on next page)

(continued from previous page)

```
[DEVICE]: 26:42:F3:D5:A0:86 (random), AD evt type 3, RSSI -73  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: 0C:61:D1:B9:5D:9E (random), AD evt type 3, RSSI -87  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: 20:C2:EE:59:85:5B (random), AD evt type 3, RSSI -66  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: 25:3F:7A:EE:0F:55 (random), AD evt type 3, RSSI -83  C:0 S:0 D:0 SR:0␣
↪E:0 Prim: LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
uart:~$ bt scan off
Scan successfully stopped
```

As you can see, this can lead to a high number of results. To reduce that number and easily find a specific device, you can enable scan filters. There are four types of filters: by name, by RSSI, by address and by periodic advertising interval. To apply a filter, use the `bt scan-set-filter` command followed by the type of filters. You can add multiple filters by using the commands again.

For example, if you want to look only for devices with the name *test shell*:

```
uart:~$ bt scan-filter-set name "test shell"
```

Or if you want to look for devices at a very close range:

```
uart:~$ bt scan-filter-set rssi -40
RSSI cutoff set at -40 dB
```

Finally, if you want to remove all filters:

```
uart:~$ bt scan-filter-clear all
```

You can use the command `bt scan on` to create an *active* scanner, meaning that the scanner will ask the advertisers for more information by sending a *scan request* packet. Alternatively, you can create a *passive scanner* by using the `bt scan passive` command, so the scanner will not ask the advertiser for more information.

Connecting to a device To connect to a device, you need to know its address and type of address and use the `bt connect` command with the address and the type as arguments.

Here is an example:

```
uart:~$ bt connect 52:84:F6:BD:CE:48 random
Connection pending
Connected: 52:84:F6:BD:CE:48 (random)
Remote LMP version 5.3 (0x0c) subversion 0xffff manufacturer 0x05f1
LE Features: 0x000000000001412f
LE PHY updated: TX PHY LE 2M, RX PHY LE 2M
LE conn  param req: int (0x0018, 0x0028) lat 0 to 42
LE conn param updated: int 0x0028 lat 0 to 42
```

You can list the active connections of the shell using the `bt connections` command. The shell maximum number of connections is defined by `CONFIG_BT_MAX_CONN`. You can disconnect from a connection with the `bt disconnect <address: XX:XX:XX:XX:XX:XX> <type: (public|random)>` command.

Note

If you were scanning just before, you can connect to the last scanned device by simply running the `bt connect` command.

Alternatively, you can use the `bt connect-name <name>` command to automatically enable scanning with a name filter and connect to the first match.

Advertising Begin advertising by using the `bt advertise on` command. This will use the default parameters and advertise a resolvable private address with the name of the device. You can choose to use the identity address instead by running the `bt advertise on identity` command. To stop advertising use the `bt advertise off` command.

To enable more advanced features of advertising, you should create an advertiser using the `bt adv-create` command. Parameters for the advertiser can be passed either at the creation of it or by using the `bt adv-param` command. To begin advertising with this newly created advertiser, use the `bt adv-start` command, and then the `bt adv-stop` command to stop advertising.

When using the custom advertisers, you can choose if it will be connectable or scannable. This leads to four options: `conn-scan`, `conn-nscan`, `nconn-scan` and `nconn-nscan`. Those parameters are mandatory when creating an advertiser or updating its parameters.

For example, if you want to create a connectable and scannable advertiser and start it:

```
uart:~$ bt adv-create conn-scan
Created adv id: 0, adv: 0x200022f0
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

You may notice that with this, the custom advertiser does not advertise the device name; you need to add it. Continuing from the previous example:

```
uart:~$ bt adv-stop
Advertiser set stopped
uart:~$ bt adv-data dev-name
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

You should now see the name of the device in the advertising data. You can also set a custom name by using `name <custom name>` instead of `dev-name`. It is also possible to set the advertising data manually with the `bt adv-data` command. The following example shows how to set the advertiser name with it using raw advertising data:

```
uart:~$ bt adv-create conn-scan
Created adv id: 0, adv: 0x20002348
uart:~$ bt adv-data 1009426C7565746F6F74682D5368656C6C
uart:~$ bt adv-start
Advertiser[0] 0x20002348 set started
```

The data must be formatted according to the Bluetooth Core Specification (see version 5.3, vol. 3, part C, 11). In this example, the first octet is the size of the data (the data and one octet for the data type), the second one is the type of data, `0x09` is the Complete Local Name and the remaining data are the name in ASCII. So, on the other device you should see the name *Bluetooth-Shell*.

When advertising, if others devices use an *active* scanner, you may receive *scan request* packets. To visualize those packets, you can add `scan-reports` to the parameters of your advertiser.

Directed Advertising It is possible to use directed advertising on the shell if you want to reconnect to a device. The following example demonstrates how to create a directed advertiser with the address specified right after the parameter `directed`. The `low` parameter indicates that we want to use the low duty cycle mode, and the `dir-rpa` parameter is required if the remote device is privacy-enabled and supports address resolution of the target address in directed advertisement.

```
uart:~$ bt adv-create conn-scan directed D7:54:03:CE:F3:B4 random low dir-rpa
Created adv id: 0, adv: 0x20002348
```

After that, you can start the advertiser and then the target device will be able to reconnect.

Extended Advertising Let's now have a look at some extended advertising features. To enable extended advertising, use the `ext-adv` parameter.

```
uart:~$ bt adv-create conn-nscan ext-adv
Created adv id: 0, adv: 0x200022f0
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

This will create an extended advertiser, that is connectable and non-scannable.

Encrypted Advertising Data Zephyr has support for the Encrypted Advertising Data feature. The `bt encrypted-ad` sub-commands allow managing the advertising data of a given advertiser.

To encrypt the advertising data, key materials need to be provided, that can be done with `bt encrypted-ad set-keys <session key> <init vector>`. The session key is 16 bytes long and the initialisation vector is 8 bytes long.

You can add advertising data by using `bt encrypted-ad add-ad` and `bt encrypted-ad add-ead`. The former will take add one advertising data structure (as defined in the Core Specification), when the later will read the given data, encrypt them and then add the generated encrypted advertising data structure. It's possible to mix encrypted and non-encrypted data, when done adding advertising data, `bt encrypted-ad commit-ad` can be used to apply the change to the data to the selected advertiser. After that the advertiser can be started as described previously. It's possible to clear the advertising data by using `bt encrypted-ad clear-ad`.

On the Central side, it's possible to decrypt the received encrypted advertising data by setting the correct keys material as described earlier and then enabling the decrypting of the data with `bt encrypted-ad decrypt-scan on`.

Note

To see the advertising data in the scan report `bt scan-verbose-output` need to be enabled.

Note

It's possible to increase the length of the advertising data by increasing the value of `CONFIG_BT_CTLR_ADV_DATA_LEN_MAX` and `CONFIG_BT_CTLR_SCAN_DATA_LEN_MAX`.

Here is a simple example demonstrating the usage of EAD:

Peripheral

```
uart:~$ bt init
...
uart:~$ bt adv-create conn-nscan ext-adv
Created adv id: 0, adv: 0x81769a0
uart:~$ bt encrypted-ad set-keys 9ba22d3824efc70feb800c80294cba38 2e83f3d4d47695b6
session key set to:
00000000: 9b a2 2d 38 24 ef c7 0f  eb 80 0c 80 29 4c ba 38 |..-8$... ....)L.8|
initialisation vector set to:
00000000: 2e 83 f3 d4 d4 76 95 b6                         |.....v..         |
```

(continues on next page)

(continued from previous page)

```
uart:~$ bt encrypted-ad add-ad 06097368656C6C
uart:~$ bt encrypted-ad add-ead 03ffdead03ffbeef
uart:~$ bt encrypted-ad commit-ad
Advertising data for Advertiser[0] 0x81769a0 updated.
uart:~$ bt adv-start
Advertiser[0] 0x81769a0 set started
```

Central

```
uart:~$ bt init
...
uart:~$ bt scan-verbose-output on
uart:~$ bt encrypted-ad set-keys 9ba22d3824efc70feb800c80294cba38 2e83f3d4d47695b6
session key set to:
00000000: 9b a2 2d 38 24 ef c7 0f  eb 80 0c 80 29 4c ba 38 |..-8$... ....)L.8|
initialisation vector set to:
00000000: 2e 83 f3 d4 d4 76 95 b6                          |.....v..         |
uart:~$ bt encrypted-ad decrypt-scan on
Received encrypted advertising data will now be decrypted using provided key␣
↪materials.
uart:~$ bt scan on
Bluetooth active scan enabled
[DEVICE]: 68:49:30:68:49:30 (random), AD evt type 5, RSSI -59   shell C:1 S:0 D:0␣
↪SR:0 E:1 Prim: LE 1M, Secn: LE 2M, Interval: 0x0000 (0 us), SID: 0x0
        [SCAN DATA START - EXT_ADV]
        Type 0x09:    shell
        Type 0x31: Encrypted Advertising Data: 0xe2, 0x17, 0xed, 0x04, 0xe7, 0x02,␣
↪0x1d, 0xc9, 0x40, 0x07, uart:~0x18, 0x90, 0x6c, 0x4b, 0xfe, 0x34, 0xad
        [START DECRYPTED DATA]
        Type 0xff: 0xde, 0xad
        Type 0xff: 0xbe, 0xef
        [END DECRYPTED DATA]
        [SCAN DATA END]
...
```

Filter Accept List It's possible to create a list of allowed addresses that can be used to connect to those addresses automatically. Here is how to do it:

```
uart:~$ bt fal-add 47:38:76:EA:29:36 random
uart:~$ bt fal-add 66:C8:80:2A:05:73 random
uart:~$ bt fal-connect on
```

The shell will then connect to the first available device. In the example, if both devices are advertising at the same time, we will connect to the first address added to the list.

The Filter Accept List can also be used for scanning or advertising by using the option `fal`. For example, if we want to scan for a bunch of selected addresses, we can set up a Filter Accept List:

```
uart:~$ bt fal-add 65:4B:9E:83:AF:73 random
uart:~$ bt fal-add 73:72:82:B4:8F:B9 random
uart:~$ bt fal-add 5D:85:50:1C:72:64 random
uart:~$ bt scan on fal
```

You should see only those three addresses reported by the scanner.

Enabling security When connected to a device, you can enable multiple levels of security, here is the list for Bluetooth LE:

- **1** No encryption and no authentication;
- **2** Encryption and no authentication;
- **3** Encryption and authentication;
- **4** Bluetooth LE Secure Connection.

To enable security, use the `bt security <level>` command. For levels requiring authentication (level 3 and above), you must first set the authentication method. To do it, you can use the `bt auth all` command. After that, when you will set the security level, you will be asked to confirm the passkey on both devices. On the shell side, do it with the command `bt auth-passkey-confirm`.

Pairing Enabling authentication requires the devices to be bondable. By default the shell is bondable. You can make the shell not bondable using `bt bondable off`. You can list all the devices you are paired with using the command `bt bonds`.

The maximum number of paired devices is set using `CONFIG_BT_MAX_PAIRED`. You can remove a paired device using `bt clear <address: XX:XX:XX:XX:XX:XX> <type: (public|random)>` or remove all paired devices with the command `bt clear all`.

Bluetooth: GATT Shell

The following examples assume that you have two devices already connected.

To perform service discovery on the client side, use the `gatt discover` command. This should print all the services that are available on the GATT server.

On the server side, you can register pre-defined test services using the `gatt register` command. When done, you should see the newly added services on the client side when running the discovery command.

You can now subscribe to those new services on the client side. Here is an example on how to subscribe to the test service:

```
uart:~$ gatt subscribe 26 25
Subscribed
```

The server can now notify the client with the command `gatt notify`.

Another option available through the GATT command is initiating the MTU exchange. To do it, use the `gatt exchange-mtu` command. To update the shell maximum MTU, you need to update Kconfig symbols in the configuration file of the shell. For more details, see bluetooth_mtu_update.

Bluetooth: Isochronous Channels Shell

Commands

```
iso --help
iso - Bluetooth ISO shell commands
Subcommands:
   cig_create  :[dir=tx,rx,txrx] [interval] [packing] [framing] [latency] [sdu]
               [phy] [rtn]
   cig_term    :Terminate the CIG
   connect     :Connect ISO Channel
   listen      :<dir=tx,rx,txrx> [security level]
   send        :Send to ISO Channel [count]
   disconnect  :Disconnect ISO Channel
   create-big  :Create a BIG as a broadcaster [enc <broadcast code>]
   broadcast   :Broadcast on ISO channels
   sync-big    :Synchronize to a BIG as a receiver <BIS bitfield> [mse] [timeout]
```

(continues on next page)

(continued from previous page)

```
                [enc <broadcast code>]
   term-big     :Terminate a BIG
```

Unicast examples

1. [Central] Create CIG:

Requires to be connected:

```
uart:~$ iso cig_create
CIG created
```

2. [Peripheral] Listen to ISO connections

```
uart:~$ iso listen txrx
```

3. [Central] Connect ISO channel:

```
uart:~$ iso connect
ISO Connect pending...
ISO Channel 0x20000f88 connected
```

4. Send data:

```
uart:~$ iso send
send: 40 bytes of data
ISO sending...
```

5. Disconnect ISO channel:

```
uart:~$ iso disconnect
ISO Disconnect pending...
ISO Channel 0x20000f88 disconnected with reason 0x16
```

Broadcast examples

Setting up broadcaster

```
uart:~$ bt init
Bluetooth initialized
uart:~$ bt adv-create nconn-nscan ext-adv
Created adv id: 0, adv: 0x200025d0
uart:~$ bt per-adv-param
uart:~$ iso create-big
BIG created
ISO Channel 0x200008c0 connected
uart:~$
uart:~$ bt adv-start
Advertiser[0] 0x200025d0 set started
uart:~$
uart:~$ bt per-adv on
Periodic advertising started
uart:~$
uart:~$ iso broadcast
send: 247 bytes of data with PSN 4350
ISO broadcasting...
```

If encrypted broadcast is required, then a broadcast code can be provided as

```
uart:~$ iso create-big enc 00112233445566778899aabbccddffff
BIG created
```

Setting up sync receiver

```
uart:~$ bt init
Bluetooth initialized
uart:~$ bt scan on
[DEVICE]: 42:0F:7A:40:AE:21 (random), AD evt type 5, RSSI -27  C:0 S:0 D:0 SR:0␣
↪E:1 Prim: LE 1M, Secn: LE 2M, Interval: 0x0780 (2400000 us), SID: 0x0
uart:~$ bt per-adv-sync-create 42:0F:7A:40:AE:21 (random) 0
Per adv sync pending

↪encrypted
uart:~$ iso sync-big 1
BIG syncing
ISO Channel 0x200008c0 connected
```

If encrypted broadcast is required, then a broadcast code can be provided as

```
uart:~$ iso sync-big 1 enc 00112233445566778899aabbccddffff
BIG syncing
ISO Channel 0x200008c0 connected
```

Bluetooth: L2CAP Shell

The `l2cap` command exposes parts of the L2CAP API. The following example shows how to register a LE PSM, connect to it from another device and send 3 packets of 14 octets each.

The example assumes that the two devices are already connected.

On device A, register the LE PSM:

```
uart:~$ l2cap register 29
L2CAP psm 41 sec_level 1 registered
```

On device B, connect to the registered LE PSM and send data:

```
uart:~$ l2cap connect 29
Chan sec: 1
L2CAP connection pending
Channel 0x20000210 connected
Channel 0x20000210 status 1
uart:~$ l2cap send 3 14
Rem 2
Rem 1
Rem 0
Outgoing data channel 0x20000210 transmitted
Outgoing data channel 0x20000210 transmitted
Outgoing data channel 0x20000210 transmitted
```

On device A, you should have received the data:

```
Incoming conn 0x20002398
Channel 0x20000210 status 1
Channel 0x20000210 connected
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
```

Bluetooth Shell Setup and Usage

First you need to build and flash your board with the Bluetooth shell. For how to do that, see the *Getting Started Guide*. The Bluetooth shell itself is located in tests/bluetooth/shell/.

When it's done, connect to the CLI using your favorite serial terminal application. You should see the following prompt:

```
uart:~$
```

For more details on general usage of the shell, see *Shell*.

The first step is enabling Bluetooth. To do so, use the `bt init` command. The following message is printed to confirm Bluetooth has been initialized.

```
uart:~$ bt init
Bluetooth initialized
Settings Loaded
[00:02:26.771,148] <inf> fs_nvs: nvs_mount: 8 Sectors of 4096 bytes
[00:02:26.771,148] <inf> fs_nvs: nvs_mount: alloc wra: 0, fe8
[00:02:26.771,179] <inf> fs_nvs: nvs_mount: data wra: 0, 0

↪subver 0xffff
```

Logging

You can configure the logging level per module at runtime. This depends on the maximum logging level that is compiled in. To configure, use the `log` command. Here are some examples:

- List the available modules and their current logging level

```
uart:~$ log status
```

- Disable logging for *bt_hci_core*

```
uart:~$ log disable bt_hci_core
```

- Enable error logs for *bt_att* and *bt_smp*

```
uart:~$ log enable err bt_att bt_smp
```

- Disable logging for all modules

```
uart:~$ log disable
```

- Enable warning logs for all modules

```
uart:~$ log enable wrn
```

6.2 Controller Area Network (CAN) Bus Protocols

6.2.1 ISO-TP Transport Protocol

- *Overview*
- *API Reference*

Overview

ISO-TP is a transport protocol defined in the ISO-Standard ISO15765-2 Road vehicles - Diagnostic communication over Controller Area Network (DoCAN). Part2: Transport protocol and network layer services. As its name already implies, it is originally designed, and still used in road vehicle diagnostic over Controller Area Networks. Nevertheless, it's not limited to applications in road vehicles or the automotive domain.

This transport protocol extends the limited payload data size for classical CAN (8 bytes) and CAN FD (64 bytes) to theoretically four gigabytes. Additionally, it adds a flow control mechanism to influence the sender's behavior. ISO-TP segments packets into small fragments depending on the payload size of the CAN frame. The header of those segments is called Protocol Control Information (PCI).

Packets smaller or equal to seven bytes on Classical CAN are called single-frames (SF). They don't need to fragment and do not have any flow-control.

Packets larger than that are segmented into a first-frame (FF) and as many consecutive-frames (CF) as required. The FF contains information about the length of the entire payload data and additionally, the first few bytes of payload data. The receiving peer sends back a flow-control-frame (FC) to either deny, postpone, or accept the following consecutive frames. The FC also defines the conditions of sending, namely the block-size (BS) and the minimum separation time between frames (STmin). The block size defines how many CF the sender is allowed to send, before he has to wait for another FC.

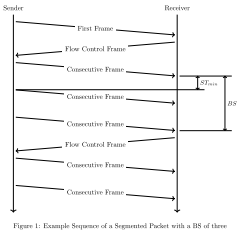

Figure 1: Example Sequence of a Segmented Packet with a BS of three

6.3 Networking

The networking section contains information regarding the network stack of the Zephyr kernel. Use the information to understand the principles behind the operation of the stacks and how they were implemented.

6.3.1 Overview

- *Supported Features*
- *Source Tree Layout*

Supported Features

The networking IP stack is modular and highly configurable via build-time configuration options. You can minimize system memory consumption by enabling only those network features required by your application. Almost all features can be disabled if not needed.

- **IPv6** (RFC 8200) is supported. Various IPv6 sub-options can be enabled or disabled depending on networking needs.
  - Developer can set the number of unicast and multicast IPv6 addresses that are active at the same time.
  - The IPv6 address for the device can be set either statically or dynamically using SLAAC (Stateless Address Auto Configuration, RFC 4862).
  - The system also supports multiple IPv6 prefixes and the maximum IPv6 prefix count can be configured at build time.
  - The IPv6 neighbor cache can be disabled if not needed, and its size can be configured at build time.
  - The IPv6 neighbor discovery support (RFC 4861) is enabled by default.
  - Multicast Listener Discovery v2 support (RFC 3810) is enabled by default.
  - IPv6 header compression (6lo) is available for IPv6 connectivity for IEEE 802.15.4 networks (RFC 4944).
  - DHCPv6 (Dynamic Host Configuration Protocol for IPv6) (RFC 8415) client functionality is supported.
  - The IPv6 privacy extension (RFC 8981) is supported.
- **IPv4** (RFC 791) is supported. It cannot be used by IEEE 802.15.4 as this network technology supports only IPv6. IPv4 can be used for example in Ethernet, Wi-Fi and Cellular based networks.
  - DHCP (Dynamic Host Configuration Protocol) client and server is supported (RFC 2131).

  - The IPv4 address can also be configured manually. Static IPv4 addresses are supported by default.

- **Dual stack support.** The networking stack allows a developer to configure the system to use both IPv6 and IPv4 at the same time.
- **UDP** User Datagram Protocol (**RFC 768**) is supported. The developer can send UDP datagrams (client side support) or create a listener to receive UDP packets destined to certain port (server side support).
- **TCP** Transmission Control Protocol (**RFC 793**) is supported. Both server and client roles can be used the application. The amount of TCP sockets that are available to applications can be configured at build time.
- **BSD Sockets API** Support for a subset of a *BSD sockets compatible API* is implemented. Both blocking and non-blocking datagram (UDP) and stream (TCP) sockets are supported. Packet sockets (`AF_PACKET`) are also supported.
- **Secure Sockets API** Experimental support for TLS/DTLS secure protocols and configuration options for sockets API. Secure functions for the implementation are provided by mbedTLS library.
- **MQTT** Message Queue Telemetry Transport (ISO/IEC PRF 20922) versions 3.1.1 and 5.0 are supported. A sample mqtt-publisher client application for MQTT v3.1.1 and v5.0 is provided.
- **MQTT-SN** MQTT for Sensor Networks version 1.2 is supported. A sample mqtt-sn-publisher client application is provided.
- **CoAP** Constrained Application Protocol (**RFC 7252**) is supported. Both coap-client and coap-server sample applications are provided.
- **LWM2M** OMA Lightweight Machine-to-Machine Protocol (LwM2M specification 1.0.2) is supported via the "Bootstrap", "Client Registration", "Device Management & Service Enablement" and "Information Reporting" interfaces. The required core LwM2M objects are implemented as well as several IPSO Smart Objects. (LwM2M specification 1.1.1) is supported in similar manner when enabled with a Kconfig option. lwm2m-client sample implements the library as an example.
- **HTTP** Hypertext Transfer Protocol client and server are supported. *HTTP Client* library supports HTTP/1.1 (**RFC 2616**). *HTTP Server* library supports HTTP/1.1 (**RFC 2616**) and HTTP/2 (**RFC 9113**). sockets-http-client and sockets-http-server samples are provided.
- **Websocket** (**RFC 6455**) client is supported. sockets-websocket-client sample is provided.
- **DNS** Domain Name Service (**RFC 1035**) client functionality is supported. Applications can use the DNS API to query domain name information or IP addresses from the DNS server. Both IPv4 (A) and IPv6 (AAAA) records can be queried. Both multicast DNS (mDNS) (**RFC 6762**) and link-local multicast name resolution (LLMNR, **RFC 4795**) are supported. The DNS Service Discovery (**RFC 6763**) is also supported.
- **Network Management API.** Applications can use network management API to listen management events generated by core network stack when for example IP address is added to the device, or network interface is coming up etc.
- **Wi-Fi Management API.** Applications can use Wi-Fi management API to manage the interface, in example to connect to Wi-Fi network and to scan available Wi-Fi networks.
- **Wi-Fi Network Manager API.** Wi-Fi Network Managers can now register themselves to the Wi-Fi stack. The Network Managers can then implement the Wi-Fi Management API and manage the Wi-Fi interface.
- **Multiple Network Technologies.** The Zephyr OS can be configured to support multiple network technologies at the same time simply by enabling them in Kconfig: for example, Ethernet, Wi-Fi and 802.15.4 support. Note that no automatic IP routing functionality is

provided between these technologies. Applications can send data according to their needs to desired network interface.

- **Minimal Copy Network Buffer Management.** It is possible to have minimal copy network data path. This means that the system tries to avoid copying application data when it is sent to the network.
- **Virtual LAN support.** Virtual LANs (VLANs) allow partitioning of physical ethernet networks into logical networks. See *VLAN support* for more details.
- **Network traffic classification.** The sent and received network packets can be prioritized depending on application needs. See *traffic classification* for more details.
- **Time Sensitive Networking.** Both the gPTP (generalized Precision Time Protocol) and PTP (Precision Time Protocol, IEEE 1588) are supported. See *gPTP support* and *PTP support* for more details.
- **SNTP** Simple Network Time Protocol (**RFC 5905**) client is supported. sntp-client sample is provided.
- **SOCKS5** proxy version 5 (**RFC 1928**) is supported.
- **TFTP** Trivial File Transfer Protocol (**RFC 1350**) client is supported. tftp-client sample is provided.
- **MIDI2** MIDI 2.0 network UDP transport is supported. netmidi2 sample is provided.
- **OCPP** Open Charge Point Protocol is supported. ocpp sample is provided.
- **Prometheus** Metric Server functionality is supported. prometheus is provided.
- **Network shell.** The network shell provides helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. The net-shell is useful when developing network software. See *network shell* for more details.
- **zperf** is an iPerf v2 network performance and bandwidth measurement tool. Both client and server functionality is supported. zperf sample is provided.

Additionally these network technologies (link layers) are supported in Zephyr OS:

- IEEE 802.15.4
- Bluetooth
- Ethernet, IEEE 802.3
- Wi-Fi, IEEE 802.11
- Cellular / PPP (**RFC 1661**)
- Thread (openthread samples are provided)
- CAN bus for SocketCAN
- SLIP (IP over serial line). Used for testing with QEMU. It provides ethernet interface to host system (like Linux) and test applications can be run in Linux host and send network data to Zephyr OS device.

Source Tree Layout

The networking stack source code tree is organized as follows:

subsys/net/
: Various optional network stack components like connection manager, packet filter code and hostname handling are located here.

subsys/net/ip/
: This is where the core network stack code is located.

subsys/net/l2
: This is where the IP stack layer 2 code is located. This includes generic support for Ethernet, IEEE 802.15.4 and Wi-Fi.

subsys/net/lib/
: Application-level protocols (DNS, MQTT, etc.) and additional stack components (BSD Sockets, etc.).

include/zephyr/net/
: Public API header files. These are the header files applications need to include to use IP networking functionality.

samples/net/
: Sample networking code. This is a good reference to get started with network application development.

tests/net/
: Test applications. These applications are used to verify the functionality of the IP stack, but are not the best source for sample code (see samples/net/ instead).

6.3.2 Network Stack Architecture

Network Packet Processing Statistics

This page describes how to get information about network packet processing statistics inside network stack.

Network stack contains infrastructure to figure out how long the network packet processing takes either in sending or receiving path. There are two Kconfig options that control this. For transmit (TX) path the option is called `CONFIG_NET_PKT_TXTIME_STATS` and for receive (RX) path the options is called `CONFIG_NET_PKT_RXTIME_STATS`. Note that for TX, all kind of network packet statistics is collected. For RX, only UDP, TCP or raw packet type network packet statistics is collected.

After enabling these options, the *net stats* network shell command will show this information:

```
Avg TX net_pkt (11484) time 67 us
Avg RX net_pkt (11474) time 43 us
```

Note

The values above and below are from emulated qemu_x86 board and UDP traffic

The TX time tells how long it took for network packet from its creation to when it was sent to the network. The RX time tells the time from its creation to when it was passed to the application. The values are in microseconds. The statistics will be collected per traffic class if there are more than one transmit or receive queues defined in the system. These are controlled by `CONFIG_NET_TC_TX_COUNT` and `CONFIG_NET_TC_RX_COUNT` options.

If you enable `CONFIG_NET_PKT_TXTIME_STATS_DETAIL` or `CONFIG_NET_PKT_RXTIME_STATS_DETAIL` options, then additional information for TX or RX network packets are collected when the network packet traverses the IP stack.

After enabling these options, the *net stats* will show this information:

```
Avg TX net_pkt (18902) time 63 us    [0->22->15->23=60 us]
Avg RX net_pkt (18892) time 42 us    [0->9->6->11->13=39 us]
```

The numbers inside the brackets contain information how many microseconds it took for a network packet to go from previous state to next.

In the TX example above, the values are averages over **18902** packets and contain this information:

- Packet was created by application so the time is **0**.
- Packet is about to be placed to transmit queue. The time it took from network packet creation to this state, is **22** microseconds in this example.
- The correct TX thread is invoked, and the packet is read from the transmit queue. It took **15** microseconds from previous state.
- The network packet was just sent and the network stack is about to free the network packet. It took **23** microseconds from previous state.
- In total it took on average **60** microseconds to get the network packet sent. The value **63** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

In the RX example above, the values are averages over **18892** packets and contain this information:

- Packet was created network device driver so the time is **0**.
- Packet is about to be placed to receive queue. The time it took from network packet creation to this state, is **9** microseconds in this example.
- The correct RX thread is invoked, and the packet is read from the receive queue. It took **6** microseconds from previous state.
- The network packet is then processed and placed to correct socket queue. It took **11** microseconds from previous state.
- The last value tells how long it took from there to the application. Here the value is **13** microseconds.
- In total it took on average **39** microseconds to get the network packet sent. The value **42** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

The Zephyr network stack is a native network stack specifically designed for Zephyr OS. It consists of layers, each meant to provide certain services to other layers. Network stack functionality is highly configurable via Kconfig options.

- *High level overview of the network stack*
- *Network data flow*
  - *Data receiving (RX)*
  - *Data sending (TX)*
- *Network packet processing statistics*

High level overview of the network stack

The network stack is layered and consists of the following parts:

- **Network Application.** The network application can either use the provided application-level protocol libraries or access the *BSD socket API* directly to create a network connection, send or receive data, and close a connection. The application can also use the *network management API* to configure the network and set related parameters such as network link options, starting a scan (when applicable), listen network configuration events, etc. The *network interface API* can be used to set IP address to a network interface, taking the network interface down, etc.

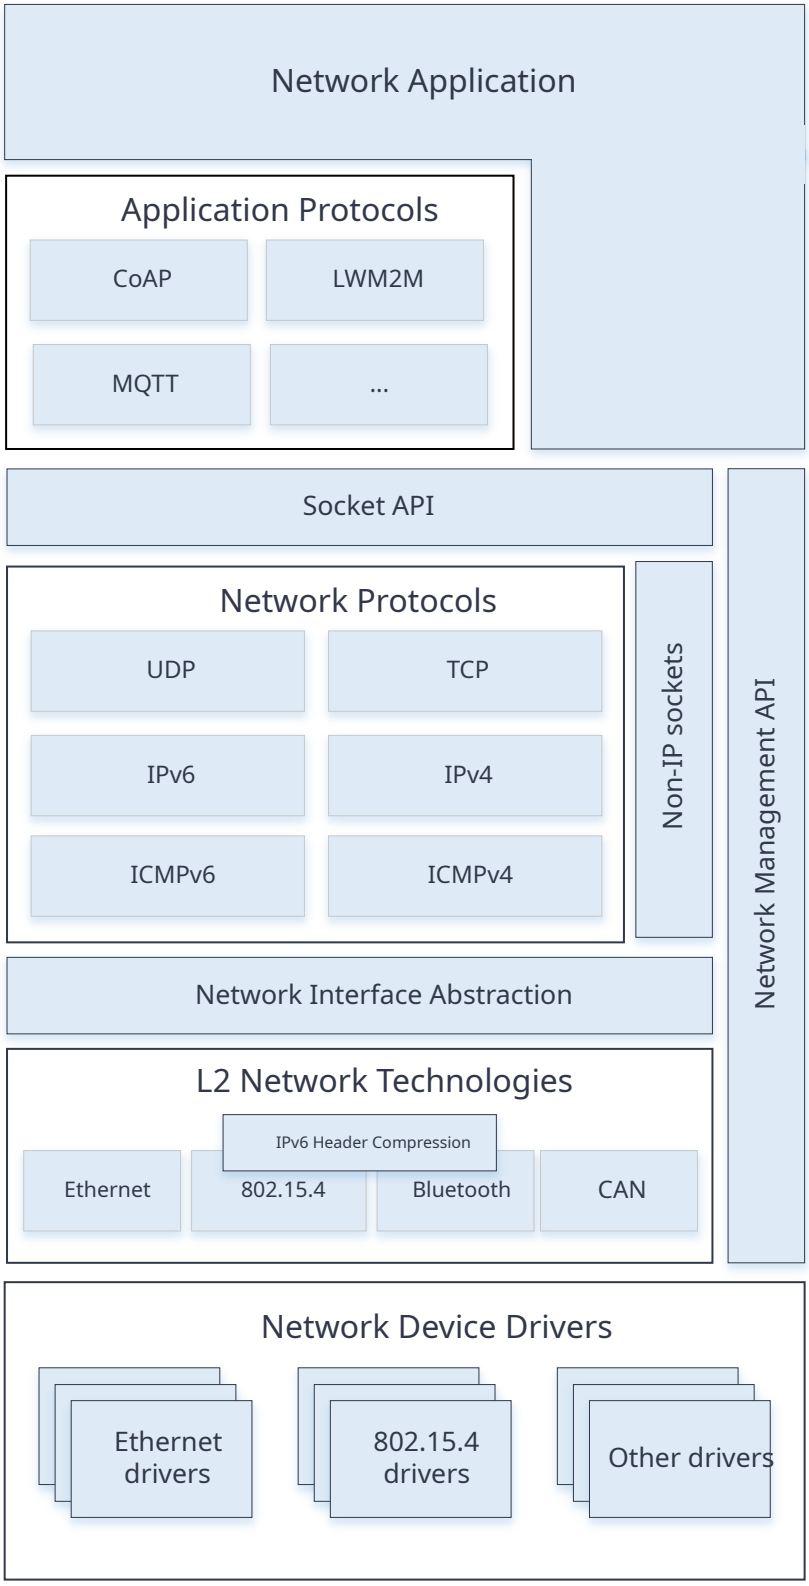

Fig. 12: Network stack overview

- **Network Protocols.** This provides implementations for various protocols such as
  - Application-level network protocols like CoAP, LWM2M, and MQTT. See *application protocols chapter* for information about them.
  - Core network protocols like IPv6, IPv4, UDP, TCP, ICMPv4, and ICMPv6. You access these protocols by using the *BSD socket API*.
- **Network Interface Abstraction.** This provides functionality that is common in all the network interfaces, such as setting network interface down, etc. There can be multiple network interfaces in the system. See *network interface overview* for more details.
- **L2 Network Technologies.** This provides a common API for sending and receiving data to and from an actual network device. See *L2 overview* for more details.

  These network technologies include *Ethernet*, *IEEE 802.15.4*, *Bluetooth*, *CANBUS*, etc.

  Some of these technologies support IPv6 header compression (6Lo), see **RFC 6282** for details. For example ARP (**RFC 826**) for IPv4 is done by the *Ethernet component*.
- **Network Device Drivers.** The actual low-level device drivers handle the physical sending or receiving of network packets.

Network data flow

An application typically consists of one or more *threads* that execute the application logic. When using the *BSD socket API*, the following things will happen.

Data receiving (RX)

1. A network data packet is received by a device driver.
2. The device driver allocates enough network buffers to store the received data. The network packet is placed in the proper RX queue (implemented by *k_fifo*). By default there is only one receive queue in the system, but it is possible to have up to 8 receive queues. These queues will process incoming packets with different priority. See *Traffic Classification* for more details. The receive queues also act as a way to separate the data processing pipeline (bottom-half) as the device driver is running in an interrupt context and it must do its processing as fast as possible.
3. The network packet is then passed to the correct L2 driver. The L2 driver can check if the packet is proper and modify it if needed, e.g. strip L2 header and frame check sequence, etc.
4. The packet is processed by a network interface. The network statistics are collected if enabled by `CONFIG_NET_STATISTICS`.
5. The packet is then passed to L3 processing. If the packet is IP based, then the L3 layer checks if the packet is a proper IPv6 or IPv4 packet.
6. A socket handler then finds an active socket to which the network packet belongs and puts it in a queue for that socket, in order to separate the networking code from the application. Typically the application is run in userspace context and the network stack is run in kernel context.
7. The application will then receive the data and can process it as needed. The application should have used the *BSD socket API* to create a socket that will receive the data.

Data sending (TX)

1. The application should use the *BSD socket API* when sending the data.
2. The application data is prepared for sending to kernel space and then copied to internal net_buf structures.

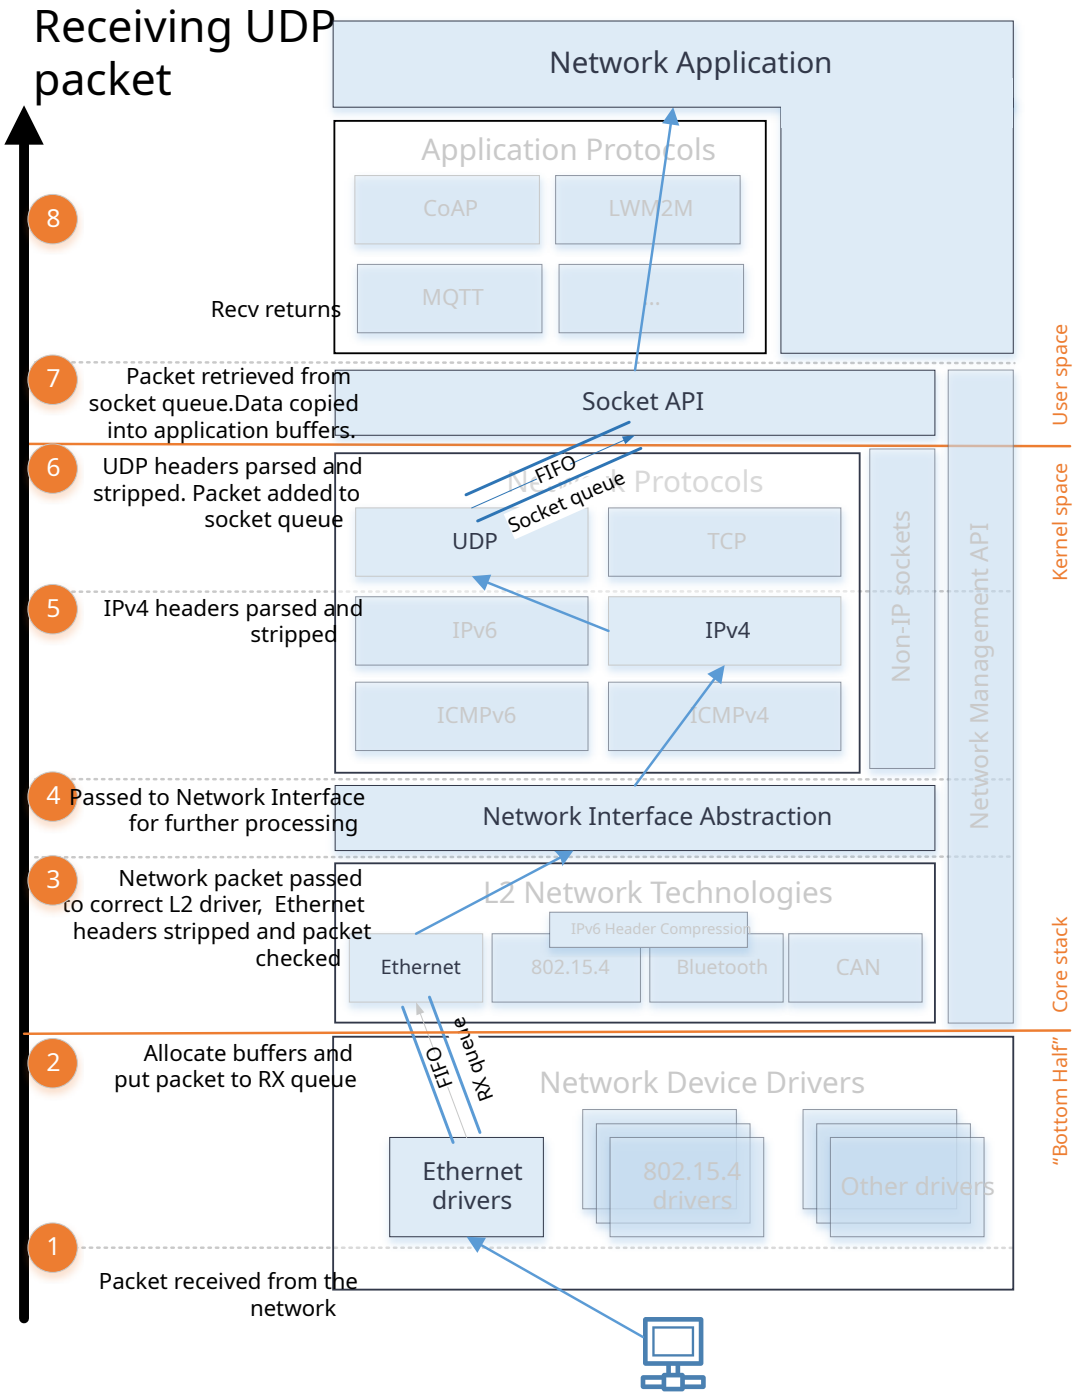

Fig. 13: Network RX data flow

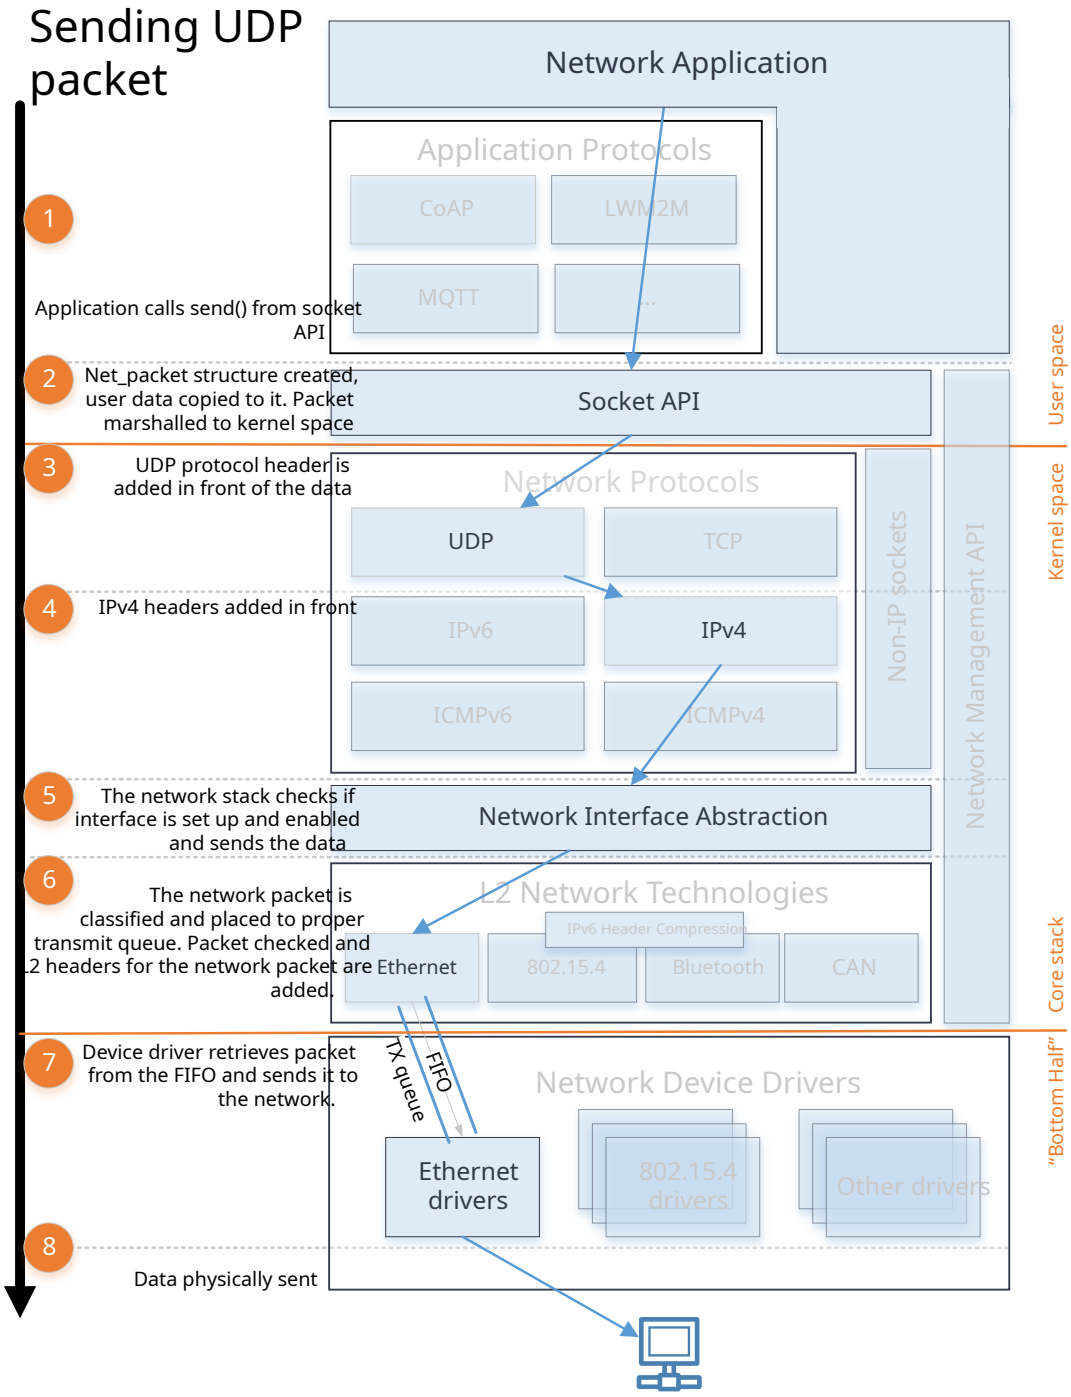

Fig. 14: Network TX data flow

3. Depending on the socket type, a protocol header is added in front of the data. For example, if the socket is a UDP socket, then a UDP header is constructed and placed in front of the data.
4. An IP header is added to the network packet for a UDP or TCP packet.
5. The network stack will check that the network interface is properly set for the network packet, and also will make sure that the network interface is enabled before the data is queued to be sent.
6. The network packet is then classified and placed to the proper transmit queue (implemented by *k_fifo*). By default there is only one transmit queue in the system, but it is possible to have up to 8 transmit queues. These queues will process the sent packets with different priority. See *Traffic Classification* for more details. After the transmit packet classification, the packet is checked by the correct L2 layer module. The L2 module will do additional checks for the data and it will also create any L2 headers for the network packet. If everything is ok, the data is given to the network device driver to be sent out.
7. The device driver will send the packet to the network.

Note that in both the TX and RX data paths, the queues (*k_fifo's*) form separation points where data is passed from one *thread* to another. These *threads* might run in different contexts (*kernel* vs. *userspace*) and with different *priorities*.

Network packet processing statistics

See information about network processing statistics *here*.

6.3.3 Network Configuration Guide

- *Network Buffer Configuration Options*
- *Connection Options*
- *Socket Options*
- *TLS Options*
- *IPv4/6 Options*
- *TCP Options*
- *Traffic Class Options*
- *Stack Size Options*

This document describes how various network configuration options can be set according to available resources in the system.

Network Buffer Configuration Options

The network buffer configuration options control how much data we are able to either send or receive at the same time.

`CONFIG_NET_PKT_RX_COUNT`
: Maximum amount of network packets we can receive at the same time.

`CONFIG_NET_PKT_TX_COUNT`
: Maximum amount of network packet sends pending at the same time.

`CONFIG_NET_BUF_RX_COUNT`
: How many network buffers are allocated for receiving data. Each net_buf contains a small header and either a fixed or variable length data buffer. The `CONFIG_NET_BUF_DATA_SIZE` is

used when CONFIG_NET_BUF_FIXED_DATA_SIZE is set. This is the default setting. The default size of the buffer is 128 bytes.

The CONFIG_NET_BUF_VARIABLE_DATA_SIZE is an experimental setting. There each net_buf data portion is allocated from a memory pool and can be the amount of data we have received from the network. When data is received from the network, it is placed into net_buf data portion. Depending on device resources and desired network usage, user can tweak the size of the fixed buffer by setting CONFIG_NET_BUF_DATA_SIZE, and the size of the data pool size by setting CONFIG_NET_PKT_BUF_RX_DATA_POOL_SIZE and CONFIG_NET_PKT_BUF_TX_DATA_POOL_SIZE if variable size buffers are used.

When using the fixed size data buffers, the memory consumption of network buffers can be tweaked by selecting the size of the data part according to what kind of network data we are receiving. If one sets the data size to 256, but only receives packets that are 32 bytes long, then we are "wasting" 224 bytes for each packet because we cannot utilize the remaining data. One should not set the data size too low because there is some overhead involved for each net_buf. For these reasons the default network buffer size is set to 128 bytes.

The variable size data buffer feature is marked as experimental as it has not received as much testing as the fixed size buffers. Using variable size data buffers tries to improve memory utilization by allocating minimum amount of data we need for the network data. The extra cost here is the amount of time that is needed when dynamically allocating the buffer from the memory pool.

For example, in Ethernet the maximum transmission unit (MTU) size is 1500 bytes. If one wants to receive two full frames, then the net_pkt RX count should be set to 2, and net_buf RX count to (1500 / 128) * 2 which is 24. If TCP is being used, then these values need to be higher because we can queue the packets internally before delivering to the application.

CONFIG_NET_BUF_TX_COUNT
: How many network buffers are allocated for sending data. This is similar setting as the receive buffer count but for sending.

Connection Options

CONFIG_NET_MAX_CONN
: This option tells how many network connection endpoints are supported. For example each TCP connection requires one connection endpoint. Similarly each listening UDP connection requires one connection endpoint. Also various system services like DHCP and DNS need connection endpoints to work. The network shell command **net conn** can be used at runtime to see the network connection information.

CONFIG_NET_MAX_CONTEXTS
: Number of network contexts to allocate. Each network context describes a network 5-tuple that is used when listening or sending network traffic. Each BSD socket in the system uses one network context.

Socket Options

CONFIG_ZVFS_POLL_MAX
: Maximum number of supported poll() entries. One needs to select proper value here depending on how many BSD sockets are polled in the system.

CONFIG_ZVFS_OPEN_MAX
: Maximum number of open file descriptors, this includes files, sockets, special devices, etc. One needs to select proper value here depending on how many BSD sockets are created in the system.

CONFIG_NET_SOCKETPAIR_BUFFER_SIZE
: This option is used by socketpair() function. It sets the size of the internal intermediate buffer, in bytes. This sets the limit how large messages can be passed between two socketpair endpoints.

TLS Options

CONFIG_NET_SOCKETS_TLS_MAX_CONTEXTS
: Maximum number of TLS/DTLS contexts. Each TLS/DTLS connection needs one context.

CONFIG_NET_SOCKETS_TLS_MAX_CREDENTIALS
: This variable sets maximum number of TLS/DTLS credentials that can be used with a specific socket.

CONFIG_NET_SOCKETS_TLS_MAX_CIPHERSUITES
: Maximum number of TLS/DTLS ciphersuites per socket. This variable sets maximum number of TLS/DTLS ciphersuites that can be used with specific socket, if set explicitly by socket option. By default, all ciphersuites that are available in the system are available to the socket.

CONFIG_NET_SOCKETS_TLS_MAX_APP_PROTOCOLS
: Maximum number of supported application layer protocols. This variable sets maximum number of supported application layer protocols over TLS/DTLS that can be set explicitly by a socket option. By default, no supported application layer protocol is set.

CONFIG_NET_SOCKETS_TLS_MAX_CLIENT_SESSION_COUNT
: This variable specifies maximum number of stored TLS/DTLS sessions, used for TLS/DTLS session resumption.

CONFIG_TLS_MAX_CREDENTIALS_NUMBER
: Maximum number of TLS credentials that can be registered. Make sure that this value is high enough so that all the certificates can be loaded to the store.

IPv4/6 Options

CONFIG_NET_IF_MAX_IPV4_COUNT
: Maximum number of IPv4 network interfaces in the system. This tells how many network interfaces there will be in the system that will have IPv4 enabled. For example if you have two network interfaces, but only one of them can use IPv4 addresses, then this value can be set to 1. If both network interface could use IPv4, then the setting should be set to 2.

CONFIG_NET_IF_MAX_IPV6_COUNT
: Maximum number of IPv6 network interfaces in the system. This is similar setting as the IPv4 count option but for IPv6.

TCP Options

CONFIG_NET_TCP_TIME_WAIT_DELAY
: How long to wait in TCP *TIME_WAIT* state (in milliseconds). To avoid a (low-probability) issue when delayed packets from previous connection get delivered to next connection reusing the same local/remote ports, RFC 793 (TCP) suggests to keep an old, closed connection in a special *TIME_WAIT* state for the duration of 2*MSL (Maximum Segment Lifetime). The RFC suggests to use MSL of 2 minutes, but notes

  This is an engineering choice, and may be changed if experience indicates it is desirable to do so.

  For low-resource systems, having large MSL may lead to quick resource exhaustion (and related DoS attacks). At the same time, the issue of packet misdelivery is largely alleviated in the modern TCP stacks by using random, non-repeating port numbers and initial sequence numbers. Due to this, Zephyr uses much lower value of 1500ms by default. Value of 0 disables *TIME_WAIT* state completely.

CONFIG_NET_TCP_RETRY_COUNT
: Maximum number of TCP segment retransmissions. The following formula can be used to

determine the time (in ms) that a segment will be buffered awaiting retransmission:

$$\sum_{n=0}^{\texttt{NET_TCP_RETRY_COUNT}} \left(1 \ll n\right) \times \texttt{NET_TCP_INIT_RETRANSMISSION_TIMEOUT}$$

With the default value of 9, the IP stack will try to retransmit for up to 1:42 minutes. This is as close as possible to the minimum value recommended by RFC 1122 (1:40 minutes). Only 5 bits are dedicated for the retransmission count, so accepted values are in the 0-31 range. It's highly recommended to not go below 9, though.

Should a retransmission timeout occur, the receive callback is called with `-ETIMEDOUT` error code and the context is dereferenced.

`CONFIG_NET_TCP_MAX_SEND_WINDOW_SIZE`
: Maximum sending window size to use. This value affects how the TCP selects the maximum sending window size. The default value 0 lets the TCP stack select the value according to amount of network buffers configured in the system. Note that if there are multiple active TCP connections in the system, then this value might require finetuning (lowering), otherwise multiple TCP connections could easily exhaust net_buf pool for the queued TX data.

`CONFIG_NET_TCP_MAX_RECV_WINDOW_SIZE`
: Maximum receive window size to use. This value defines the maximum TCP receive window size. Increasing this value can improve connection throughput, but requires more receive buffers available in the system for efficient operation. The default value 0 lets the TCP stack select the value according to amount of network buffers configured in the system.

`CONFIG_NET_TCP_RECV_QUEUE_TIMEOUT`
: How long to queue received data (in ms). If we receive out-of-order TCP data, we queue it. This value tells how long the data is kept before it is discarded if we have not been able to pass the data to the application. If set to 0, then receive queueing is not enabled. The value is in milliseconds.

  Note that we only queue data sequentially in current version i.e., there should be no holes in the queue. For example, if we receive SEQs 5,4,3,6 and are waiting SEQ 2, the data in segments 3,4,5,6 is queued (in this order), and then given to application when we receive SEQ 2. But if we receive SEQs 5,4,3,7 then the SEQ 7 is discarded because the list would not be sequential as number 6 is be missing.

Traffic Class Options

It is possible to configure multiple traffic classes (queues) when receiving or sending network data. Each traffic class queue is implemented as a thread with different priority. This means that higher priority network packet can be placed to a higher priority network queue in order to send or receive it faster or slower. Because of thread scheduling latencies, in practice the fastest way to send a packet out, is to directly send the packet without using a dedicated traffic class thread. This is why by default the `CONFIG_NET_TC_TX_COUNT` option is set to 0 if userspace is not enabled. If userspace is enabled, then the minimum TX traffic class count is 1. Reason for this is that the userspace application does not have enough permissions to deliver the message directly.

In receiving side, it is recommended to have at least one receiving traffic class queue. Reason is that typically the network device driver is running in IRQ context when it receives the packet, in which case it should not try to deliver the network packet directly to the upper layers, but to place the packet to the traffic class queue. If the network device driver is not running in IRQ context when it gets the packet, then the RX traffic class option `CONFIG_NET_TC_RX_COUNT` could be set to 0.

Stack Size Options

There several network specific threads in a network enabled system. Some of the threads might depend on a configure option which can be used to enable or disable a feature. Each thread stack size is optimized to allow normal network operations.

The network management API is using a dedicated thread by default. The thread is responsible to deliver network management events to the event listeners that are setup in the system if the `CONFIG_NET_MGMT` and `CONFIG_NET_MGMT_EVENT` options are enabled. If the options are enabled, the user is able to register a callback function that the net_mgmt thread is calling for each network management event. By default the net_mgmt event thread stack size is rather small. The idea is that the callback function does minimal things so that new events can be delivered to listeners as fast as possible and they are not lost. The net_mgmt event thread stack size is controlled by `CONFIG_NET_MGMT_EVENT_QUEUE_SIZE` option. It is recommended to not do any blocking operations in the callback function.

The network thread stack utilization can be monitored from kernel shell by the **kernel threads** command.

6.3.4 Networking with the host system

Networking with native_sim board

- *Using virtual/TAP Ethernet driver*
  - *Prerequisites*
  - *Basic Setup*
- *Using offloaded sockets*
  - *Step 1 - Start app in native_sim board*
  - *Step 2 - run echo-client from net-tools*
- *Setting interface name and IPv4 parameters from command line*

Using virtual/TAP Ethernet driver This paragraph describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a native_sim board.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in native_sim board. The Zephyr native_sim board instance is connected to a Linux host using a tuntap device which is modeled in Linux as an Ethernet network interface.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need three terminal windows:

- Terminal #1 is terminal window with net-tools being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.
- Terminal #3 is the console to the running Zephyr native_sim instance (optional).

Step 1 - Create Ethernet interface Before starting native_sim with network emulation, a network interface should be created.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the net-setup.sh script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

Step 2 - Start app in native_sim board Build and start the `echo_server` sample application.

In terminal #2, type:

```
west build -b native_sim samples/net/sockets/echo_server
west build -t run
```

Step 3 - Connect to console (optional) The console window should be launched automatically when the Zephyr instance is started but if it does not show up, you can manually connect to the console. The native_sim board will print a string like this when it starts:

```
UART connected to pseudotty: /dev/pts/5
```

You can manually connect to it like this:

```
screen /dev/pts/5
```

Using offloaded sockets The main advantage over *Using virtual/TAP Ethernet driver* is not needing to setup a virtual network interface on the host machine. This means that no leveraged (root) privileges are needed.

Step 1 - Start app in native_sim board Build and start the `echo_server` sample application:

```
west build -b native_sim samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-nsos.conf
west build -t run
```

Step 2 - run echo-client from net-tools On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Note

Native Simulator with the offloaded sockets network driver is using the same network interface/namespace as any other (Linux) application that uses BSD sockets API. This means that sockets-echo-server and `echo-client` applications will communicate over localhost/loopback interface (address `127.0.0.1`).

To run UDP test, type:

```
./echo-client 127.0.0.1
```

For TCP test, type:

```
./echo-client -t 127.0.0.1
```

Setting interface name and IPv4 parameters from command line By default the Ethernet interface name used by native_sim is determined by `CONFIG_ETH_NATIVE_TAP_DRV_NAME`, but is also possible to set it from the command line using `--eth-if=<interface_name>`.

The same applies to the IPv4 address, gateway and netmask. They can be set from the command line using `--ipv4-addr=<ip_address>`, `--ipv4-gw=<gateway>` and `--ipv4-nm=<netmask>`.

Note that the configuration `CONFIG_NET_CONFIG_MY_IPV4_ADDR` and the command line arguments work in parallel. This means that if both are set, the interface might end up with two IP addresses. In most cases, it does make sense to only use one of both at the same time.

This can be useful if the application has to be run in multiple instances and recompiling it for each instance would be troublesome.

```
./zephyr.exe --eth-if=zeth2 --ipv4-addr=192.0.2.2 --ipv4-gw=192.0.0.1
--ipv4-nm=255.255.0.0
```

Networking with QEMU Ethernet

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create Ethernet interface*
  - *Step 2 - Start app in QEMU board*

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in QEMU.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in QEMU. The Zephyr instance is connected to a Linux host using a tuntap device which is modeled in Linux as an Ethernet network interface.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with net-tools being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.

When configuring the Zephyr instance, you must select the correct Ethernet driver for QEMU connectivity:

- For `qemu_x86`, select `Intel(R) PRO/1000 Gigabit Ethernet driver` Ethernet driver. Driver is called `e1000` in Zephyr source tree.
- For `qemu_cortex_m3`, select `TI Stellaris MCU family ethernet driver` Ethernet driver. Driver is called `stellaris` in Zephyr source tree.

- For `mps2_an385`, select `SMSC911x/9220 Ethernet driver` Ethernet driver. Driver is called `smsc911x` in Zephyr source tree.
- For `qemu_cortex_a53`, `Intel(R) PRO/1000 Gigabit Ethernet driver` Ethernet driver is selected by default.
- Additionally, the sockets-echo-server sample contains overlay files for the VIRTIO Network device on `qemu_x86_64`.

Step 1 - Create Ethernet interface Before starting QEMU with network connectivity, a network interface should be created in the host system.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the `net-setup.sh` script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

Step 2 - Start app in QEMU board Build and start the sockets-echo-server sample application. In this example, the qemu_x86 board is used.

In terminal #2, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-e1000.conf
west build -t run
```

Alternatively, if you decided to use the VIRTIO Network device on qemu_x86_64:

```
west build -b qemu_x86_64 samples/net/sockets/echo_server -- -
↪DDTC_OVERLAY_FILE=virtnet.overlay -DEXTRA_CONF_FILE=overlay-virtnet.conf
west build -t run
```

Exit QEMU by pressing `CTRL+A x`.

Networking with QEMU

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create helper socket*
  - *Step 2 - Start TAP device routing daemon*
  - *Step 3 - Start app in QEMU*
  - *Step 4 - Run apps on host*
  - *Step 5 - Stop supporting daemons*
- *Setting up Zephyr and NAT/masquerading on host to access Internet*
- *Network connection between two QEMU VMs*
  - *Terminal #1:*
  - *Terminal #2:*

- *Running multiple QEMU VMs of the same sample*
  - *Terminal #1:*
  - *Terminal #2:*

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a QEMU virtual machine (built for Zephyr targets such as qemu_x86 and qemu_cortex_m3). Some virtual ARM boards (such as qemu_cortex_a53) only support a single UART, in this case QEMU Ethernet is preferred, see *Networking with QEMU Ethernet* for details.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in QEMU. The QEMU instance is connected to a Linux host using a serial port, and SLIP is used to transfer data between the Zephyr application and Linux (over a chain of virtual connections).

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
sudo apt install -y socat libpcap-dev
git clone https://github.com/zephyrproject-rtos/net-tools
cd net-tools
make
```

Note

If you get an error about AX_CHECK_COMPILE_FLAG, install package `autoconf-archive` package on Debian/Ubuntu.

Basic Setup For the steps below, you will need at least 4 terminal windows:

- Terminal #1 is your usual Zephyr development terminal, with the Zephyr environment initialized.
- Terminals #2, #3, and #4 are terminal windows with net-tools being the current directory (`cd net-tools`)

Step 1 - Create helper socket Before starting QEMU with network emulation, a Unix socket for the emulation should be created.

In terminal #2, type:

```
./loop-socat.sh
```

Step 2 - Start TAP device routing daemon In terminal #3, type:

```
sudo ./loop-slip-tap.sh
```

For applications requiring DNS, you may need to restart the host's DNS server at this point, as described in *Setting up Zephyr and NAT/masquerading on host to access Internet*.

Step 3 - Start app in QEMU Build and start the `echo_server` sample application.

In terminal #1, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server
west build -t run
```

If you see an error from QEMU about unix:/tmp/slip.sock, it means you missed Step 1 above.

Step 4 - Run apps on host Now in terminal #4, you can run various tools to communicate with the application running in QEMU.

You can start with pings:

```
ping 192.0.2.1
ping6 2001:db8::1
```

You can use the netcat ("nc") utility, connecting using UDP:

```
echo foobar | nc -6 -u 2001:db8::1 4242
foobar
```

```
echo foobar | nc -u 192.0.2.1 4242
foobar
```

If echo_server is compiled with TCP support (now enabled by default for the echo_server sample, CONFIG_NET_TCP=y):

```
echo foobar | nc -6 -q2 2001:db8::1 4242
foobar
```

Note

Use Ctrl+C to exit.

You can also use the telnet command to achieve the above.

Step 5 - Stop supporting daemons When you are finished with network testing using QEMU, you should stop any daemons or helpers started in the initial steps, to avoid possible networking or routing problems such as address conflicts in local network interfaces. For example, stop them if you switch from testing networking with QEMU to using real hardware, or to return your host laptop to normal Wi-Fi use.

To stop the daemons, press Ctrl+C in the corresponding terminal windows (you need to stop both `loop-slip-tap.sh` and `loop-socat.sh`).

Exit QEMU by pressing `CTRL+A x`.

Setting up Zephyr and NAT/masquerading on host to access Internet To access the internet from a Zephyr application, some additional setup on the host may be required. This setup is common for both application running in QEMU and on real hardware, assuming that a development board is connected to the development host. If a board is connected to a dedicated router, it should not be needed.

To access the internet from a Zephyr application using IPv4, a gateway should be set via DHCP or configured manually. For applications using the "Settings" facility (with the config option `CONFIG_NET_CONFIG_SETTINGS` enabled), set the `CONFIG_NET_CONFIG_MY_IPV4_GW` option to the IP address of the gateway. For apps not using the "Settings" facility, set up the gateway by calling the `net_if_ipv4_set_gw()` at runtime. For example: `CONFIG_NET_CONFIG_MY_IPV4_GW="192.0.2.2"`

To access the internet from a custom application running in QEMU, NAT (masquerading) should be set up for QEMU's source address. Assuming `192.0.2.1` is used and the Zephyr network interface is `zeth`, the following command should be run as root:

```
iptables -t nat -A POSTROUTING -j MASQUERADE -s 192.0.2.1/24
iptables -I FORWARD 1 -i zeth -j ACCEPT
iptables -I FORWARD 1 -o zeth -m state --state RELATED,ESTABLISHED -j ACCEPT
```

Additionally, IPv4 forwarding should be enabled on the host, and you may need to check that other firewall (iptables) rules don't interfere with masquerading. To enable IPv4 forwarding the following command should be run as root:

```
sysctl -w net.ipv4.ip_forward=1
```

Some applications may also require a DNS server. A number of Zephyr-provided samples assume by default that the DNS server is available on the host (IP `192.0.2.2`), which, in modern Linux distributions, usually runs at least a DNS proxy. When running with QEMU, it may be required to restart the host's DNS, so it can serve requests on the newly created TAP interface. For example, on Debian-based systems:

```
service dnsmasq restart
```

An alternative to relying on the host's DNS server is to use one in the network. For example, `8.8.8.8` is a publicly available DNS server. You can configure it using `CONFIG_DNS_SERVER1` option.

Network connection between two QEMU VMs Unlike the VM-to-Host setup described above, VM-to-VM setup is automatic. For sample applications that support this mode (such as the echo_server and echo_client samples), you will need two terminal windows, set up for Zephyr development.

Terminal #1:

```
west build -b qemu_x86 -o server samples/net/sockets/echo_server
```

This will start QEMU, waiting for a connection from a client QEMU.

Terminal #2:

```
west build -b qemu_x86 -o client samples/net/sockets/echo_client
```

This will start a second QEMU instance, where you should see logging of data sent and received in both.

Running multiple QEMU VMs of the same sample If you find yourself wanting to run multiple instances of the same Zephyr sample application, which do not need to talk to each other, use the `QEMU_INSTANCE` argument.

Start `socat` and `tunslip6` manually (instead of using the `loop-xxx.sh` scripts) for as many instances as you want. Use the following as a guide, replacing MAIN or OTHER.

Terminal #1:

```
socat PTY,link=/tmp/slip.devMAIN UNIX-LISTEN:/tmp/slip.sockMAIN &
sudo $ZEPHYR_BASE/../tools/net-tools/tunslip6 -t tapMAIN -T -s /tmp/slip.devMAIN␣
↪2001:db8::1/64 &
# Now run Zephyr
make -Cbuild run QEMU_INSTANCE=MAIN
```

Terminal #2:

```
socat PTY,link=/tmp/slip.devOTHER UNIX-LISTEN:/tmp/slip.sockOTHER &
sudo $ZEPHYR_BASE/../tools/net-tools/tunslip6 -t tapOTHER -T -s /tmp/slip.devOTHER␣
↪2001:db8::1/64 &
make -Cbuild run QEMU_INSTANCE=OTHER
```

USB Device Networking

- *Basic Setup*
  - *Choosing IP addresses*
  - *Setting IPv4 address and routing*
  - *Setting IPv6 address and routing*
- *Testing connection*

This page describes how to set up networking between a Linux host and a Zephyr application running on USB supported devices.

The board is connected to Linux host using USB cable and provides an Ethernet interface to the host. The sockets-echo-server application from the Zephyr source distribution is run on supported board. The board is connected to a Linux host using a USB cable providing an Ethernet interface to the host.

Basic Setup To communicate with the Zephyr application over a newly created Ethernet interface, we need to assign IP addresses and set up a routing table for the Linux host. After plugging a USB cable from the board to the Linux host, the `cdc_ether` driver registers a new Ethernet device with a provided MAC address.

You can check that network device is created and MAC address assigned by running dmesg from the Linux host.

```
cdc_ether 1-2.7:1.0 eth0: register 'cdc_ether' at usb-0000:00:01.2-2.7, CDC␣
↪Ethernet Device, 00:00:5e:00:53:01
```

We need to set it up and assign IP addresses as explained in the following section.

Choosing IP addresses To establish network connection to the board we need to choose IP address for the interface on the Linux host.

It make sense to choose addresses in the same subnet we have in Zephyr application. IP addresses usually set in the project configuration files and may be checked also from the shell with following commands. Connect a serial console program (such as puTTY) to the board, and enter this command to the Zephyr shell:

```
shell> net iface

Interface 0xa800e580 (Ethernet)
===============================
Link addr : 00:00:5E:00:53:00
MTU       : 1500
IPv6 unicast addresses (max 2):
        fe80::200:5eff:fe00:5300 autoconf preferred infinite
        2001:db8::1 manual preferred infinite
...
```

(continues on next page)

(continued from previous page)

```
IPv4 unicast addresses (max 1):
        192.0.2.1 manual preferred infinite
```

This command shows that one IPv4 address and two IPv6 addresses have been assigned to the board. We can use either IPv4 or IPv6 for network connection depending on the board network configuration.

Next step is to assign IP addresses to the new Linux host interface, in the following steps `enx00005e005301` is the name of the interface on my Linux system.

Setting IPv4 address and routing

```
# ip address add dev enx00005e005301 192.0.2.2
# ip link set enx00005e005301 up
# ip route add 192.0.2.0/24 dev enx00005e005301
```

Setting IPv6 address and routing

```
# ip address add dev enx00005e005301 2001:db8::2
# ip link set enx00005e005301 up
# ip -6 route add 2001:db8::/64 dev enx00005e005301
```

Testing connection From the host we can test the connection by pinging Zephyr IP address of the board with:

```
$ ping 192.0.2.1
PING 192.0.2.1 (192.0.2.1) 56(84) bytes of data.
64 bytes from 192.0.2.1: icmp_seq=1 ttl=64 time=2.30 ms
64 bytes from 192.0.2.1: icmp_seq=2 ttl=64 time=1.43 ms
64 bytes from 192.0.2.1: icmp_seq=3 ttl=64 time=2.45 ms
...
```

Networking with QEMU User

- *Introduction*
- *Using SLIRP with Zephyr*
- *Limitations*

This page is intended to serve as a starting point for anyone interested in using QEMU SLIRP with Zephyr.

Introduction SLIRP is a network backend which provides the complete TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As there are no dependencies on the host, SLIRP is simple to setup.

By default, QEMU uses the `10.0.2.X/24` network and runs a gateway at `10.0.2.2`. All traffic intended for the host network has to travel through this gateway, which will filter out packets based on the QEMU command line parameters. This gateway also functions as a DHCP server for all GOS, allowing them to be automatically assigned with an IP address starting from `10.0.2.15`.

More details about User Networking can be obtained from here: https://wiki.qemu.org/Documentation/Networking#User_Networking_.28SLIRP.29

Using SLIRP with Zephyr In order to use SLIRP with Zephyr, the user has to set the Kconfig option to enable User Networking.

```
CONFIG_NET_QEMU_USER=y
```

Once this configuration option is enabled, all QEMU launches will use SLIRP. In the default configuration, Zephyr only enables User Networking, and does not pass any arguments to it. This means that the Guest will only be able to communicate to the QEMU gateway, and any data intended for the host machine will be dropped by QEMU.

In general, QEMU User Networking can take in a lot of arguments including,

- Information about host/guest port forwarding. This must be provided to create a communication channel between the guest and host.
- Information about network to use. This may be valuable if the user does not want to use the default `10.0.2.X` network.
- Tell QEMU to start DHCP server at user-defined IP address.
- ID and other information.

As this information varies with every use case, it is difficult to come up with good defaults that work for all. Therefore, Zephyr Implementation offloads this to the user, and expects that they will provide arguments based on requirements. For this, there is a Kconfig string which can be populated by the user.

```
CONFIG_NET_QEMU_USER_EXTRA_ARGS="net=192.168.0.0/24,hostfwd=tcp::8080-:8080"
```

This option is appended as-is to the QEMU command line. Therefore, any problems with this command line will be reported by QEMU only. Here's what this particular example will do,

- Make QEMU use the `192.168.0.0/24` network instead of the default.
- Enable forwarding of any TCP data received from port 8080 of host to port 8080 of guest, and vice versa.

Limitations If the user does not have any specific networking requirements other than the ability to access a web page from the guest, user networking (slirp) is a good choice. However, it has several limitations

- There is a lot of overhead so the performance is poor.
- The guest is not directly accessible from the host or the external network.
- In general, ICMP traffic does not work (so you cannot use ping within a guest).
- As port mappings need to be defined before launching qemu, clients which use dynamically generated ports cannot communicate with external network.
- There is a bug in the SLIRP implementation which filters out all IPv6 packets from the guest. See https://bugs.launchpad.net/qemu/+bug/1724590 for details. Therefore, IPv6 will not work with User Networking.

Networking with multiple Zephyr instances

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create configuration files*
  - *Step 2 - Create Ethernet interfaces*

- *Step 3 - Setup network bridging*
- *Step 4 - Start Zephyr instances*

This page describes how to set up a virtual network between multiple Zephyr instances. The Zephyr instances could be running inside QEMU or could be native_sim board processes. The Linux host can be used to route network traffic between these systems.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need five terminal windows:

- Terminal #1 and #2 are terminal windows with net-tools being the current directory (`cd net-tools`)
- Terminal #3, where you setup bridging in Linux host
- Terminal #4 and #5 are your usual Zephyr development terminal, with the Zephyr environment initialized.

As there are multiple ways to setup the Zephyr network, the example below uses `qemu_x86` board with `e1000` Ethernet controller and native_sim board to simplify the setup instructions. You can use other QEMU boards and drivers if needed, see *Networking with QEMU Ethernet* for details. You can also use two or more native_sim board Zephyr instances and connect them together.

Step 1 - Create configuration files Before starting QEMU with network connectivity, a network interfaces for each Zephyr instance should be created in the host system. The default setup for creating network interface cannot be used here as that is for connecting one Zephyr instance to Linux host.

For Zephyr instance #1, create file called `zephyr1.conf` to `net-tools` project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:11"
IPV6_ADDR_1="2001:db8:100::2"
IPV6_ROUTE_1="2001:db8:100::/64"
IPV4_ADDR_1="198.51.100.2/24"
IPV4_ROUTE_1="198.51.100.0/24"
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

For Zephyr instance #2, create file called `zephyr2.conf` to `net-tools` project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:22"
```

(continues on next page)

(continued from previous page)

```
IPV6_ADDR_1="2001:db8:200::2"
IPV6_ROUTE_1="2001:db8:200::/64"
IPV4_ADDR_1="203.0.113.2/24"
IPV4_ROUTE_1="203.0.113.0/24"
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

Step 2 - Create Ethernet interfaces The following `net-setup.sh` commands should be typed in net-tools directory (`cd net-tools`).

In terminal #1, type:

```
./net-setup.sh -c zephyr1.conf -i zeth.1
```

In terminal #2, type:

```
./net-setup.sh -c zephyr2.conf -i zeth.2
```

Step 3 - Setup network bridging In terminal #3, type:

```
sudo brctl addbr zeth-br
sudo brctl addif zeth-br zeth.1
sudo brctl addif zeth-br zeth.2
sudo ifconfig zeth-br up
```

Step 4 - Start Zephyr instances In this example we start sockets-echo-server and sockets-echo-client sample applications. You can use other applications too as needed.

In terminal #4, if you are using QEMU, type this:

```
west build -d build/server -b qemu_x86 -t run \
   samples/net/sockets/echo_server -- \
   -DEXTRA_CONF_FILE=overlay-e1000.conf \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"203.0.113.1\" \
   -DCONFIG_ETH_QEMU_IFACE_NAME=\"zeth.1\" \
   -DCONFIG_ETH_QEMU_EXTRA_ARGS=\"mac=00:00:5e:00:53:01\"
```

or if you want to use native_sim board, type this:

```
west build -d build/server -b native_sim -t run \
   samples/net/sockets/echo_server -- \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"203.0.113.1\" \
   -DCONFIG_ETH_NATIVE_TAP_DRV_NAME=\"zeth.1\" \
```

(continues on next page)

(continued from previous page)

```
   -DCONFIG_ETH_NATIVE_TAP_MAC_ADDR=\"00:00:5e:00:53:01\" \
   -DCONFIG_ETH_NATIVE_TAP_RANDOM_MAC=n
```

In terminal #5, if you are using QEMU, type this:

```
west build -d build/client -b qemu_x86 -t run \
   samples/net/sockets/echo_client -- \
   -DEXTRA_CONF_FILE=overlay-e1000.conf \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"198.51.100.1\" \
   -DCONFIG_ETH_QEMU_IFACE_NAME=\"zeth.2\" \
   -DCONFIG_ETH_QEMU_EXTRA_ARGS=\"mac=00:00:5e:00:53:02\"
```

or if you want to use native_sim board, type this:

```
west build -d build/client -b native_sim -t run \
   samples/net/sockets/echo_client -- \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"198.51.100.1\" \
   -DCONFIG_ETH_NATIVE_TAP_DRV_NAME=\"zeth.2\" \
   -DCONFIG_ETH_NATIVE_TAP_MAC_ADDR=\"00:00:5e:00:53:02\" \
   -DCONFIG_ETH_NATIVE_TAP_RANDOM_MAC=n
```

Also if you have firewall enabled in your host, you need to allow traffic between `zeth.1`, `zeth.2` and `zeth-br` interfaces.

Ethernet bridge with native_sim board

This document describes how to set up a bridged Ethernet network between a (Linux) host and a Zephyr application running in a native_sim board.

This setup is useful when testing the Ethernet bridging feature that can be enabled with `CONFIG_NET_ETHERNET_BRIDGE` Kconfig option. In this setup, the net-tools configuration creates two host network interfaces `zeth0` and `zeth1` and connects them to Zephyr's native_sim application.

First create the host interfaces. In this example two interfaces are created.

```
cd $ZEPHYR_BASE/../tools/net-tools
./net-setup.sh -c zeth-multiface.conf -i zeth0 -t 2
```

The `-c` tells which configuration file to use, where `zeth-multiface.conf` is tailored for generating multiple network interfaces in the host. The `-i` option tells what is the first host interface name. The `-t` tells how many network interfaces to create.

Example output of the host interfaces:

```
zeth0: flags=4099<UP,BROADCAST,MULTICAST>  mtu 1500
       inet 192.0.2.2  netmask 255.255.255.255  broadcast 0.0.0.0
       inet6 2001:db8::2  prefixlen 128  scopeid 0x0<global>
       inet6 fe80::200:5eff:fe00:5300  prefixlen 64  scopeid 0x20<link>
       ether 00:00:5e:00:53:00  txqueuelen 1000  (Ethernet)
       RX packets 33  bytes 2408 (2.4 KB)
```

(continues on next page)

(continued from previous page)

```
       RX errors 0  dropped 0  overruns 0  frame 0
       TX packets 49  bytes 4092 (4.0 KB)
       TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

zeth1: flags=4099<UP,BROADCAST,MULTICAST>  mtu 1500
       inet 198.51.100.1  netmask 255.255.255.255  broadcast 0.0.0.0
       inet6 fe80::200:5eff:fe00:5301  prefixlen 64  scopeid 0x20<link>
       inet6 2001:db8:2::1  prefixlen 128  scopeid 0x0<global>
       ether 00:00:5e:00:53:01  txqueuelen 1000  (Ethernet)
       RX packets 21  bytes 1340 (1.3 KB)
       RX errors 0  dropped 0  overruns 0  frame 0
       TX packets 45  bytes 3916 (3.9 KB)
       TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

Then create a sample and enable Ethernet bridging support. In this example we create sockets-echo-server sample application.

```
west build -p -b native_sim -d ../build/echo-server \
   samples/net/sockets/echo_server -- \
   -DCONFIG_UART_NATIVE_PTY_AUTOATTACH_DEFAULT_CMD="\"gnome-terminal -- screen
↪%s\"" \
   -DCONFIG_NET_ETHERNET_BRIDGE=y \
   -DCONFIG_NET_ETHERNET_BRIDGE_SHELL=y \
   -DCONFIG_ETH_NATIVE_TAP_INTERFACE_COUNT=2 \
   -DCONFIG_NET_IF_MAX_IPV6_COUNT=2 \
   -DCONFIG_NET_IF_MAX_IPV4_COUNT=2
../build/echo-server/zephyr/zephyr.exe -attach_uart
```

This will create and run sockets-echo-server with bridging enabled but not yet configured. To configure the bridging, you either need to use the bridge shell or call the bridging API directly from the application. We setup the bridging using the bridge shell like this:

```
net bridge addif 1 3 2
net iface up 1
```

In the above example, the bridge interface index is 1, and interfaces 2 and 3 are Ethernet interfaces which are linked to interfaces `zeth0` and `zeth1` in the host side.

The network interfaces look like this in Zephyr's side:

```
net iface
Hostname: zephyr

Interface bridge0 (0x8090ebc) (Virtual) [1]
===================================
Virtual name : <enabled>
No attached network interface.
Link addr : 3B:DB:31:0F:CC:B6
MTU       : 1500
Flags     : NO_AUTO_START
Device    : BRIDGE_0 (0x8088354)
Promiscuous mode : disabled
IPv6 not enabled for this interface.
IPv4 not enabled for this interface.

Interface eth0 (0x8090fcc) (Ethernet) [2]
===================================
```

(continues on next page)

(continued from previous page)

```
Link addr : 02:00:5E:00:53:D2
MTU       : 1500
Flags     : AUTO_START,IPv4,IPv6
Device    : zeth0 (0x808837c)
Promiscuous mode : disabled
Ethernet capabilities supported:
        TXTIME
        Promiscuous mode
Ethernet PHY device: <none> (0)
IPv6 unicast addresses (max 3):
        fe80::5eff:fe00:53d2 autoconf preferred infinite
        2001:db8::1 manual preferred infinite
IPv6 multicast addresses (max 4):
        ff02::1
        ff02::1:ff00:53d2
        ff02::1:ff00:1
IPv6 prefixes (max 2):

```

The `net bridge` command will show the current status of the bridging:

```
net bridge
Bridge Status   Config   Interfaces
1      up       ok       2 3
```

The `addif` command adds Ethernet interfaces 2 and 3 to the bridge interface 1. After the `addif` command, the bridging is still disabled because the bridge interface is not up by default. The `net iface up` command will turn on bridging.

If you have wireshark running in host side and monitoring `zeth0` and `zeth1`, you should see the same network traffic in both host interfaces.

Note that interface index numbers are not fixed, the bridge and Ethernet interface index values might be different in your setup.

The bridging can be disabled by taking the bridge interface down, and the Ethernet interfaces can be removed from the bridge using `delif` command.

```
net iface down 1
net bridge delif 1 2 3
```

Networking with QEMU and IEEE 802.15.4

- *Basic Setup*
  - *Step 1 - Compile and start echo-server*
  - *Step 2 - Compile and start echo-client*

This page describes how to set up a virtual network between two QEMUs that are connected together via UART and are running IEEE 802.15.4 link layer between them. Note that this only works in Linux host.

Basic Setup For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with `echo-server` Zephyr sample application.
- Terminal #2 is terminal window with `echo-client` Zephyr sample application.

If you want to capture the transferred network data, you must compile the `monitor_15_4` program in the `tools/net-tools` directory.

Open a terminal window and type:

```
cd $ZEPHYR_BASE/../tools/net-tools
make monitor_15_4
```

Step 1 - Compile and start echo-server In terminal #1, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-qemu_802154.conf
west build -t server -d build/server
```

If you want to capture the network traffic between the two QEMUs, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -G'Unix␣
↪Makefiles' -DEXTRA_CONF_FILE=overlay-qemu_802154.conf -DPCAP=capture.pcap
west build -t server -d build/server
```

Note that the `make` must be used for `server` target if packet capture option is set in command line. The `build/server/capture.pcap` file will contain the transferred data.

Step 2 - Compile and start echo-client In terminal #2, type:

```
west build -b qemu_x86 -d build/client samples/net/sockets/echo_client -- -
↪DEXTRA_CONF_FILE=overlay-qemu_802154.conf
west build -t client -d build/client
```

You should see data passed between the two QEMUs. Exit QEMU by pressing `CTRL+A x`.

Networking with Arm FVP User Mode

- *Introduction*
- *Using Arm FVP User Mode Networking with Zephyr*
- *Limitations*

This page is intended to serve as a starting point for anyone interested in using Arm FVP user mode networking with Zephyr.

Introduction User mode networking emulates a built-in IP router and DHCP server, and routes TCP and UDP traffic between the guest and host. It uses the user mode socket layer of the host to communicate with other hosts. This allows the use of a significant number of IP network services without requiring administrative privileges, or the installation of a separate driver on the host on which the model is running.

By default, Arm FVP uses the `172.20.51.0/24` network and runs a gateway at `172.20.51.254`. This gateway also functions as a DHCP server for the GOS, allowing it to be automatically assigned with an IP address `172.20.51.1`.

More details about Arm FVP user mode networking can be obtained from here: https://developer.arm.com/documentation/100964/latest/Introduction-to-Fast-Models/User-mode-networking

Using Arm FVP User Mode Networking with Zephyr Arm FVP user mode networking can be enabled in any applications and it doesn't need any configurations on the host system. This feature has been enabled in DHCPv4 client sample. See dhcpv4-client sample application.

Limitations

- You can use TCP and UDP over IP, but not ICMP (ping).
- User mode networking does not support forwarding UDP ports on the host to the model.
- You can only use DHCP within the private network.
- You can only make inward connections by mapping TCP ports on the host to the model. This is common to all implementations that provide host connectivity using NAT.
- Operations that require privileged source ports, for example NFS in its default configuration, do not work.
- If setup fails, or the parameter syntax is incorrect, there is no error reporting.

While developing networking software, it is usually necessary to connect and exchange data with the host system like a Linux desktop computer. Depending on what board is used for development, the following options are possible:

- QEMU using SLIP (Serial Line Internet Protocol).

  - Here IP packets are exchanged between Zephyr and the host system via serial port. This is the legacy way of transferring data. It is also quite slow so use it only when necessary. See *Networking with QEMU* for details.

- QEMU using built-in Ethernet driver.
  - Here IP packets are exchanged between Zephyr and the host system via QEMU's built-in Ethernet driver. Not all QEMU boards support built-in Ethernet so in some cases, you might need to use the SLIP method for host connectivity. See *Networking with QEMU Ethernet* for details.
- QEMU using SLIRP (Qemu User Networking).
  - QEMU User Networking is implemented using "slirp", which provides a full TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As this support is built into QEMU, it can be used with any model and requires no admin privileges on the host machine, unlike TAP. However, it has several limitations including performance which makes it less valuable for practical purposes. See *Networking with QEMU User* for details.
- Arm FVP (User Mode Networking).
  - User mode networking emulates a built-in IP router and DHCP server, and routes TCP and UDP traffic between the guest and host. It uses the user mode socket layer of the host to communicate with other hosts. This allows the use of a significant number of IP network services without requiring administrative privileges, or the installation of a separate driver on the host on which the model is running. See *Networking with Arm FVP User Mode* for details.
- native_sim board.
  - The Zephyr instance can be executed as a user space process in the host system. This is the most convenient way to debug the Zephyr system as one can attach host debugger directly to the running Zephyr instance. This requires that there is an adaptation driver in Zephyr for interfacing with the host system. Two possible network drivers can be used for this purpose, a TAP virtual Ethernet driver and an offloaded sockets driver. See *Networking with native_sim board* for details.
- USB device networking.
  - Here, the Zephyr instance is run on a real board and the connectivity to the host system is done via USB. See *USB Device Networking* for details.
- Connecting multiple Zephyr instances together.
  - If you have multiple Zephyr instances, either QEMU or native_sim ones, and want to create a connection between them, see *Networking with multiple Zephyr instances* for details.
- Simulating IEEE 802.15.4 network between two QEMUs.
  - Here, two Zephyr instances are running and there is IEEE 802.15.4 link layer run over an UART between them. See *Networking with QEMU and IEEE 802.15.4* for details.
- Simulating Ethernet bridge network with native_sim.
  - Here, one Zephyr instance is running with Ethernet bridge enabled via `CONFIG_NET_ETHERNET_BRIDGE` Kconfig option. There exists two host network interfaces `zeth0` and `zeth1` and the network packets are bridged between those two interfaces. See *Ethernet bridge with native_sim board* for details.

6.3.5 Monitor Network Traffic

- *Host Configuration*
- *Zephyr Configuration*
- *Wireshark Configuration*

It is useful to be able to monitor the network traffic especially when debugging a connectivity issues or when developing new protocol support in Zephyr. This page describes how to set up a way to capture network traffic so that user is able to use Wireshark or similar tool in remote host to see the network packets sent or received by a Zephyr device.

See also the net-capture sample application from the Zephyr source distribution for configuration options that need to be enabled.

Host Configuration

The instructions here describe how to setup a Linux host to capture Zephyr network RX and TX traffic. Similar instructions should work also in other operating systems.

On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

The `net-tools` project provides a configure file to setup IP-to-IP tunnel interface so that we can transfer monitoring data from Zephyr to host.

In terminal #1, type:

```
./net-setup.sh -c zeth-tunnel.conf
```

This script will create following IPIP tunnel interfaces:

Interface name	Description
`zeth-ip6ip`	IPv6-over-IPv4 tunnel
`zeth-ipip`	IPv4-over-IPv4 tunnel
`zeth-ipip6`	IPv4-over-IPv6 tunnel
`zeth-ip6ip6`	IPv6-over-IPv6 tunnel

Zephyr will send captured network packets to one of these interfaces. The actual interface will depend on how the capturing is configured. You can then use Wireshark to monitor the proper network interface.

After the tunneling interfaces have been created, you can use for example `net-capture.py` script from `net-tools` project to print or save the captured network packets. The `net-capture.py` provides an UDP listener, it can print the captured data to screen and optionally can also save the data to a pcap file.

```
$ ./net-capture.py -i zeth-ip6ip -w capture.pcap
[20210408Z14:33:08.959589] Ether / IP / ICMP 192.0.2.1 > 192.0.2.2 echo-request 0 /
↪ Raw
[20210408Z14:33:08.976178] Ether / IP / ICMP 192.0.2.2 > 192.0.2.1 echo-reply 0 /␣
↪Raw
[20210408Z14:33:16.176303] Ether / IPv6 / ICMPv6 Echo Request (id: 0x9feb seq: 0x0)
[20210408Z14:33:16.195326] Ether / IPv6 / ICMPv6 Echo Reply (id: 0x9feb seq: 0x0)
[20210408Z14:33:21.194979] Ether / IPv6 / ICMPv6ND_NS / ICMPv6 Neighbor Discovery␣
↪Option - Source Link-Layer Address 02:00:5e:00:53:3b
```

(continues on next page)

(continued from previous page)

```
[20210408Z14:33:21.217528] Ether / IPv6 / ICMPv6ND_NA / ICMPv6 Neighbor Discovery␣
↪Option - Destination Link-Layer Address 00:00:5e:00:53:ff
[20210408Z14:34:10.245408] Ether / IPv6 / UDP 2001:db8::2:47319 > 2001:db8::1:4242␣
↪/ Raw
[20210408Z14:34:10.266542] Ether / IPv6 / UDP 2001:db8::1:4242 > 2001:db8::2:47319␣
↪/ Raw
```

The `net-capture.py` has following command line options:

```
Listen captured network data from Zephyr and save it optionally to pcap file.
./net-capture.py \
     -i | --interface <network interface>
             Listen this interface for the data
     [-p | --port <UDP port>]
             UDP port (default is 4242) where the capture data is received
     [-q | --quiet]
             Do not print packet information
     [-t | --type <L2 type of the data>]
             Scapy L2 type name of the UDP payload, default is Ether
     [-w | --write <pcap file name>]
             Write the received data to file in PCAP format
```

Instead of the `net-capture.py` script, you can for example use `netcat` to provide an UDP listener so that the host will not send port unreachable message to Zephyr:

```
nc -l -u 2001:db8:200::2 4242 > /dev/null
```

The IP address above is the inner tunnel endpoint, and can be changed and it depends on how the Zephyr is configured. Zephyr will send UDP packets containing the captured network packets to the configured IP tunnel, so we need to terminate the network connection like this.

Zephyr Configuration

In this example, we use the `native_sim` board. You can also use any other board that supports networking.

In terminal #3, type:

```
west build -b native_sim samples/net/capture -- -
↪DCONFIG_UART_NATIVE_PTY_AUTOATTACH_DEFAULT_CMD=\""gnome-terminal -- screen %s"\"
```

To see the Zephyr console and shell, start Zephyr instance like this:

```
build/zephyr/zephyr.exe -attach_uart
```

Any other application can be used too, just make sure that suitable configuration options are enabled (see `samples/net/capture/prj.conf` file for examples).

The network capture can be configured automatically if needed, but currently the `capture` sample application does not do that. User has to use `net-shell` to setup and enable the monitoring.

The network packet monitoring needs to be setup first. The `net-shell` has `net capture setup` command for doing that. The command syntax is

```
net capture setup <remote-ip-addr> <local-ip-addr> <peer-ip-addr>
     <remote> is the (outer) endpoint IP address
     <local> is the (inner) local IP address
     <peer> is the (inner) peer IP address
```

(continues on next page)

(continued from previous page)

```
    Local and Peer IP addresses can have UDP port number in them (optional)
    like 198.0.51.2:9000 or [2001:db8:100::2]:4242
```

In Zephyr console, type:

```
net capture setup 192.0.2.2 2001:db8:200::1 2001:db8:200::2
```

This command will create the tunneling interface. The `192.0.2.2` is the remote host where the tunnel is terminated. The address is used to select the local network interface where the tunneling interface is attached to. The `2001:db8:200::1` tells the local IP address for the tunnel, the `2001:db8:200::2` is the peer IP address where the captured network packets are sent. The port numbers for UDP packet can be given in the setup command like this for IPv6-over-IPv4 tunnel

```
net capture setup 192.0.2.2 [2001:db8:200::1]:9999 [2001:db8:200::2]:9998
```

and like this for IPv4-over-IPv4 tunnel

```
net capture setup 192.0.2.2 198.51.100.1:9999 198.51.100.2:9998
```

If the port number is omitted, then `4242` UDP port is used as a default.

The current monitoring configuration can be checked like this:

```
uart:~$ net capture
Network packet capture disabled
                Capture  Tunnel
Device          iface    iface   Local                   Peer
NET_CAPTURE0    -        1      [2001:db8:200::1]:4242  [2001:db8:200::2]:4242
```

which will print the current configuration. As we have not yet enabled monitoring, the `Capture iface` is not set.

Then we need to enable the network packet monitoring like this:

```
net capture enable 2
```

The `2` tells the network interface which traffic we want to capture. In this example, the `2` is the `native_sim` board Ethernet interface. Note that we send the network traffic to the same interface that we are monitoring in this example. The monitoring system avoids to capture already captured network traffic as that would lead to recursion. You can use `net iface` command to see what network interfaces are available. Note that you cannot capture traffic from the tunnel interface as that would cause recursion loop. The captured network traffic can be sent to some other network interface if configured so. Just set the `<remote-ip-addr>` option properly in `net capture setup` so that the IP tunnel is attached to desired network interface. The capture status can be checked again like this:

```
uart:~$ net capture
Network packet capture enabled
                Capture  Tunnel
Device          iface    iface   Local                   Peer
NET_CAPTURE0    2        1      [2001:db8:200::1]:4242  [2001:db8:200::2]:4242
```

After enabling the monitoring, the system will send captured (either received or sent) network packets to the tunnel interface for further processing.

The monitoring can be disabled like this:

```
net capture disable
```

which will turn currently running monitoring off. The monitoring setup can be cleared like this:

```
net capture cleanup
```

It is not necessary to use `net-shell` for configuring the monitoring. The *network capture API* functions can be called by the application if needed.

Wireshark Configuration

The Wireshark tool can be used to monitor the captured network traffic in a useful way.

You can monitor either the tunnel interfaces or the `zeth` interface. In order to see the actual captured data inside an UDP packet, see Wireshark decapsulate UDP document for instructions.

6.3.6 Network Tracing

User can enable network core stack and socket API calls tracing.

The `CONFIG_TRACING_NET_CORE` option controls the core network stack tracing. This option is enabled by default if tracing and networking are enabled. The system will start to collect the receiving and sending call verdicts i.e., whether the network packet was successfully sent or received. It will also collect packet sending or receiving timings i.e., how long it took to deliver the network packet, and the network interface, priority and traffic class used.

The `CONFIG_TRACING_NET_SOCKETS` option can be used to track BSD socket call usage in the system. It is enabled if tracing and BSD socket API support are enabled. The system will start to collect what BSD socket API calls are made and what parameters the API calls are using and returning.

See the *tracing documentation* for how to use the tracing service.

6.3.7 Networking APIs

Zephyr provides support for the standard BSD socket APIs (defined in include/zephyr/net/socket.h) for the applications to use. See *BSD socket API* for more details.

Apart of the standard API, Zephyr provides a set of custom networking APIs and libraries for the application to use. See the list below for details.

> **Note**
>
> The legacy connectivity API in include/zephyr/net/net_context.h should not be used by applications.

Network APIs

BSD Sockets

- *Overview*
- *Secure Sockets*
  - *TLS credentials subsystem*
  - *Secure Socket Creation*
  - *Secure Sockets options*
- *Socket offloading*
  - *Offloaded socket creation*

  - *Dealing with multiple offloaded interfaces*
- *API Reference*
  - *BSD Sockets*
  - *TLS Credentials*

Overview Zephyr offers an implementation of a subset of the BSD Sockets API (a part of the POSIX standard). This API allows to reuse existing programming experience and port existing simple networking applications to Zephyr.

Here are the key requirements and concepts which governed BSD Sockets compatible API implementation for Zephyr:

- Has minimal overhead, similar to the requirement for other Zephyr subsystems.
- Is namespaced by default, to avoid name conflicts with well-known names like `close()`, which may be part of libc or other POSIX compatibility libraries. If enabled by `CONFIG_POSIX_API`, it will also expose POSIX compatible APIs.

BSD Sockets compatible API is enabled using `CONFIG_NET_SOCKETS` config option and implements the following operations: `socket()`, `close()`, `recv()`, `recvfrom()`, `send()`, `sendto()`, `connect()`, `bind()`, `listen()`, `accept()`, `fcntl()` (to set non-blocking mode), `getsockopt()`, `setsockopt()`, `poll()`, `select()`, `getaddrinfo()`, `getnameinfo()`.

Based on the namespacing requirements above, these operations are by default exposed as functions with `zsock_` prefix, e.g. `zsock_socket()` and `zsock_close()`. If the config option `CONFIG_POSIX_API` is defined, all the functions will be also exposed as aliases without the prefix. This includes the functions like `close()` and `fcntl()` (which may conflict with functions in libc or other libraries, for example, with the filesystem libraries).

Another entailment of the design requirements above is that the Zephyr API aggressively employs the short-read/short-write property of the POSIX API whenever possible (to minimize complexity and overheads). POSIX allows for calls like `recv()` and `send()` to actually process (receive or send) less data than requested by the user (on `SOCK_STREAM` type sockets). For example, a call `recv(sock, 1000, 0)` may return 100, meaning that only 100 bytes were read (short read), and the application needs to retry call(s) to receive the remaining 900 bytes.

The BSD Sockets API uses file descriptors to represent sockets. File descriptors are small integers, consecutively assigned from zero, shared among sockets, files, special devices (like stdin/stdout), etc. Internally, there is a table mapping file descriptors to internal object pointers. The file descriptor table is used by the BSD Sockets API even if the rest of the POSIX subsystem (filesystem, stdin/stdout) is not enabled.

Zephyr supports multiple types of BSD sockets, the following table summarizes what socket types are available:

Family	Type	Protocol	Description
AF_INET AF_INET6	SOCK_	IPPROTO_	Enabled if CONFIG_NET_UDP is set. Allows to send and receive UDP datagrams.
		IPPROTO_	Enabled if CONFIG_NET_SOCKETS_ENABLE_DTLS is set. Allows to send and receive DTLS datagrams.
	SOCK_	IPPROTO_	Enabled if CONFIG_NET_TCP is set. Allows to send and receive TCP data stream.
		IPPROTO_	Enabled if CONFIG_NET_SOCKETS_SOCKOPT_TLS is set. Allows to send and receive TLS data stream.
	SOCK_	IPPROTO_ <proto>	Enabled if CONFIG_NET_SOCKETS_INET_RAW is set. Allows to send and receive IPv4/IPv6 datagrams. Packets are filtered by L4 protocol specified. IPPROTO_IP is a wildcard protocol to receive all IP datagrams.
AF_PAC	SOCK_	ETH_P_ <proto>	Enabled if CONFIG_NET_SOCKETS_PACKET_DGRAM is set. Allows to send and receive packets without L2 header. Packets are filtered by L3 protocol specified. ETH_P_ALL is a wildcard protocol to receive all packets.
	SOCK_	ETH_P_	Enabled if CONFIG_NET_SOCKETS_PACKET is set. Allows to send and receive packets with L2 header included.
AF_CAN	SOCK_	CAN_RA	Enabled if CONFIG_NET_SOCKETS_CAN is set. Allows to send and receive CAN packets.

See sockets-echo-server and sockets-echo-client sample applications to learn how to create a simple server or client BSD socket based application.

Secure Sockets Zephyr provides an extension of standard POSIX socket API, allowing to create and configure sockets with TLS protocol types, facilitating secure communication. Secure functions for the implementation are provided by mbedTLS library. Secure sockets implementation allows use of both TLS and DTLS protocols with standard socket calls. See `net_ip_protocol_secure` type for supported secure protocol versions.

To enable secure sockets, set the `CONFIG_NET_SOCKETS_SOCKOPT_TLS` option. To enable DTLS support, use `CONFIG_NET_SOCKETS_ENABLE_DTLS` option.

TLS credentials subsystem TLS credentials must be registered in the system before they can be used with secure sockets. See `tls_credential_add()` for more information.

When a specific TLS credential is registered in the system, it is assigned with numeric value of type `sec_tag_t`, called a tag. This value can be used later on to reference the credential during secure socket configuration with socket options.

The following TLS credential types can be registered in the system:

- `TLS_CREDENTIAL_CA_CERTIFICATE`
- `TLS_CREDENTIAL_PUBLIC_CERTIFICATE`
- `TLS_CREDENTIAL_PRIVATE_KEY`
- `TLS_CREDENTIAL_PSK`
- `TLS_CREDENTIAL_PSK_ID`

An example registration of CA certificate (provided in `ca_certificate` array) looks like this:

```
ret = tls_credential_add(CA_CERTIFICATE_TAG, TLS_CREDENTIAL_CA_CERTIFICATE,
                         ca_certificate, sizeof(ca_certificate));
```

By default certificates in DER format are supported. PEM support can be enabled in mbedTLS settings.

Secure Socket Creation A secure socket can be created by specifying secure protocol type, for instance:

```
sock = socket(AF_INET, SOCK_STREAM, IPPROTO_TLS_1_2);
```

The protocol version specified when creating the secure socket indicates the minimum TLS version used for the TLS session.

Once created, it can be configured with socket options. For instance, the CA certificate and hostname can be set:

```
sec_tag_t sec_tag_opt[] = {
        CA_CERTIFICATE_TAG,
};

ret = setsockopt(sock, SOL_TLS, TLS_SEC_TAG_LIST,
                 sec_tag_opt, sizeof(sec_tag_opt));
```

```
char host[] = "google.com";

ret = setsockopt(sock, SOL_TLS, TLS_HOSTNAME, host, sizeof(host));
```

Once configured, socket can be used just like a regular TCP socket.

Note

Due to mbed TLS internal data buffering and `mbedtls_ssl_write()` function requirements, when a non-blocking `zsock_send()` returns `EAGAIN`, it is expected that the consecutive call to `zsock_send()` will contain the same data as the original call.

Several samples in Zephyr use secure sockets for communication. For a sample use see e.g. echo-server sample application or HTTP GET sample application.

Secure Sockets options Secure sockets offer the following options for socket management:

Socket options for TLS

Related code samples

- HTTP ClientImplement an HTTP(S) client that issues a variety of HTTP requests.
- HTTP GET using plain socketsImplement an HTTP(S) client using plain BSD sockets.

Socket offloading Zephyr allows to register custom socket implementations (called offloaded sockets). This allows for seamless integration for devices which provide an external IP stack and expose socket-like API.

Socket offloading can be enabled with `CONFIG_NET_SOCKETS_OFFLOAD` option. A network driver that wants to register a new socket implementation should use `NET_SOCKET_OFFLOAD_REGISTER` macro. The macro accepts the following parameters:

- `socket_name`
  An arbitrary name for the socket implementation.

- `prio`
  Socket implementation's priority. The higher the priority, the earlier this particular implementation will be processed when creating a new socket. Lower numeric value indicates higher priority.
- `_family`
  Socket family implemented by the offloaded socket. `AF_UNSPEC` indicates any family.
- `_is_supported`
  A filtering function, used to verify whether a particular socket family, type and protocol are supported by the offloaded socket implementation.
- `_handler`
  A function compatible with `socket()` API, used to create an offloaded socket.

Every offloaded socket implementation should also implement a set of socket APIs, specified in `socket_op_vtable` struct.

The function registered for socket creation should allocate a new file descriptor using `zvfs_reserve_fd()` function. Any additional actions, specific to the creation of a particular offloaded socket implementation, should take place after the file descriptor is allocated. As a final step, if the offloaded socket was created successfully, the file descriptor should be finalized with `zvfs_finalize_typed_fd()`, or `zvfs_finalize_fd()` functions. The finalize function allows to register a `socket_op_vtable` structure implementing socket APIs for an offloaded socket along with an optional socket context data pointer.

Finally, when an offloaded network interface is initialized, it should indicate that the interface is offloaded with `net_if_socket_offload_set()` function. The function registers the function used to create an offloaded socket (the same as the one provided in `NET_SOCKET_OFFLOAD_REGISTER`) at the network interface.

Offloaded socket creation When application creates a new socket with `socket()` function, the network stack iterates over all registered socket implementations (native and offloaded). Higher priority socket implementations are processed first. For each registered socket implementation, an address family is verified, and if it matches (or the socket was registered as `AF_UNSPEC`), the corresponding `_is_supported` function is called to verify the remaining socket parameters. The first implementation that fulfills the socket requirements (i. e. `_is_supported` returns true) will create a new socket with its `_handler` function.

The above indicates the importance of the socket priority. If multiple socket implementations support the same set of socket family/type/protocol, the first implementation processed by the system will create a socket. Therefore it's important to give the highest priority to the implementation that should be the system default.

The socket priority for native socket implementation is configured with Kconfig. Use `CONFIG_NET_SOCKETS_TLS_PRIORITY` to set the priority for the native TLS sockets. Use `CONFIG_NET_SOCKETS_PRIORITY_DEFAULT` to set the priority for the remaining native sockets.

Dealing with multiple offloaded interfaces As the `socket()` function does not allow to specify which network interface should be used by a socket, it's not possible to choose a specific implementation in case multiple offloaded socket implementations, supporting the same type of sockets, are available. The same problem arises when both native and offloaded sockets are available in the system.

To address this problem, a special socket implementation (called socket dispatcher) was introduced. The sole reason for this module is to postpone the socket creation for until the first operation on a socket is performed. This leaves an opening to use `SO_BINDTODEVICE` socket option, to bind a socket to a particular network interface (and thus offloaded socket implementation). The socket dispatcher can be enabled with `CONFIG_NET_SOCKETS_OFFLOAD_DISPATCHER` Kconfig option.

When enabled, the application can specify the network interface to use with `setsockopt()` function:

```
/* A "dispatcher" socket is created */
sock = socket(AF_INET, SOCK_DGRAM, IPPROTO_UDP);

struct ifreq ifreq = {
   .ifr_name = "SimpleLink"
};

/* The socket is "dispatched" to a particular network interface
 * (offloaded or not).
 */
setsockopt(sock, SOL_SOCKET, SO_BINDTODEVICE, &ifreq, sizeof(ifreq));
```

Similarly, if TLS is supported by both native and offloaded sockets, `TLS_NATIVE` socket option can be used to indicate that a native TLS socket should be created. The underlying socket can then be bound to a particular network interface:

```
/* A "dispatcher" socket is created */
sock = socket(AF_INET, SOCK_STREAM, IPPROTO_TLS_1_2);

int tls_native = 1;

/* The socket is "dispatched" to a native TLS socket implmeentation.
 * The underlying socket is a "dispatcher" socket now.
 */
setsockopt(sock, SOL_TLS, TLS_NATIVE, &tls_native, sizeof(tls_native));

struct ifreq ifreq = {
   .ifr_name = "SimpleLink"
};

/* The underlying socket is "dispatched" to a particular network interface
 * (offloaded or not).
 */
setsockopt(sock, SOL_SOCKET, SO_BINDTODEVICE, &ifreq, sizeof(ifreq));
```

In case no `SO_BINDTODEVICE` socket option is used on a socket, the socket will be dispatched according to the default priority and filtering rules on a first socket API call.

Socket Services

- *Overview*
- *API Description*
- *Application Overview*
- *API Reference*

Overview The socket service API can be used to install a handler that is called if there is data received on a socket. The API helps to avoid creating a dedicated thread for each TCP or UDP service that the application provides. Instead one thread is created that serves data to multiple listening sockets which saves memory as only one thread needs to be created in the system in this case.

See sockets-service-echo sample application to learn how to create a simple BSD socket based server application using the sockets service API. The source code for this sample application can be found at: samples/net/sockets/echo_service.

API Description Socket service API is enabled using `CONFIG_NET_SOCKETS_SERVICE` config option and implements the following operations:

- `NET_SOCKET_SERVICE_SYNC_DEFINE`

  Define a network socket service. This socket service is created with extern scope so it can be used from multiple C source files.

- `NET_SOCKET_SERVICE_SYNC_DEFINE_STATIC`

  Define a network socket service with static scope. This socket service can only be used within one C source file.

- `net_socket_service_register()`

  Register pollable sockets for this service. User must create the sockets before this call.

- `net_socket_service_unregister()`

  Remove pollable sockets for this service. User can close the sockets after this call.

- `net_socket_service_handler_t`

  User specified callback which is called when data is received on the listening socket.

Application Overview If the socket service API is enabled, an application must create the service like this:

```
#define MAX_BUF_LEN 1500
#define MAX_SERVICES 1

static void udp_service_handler(struct net_socket_service_event *pev)
{
     struct pollfd *pfd = &pev->event;
     int client = pfd->fd;
     struct sockaddr_in6 addr;
     socklen_t addrlen = sizeof(addr);

     /* In this example we use one static buffer in order to avoid
      * having a large stack.
      */
     static char buf[MAX_BUF_LEN];

     len = recvfrom(client, buf, sizeof(buf), 0,
                    (struct sockaddr *)&addr, &addrlen);
     if (len <= 0) {
             /* Error */
             ...
             return;
     }

     /* Do something with the received data. The pev variable contains
      * user data that was stored in the socket service when it was
      * registered.
      */
}

NET_SOCKET_SERVICE_SYNC_DEFINE_STATIC(service_udp, udp_service_handler,␣
↪MAX_SERVICES);
```

The application needs to create the sockets, then register them to the socket service after which the socket service thread will start to call the callback for any incoming data.

```
/* Create one or multiple sockets */

struct pollfd sockfd_udp[1] = { 0 };
int sock, ret;

sock = socket(AF_INET6, SOCK_DGRAM, IPPROTO_UDP);
if (sock < 0) {
     LOG_ERR("socket: %d", -errno);
     return -errno;
}

/* Set possible socket options after creation */
...

/* Then bind the socket to local address */
if (bind(sock, (struct sockaddr *)addr, sizeof(*addr)) < 0) {
```

(continues on next page)

(continued from previous page)

```
	LOG_ERR("bind: %d", -errno);
	return -errno;
}

/* Set the polled sockets */
sockfd_udp[0].fd = sock;
sockfd_udp[0].events = POLLIN;

/* Register UDP socket to service handler */
ret = net_socket_service_register(&service_udp, sockfd_udp,
                                  ARRAY_SIZE(sockfd_udp), NULL);
if (ret < 0) {
	LOG_ERR("Cannot register socket service handler (%d)", ret);
	return ret;
}

/* Application logic happens here. When application is ready to
 * quit, one should unregister the socket service and close the
 * socket.
 */

(void)net_socket_service_unregister(&service_udp);
close(sock);
```

The TCP socket needs slightly different logic as we need to add any accepted socket to the listening socket by calling the `net_socket_service_register()` for the accepted socket.

```
struct sockaddr_in6 client_addr;
socklen_t client_addr_len = sizeof(client_addr);
struct pollfd sockfd_tcp[1] = { 0 };
int client;

/* TCP socket service is created similar way as the UDP one */
sock = socket(AF_INET6, SOCK_STREAM, IPPROTO_TCP);
if (sock < 0) {
	LOG_ERR("socket: %d", -errno);
	return -errno;
}

if (bind(sock, (struct sockaddr *)addr, sizeof(*addr)) < 0) {
	LOG_ERR("bind: %d", -errno);
	return -errno;
}

if (listen(sock, 5) < 0) {
	LOG_ERR("listen: %d", -errno);
	return -errno;
}

while (1) {
	client = accept(tcp_sock, (struct sockaddr *)&client_addr,
	                &client_addr_len);
	if (client < 0) {
		LOG_ERR("accept: %d", -errno);
		continue;
	}
```

(continues on next page)

(continued from previous page)

```
	inet_ntop(client_addr.sin6_family, &client_addr.sin6_addr,
		  addr_str, sizeof(addr_str));
	LOG_INF("Connection from %s (%d)", addr_str, client);

	sockfd_tcp[0].fd = client;
	sockfd_tcp[0].events = POLLIN;

	/* Register all the sockets to service handler */
	ret = net_socket_service_register(&service_tcp, sockfd_tcp,
					  ARRAY_SIZE(sockfd_tcp), NULL);
	if (ret < 0) {
		LOG_ERR("Cannot register socket service handler (%d)", ret);
		break;
	}
}
```

For any closed TCP client connection we need to remove the closed socket from the polled socket list.

```
/* If the TCP socket is closed while reading the data in the handler,
 * mark it as non pollable.
 */
if (sockfd_tcp[0].fd == client) {
	sockfd_tcp[0].fd = -1;

	/* Update the handler so that client connection is
	 * not monitored any more.
	 */
	(void)net_socket_service_register(&service_tcp, sockfd_tcp,
					  ARRAY_SIZE(sockfd_tcp), NULL);
	close(client);

	LOG_INF("Connection from %s closed", addr_str);
}
```

Please see a more complete example in the `echo_service` sample source code at samples/net/sockets/echo_service/src/main.c.

DNS Resolve

- *Overview*
- *Sample usage*
- *API Reference*

Overview The DNS resolver implements a basic DNS resolver according to **RFC 1035**. Supported DNS answers are IPv4/IPv6 addresses and CNAME.

If a CNAME is received, the DNS resolver will create another DNS query. The number of additional queries is controlled by the `CONFIG_DNS_RESOLVER_ADDITIONAL_QUERIES` Kconfig variable.

The multicast DNS (mDNS) client resolver support can be enabled by setting `CONFIG_MDNS_RESOLVER` Kconfig option. See **RFC 6762** for more details about mDNS.

The link-local multicast name resolution (LLMNR) client resolver support can be enabled by setting the `CONFIG_LLMNR_RESOLVER` Kconfig variable. See **RFC 4795** for more details about LLMNR.

For more information about DNS configuration variables, see: subsys/net/lib/dns/Kconfig. The DNS resolver API can be found at include/zephyr/net/dns_resolve.h.

DNS-based service discovery queries described in **RFC 6763** can be done by `dns_resolve_service()` API. The returned service descriptions are passed to user supplied callback and the API sets the address family to `AF_LOCAL` to indicate that the value is not an IPv4 or IPv6 address but a service description.

Example:

```
#include <zephyr/net/dns_resolve.h>

#define MAX_STR_LEN CONFIG_DNS_RESOLVER_MAX_NAME_LEN

static void dns_result_cb(enum dns_resolve_status status,
                          struct dns_addrinfo *info,
                          void *user_data)
{
     if (status == DNS_EAI_CANCELED) {
             /* dns: Timeout while resolving name */
             return;
     }

     if (status == DNS_EAI_INPROGRESS && info) {
             char str[MAX_STR_LEN + 1];

             if (info->ai_family == NET_AF_INET) {
                     net_addr_ntop(NET_AF_INET,
                                   &net_sin(&info->ai_addr)->sin_addr,
                                   str, NET_IPV4_ADDR_LEN);
             } else if (info->ai_family == NET_AF_INET6) {
                     net_addr_ntop(NET_AF_INET6,
                                   &net_sin6(&info->ai_addr)->sin6_addr,
                                   str, NET_IPV6_ADDR_LEN);
             } else if (info->ai_family == AF_LOCAL) {
                     /* service discovery */
                     memset(str, 0, MAX_STR_LEN);
                     memcpy(str, info->ai_canonname,
```

(continues on next page)

(continued from previous page)

```
                                MIN(info->ai_addrlen, MAX_STR_LEN));
                } else {
                        strncpy(str, "Invalid proto family", MAX_STR_LEN + 1);
                }

                str[MAX_STR_LEN] = '\0';

                printk("dns: %s\n", str);
                return;
        }

        if (status == DNS_EAI_ALLDONE) {
                printk("dns: All results received\n");
                return;
        }

        if (status == DNS_EAI_FAIL) {
                printk("dns: No such name found.\n");
                return;
        }

        printk("dns: Unhandled status %d received (errno %d)\n", status, errno);
}

#define DNS_TIMEOUT (MSEC_PER_SEC * 5) /* in ms */

static void discover_service(void)
{
        int ret = dns_resolve_service(dns_resolve_get_default(),
                                      "_http._tcp.dns-sd.org",
                                      NULL, dns_result_cb,
                                      NULL, DNS_TIMEOUT);
        ...
}
```

The above query would return output like this:

As the service discovery query could return long strings and the packet size could be large, you might need to adjust following Kconfig options:

- `CONFIG_DNS_RESOLVER_MAX_ANSWER_SIZE`. This tells the maximum size of the answer, typical value for this option could be 1024. The default size for this option is 512 bytes.
- `CONFIG_DNS_RESOLVER_MAX_NAME_LEN`. This tells the maximum length of the returned name. The value depends on your expected data size, typical value might be 128 bytes.

Sample usage See dns-resolve sample application for details.

Network Management

- *Overview*
- *Requesting a defined procedure*
- *Listening to network events*
- *Defining a network management procedure*
- *Signaling a network event*
- *API Reference*

Overview The Network Management APIs allow applications, as well as network layer code itself, to call defined network routines at any level in the IP stack, or receive notifications on relevant network events. For example, by using these APIs, application code can request a scan be done on a Wi-Fi- or Bluetooth-based network interface, or request notification if a network interface IP address changes.

The Network Management API implementation is designed to save memory by eliminating code at build time for management routines that are not used. Distinct and statically defined APIs for network management procedures are not used. Instead, defined procedure handlers are registered by using a `NET_MGMT_REGISTER_REQUEST_HANDLER` macro. Procedure requests are done through a single `net_mgmt()` API that invokes the registered handler for the corresponding request.

The current implementation is experimental and may change and improve in future releases.

Requesting a defined procedure All network management requests are of the form `net_mgmt(mgmt_request, ...)`. The `mgmt_request` parameter is a bit mask that tells which stack layer is targeted, if a `net_if` object is implied, and the specific management procedure being requested. The available procedure requests depend on what has been implemented in the stack.

To avoid extra cost, all `net_mgmt()` calls are direct. Though this may change in a future release, it will not affect the users of this function.

Listening to network events You can receive notifications on network events by registering a callback function and specifying a set of events used to filter when your callback is invoked. The callback will have to be unique for a pair of layer and code, whereas on the command part it will be a mask of events.

At runtime two functions are available, `net_mgmt_add_event_callback()` for registering the callback function, and `net_mgmt_del_event_callback()` for unregistering a callback. A helper function, `net_mgmt_init_event_callback()`, can be used to ease the initialization of the callback structure.

Additionally `NET_MGMT_REGISTER_EVENT_HANDLER` can be used to register a callback handler at compile time.

When an event occurs that matches a callback's event set, the associated callback function is invoked with the actual event code. This makes it possible for different events to be handled by the same callback function, if desired.

Warning

Event set filtering allows false positives for events that have the same layer and layer code. A callback handler function **must** check the event code (passed as an argument) against the specific network events it will handle, **regardless** of how many events were in the set passed to `net_mgmt_init_event_callback()`.

Note that in order to receive events from multiple layers, one must have multiple listeners registered, one for each layer being listened. The callback handler function can be shared between different layer events.

(False positives can occur for events which have the same layer and layer code.)

An example follows.

```
/*
 * Set of events to handle.
 * See e.g. include/zephyr/net/net_event.h for some NET_EVENT_xxx values.
 */
#define EVENT_IFACE_SET (NET_EVENT_IF_xxx | NET_EVENT_IF_yyy)
#define EVENT_IPV4_SET (NET_EVENT_IPV4_xxx | NET_EVENT_IPV4_yyy)

struct net_mgmt_event_callback iface_callback;
struct net_mgmt_event_callback ipv4_callback;

void callback_handler(struct net_mgmt_event_callback *cb,
                      uint64_t mgmt_event,
                      struct net_if *iface)
{
        if (mgmt_event == NET_EVENT_IF_xxx) {
                /* Handle NET_EVENT_IF_xxx */
        } else if (mgmt_event == NET_EVENT_IF_yyy) {
                /* Handle NET_EVENT_IF_yyy */
        } else if (mgmt_event == NET_EVENT_IPV4_xxx) {
                /* Handle NET_EVENT_IPV4_xxx */
        } else if (mgmt_event == NET_EVENT_IPV4_yyy) {
                /* Handle NET_EVENT_IPV4_yyy */
        } else {
                /* Spurious (false positive) invocation. */
        }
}

void register_cb(void)
{
        net_mgmt_init_event_callback(&iface_callback, callback_handler,
                                     EVENT_IFACE_SET);
        net_mgmt_init_event_callback(&ipv4_callback, callback_handler,
                                     EVENT_IPV4_SET);
        net_mgmt_add_event_callback(&iface_callback);
        net_mgmt_add_event_callback(&ipv4_callback);
}
```

Or similarly using `NET_MGMT_REGISTER_EVENT_HANDLER`.

Note

The `info` and `info_length` arguments are only usable if `CONFIG_NET_MGMT_EVENT_INFO` is en-

abled. Otherwise these are NULL and zero.

```
/*
 * Set of events to handle.
 */
#define EVENT_IFACE_SET (NET_EVENT_IF_xxx | NET_EVENT_IF_yyy)
#define EVENT_IPV4_SET (NET_EVENT_IPV4_xxx | NET_EVENT_IPV4_yyy)

static void event_handler(uint64_t mgmt_event, struct net_if *iface,
                          void *info, size_t info_length,
                          void *user_data)
{
        if (mgmt_event == NET_EVENT_IF_xxx) {
                /* Handle NET_EVENT_IF_xxx */
        } else if (mgmt_event == NET_EVENT_IF_yyy) {
                /* Handle NET_EVENT_IF_yyy */
        } else if (mgmt_event == NET_EVENT_IPV4_xxx) {
                /* Handle NET_EVENT_IPV4_xxx */
        } else if (mgmt_event == NET_EVENT_IPV4_yyy) {
                /* Handle NET_EVENT_IPV4_yyy */
        } else {
                /* Spurious (false positive) invocation. */
        }
}

NET_MGMT_REGISTER_EVENT_HANDLER(iface_event_handler, EVENT_IFACE_SET,
                                event_handler, NULL);
NET_MGMT_REGISTER_EVENT_HANDLER(ipv4_event_handler, EVENT_IPV4_SET,
                                event_handler, NULL);
```

See include/zephyr/net/net_event.h for available generic core events that can be listened to.

Defining a network management procedure You can provide additional management procedures specific to your stack implementation by defining a handler and registering it with an associated mgmt_request code.

Management request code are defined in relevant places depending on the targeted layer or eventually, if l2 is the layer, on the technology as well. For instance, all IP layer management request code will be found in the include/zephyr/net/net_event.h header file. But in case of an L2 technology, let's say Ethernet, these would be found in include/zephyr/net/ethernet.h

You define your handler modeled with this signature:

```
static int your_handler(uint64_t mgmt_event, struct net_if *iface,
                        void *data, size_t len);
```

and then register it with an associated mgmt_request code:

```
NET_MGMT_REGISTER_REQUEST_HANDLER(<mgmt_request code>, your_handler);
```

This new management procedure could then be called by using:

```
net_mgmt(<mgmt_request code>, ...);
```

Signaling a network event You can signal a specific network event using the net_mgmt_event_notify() function and provide the network event code. See include/zephyr/net/net_mgmt.h for details. As for the management request code, event

code can be also found on specific L2 technology mgmt headers, for example include/zephyr/net/ieee802154_mgmt.h would be the right place if 802.15.4 L2 is the technology one wants to listen to events.

Network Statistics

- *Overview*
- *API Reference*

Overview Network statistics are collected if `CONFIG_NET_STATISTICS` is set. Individual component statistics for IPv4 or IPv6 can be turned off if those statistics are not needed. See various options in subsys/net/ip/Kconfig.stats file for details.

By default, the system collects network statistics per network interface. This can be controlled by `CONFIG_NET_STATISTICS_PER_INTERFACE` option.

The `CONFIG_NET_STATISTICS_USER_API` option can be set if the application wants to collect statistics for further processing. The network management interface API is used for that. See *Network Management* for details.

The `CONFIG_NET_STATISTICS_ETHERNET` option can be set to collect generic Ethernet statistics. If the `CONFIG_NET_STATISTICS_ETHERNET_VENDOR` option is set, then Ethernet device driver can collect Ethernet device specific statistics. These statistics can then be transferred to application for processing.

If the `CONFIG_NET_SHELL` option is set, then network shell can show statistics information with `net stats` command.

Network Timeout

- *Overview*
- *Use*
- *API Reference*

Overview Zephyr's network infrastructure mostly uses the millisecond-resolution uptime clock to track timeouts, with both deadlines and durations measured with 32-bit unsigned values. The 32-bit value rolls over at 49 days 17 hours 2 minutes 47.296 seconds.

Timeout processing is often affected by latency, so that the time at which the timeout is checked may be some time after it should have expired. Handling this correctly without arbitrary expectations of maximum latency requires that the maximum delay that can be directly represented be a 31-bit non-negative number (`INT32_MAX`), which overflows at 24 days 20 hours 31 minutes 23.648 seconds.

Most network timeouts are shorter than the delay rollover, but a few protocols allow for delays that are represented as unsigned 32-bit values counting seconds, which corresponds to a 42-bit millisecond count.

The net_timeout API provides a generic timeout mechanism to correctly track the remaining time for these extended-duration timeouts.

Use The simplest use of this API is:

1. Configure a network timeout using `net_timeout_set()`.
2. Use `net_timeout_evaluate()` to determine how long it is until the timeout occurs. Schedule a timeout to occur after this delay.
3. When the timeout callback is invoked, use `net_timeout_evaluate()` again to determine whether the timeout has completed, or whether there is additional time remaining. If the latter, reschedule the callback.
4. While the timeout is running, use `net_timeout_remaining()` to get the number of seconds until the timeout expires. This may be used to explicitly update the timeout, which should be done by canceling any pending callback and restarting from step 1 with the new timeout.

The `net_timeout` contains a `sys_snode_t` that allows multiple timeout instances to be aggregated to share a single kernel timer element. The application must use `net_timeout_evaluate()` on all instances to determine the next timeout event to occur.

`net_timeout_deadline()` may be used to reconstruct the full-precision deadline of the timeout. This exists primarily for testing but may have use in some applications, as it does allow a millisecond-resolution calculation of remaining time.

Network long timeout primitives and helpers

Networking Context The net_context API is not meant for application use. Application should use *BSD Sockets* API instead.

Promiscuous Mode

- *Overview*

- *Sample usage*
- *API Reference*

Overview Promiscuous mode is a mode for a network interface controller that causes it to pass all traffic it receives to the application rather than passing only the frames that the controller is specifically programmed to receive. This mode is normally used for packet sniffing as used to diagnose network connectivity issues by showing an application all the data being transferred over the network. (See the Wikipedia article on promiscuous mode for more information.)

The network promiscuous APIs are used to enable and disable this mode, and to wait for and receive a network data to arrive. Not all network technologies or network device drivers support promiscuous mode.

Sample usage First the promiscuous mode needs to be turned ON by the application like this:

```
ret = net_promisc_mode_on(iface);
if (ret < 0) {
        if (ret == -EALREADY) {
                printf("Promiscuous mode already enabled\n");
        } else {
                printf("Cannot enable promiscuous mode for "
                       "interface %p (%d)\n", iface, ret);
        }
}
```

If there is no error, then the application can start to wait for network data:

```
while (true) {
        pkt = net_promisc_mode_wait_data(K_FOREVER);
        if (pkt) {
                print_info(pkt);
        }

        net_pkt_unref(pkt);
}
```

Finally the promiscuous mode can be turned OFF by the application like this:

```
ret = net_promisc_mode_off(iface);
if (ret < 0) {
        if (ret == -EALREADY) {
                printf("Promiscuous mode already disabled\n");
        } else {
                printf("Cannot disable promiscuous mode for "
                       "interface %p (%d)\n", iface, ret);
        }
}
```

See net-promiscuous-mode for a more comprehensive example.

SOCKS5 Proxy Support

- *Overview*
- *SOCKS5 API*
- *SOCKS5 Proxy Usage in MQTT*

Overview The SOCKS library implements SOCKS5 support, which allows Zephyr to connect to peer devices via a network proxy.

See this SOCKS5 Wikipedia article for a detailed overview of how SOCKS5 works.

For more information about the protocol itself, see **RFC 1928**.

SOCKS5 API The SOCKS5 support is enabled by `CONFIG_SOCKS` Kconfig variable. Application wanting to use the SOCKS5 must set the SOCKS5 proxy host address by calling `setsockopt()` like this:

```
static int set_proxy(int sock, const struct sockaddr *proxy_addr,
                     socklen_t proxy_addrlen)
{
    int ret;

    ret = setsockopt(sock, SOL_SOCKET, SO_SOCKS5,
                     proxy_addr, proxy_addrlen);
    if (ret < 0) {
```

(continues on next page)

(continued from previous page)

```
            return -errno;
    }

    return 0;
}
```

SOCKS5 Proxy Usage in MQTT For MQTT client, there is `mqtt_client_set_proxy()` API that the application can call to setup SOCKS5 proxy. See mqtt-publisher sample application for usage example.

Trickle Timer Library

- *Overview*

Trickle Algorithm Library

Websocket Client API

- *Overview*
- *Websocket Transport*
- *API Reference*

Overview The Websocket client library allows Zephyr to connect to a Websocket server. The Websocket client API can be used directly by application to establish a Websocket connection to server, or it can be used as a transport for other network protocols like MQTT.

See this Websocket Wikipedia article for a detailed overview of how Websocket works.

For more information about the protocol itself, see **RFC 6455**.

Websocket Transport The Websocket API allows it to be used as a transport for other high level protocols like MQTT. The Zephyr MQTT client library can be configured to use Websocket transport by enabling `CONFIG_MQTT_LIB_WEBSOCKET` and `CONFIG_WEBSOCKET_CLIENT` Kconfig options.

First a socket needs to be created and connected to the Websocket server:

```
sock = socket(family, SOCK_STREAM, IPPROTO_TCP);
...
ret = connect(sock, addr, addr_len);
...
```

The Websocket transport socket is then created like this:

```
ws_sock = websocket_connect(sock, &config, timeout, user_data);
```

The Websocket socket can then be used to send or receive data, and the Websocket client API will encapsulate the sent or received data to/from Websocket packet payload. Both the `websocket_xxx()` API or normal BSD socket API functions can be used to send and receive application data.

```
ret = websocket_send_msg(ws_sock, buf_to_send, buf_len,
                         WEBSOCKET_OPCODE_DATA_BINARY, true, true,
                         K_FOREVER);
...
ret = send(ws_sock, buf_to_send, buf_len, 0);
```

If normal BSD socket functions are used, then currently only TEXT data is supported. In order to send BINARY data, the `websocket_send_msg()` must be used.

When done, the Websocket transport socket must be closed. User should handle the lifecycle(close/reuse) of tcp socket after websocket_disconnect.

```
ret = close(ws_sock);
or
ret = websocket_disconnect(ws_sock);
```

Network Packet Capture

- *Overview*
- *Cooked Mode Capture*
- *Sample usage*
- *API Reference*

Overview The `net_capture` API allows user to monitor the network traffic in one of the Zephyr network interfaces and send that traffic to external system for analysis. The monitoring can be setup either manually using `net-shell` or automatically by using the `net_capture` API.

Cooked Mode Capture If capturing is enabled and configured, the system will automatically capture network traffic for a given network interface. If you would like to capture network data when there is no network interface involved, then you need to use the cooked mode capture API.

In cooked mode capture, arbitrary network packets can be captured and there does not need to be network interface involved. For example low level HDLC packets in PPP can be captured, as the HDLC L2 layer data is stripped away when using the normal network interface based capture. Also CANBUS or Bluetooth network data could be captured although currently there is no support in the network stack to capture those.

The cooked mode capture works like this:

- An any network interface is created. It acts as a sink where the cooked mode captured packets are written by the cooked mode capture API.
- A cooked virtual network interface is attached on top of this any interface.
- The cooked interface must be configured to capture certain L2 packet types using the network interface configuration API.
- When cooked mode capture API is used, the caller must specify what is the layer 2 protocol type of the captured data. The cooked mode capture API is then able to determine what to capture when receiving such a L2 packet.
- The network packet capturing infrastructure is then setup so that the cooked interface is marked as captured network interface. The packets received by the cooked interface via the any interface are then automatically placed to the capture IP tunnel and sent to remote host for analysis.

For example, in the sample capture application, these network interfaces are created:

```
Interface any (0x808ab3c) (Dummy) [1]
================================
Virtual interfaces attached to this : 2
Device    : NET_ANY (0x80849a4)

Interface cooked (0x808ac94) (Virtual) [2]
==================================
Virtual name : Cooked mode capture
Attached  : 1 (Dummy / 0x808ab3c)
Device    : NET_COOKED (0x808497c)

Interface eth0 (0x808adec) (Ethernet) [3]
==================================
Virtual interfaces attached to this : 4
Device    : zeth0 (0x80849b8)
IPv6 unicast addresses (max 4):
     fe80::5eff:fe00:53e6 autoconf preferred infinite
     2001:db8::1 manual preferred infinite
IPv4 unicast addresses (max 2):
     192.0.2.1/255.255.255.0 overridable preferred infinite

Interface net0 (0x808af44) (Virtual) [4]
================================
Virtual name : Capture tunnel
Attached  : 3 (Ethernet / 0x808adec)
Device    : IP_TUNNEL0 (0x8084990)
IPv6 unicast addresses (max 4):
     2001:db8:200::1 manual preferred infinite
     fe80::efed:6dff:fef2:b1df autoconf preferred infinite
     fe80::56da:1eff:fe5e:bc02 autoconf preferred infinite
```

In this example, the `192.0.2.2` is the address of the outer end point of the host that terminates the tunnel. Zephyr uses this address to select the internal interface to use for the tunnel. In this example it is interface 3.

The interface 2 is a virtual interface that runs on top of interface 1. The cooked capture packets are written by the capture API to sink interface 1. The packets propagate to interface 2 because it is linked to the first interface. The `net capture enable 2` net-shell command will cause the packets sent to interface 2 to be written to capture interface 4, which in turn then capsulates the packets and tunnels them to peer via the Ethernet interface 3.

The above IP addresses might change if you change the addresses in the sample samples/net/capture/overlay-tunnel.conf file.

Sample usage See net-capture sample application and *Monitor Network Traffic* for details.

Network Packet Management

Packet Management

- *Overview*
  - *Architectural notes*
- *Memory management*
  - *Allocation*
  - *Buffer allocation*
  - *Deallocation*
- *Operations*
  - *Read and Write access*
  - *Data access*
- *API Reference*

Overview Network packets are the main data the networking stack manipulates. Such data is represented through the net_pkt structure which provides a means to hold the packet, write and read it, as well as necessary metadata for the core to hold important information. Such an object is called net_pkt in this document.

The data structure and the whole API around it are defined in include/zephyr/net/net_pkt.h.

Architectural notes There are two network packets flows within the stack, **TX** for the transmission path, and **RX** for the reception one. In both paths, each net_pkt is written and read from the beginning to the end, or more specifically from the headers to the payload.

Memory management

Allocation All net_pkt objects come from a pre-defined pool of struct net_pkt. Such pool is defined via

```
NET_PKT_SLAB_DEFINE(name, count)
```

Note, however, one will rarely have to use it, as the core provides already two pools, one for the TX path and one for the RX path.

Allocating a raw net_pkt can be done through:

```
pkt = net_pkt_alloc(timeout);
```

However, by its nature, a raw net_pkt is useless without a buffer and needs various metadata information to become relevant as well. It requires at least to get the network interface it is meant to be sent through or through which it was received. As this is a very common operation, a helper exist:

```
pkt = net_pkt_alloc_on_iface(iface, timeout);
```

A more complete allocator exists, where both the net_pkt and its buffer can be allocated at once:

```
pkt = net_pkt_alloc_with_buffer(iface, size, family, proto, timeout);
```

See below how the buffer is allocated.

Buffer allocation The net_pkt object does not define its own buffer, but instead uses an existing object for this: `net_buf`. (See *Network Buffers* for more information). However, it mostly hides the usage of such a buffer because net_pkt brings network awareness to buffer allocation and, as we will see later, its operation too.

To allocate a buffer, a net_pkt needs to have at least its network interface set. This works if the family of the packet is unknown at the time of buffer allocation. Then one could do:

```
net_pkt_alloc_buffer(pkt, size, proto, timeout);
```

Where proto could be 0 if unknown (there is no IPPROTO_UNSPEC).

As seen previously, the net_pkt and its buffer can be allocated at once via `net_pkt_alloc_with_buffer()`. It is actually the most widely used allocator.

The network interface, the family, and the protocol of the packet are used by the buffer allocation to determine if the requested size can be allocated. Indeed, the allocator will use the network interface to know the MTU and then the family and protocol for the headers space (if only these 2 are specified). If the whole fits within the MTU, the allocated space will be of the requested size plus, eventually, the headers space. If there is insufficient MTU space, the requested size will be shrunk so the possible headers space and new size will fit within the MTU.

For instance, on an Ethernet network interface, with an MTU of 1500 bytes:

```
pkt = net_pkt_alloc_with_buffer(iface, 800, NET_AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 800 + 20 + 8 bytes of buffer for the new net_pkt where:

```
pkt = net_pkt_alloc_with_buffer(iface, 1600, NET_AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 1500 bytes, and where 20 + 8 bytes (IPv4 + UDP headers) will not be used for the payload.

On the receiving side, when the family and protocol are not known:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 800, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 800 bytes and no extra header space. But a:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 1600, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 1514 bytes, the MTU + Ethernet header space.

One can increase the amount of buffer space allocated by calling `net_pkt_alloc_buffer()`, as it will take into account the existing buffer. It will also account for the header space if net_pkt's family is a valid one, as well as the proto parameter. In that case, the newly allocated buffer space will be appended to the existing one, and not inserted in the front. Note however such

a use case is rather limited. Usually, one should know from the start how much size should be requested.

Deallocation Each net_pkt is reference counted. At allocation, the reference is set to 1. The reference count can be incremented with `net_pkt_ref()` or decremented with `net_pkt_unref()`. When the count drops to zero the buffer is also un-referenced and net_pkt is automatically placed back into the free net_pkt_slabs

If net_pkt's buffer is needed even after net_pkt deallocation, one will need to reference once more all the chain of net_buf before calling last net_pkt_unref. See *Network Buffers* for more information.

Operations There are two ways to access the net_pkt buffer, explained in the following sections: basic read/write access and data access, the latter being the preferred way.

Read and Write access As said earlier, though net_pkt uses net_buf for its buffer, it provides its own API to access it. Indeed, a network packet might be scattered over a chain of net_buf objects, the functions provided by net_buf are then limited for such case. Instead, net_pkt provides functions which hide all the complexity of potential non-contiguous access.

Data movement into the buffer is made through a cursor maintained within each net_pkt. All read/write operations affect this cursor. Note as well that read or write functions are strict on their length parameters: if it cannot r/w the given length it will fail. Length is not interpreted as an upper limit, it is instead the exact amount of data that must be read or written.

As there are two paths, TX and RX, there are two access modes: write and overwrite. This might sound a bit unusual, but is in fact simple and provides flexibility.

In write mode, whatever is written in the buffer affects the length of actual data present in the buffer. Buffer length should not be confused with the buffer size which is a limit any mode cannot pass. In overwrite mode then, whatever is written must happen on valid data, and will not affect the buffer length. By default, a newly allocated net_pkt is on write mode, and its cursor points to the beginning of its buffer.

Let's see now, step by step, the functions and how they behave depending on the mode.

When freshly allocated with a buffer of 500 bytes, a net_pkt has 0 length, which means no valid data is in its buffer. One could verify this by:

```
len = net_pkt_get_len(pkt);
```

Now, let's write 8 bytes:

```
net_pkt_write(pkt, data, 8);
```

The buffer length is now 8 bytes. There are various helpers to write a byte, or big endian uint16_t, uint32_t.

```
net_pkt_write_u8(pkt, &foo);
net_pkt_write_be16(pkt, &ba);
net_pkt_write_be32(pkt, &bar);
```

Logically, net_pkt's length is now 15. But if we try to read at this point, it will fail because there is nothing to read at the cursor where we are at in the net_pkt. It is possible, while in write mode, to read what has been already written by resetting the cursor of the net_pkt. For instance:

```
net_pkt_cursor_init(pkt);
net_pkt_read(pkt, data, 15);
```

This will reset the cursor of the pkt to the beginning of the buffer and then let you read the actual 15 bytes present. The cursor is then again pointing at the end of the buffer.

To set a large area with the same byte, a memset function is provided:

```
net_pkt_memset(pkt, 0, 5);
```

Our net_pkt has now a length of 20 bytes.

Switching between modes can be achieved via `net_pkt_set_overwrite()` function. It is possible to switch mode back and forth at any time. The net_pkt will be set to overwrite and its cursor reset:

```
net_pkt_set_overwrite(pkt, true);
net_pkt_cursor_init(pkt);
```

Now the same operators can be used, but it will be limited to the existing data in the buffer, i.e. 20 bytes.

If it is necessary to know how much space is available in the net_pkt call:

```
net_pkt_available_buffer(pkt);
```

Or, if headers space needs to be accounted for, call:

```
net_pkt_available_payload_buffer(pkt, proto);
```

If you want to place the cursor at a known position use the function `net_pkt_skip()`. For example, to go after the IP header, use:

```
net_pkt_cursor_init(pkt);
net_pkt_skip(pkt, net_pkt_ip_header_len(pkt));
```

Data access Though the API shown previously is rather simple, it involves always copying things to and from the net_pkt buffer. In many occasions, it is more relevant to access the information stored in the buffer contiguously, especially with network packets which embed headers.

These headers are, most of the time, a known fixed set of bytes. It is then more natural to have a structure representing a certain type of header. In addition to this, if it is known the header size appears in a contiguous area of the buffer, it will be way more efficient to cast the actual position in the buffer to the type of header. Either for reading or writing the fields of such header, accessing it directly will save memory.

Net pkt comes with a dedicated API for this, built on top of the previously described API. It is able to handle both contiguous and non-contiguous access transparently.

There are two macros used to define a data access descriptor: `NET_PKT_DATA_ACCESS_DEFINE` when it is not possible to tell if the data will be in a contiguous area, and `NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE` when it is guaranteed the data is in a contiguous area.

Let's take the example of IP and UDP. Both IPv4 and IPv6 headers are always found at the beginning of the packet and are small enough to fit in a net_buf of 128 bytes (for instance, though 64 bytes could be chosen).

```
NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE(ipv4_access, struct net_ipv4_hdr);
struct net_ipv4_hdr *ipv4_hdr;

ipv4_hdr = (struct net_ipv4_hdr *)net_pkt_get_data(pkt, &ipv4_access);
```

It would be the same for struct net_ipv4_hdr. For a UDP header it is likely not to be in a contiguous area in IPv6 for instance so:

```
NET_PKT_DATA_ACCESS_DEFINE(udp_access, struct net_udp_hdr);
struct net_udp_hdr *udp_hdr;

udp_hdr = (struct net_udp_hdr *)net_pkt_get_data(pkt, &udp_access);
```

At this point, the cursor of the net_pkt points at the beginning of the requested data. On the RX path, these headers will be read but not modified so to proceed further the cursor needs to advance past the data. There is a function dedicated for this:

```
net_pkt_acknowledge_data(pkt, &ipv4_access);
```

On the TX path, however, the header fields have been modified. In such a case:

```
net_pkt_set_data(pkt, &ipv4_access);
```

If the data are in a contiguous area, it will advance the cursor relevantly. If not, it will write the data and the cursor will be updated. Note that `net_pkt_set_data()` could be used in the RX path as well, but it is slightly faster to use `net_pkt_acknowledge_data()` as this one does not care about contiguity at all, it just advances the cursor via `net_pkt_skip()` directly.

Networking Technologies

Ethernet

- *Overview*
- *API Reference*

MAC Address Configuration Ethernet drivers can delegate most MAC address handling during initialization to `net_eth_mac_config` and `net_eth_mac_load()`. The structure is typically stored in the driver configuration and initialized with `NET_ETH_MAC_DT_CONFIG_INIT` or `NET_ETH_MAC_DT_INST_CONFIG_INIT`, which translate the devicetree properties into one of the following behaviors:

- `NET_ETH_MAC_STATIC` – use the full `local-mac-address` property.
- `NET_ETH_MAC_RANDOM` – generate a random locally administered MAC address, optionally using the bytes provided in `zephyr,mac-address-prefix` as the first octets.
- `NET_ETH_MAC_NVMEM` – read the remaining bytes from the `"mac-address"` *NVMEM* cell, again optionally prefixed by `zephyr,mac-address-prefix`.
- `NET_ETH_MAC_DEFAULT` – fall back to the driver's default logic (for example, a factory-programmed MAC address stored in peripheral registers).

Driver integration Embed the `net_eth_mac_config` structure inside the driver's configuration and a static buffer inside the driver's data:

```
struct my_eth_config {
    struct net_eth_mac_config mac_cfg;
    /* more config fields */
};

struct my_eth_data {
    uint8_t mac_addr[NET_ETH_ADDR_LEN];
    /* more data fields */
};

static const struct my_eth_config my_eth_config_0 = {
    .mac_cfg = NET_ETH_MAC_DT_INST_CONFIG_INIT(0),
};
static struct my_eth_data my_eth_data_0;
```

During initialization, call `net_eth_mac_load()` before registering the address with the network interface. The helper copies any statically provided bytes, fills the remaining octets, and performs the necessary validation. Drivers can still fall back to SoC-specific storage when no configuration was provided:

```
static int my_eth_init(const struct device *dev)
{
    const struct my_eth_config *cfg = dev->config;
    struct my_eth_data *data = dev->data;
    int ret;

    ret = net_eth_mac_load(&cfg->mac_cfg, data->mac_addr);
    if (ret == -ENODATA) {
        ret = my_eth_hw_read_mac(dev, data->mac_addr);
    }

    return ret;
}

static void my_eth_iface_init(struct net_if *iface)
{
    const struct device *dev = net_if_get_device(iface);
    struct my_eth_data *data = dev->data;

    net_if_set_link_addr(iface, data->mac_addr, sizeof(data->mac_addr),␣
↪NET_LINK_ETHERNET);
}
```

Devicetree examples The examples below show how to pick a MAC address configuration for an ethernet controller node such as `&eth0`.

Static MAC address

```
&eth0 {
    local-mac-address = [00 11 22 33 44 55];
};
```

Random MAC address with prefix

```
&eth0 {
    zephyr,mac-address-prefix = [00 04 25];
    zephyr,random-mac-address;
};
```

NVMEM-provided MAC address with prefix

```
&eth0 {
    zephyr,mac-address-prefix = [00 12 34];
    nvmem-cells = <&macaddr_cell>;
    nvmem-cell-names = "mac-address";
};

&eeprom0 {
    nvmem-layout {
        compatible = "fixed-layout";
        #address-cells = <1>;
        #size-cells = <1>;

        macaddr_cell: cell@0 {
            reg = <0x0 0x6>;
            #nvmem-cell-cells = <0>;
        };
    };
};
```

When no MAC-related properties are present, `net_eth_mac_load()` returns `-ENODATA` and the driver is expected to use its existing mechanism (for example, reading the hardware registers or using a build-time constant).

Changing the MAC address at runtime Applications that need to set MAC addresses dynamically (for example to adopt an address obtained from a management interface) need to enable the networking management API with `CONFIG_NET_MGMT` and use `net_mgmt` with `NET_REQUEST_ETHERNET_SET_MAC_ADDRESS`. The request internally calls the driver's `ethernet_api.set_config()` implementation.

```
static int app_set_mac_address(const struct device *dev)
{
    struct net_if *iface = net_if_lookup_by_dev(dev);
    struct ethernet_req_params params = {
        .mac_address = { { 0x02, 0x00, 0x5E, 0x01, 0x02, 0x03 } },
    };

    /* Make sure the iface is down */

    return net_mgmt(NET_REQUEST_ETHERNET_SET_MAC_ADDRESS, iface,
                    &params, sizeof(params));
}
```

Virtual LAN (VLAN) Support

- *Overview*
- *API Reference*

Overview Virtual LAN (VLAN) is a partitioned and isolated computer network at the data link layer (OSI layer 2). For ethernet network this refers to IEEE 802.1Q

In Zephyr, each individual VLAN is modeled as a virtual network interface. This means that there is an ethernet network interface that corresponds to a real physical ethernet port in the system. A virtual network interface is created for each VLAN, and this virtual network interface connects to the real network interface. This is similar to how Linux implements VLANs. The *eth0* is the real network interface and *vlan0* is a virtual network interface that is run on top of *eth0*.

VLAN support must be enabled at compile time by setting option `CONFIG_NET_VLAN` and `CONFIG_NET_VLAN_COUNT` to reflect how many network interfaces there will be in the system. For example, if there is one network interface without VLAN support, and two with VLAN support, the `CONFIG_NET_VLAN_COUNT` option should be set to 3.

Even if VLAN is enabled in a `prj.conf` file, the VLAN needs to be activated at runtime by the application. The VLAN API provides a `net_eth_vlan_enable()` function to do that. The application needs to give the network interface and desired VLAN tag as a parameter to that function. The VLAN tagging for a given network interface can be disabled by a `net_eth_vlan_disable()` function. The application needs to configure the VLAN network interface itself, such as setting the IP address, etc.

See also the VLAN sample application for API usage example. The source code for that sample application can be found at samples/net/ethernet/vlan.

The net-shell module contains *net vlan add* and *net vlan del* commands that can be used to enable or disable VLAN tags for a given network interface.

See the IEEE 802.1Q spec for more information about ethernet VLANs.

IEEE 802.1Qav

Overview Credit-based shaping is an alternative scheduling algorithm used in network schedulers to achieve fairness when sharing a limited network resource. Zephyr has support for configuring a credit-based shaper described in the IEEE 802.1Qav-2009 standard. Zephyr does not implement the actual shaper; it only provides a way to configure the shaper implemented by the Ethernet device driver.

Enabling 802.1Qav To enable 802.1Qav shaper, the Ethernet device driver must declare that it supports credit-based shaping. The Ethernet driver's capability function must return `ETHERNET_QAV` value for this purpose. Typically also priority queues `ETHERNET_PRIORITY_QUEUES` need to be supported.

```
static enum ethernet_hw_caps eth_get_capabilities(const struct device *dev)
{
        ARG_UNUSED(dev);

        return ETHERNET_QAV | ETHERNET_PRIORITY_QUEUES |
               ETHERNET_HW_VLAN | ETHERNET_LINK_10BASE |
               ETHERNET_LINK_100BASE;
}
```

See `sam-e70-xplained` board Ethernet driver drivers/ethernet/eth_sam_gmac.c for an example.

Configuring 802.1Qav The application can configure the credit-based shaper like this:

```
#include <zephyr/net/net_if.h>
#include <zephyr/net/ethernet.h>
#include <zephyr/net/ethernet_mgmt.h>

static void qav_set_status(struct net_if *iface,
                           int queue_id, bool enable)
{
        struct ethernet_req_params params;
        int ret;

        memset(&params, 0, sizeof(params));

        params.qav_param.queue_id = queue_id;
        params.qav_param.enabled = enable;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_STATUS;

        /* Disable or enable Qav for a queue */
        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot %s Qav for queue %d for interface %p",
                        enable ? "enable" : "disable",
                        queue_id, iface);
        }
}

static void qav_set_bandwidth_and_slope(struct net_if *iface,
                                        int queue_id,
                                        unsigned int bandwidth,
```

(continues on next page)

(continued from previous page)

```
                                        unsigned int idle_slope)
{
        struct ethernet_req_params params;
        int ret;

        memset(&params, 0, sizeof(params));

        params.qav_param.queue_id = queue_id;
        params.qav_param.delta_bandwidth = bandwidth;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_DELTA_BANDWIDTH;

        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot set Qav delta bandwidth %u for "
                        "queue %d for interface %p",
                        bandwidth, queue_id, iface);
        }

        params.qav_param.idle_slope = idle_slope;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_IDLE_SLOPE;

        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot set Qav idle slope %u for "
                        "queue %d for interface %p",
                        idle_slope, queue_id, iface);
        }
}
```

Overview Ethernet is a networking technology commonly used in local area networks (LAN). For more information, see this Ethernet Wikipedia article.

Zephyr supports following Ethernet features:

- 10, 100 and 1000 Mbit/sec links
- Auto negotiation
- Half/full duplex
- Promiscuous mode
- TX and RX checksum offloading
- MAC address filtering
- *MAC address configuration*
- *Virtual LANs*
- *Priority queues*
- *IEEE 802.1AS (gPTP)*
- *IEEE 802.1Qav (credit based shaping)*
- *LLDP (Link Layer Discovery Protocol)*

Not all Ethernet device drivers support all of these features. You can see what is supported by `net iface` net-shell command. It will print currently supported Ethernet features.

IEEE 802.15.4

- *Introduction*
- *API Reference*
  - *IEEE 802.15.4 API Overview*
  - *IEEE 802.15.4 Management API*
  - *IEEE 802.15.4 Driver API*
  - *IEEE 802.15.4 L2 / Native Stack API*
  - *OpenThread L2 Adaptation Layer API*

Introduction IEEE 802.15.4 is a technical standard which defines the operation of low-rate wireless personal area networks (LR-WPANs). For a more detailed overview of this standard, see the IEEE 802.15.4 Wikipedia article.

The most recent version of the standard is accessible through the IEEE GET Program. You need to create a free IEEE account and can then downloading it.

We're currently following the IEEE 802.15.4-2020 specification. This version is backwards compatible with IEEE 802.15.4-2015, parts of which are contained in the Thread protocol stack. The 2020 version also includes prior extensions that were accepted into the standard, namely IEEE 802.15.4g (SUN FSK) and IEEE 802.15.4e (TSCH) which are of relevance to industrial IoT and automation. For recent developments in UWB ranging technology, see IEEE 802.15.4z which is not yet integrated into the standard's mainline.

Whenever sections from the standard are cited in the documentation, they refer to IEEE 802.15.4-2020 section, table and figure numbering - unless otherwise specified.

Zephyr supports both, native IEEE 802.15.4 and Thread, with 6LoWPAN. Zephyr's *Thread protocol* implementation is based on OpenThread. The IPv6 header compression in 6LoWPAN is used for native IEEE 802.15.4.

API Reference

IEEE 802.15.4 API Overview Gives an introduction and overview over the whole IEEE 802.15.4 subsystem and all of its APIs, configuration and user interfaces for all audiences.

IEEE 802.15.4 Management API This is the main subsystem-specific API of interest to IEEE 802.15.4 **application developers** as it allows to configure the IEEE 802.15.4 subsystem at runtime. Other relevant interfaces for application developers are the typical shell, socket, Kconfig and devicetree APIs that can be accessed through Zephyr's generic subsystem-independent documentation. Look out for IEEE802154/ieee802154 prefixes there.

IEEE 802.15.4 Net Management

IEEE 802.15.4 Driver API This is the main API of interest to IEEE 802.15.4 **driver developers**.

IEEE 802.15.4 Drivers

IEEE 802.15.4 L2 / Native Stack API This documents the IEEE 802.15.4 L2 native stack, which neither applications nor drivers will ever access directly. It is called internally by Zephyr's upper network layers (L3+), its socket and network context abstractions. This API is therefore of interest to IEEE 802.15.4 **subsystem contributors** only.

IEEE 802.15.4 L2

OpenThread L2 Adaptation Layer API Zephyr's OpenThread L2 platform adaptation layer glues the external OpenThread stack together with Zephyr's IEEE 802.15.4 protocol agnostic driver API. This API is of interest to OpenThread L2 **subsystem contributors** only.

The OpenThread API is part of the *Thread protocol* subsystem and documented there.

Thread protocol

- *Overview*
- *Internet connectivity*
- *Sample usage*
- *Thread related APIs*
  - *OpenThread Driver API*
  - *OpenThread L2 Adaptation Layer API*
  - *OpenThread Platform API*

Overview Thread is a low-power mesh networking technology, designed specifically for home automation applications. It is an IPv6-based standard, which uses 6LoWPAN technology over IEEE 802.15.4 protocol. IP connectivity lets you easily connect a Thread mesh network to the internet with a Thread Border Router.

The Thread specification provides a high level of network security. Mesh networks built with Thread are secure - only authenticated devices can join the network and all communications

within the mesh are encrypted. More information about Thread protocol can be found at Thread Group website.

Zephyr integrates an open source Thread protocol implementation called OpenThread, documented on the OpenThread website.

Internet connectivity A Thread Border Router is required to connect mesh network to the internet. An open source implementation of Thread Border Router is provided by the OpenThread community. See OpenThread Border Router guide for instructions on how to set up a Border Router.

Sample usage You can try using OpenThread with the Zephyr Echo server and Echo client samples, which provide out-of-the-box configuration for OpenThread. To enable OpenThread support in these samples, build them with `overlay-ot.conf` overlay config file. See sockets-echo-server and sockets-echo-client samples for details.

Zephyr also provides an openthread-shell, which is useful for testing and debugging Thread and its underlying IEEE 802.15.4 drivers.

Thread related APIs

OpenThread Driver API OpenThread L2 uses Zephyr's protocol agnostic IEEE 802.15.4 driver API internally. This API is of interest to **driver developers** that want to support OpenThread.

The driver API is part of the *IEEE 802.15.4 Driver API* subsystem and documented there.

OpenThread L2 Adaptation Layer API Zephyr's OpenThread L2 platform adaptation layer glues the external OpenThread stack together with Zephyr's IEEE 802.15.4 protocol agnostic driver API. This API is of interest to OpenThread L2 **subsystem contributors** only.

OpenThread Platform API The OpenThread platform API is defined by the OpenThread stack and implemented in Zephyr as an OpenThread module. Applications can use this implementation directly, or access it through the OpenThread L2 adaptation layer.

Using the OpenThread L2 Adaptation Layer API To use the OpenThread platform API via the OpenThread L2 adaptation layer, enable both the `CONFIG_NET_L2_OPENTHREAD` and `CONFIG_NETWORKING` Kconfig options by setting them to `y`. The adaptation layer will use the OpenThread radio API implementation found in `modules/openthread/platform/radio.c`. In this setup, the OpenThread stack is initialized and managed by the adaptation layer.

Using the OpenThread Platform API Directly You can also use the OpenThread platform API directly, bypassing the OpenThread L2 adaptation layer. However, this approach requires you to provide your own implementation of the OpenThread radio API that is compatible with your specific radio driver.

To use the OpenThread platform API directly, set the `CONFIG_OPENTHREAD` Kconfig option to `y`, and do **not** set `CONFIG_NET_L2_OPENTHREAD`. In this case, you must implement the following functions from the OpenThread radio API using your own radio driver:

- `otPlatRadioGetPromiscuous`
- `otPlatRadioGetCcaEnergyDetectThreshold`
- `otPlatRadioGetTransmitPower`
- `otPlatRadioGetIeeeEui64`
- `otPlatRadioSetPromiscuous`
- `otPlatRadioGetCaps`

- otPlatRadioGetTransmitBuffer
- otPlatRadioSetPanId
- otPlatRadioEnable
- otPlatRadioDisable
- otPlatRadioReceive
- otPlatRadioGetRssi
- otPlatRadioGetReceiveSensitivity
- otPlatRadioEnergyScan
- otPlatRadioSetExtendedAddress
- otPlatRadioSetShortAddress
- otPlatRadioAddSrcMatchExtEntry
- otPlatRadioTransmit
- otPlatRadioClearSrcMatchShortEntries
- otPlatRadioClearSrcMatchExtEntries
- otPlatRadioEnableSrcMatch
- otPlatRadioAddSrcMatchShortEntry
- otPlatRadioClearSrcMatchShortEntry
- otPlatRadioClearSrcMatchExtEntry

Additionally, you must implement the following functions from the OpenThread radio API (see include/zephyr/net/openthread.h) to handle radio initialization and event processing:

- platformRadioInit()
- platformRadioProcess()

To initialize the OpenThread stack in this approach, either call the ot_platform_init() function in your application, or enable the CONFIG_OPENTHREAD_SYS_INIT Kconfig option to automatically initialize OpenThread during system startup. You can set the initialization priority using the CONFIG_OPENTHREAD_SYS_INIT_PRIORITY Kconfig option.

Point-to-Point Protocol (PPP) Support

- *Overview*
- *Testing*

Overview Point-to-Point Protocol (PPP) is a data link layer (layer 2) communications protocol used to establish a direct connection between two nodes. PPP is used over many types of serial links since IP packets cannot be transmitted over a modem line on their own, without some data link protocol.

In Zephyr, each individual PPP link is modelled as a network interface. This is similar to how Linux implements PPP.

PPP support must be enabled at compile time by setting option `CONFIG_NET_L2_PPP`. The PPP implementation supports only these protocols:

- LCP (Link Control Protocol, **RFC 1661**)
- HDLC (High-level data link control, **RFC 1662**)
- IPCP (IP Control Protocol, **RFC 1332**)
- IPV6CP (IPv6 Control Protocol, **RFC 5072**)

For using PPP with a cellular modem, see cellular-modem sample for additional information.

Testing See the net-tools README file for more details on how to test the Zephyr PPP against pppd running in Linux.

Wi-Fi Management

Overview The Wi-Fi management API is used to manage Wi-Fi networks. It supports below modes:

- IEEE802.11 Station (STA)
- IEEE802.11 Access Point (AP)
- IEEE802.11 P2P (Wi-Fi Direct)

Only personal mode security is supported with below types:

- Open
- WEP
- WPA2-PSK
- WPA2-PSK-256
- WPA3-SAE

The Wi-Fi management API is implemented in the `wifi_mgmt` module as a part of the networking L2 stack. Currently, two types of Wi-Fi drivers are supported:

- Networking or socket offloaded drivers
- Native L2 Ethernet drivers

Compiled Features To support applications that only require a certain subset of Wi-Fi features, `CONFIG_WIFI_USAGE_MODE` can be used as a hint for drivers to limit the functionality that needs to be compiled in. The following usage hints are available:

- `CONFIG_WIFI_USAGE_MODE_STA` (Connecting to an access point)
- `CONFIG_WIFI_USAGE_MODE_AP` (Being an access point)
- `CONFIG_WIFI_USAGE_MODE_STA_AP` (Both being and connecting to an access point)
- `CONFIG_WIFI_USAGE_MODE_SCAN_ONLY` (Access point SSID scanning only)

Note

Support for a requested usage mode is hardware dependent.

Wi-Fi PSA crypto supported build To enable PSA crypto API supported Wi-Fi build, the `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ALT` and the `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` need to be set.

Wi-Fi feature to crypto mapping For a mapping of Wi-Fi features (WPA3-SAE, DPP, SAE-PK, WPA2-PSK, Enterprise EAP, etc.) to crypto primitives (bignum, ECDH, TLS, hashes, AES) and which use **Legacy crypto** vs **PSA crypto**, see the dedicated sub-page:

Wi-Fi feature to crypto mapping This page maps Wi-Fi features supported in Zephyr (via the hostap-based wpa_supplicant) to the underlying MbedTLS crypto primitives. Use it to see which features need bignum, ECDH, TLS, etc., and which code paths use **Legacy crypto** (MbedTLS legacy APIs) vs **PSA crypto** (Platform Security Architecture APIs) when `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` is enabled.

The implementation lives in the hostap module: `crypto_mbedtls_alt.c` (generic crypto) and `tls_mbedtls_alt.c` (TLS/EAP). Only the MbedTLS backend is considered here.

Feature set (from hostap Kconfig) Features are gated by Kconfig. Relevant options include:

- `CONFIG_WIFI_NM_WPA_SUPPLICANT_WEP` — WEP (legacy)
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_WPA3` — WPA3-SAE (default on)
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_DPP` — Wi-Fi Easy Connect (DPP)
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_WPS` — Wi-Fi Protected Setup
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_P2P` — P2P / Wi-Fi Direct (implies WPS)
- `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE` — EAP (EAP-TLS, EAP-TTLS-MSCHAPV2, EAP-PEAP-MSCHAPV2, EAP-PEAP-GTC, EAP-PEAP-TLS)

WPA2-PSK and WPA2-PSK-256 are available whenever crypto is not set to `CRYPTO_NONE`.

Feature crypto primitives (MbedTLS)

Table 30: Wi-Fi feature to crypto mapping

Feature	Crypto primitives	Legacy crypto	PSA crypto
WPA3-SAE	• Bignum (mpi), modulo, exponentiation • EC group • HMAC-SHA256 • AES (CCMP). SAE uses Dragonfly (PWE) with bignum + modulo.	• Bignum (mbedtls_mpi) • EC • HMAC, AES (unless PSA build)	• Hashes, HMAC, AES when PSA enabled • Bignum/EC still legacy
SAE-PK	Same as WPA3-SAE plus ECDH and EC key operations (certificate-based SAE).	ECDH/EC key ops (legacy MbedTLS or PSA ECDH depending on config).	• ECDH can use PSA • Bignum/SAE core remain legacy
DPP (Easy Connect)	• ECDH (P-256, P-384, P-521) • EC key gen/sign/verify • Hashes, AES. DPP2 adds PKCS#7; DPP3 adds HPKE.	• ECDH, EC, RSA (if used) • X.509/CSR in TLS/crypto layer	• Hashes, HMAC, AES via PSA • ECDH/EC may use PSA • TLS/CSR/PKCS#7/HPKE layer legacy
WPA2-PSK / WPA2-PSK-256	• PBKDF2-SHA1 (or SHA256 for -256) • HMAC • AES (CCMP) • OMAC1-AES (key wrap)	All via mbedtls (PBKDF2, HMAC, AES, CMAC) if PSA disabled.	PBKDF2, HMAC, AES, OMAC1 implemented via PSA when PSA enabled.
WEP	• RC4/ARC4 (stream cipher) • Optionally AES for some wrappers. Deprecated.	Legacy MbedTLS only (no PSA path for WEP in current code).	N/A (WEP not migrated to PSA).
WPS	• DH (finite-field) • Bignum • Hashes, HMAC, AES, TLS-PRF. Registrar uses TLS.	• DH (mbedtls_dhm), bignum (mbedtls_mpi) • TLS in tls_mbedtls_alt	• Hashes, HMAC, AES, PBKDF2 via PSA • DH/bignum and TLS legacy
EAP-TLS / EAP-TTLS / EAP-PEAP	• TLS 1.2 (and optionally 1.3) • RSA • X.509 parse/verify • Hashes, HMAC, AES (cipher suites)	• Full TLS stack (mbedtls_ssl_*, mbedtls_x509_*) • RSA • No PSA in tls_mbedtls_alt	• TLS layer remains legacy • Underlying hashes/HMAC/AES can use PSA in crypto_mbedtls_alt

Note

WEP must be explicitly enabled with `CONFIG_WIFI_NM_WPA_SUPPLICANT_WEP`. It is deprecated and insecure; use only for legacy networks.

Summary: Legacy vs PSA (MbedTLS backend) When `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` is enabled, the implementation in `crypto_mbedtls_alt.c` (and `supp_psa_api.h` / `supp_psa_api.c`) splits as below. Use this table to see which operations use **PSA** vs **Legacy** MbedTLS.

Table 31: Legacy vs PSA by crypto operation

Operation	API	Used by / notes
Message digests (MD5, SHA1, SHA256, SHA384, SHA512)	PSA	
HMAC (all above hash types)	PSA	
PBKDF2-SHA1	PSA	WPA2-PSK key derivation
AES (block, CBC, CTR, OMAC1-AES)	PSA	Key wrap, CCMP, etc.
Bignum (crypto_bignum_*)	Legacy	SAE, EAP-PWD, EAP-EKE, EAP-IKEV2, WPS; no PSA bignum in hostap
ECDH / EC key operations	Legacy	DPP, SAE-PK, EAP-PWD (EC). May be PSA-backed when `MBEDTLS_ECDH_C` / `CONFIG_PSA_WANT_ALG_ECDH`; wrapper layer common
TLS/SSL	Legacy	EAP-TLS, EAP-TTLS, EAP-PEAP; full stack in `tls_mbedtls_alt.c`
RSA	Legacy	TLS, X.509
X.509 / CSR	Legacy	Parse and generation
WEP	Legacy	No PSA path

So: **WPA2-PSK and WPA2-PSK-256** use only PSA for their crypto; **WPA3-SAE**, **DPP**, **SAE-PK**, **WPS**, and **Enterprise EAP** still rely on legacy bignum, EC, or TLS. See the feature table above for per-feature impact.

Wi-Fi Enterprise test: X.509 Certificate management Wi-Fi enterprise security requires use of X.509 certificates, two methods of installing certificates are supported:

Compile time certificates Test certificates in PEM format are committed to the repo at samples/net/wifi/test_certs and the during the build process the certificates are converted to a C header file that is included by the Wi-Fi shell module.

If you want to use your own certificates, you can replace the existing certificates with your own certificates in the same directory.

```
$ export WIFI_TEST_CERTS_DIR=samples/net/wifi/test_certs/rsa3k
$ cp client.pem $WIFI_TEST_CERTS_DIR
$ cp client-key.pem $WIFI_TEST_CERTS_DIR
$ cp ca.pem $WIFI_TEST_CERTS_DIR
$ cp client2.pem $WIFI_TEST_CERTS_DIR
$ cp client-key2.pem $WIFI_TEST_CERTS_DIR
$ cp ca2.pem $WIFI_TEST_CERTS_DIR
$ west build -p -b <board> samples/net/wifi -S wifi-enterprise
```

or alternatively copy `rsa2k` certificates by changing the `WIFI_TEST_CERTS_DIR` environment variable.

```
$ export WIFI_TEST_CERTS_DIR=samples/net/wifi/test_certs/rsa2k
```

or you can set the `WIFI_TEST_CERTS_DIR` environment variable to point to the directory containing your certificates.

```
$ west build -p -b <board> samples/net/wifi -S wifi-enterprise -- -
↪DWIFI_TEST_CERTS_DIR=<path_to_your_certificates>
```

Run time certificates The Wi-Fi shell module uses TLS credentials subsystem to store and manage the certificates. The certificates can be added at runtime using the shell commands, see *TLS Credentials Shell* for more details. The sample or application need to enable the `CONFIG_WIFI_SHELL_RUNTIME_CERTIFICATES` option to use this feature.

To facilitate installation of the certificates, a helper script is provided, see below for usage.

```
$ ./scripts/utils/wifi_ent_cert_installer.py -p samples/net/wifi/test_certs/rsa2k
```

The script will install the certificates in the `rsa2k` directory to the TLS credentials store in the device over UART and using TLS credentials shell commands.

To initiate a Wi-Fi connection using enterprise security, use one of the following commands depending on the EAP method:

- EAP-TLS

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 7 -w 2 -a <Anonymous identity>␣
↪--key1-pwd <Password EAP phase1> --key2-pwd <Password EAP phase2>
```

- EAP-TTLS-MSCHAPV2

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 14 -K <Private key Password> --
↪eap-id1 <Client Identity> --eap-pwd1 <Client Password> -a <Anonymous␣
↪identity>
```

- EAP-PEAP-MSCHAPV2

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> --
↪eap-id1 <Client Identity> --eap-pwd1 <Client Password> -a <Anonymous␣
↪identity>
```

Server certificate is also provided in the same directory for testing purposes. Any AAA server can be used for testing purposes, for example, `FreeRADIUS` or `hostapd`.

Server certificate domain name verification The authentication server's identity is verified by validating the domain name in the X.509 certificate received from the server, using the `Common Name` (CN) field.

- Exact domain match — Verifies that the certificate's CN exactly matches the specified domain.
- Domain suffix match — Allows a certificate whose CN ends with the specified domain suffix.

To initiate a Wi-Fi connection using enterprise security with server certificate validation, use one of the following commands, depending on the desired validation mode:

- Exact domain match

```
wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> -e
↪<Domain match>
```

- Domain suffix match

```
wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> -x
↪<Domain suffix name>
```

Certificate requirements for EAP methods Different EAP methods have varying client-side certificate requirements, as outlined below:

- **EAP-TLS - Requires both a client certificate (and its private key) and a CA certificate on the client.**
  The client authenticates itself to the server using its certificate.
- **EAP-TTLS-MSCHAPV2 - Requires only the CA certificate on the client.**
  The client authenticates to the server using a username and password <MSCHAPV2> inside the TLS tunnel. No client certificate is needed.
- **EAP-PEAP-MSCHAPV2 - Requires only the CA certificate on the client.**
  Like TTLS, the client uses a username and password <MSCHAPV2> inside the TLS tunnel and does not require a client certificate.

Note

The certificates are for testing purposes only and should not be used in production. They are generated using FreeRADIUS raddb scripts.

Note

When using TLS credentials subsystem, by default the volatile backend i.e., `CONFIG_TLS_CREDENTIALS_BACKEND_VOLATILE` is chosen. When using the volatile backend, the certificates are stored in RAM and are lost on reboot, so the certificates need to be installed again after reboot. As an alternative, the PS (protected storage) backend i.e., `CONFIG_TLS_CREDENTIALS_BACKEND_PROTECTED_STORAGE` can be used to store the certificates in the non-volatile storage.

How to Generate Test Certificates Using FreeRADIUS The test certificates in `samples/net/wifi/test_certs/rsa2k` are generated using the FreeRADIUS raddb/certs scripts. You can generate your own certificates for testing as follows:

1. **Prerequisites** - Install OpenSSL and GNU Make. - Download the FreeRADIUS raddb/certs directory.
2. **Edit the Makefile** In the `raddb/certs` directory, edit the `Makefile` to add `-nodes` to the OpenSSL commands for server and client keys. This ensures the private keys are not password-protected (Zephyr Wi-Fi shell does not support private key passwords):

   ```
   $(OPENSSL) req -new -out server.csr -keyout server.key -nodes -config ./
   ↪server.cnf
   $(OPENSSL) req -new -out client.csr -keyout client.key -nodes -config ./
   ↪client.cnf
   ```

3. **(Optional) Edit the .cnf files** Customize `server.cnf` and `client.cnf` as needed for your environment.
4. **Generate Certificates** Run the following commands in the `raddb/certs` directory:

   ```
   make destroycerts
   make server
   make client
   ```

5. **Rename Files for Zephyr** Match the filenames used in Zephyr samples:

FreeRADIUS Output	Zephyr Sample Name
ca.pem server.key server.pem client.key client.pem	ca.pem server-key.pem server.pem client-key.pem client.pem

6. **Copy the files** Place the renamed files in your Zephyr project's certificate directory (e.g., `samples/net/wifi/test_certs/rsa2k`).

Note

These certificates are for testing only and should not be used in production.

Wi-Fi P2P (Wi-Fi Direct) Wi-Fi P2P or Wi-Fi Direct enables devices to communicate directly with each other without requiring a traditional access point. This feature is particularly useful for device-to-device communication scenarios.

To enable and build with Wi-Fi P2P support:

```
$ west build -p -b <board> samples/net/wifi/shell -- -
↪DCONFIG_WIFI_NM_WPA_SUPPLICANT_P2P=y
```

Wi-Fi credentials Library

- *Overview*
- *Configuration*
- *Adding credentials*
- *Querying credentials*
- *Removing credentials*
- *Shell commands*
- *Limitations*
- *API documentation*

The Wi-Fi credentials library provides means to load and store Wi-Fi® network credentials.

Overview This library uses either Zephyr's settings subsystem or Platform Security Architecture (PSA) Internal Trusted Storage (ITS) to store credentials. It also holds a list of SSIDs in RAM to provide dictionary-like access using SSIDs as keys.

Configuration To use the Wi-Fi credentials library, enable the `CONFIG_WIFI_CREDENTIALS` Kconfig option.

You can pick the backend using the following options:

- `CONFIG_WIFI_CREDENTIALS_BACKEND_PSA` - Default option for non-secure targets, which includes a TF-M partition (non-minimal TF-M profile type).
- `CONFIG_WIFI_CREDENTIALS_BACKEND_SETTINGS` - Default option for secure targets.

To configure the maximum number of networks, use the `CONFIG_WIFI_CREDENTIALS_MAX_ENTRIES` Kconfig option.

The IEEE 802.11 standard does not specify the maximum length of SAE passwords. To change the default, use the `CONFIG_WIFI_CREDENTIALS_SAE_PASSWORD_LENGTH` Kconfig option.

Adding credentials You can add credentials using the `wifi_credentials_set_personal()` and `wifi_credentials_set_personal_struct()` functions. The former will build the internally used struct from given fields, while the latter takes the struct directly. If you add credentials with the same SSID twice, the older entry will be overwritten.

Querying credentials With an SSID, you can query credentials using the `wifi_credentials_get_by_ssid_personal()` and `wifi_credentials_get_by_ssid_personal_struct()` functions.

You can iterate over all stored credentials with the `wifi_credentials_for_each_ssid()` function. Deleting or overwriting credentials while iterating is allowed, since these operations do not change internal indices.

Removing credentials You can remove credentials using the `wifi_credentials_delete_by_ssid()` function.

Shell commands `wifi cred` is an extension to the Wi-Fi command line. It adds the following subcommands to interact with the Wi-Fi credentials library:

Table 32: Wi-Fi credentials shell subcommands

Subcommands	Description
add	Add a network to the credentials storage with following parameters: <-s –ssid "<SSID>">: SSID. [-c –channel]: Channel that needs to be scanned for connection. 0:any channel [-b, –band] 0: any band (2:2.4GHz, 5:5GHz, 6:6GHz) [-p, –passphrase]: Passphrase (valid only for secure SSIDs) [-k, –key-mgmt]: Key management type. 0:None, 1:WPA2-PSK, 2:WPA2-PSK-256, 3:SAE-HNP, 4:SAE-H2E, 5:SAE-AUTO, 6:WAPI," " 7:EAP-TLS, 8:WEP, 9: WPA-PSK, 10: WPA-Auto-Personal, 11: DPP [-w, –ieee-80211w]: MFP (optional: needs security type to be specified) : 0:Disable, 1:Optional, 2:Required. [-m, –bssid]: MAC address of the AP (BSSID). [-t, –timeout]: Duration after which connection attempt needs to fail. [-a, –identity]: Identity for enterprise mode. [-K, –key-passwd]: Private key passwd for enterprise mode. [-h, –help]: Print out the help for the connect command.
delete <SSID>	Removes network from credentials storage.
list	Lists networks in credential storage.
auto_connect	Automatically connects to any stored network.

Limitations The library has the following limitations:

- Although permitted by the IEEE 802.11 standard, this library does not support zero-length SSIDs.
- Wi-Fi Protected Access (WPA) Enterprise credentials are only partially supported.
- The number of networks stored is fixed compile time.

API documentation The following section provides an overview and reference for the Wi-Fi credentials API available in Zephyr:

Wi-Fi credentials library

Protocols

CoAP

- *Overview*
- *Sample Usage*
  - *CoAP Server*
  - *CoAP Client*
- *Testing*
  - *libcoap*

- *TTCN3*
- *API Reference*

Overview The Constrained Application Protocol (CoAP) is a specialized web transfer protocol for use with constrained nodes and constrained (e.g., low-power, lossy) networks. It provides a convenient API for RESTful Web services that support CoAP's features. For more information about the protocol itself, see **RFC 7252**.

Zephyr provides a CoAP library which supports client and server roles. The library can be enabled with `CONFIG_COAP` Kconfig option and is configurable as per user needs. The Zephyr CoAP library is implemented using plain buffers. Users of the API create sockets for communication and pass the buffer to the library for parsing and other purposes. The library itself doesn't create any sockets for users.

On top of CoAP, Zephyr has support for LWM2M "Lightweight Machine 2 Machine" protocol, a simple, low-cost remote management and service enablement mechanism. See *Lightweight M2M (LWM2M)* for more information.

Supported RFCs:

- **RFC 7252** - The Constrained Application Protocol (CoAP)
- **RFC 6690** - Constrained RESTful Environments (CoRE) Link Format
- **RFC 7959** - Block-Wise Transfers in the Constrained Application Protocol (CoAP)
- **RFC 7641** - Observing Resources in the Constrained Application Protocol (CoAP)

Note

Not all parts of these RFCs are supported. Features are supported based on Zephyr requirements.

Sample Usage

Note

A *CoAP server* subsystem is available, the following is for creating a custom server implementation.

CoAP Server To create a CoAP server, resources for the server need to be defined. The `.well-known/core` resource should be added before all other resources that should be included in the responses of the `.well-known/core` resource.

```
static struct coap_resource resources[] = {
    { .get = well_known_core_get,
      .path = COAP_WELL_KNOWN_CORE_PATH,
    },
    { .get  = sample_get,
      .post = sample_post,
      .del  = sample_del,
      .put  = sample_put,
      .path = sample_path
    },
```

(continues on next page)

(continued from previous page)

```
    { },
};
```

An application reads data from the socket and passes the buffer to the CoAP library to parse the message. If the CoAP message is proper, the library uses the buffer along with resources defined above to call the correct callback function to handle the CoAP request from the client. It's the callback function's responsibility to either reply or act according to CoAP request.

```
coap_packet_parse(&request, data, data_len, options, opt_num);
...
coap_handle_request(&request, resources, options, opt_num,
                    client_addr, client_addr_len);
```

If `CONFIG_COAP_URI_WILDCARD` enabled, server may accept multiple resources using MQTT-like wildcard style:

- the plus symbol represents a single-level wild card in the path;
- the hash symbol represents the multi-level wild card in the path.

```
static const char * const led_set[] = { "led","+","set", NULL };
static const char * const btn_get[] = { "button","#", NULL };
static const char * const no_wc[] = { "test","+1", NULL };
```

It accepts /led/0/set, led/1234/set, led/any/set, /button/door/1, /test/+1, but returns -ENOENT for /led/1, /test/21, /test/1.

This option is enabled by default, disable it to avoid unexpected behaviour with resource path like '/some_resource/+/#'.

Note

A *CoAP client* subsystem is available, the following is for creating a custom client implementation.

CoAP Client If the CoAP client knows about resources in the CoAP server, the client can start prepare CoAP requests and wait for responses. If the client doesn't know about resources in the CoAP server, it can request resources through the `.well-known/core` CoAP message.

```
/* Initialize the CoAP message */
char *path = "test";
struct coap_packet request;
uint8_t data[100];
uint8_t payload[20];

coap_packet_init(&request, data, sizeof(data),
                 1, COAP_TYPE_CON, 8, coap_next_token(),
                 COAP_METHOD_GET, coap_next_id());

/* Append options */
coap_packet_append_option(&request, COAP_OPTION_URI_PATH,
                          path, strlen(path));

/* Append Payload marker if you are going to add payload */
coap_packet_append_payload_marker(&request);
```

(continues on next page)

(continued from previous page)

```
/* Append payload */
coap_packet_append_payload(&request, (uint8_t *)payload,
                           sizeof(payload) - 1);

/* send over sockets */
```

Testing There are various ways to test Zephyr CoAP library.

libcoap libcoap implements a lightweight application-protocol for devices that are resource constrained, such as by computing power, RF range, memory, bandwidth, or network packet sizes. Sources can be found here libcoap. libcoap has a script (`examples/etsi_coaptest.sh`) to test coap-server functionality in Zephyr.

See the net-tools project for more details

The coap-server sample can be built and executed on QEMU as described in *Networking with QEMU*.

Use this command on the host to run the libcoap implementation of the ETSI test cases:

```
sudo ./libcoap/examples/etsi_coaptest.sh -i tap0 2001:db8::1
```

TTCN3 Eclipse has TTCN3 based tests to run against CoAP implementations.

Install eclipse-titan and set symbolic links for titan tools

```
sudo apt-get install eclipse-titan

cd /usr/share/titan

sudo ln -s /usr/bin bin
sudo ln /usr/bin/titanver bin
sudo ln -s /usr/bin/mctr_cli bin
sudo ln -s /usr/include/titan include
sudo ln -s /usr/lib/titan lib

export TTCN3_DIR=/usr/share/titan

git clone https://gitlab.eclipse.org/eclipse/titan/titan.misc.git

cd titan.misc
```

Follow the instruction to setup CoAP test suite from here:

- https://gitlab.eclipse.org/eclipse/titan/titan.misc
- https://gitlab.eclipse.org/eclipse/titan/titan.misc/-/tree/master/CoAP_Conf

After the build is complete, the coap-server sample can be built and executed on QEMU as described in *Networking with QEMU*.

Change the client (test suite) and server (Zephyr coap-server sample) addresses in coap.cfg file as per your setup.

Execute the test cases with following command.

```
ttcn3_start coaptests coap.cfg
```

Sample output of ttcn3 tests looks like this.

```
Verdict statistics: 0 none (0.00 %), 10 pass (100.00 %), 0 inconc (0.00 %), 0 fail␣
↪(0.00 %), 0 error (0.00 %).
Test execution summary: 10 test cases were executed. Overall verdict: pass
```

CoAP client

- *Overview*
- *Sample Usage*
- *API Reference*

Overview The CoAP client library allows application to send CoAP requests and parse CoAP responses. The library can be enabled with `CONFIG_COAP_CLIENT` Kconfig option. The application is notified about the response via a callback that is provided to the API in the request. The CoAP client handles the communication over sockets. As the CoAP client doesn't create socket it is using, the application is responsible for creating the socket. Plain UDP or DTLS sockets are supported.

Sample Usage The following is an example of a CoAP client initialization and request sending:

```
static struct coap_client;
struct coap_client_request req = { 0 };

coap_client_init(&client, NULL);

req.method = COAP_METHOD_GET;
req.confirmable = true;
strcpy(req.path, "test");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.payload = NULL;
req.len = 0;

/* Sock is a file descriptor referencing a socket, address is the net_sockaddr␣
↪struct for the
 * destination address of the request or NULL if the socket is already connected.
 */
ret = coap_client_req(&client, sock, &address, &req, -1);
```

Before any requests can be sent, the CoAP client needs to be initialized. After initialization, the application can send a CoAP request and wait for the response. Currently only one request can be sent for a single CoAP client at a time. There can be multiple CoAP clients.

The callback provided in the callback will be called in following cases:

- There is a response for the request
- The request failed for some reason

The callback contains a flag `last_block`, which indicates if there is more data to come in the response and means that the current response is part of a blockwise transfer. When the `last_block` is set to true, the response is finished and the client is ready for the next request after returning from the callback.

If the server responds to the request, the library provides the response to the application through the response callback registered in the request structure. As the response can be a blockwise transfer and the client calls the callback once per each block, the application should be to process all of the blocks to be able to process the response.

The following is an example of a very simple response handling function:

```
void response_cb(const struct coap_client_response_data *data, void *user_data)
{
    if (data->result_code >= 0) {
            LOG_INF("CoAP response from server %d", data->result_code);
            if (data->last_block) {
                    LOG_INF("Last packet received");
            }
    } else {
            LOG_ERR("Error in sending request %d", data->result_code);
    }
}
```

CoAP options may also be added to the request by the application. The following is an example of the application adding a Block2 option to the initial request, to suggest a maximum block size to the server for a resource that it expects to be large enough to require a blockwise transfer (see **RFC 7959** Figure 3: Block-Wise GET with Early Negotiation).

```
static struct coap_client;
struct coap_client_request req = { 0 };

coap_client_init(&client, NULL);

req.method = COAP_METHOD_GET;
req.confirmable = true;
strcpy(req.path, "test");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.options[0] = coap_client_option_initial_block2();
req.num_options = 1;
req.payload = NULL;
req.len = 0;

ret = coap_client_req(&client, sock, &address, &req, -1);
```

Optionally, the application can register a payload callback instead of providing a payload pointer for the CoAP upload. In such cases, the CoAP client library will call this callback when preparing a PUT/POST request, so that the application can provide the payload in blocks, instead of having to provide a single contiguous buffer with the entire payload. An example callback, providing the content of the Lorem Ipsum string can look like this:

```
static int lorem_ipsum_cb(size_t offset, const uint8_t **payload, size_t *len,
                          bool *last_block, void *user_data)
{
    size_t data_left;

    if (offset > LOREM_IPSUM_STRLEN) {
        return -EINVAL;
    }

    *payload = LOREM_IPSUM + offset;

    data_left = LOREM_IPSUM_STRLEN - offset;
    if (data_left <= *len) {
        *len = data_left;
        *last_block = true;
    } else {
        *last_block = false;
    }

    return 0;
}
```

The callback can then be registered for the PUT/POST request instead of a payload pointer:

```
struct coap_client_request req = { 0 };

req.method = COAP_METHOD_PUT;
req.confirmable = true;
strcpy(req.path, "lorem-ipsum");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.payload_cb = lore_ipsum_cb,

ret = coap_client_req(&client, sock, &address, &req, -1);
```

API Reference

CoAP client API

CoAP server

- *Overview*
- *Setup*
- *Sample Usage*
- *Observable resources*
- *CoAP Events*
- *CoRE Link Format*
- *API Reference*

Overview Zephyr comes with a batteries-included CoAP server, which uses services to listen for CoAP requests. The CoAP services handle communication over sockets and pass requests to registered CoAP resources.

Setup Some configuration is required to make sure services can be started using the CoAP server. The CONFIG_COAP_SERVER option should be enabled in your project:

Listing 1: prj.conf

```
CONFIG_COAP_SERVER=y
```

All services are added to a predefined linker section and all resources for each service also get their respective linker sections. If you would have a service my_service it has to be prefixed with coap_resource_ and added to a linker file:

Listing 2: sections-ram.ld

```
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_RAM(coap_resource_my_service, Z_LINK_ITERABLE_SUBALIGN)
```

Add this linker file to your application using CMake:

Listing 3: CMakeLists.txt

```
# Support LD linker template
zephyr_linker_sources(DATA_SECTIONS sections-ram.ld)

# Support CMake linker generator
zephyr_iterable_section(NAME coap_resource_my_service
                        GROUP DATA_REGION ${XIP_ALIGN_WITH_INPUT})
```

You can now define your service as part of the application:

```
#include <zephyr/net/coap_service.h>

static const uint16_t my_service_port = 5683;

COAP_SERVICE_DEFINE(my_service, "0.0.0.0", &my_service_port,␣
↪COAP_SERVICE_AUTOSTART);
```

Note

Services defined with the COAP_SERVICE_AUTOSTART flag will be started together with the CoAP server thread. Services can be manually started and stopped with coap_service_start and coap_service_stop respectively.

Sample Usage The following is an example of a CoAP resource registered with our service:

```
#include <zephyr/net/coap_service.h>

static int my_get(struct coap_resource *resource, struct coap_packet *request,
                  struct net_sockaddr *addr, socklen_t addr_len)
{
    static const char *msg = "Hello, world!";
    uint8_t data[CONFIG_COAP_SERVER_MESSAGE_SIZE];
    struct coap_packet response;
    uint16_t id;
    uint8_t token[COAP_TOKEN_MAX_LEN];
    uint8_t tkl, type;
```

(continues on next page)

(continued from previous page)

```
    type = coap_header_get_type(request);
    id = coap_header_get_id(request);
    tkl = coap_header_get_token(request, token);

    /* Determine response type */
    type = (type == COAP_TYPE_CON) ? COAP_TYPE_ACK : COAP_TYPE_NON_CON;

    coap_packet_init(&response, data, sizeof(data), COAP_VERSION_1, type, tkl,␣
↪token,
                     COAP_RESPONSE_CODE_CONTENT, id);

    /* Set content format */
    coap_append_option_int(&response, COAP_OPTION_CONTENT_FORMAT,
                           COAP_CONTENT_FORMAT_TEXT_PLAIN);

    /* Append payload */
    coap_packet_append_payload_marker(&response);
    coap_packet_append_payload(&response, (uint8_t *)msg, strlen(msg));

    /* Send to response back to the client */
    return coap_resource_send(resource, &response, addr, addr_len, NULL);
}

static int my_put(struct coap_resource *resource, struct coap_packet *request,
                  struct net_sockaddr *addr, socklen_t addr_len)
{
    /* ... Handle the incoming request ... */

    /* Return a CoAP response code as a shortcut for an empty ACK message */
    return COAP_RESPONSE_CODE_CHANGED;
}

static const char * const my_resource_path[] = { "test", NULL };
COAP_RESOURCE_DEFINE(my_resource, my_service, {
    .path = my_resource_path,
    .get = my_get,
    .put = my_put,
});
```

Note

As demonstrated in the example above, a CoAP resource handler can return response codes to let the server respond with an empty ACK response.

Observable resources The CoAP server provides logic for parsing observe requests and stores these using the runtime data of CoAP services. An example using a temperature sensor can look like:

```
#include <zephyr/kernel.h>
#include <zephyr/drivers/sensor.h>
#include <zephyr/net/coap_service.h>

static void notify_observers(struct k_work *work);
K_WORK_DELAYABLE_DEFINE(temp_work, notify_observers);
```

(continues on next page)

(continued from previous page)

```
static int send_temperature(struct coap_resource *resource,
                            const struct net_sockaddr *addr, socklen_t addr_len,
                            uint16_t age, uint16_t id, const uint8_t *token,␣
↪uint8_t tkl,
                            bool is_response)
{
    const struct device *dev = DEVICE_DT_GET(DT_ALIAS(ambient_temp0));
    uint8_t data[CONFIG_COAP_SERVER_MESSAGE_SIZE];
    struct coap_packet response;
    char payload[14];
    struct sensor_value value;
    double temp;
    uint8_t type;

    /* Determine response type */
    type = is_response ? COAP_TYPE_ACK : COAP_TYPE_CON;

    if (!is_response) {
        id = coap_next_id();
    }

    coap_packet_init(&response, data, sizeof(data), COAP_VERSION_1, type, tkl,␣
↪token,
                     COAP_RESPONSE_CODE_CONTENT, id);

    if (age >= 2U) {

CoAP Events By enabling `CONFIG_NET_MGMT_EVENT` the user can register for CoAP events. The following example simply prints when an event occurs.

```
#include <zephyr/sys/printk.h>
#include <zephyr/net/coap_mgmt.h>
#include <zephyr/net/coap_service.h>

#define COAP_EVENTS_SET (NET_EVENT_COAP_OBSERVER_ADDED |␣
↪NET_EVENT_COAP_OBSERVER_REMOVED | \
                         NET_EVENT_COAP_SERVICE_STARTED |␣
↪NET_EVENT_COAP_SERVICE_STOPPED)

void coap_event_handler(uint64_t mgmt_event, struct net_if *iface,
                        void *info, size_t info_length, void *user_data)
{
    switch (mgmt_event) {
    case NET_EVENT_COAP_OBSERVER_ADDED:
        printk("CoAP observer added");
        break;
    case NET_EVENT_COAP_OBSERVER_REMOVED:
```

(continues on next page)

(continued from previous page)

```
        printk("CoAP observer removed");
        break;
    case NET_EVENT_COAP_SERVICE_STARTED:
        if (info != NULL && info_length == sizeof(struct net_event_coap_service)) {
            struct net_event_coap_service *net_event = info;

            printk("CoAP service %s started", net_event->service->name);
        } else {
            printk("CoAP service started");
        }
        break;
    case NET_EVENT_COAP_SERVICE_STOPPED:
        if (info != NULL && info_length == sizeof(struct net_event_coap_service)) {
            struct net_event_coap_service *net_event = info;

            printk("CoAP service %s stopped", net_event->service->name);
        } else {
            printk("CoAP service stopped");
        }
        break;
    }
}

NET_MGMT_REGISTER_EVENT_HANDLER(coap_events, COAP_EVENTS_SET, coap_event_handler,␣
↪NULL);
```

CoRE Link Format The `CONFIG_COAP_SERVER_WELL_KNOWN_CORE` option enables handling the `.well-known/core` GET requests by the server. This allows clients to get a list of hypermedia links to other resources hosted in that server.

CoAP Manager Events

FTP client

- *Overview*
- *Protocols*
- *Limitations*
- *API Reference*

Overview The FTP client library can be used to download or upload files to FTP server.

The FTP client library reports FTP control message and download data with two separate callback functions `ftp_client.ctrl_callback` and `ftp_client.data_callback`. The library can be

configured to automatically send KEEPALIVE message to the server through a timer if CONFIG_FTP_CLIENT_KEEPALIVE_TIME is not zero. The KEEPALIVE message is sent periodically at the completion of the time interval indicated by the value of CONFIG_FTP_CLIENT_KEEPALIVE_TIME.

Protocols The library is implemented in accordance with the **RFC 959** specification.

Limitations The library implements only a minimal set of commands as of now. However, new command support can be easily added.

Due to the differences in the implementation of FTP servers, the library might need customization to work with a specific server.

HTTP Client

- *Overview*
- *Sample Usage*
- *API Reference*

Overview The HTTP client library allows you to send HTTP requests and parse HTTP responses. The library communicates over the sockets API but it does not create sockets on its own. It can be enabled with CONFIG_HTTP_CLIENT Kconfig option.

The application must be responsible for creating a socket and passing it to the library. Therefore, depending on the application's needs, the library can communicate over either a plain TCP socket (HTTP) or a TLS socket (HTTPS).

Sample Usage The API of the HTTP client library has a single function.

The following is an example of a request structure created correctly:

```
struct http_request req = { 0 };
static uint8_t recv_buf[512];

req.method = HTTP_GET;
req.url = "/";
req.host = "localhost";
req.protocol = "HTTP/1.1";
req.response = response_cb;
req.recv_buf = recv_buf;
req.recv_buf_len = sizeof(recv_buf);

/* sock is a file descriptor referencing a socket that has been connected
 * to the HTTP server.
 */
ret = http_client_req(sock, &req, 5000, NULL);
```

If the server responds to the request, the library provides the response to the application through the response callback registered in the request structure. As the library can provide the response in chunks, the application must be able to process these.

Together with the structure containing the response data, the callback function also provides information about whether the library expects to receive more data.

The following is an example of a very simple response handling function:

```
static int response_cb(struct http_response *rsp,
                       enum http_final_call final_data,
                       void *user_data)
{
    if (final_data == HTTP_DATA_MORE) {
        LOG_INF("Partial data received (%zd bytes)", rsp->data_len);
    } else if (final_data == HTTP_DATA_FINAL) {
        LOG_INF("All the data received (%zd bytes)", rsp->data_len);
    }

    LOG_INF("Response status %s", rsp->http_status);

    return 0;
}
```

See HTTP client sample application for more information about the library usage.

HTTP Server

- *Overview*
- *Server Setup*
- *Sample Usage*
  - *Services*
  - *Per-service configuration*
  - *Fallback Resources*
  - *Static resources*
  - *Static filesystem resources*
  - *Dynamic resources*
  - *Websocket resources*
  - *Accessing request headers*
- *API Reference*

Overview Zephyr provides an HTTP server library, which allows to register HTTP services and HTTP resources associated with those services. The server creates a listening socket for every registered service, and handles incoming client connections. It's possible to communicate over a plain TCP socket (HTTP) or a TLS socket (HTTPS). Both, HTTP/1.1 (RFC 2616) and HTTP/2 (RFC 9113) protocol versions are supported.

The server operation is generally transparent for the application, running in a background thread. The application can control the server activity with respective API functions.

Certain resource types (for example dynamic resource) provide resource-specific application callbacks, allowing the server to interact with the application (for instance provide resource content, or process request payload).

Currently, the following resource types are supported:

- Static resources - content defined compile-time, cannot be modified at runtime (`HTTP_RESOURCE_TYPE_STATIC`).
- Static file system resources - the path at which the filesystem is mounted, and the URL at which the filesystem is made available are fixed at build time, but the content within the filesystem can be changed dynamically. This means that the files can be created, modified or deleted by some other code outside the HTTP server (`HTTP_RESOURCE_TYPE_STATIC_FS`).
- Dynamic resources - content provided at runtime by respective application callback (`HTTP_RESOURCE_TYPE_DYNAMIC`).
- Websocket resources - allowing to establish Websocket connections with the server (`HTTP_RESOURCE_TYPE_WEBSOCKET`).

Zephyr provides a sample demonstrating HTTP(s) server operation and various resource types usage. See sockets-http-server for more information.

Server Setup A few prerequisites are needed in order to enable HTTP server functionality in the application.

First of all, the HTTP server has to be enabled in applications configuration file with `CONFIG_HTTP_SERVER` Kconfig option:

Listing 4: `prj.conf`

```
CONFIG_HTTP_SERVER=y
```

All HTTP services and HTTP resources are placed in a dedicated linker section. The linker section for services is predefined locally, however the application is responsible for defining linker sections for resources associated with respective services. Linker section names for resources should be prefixed with `http_resource_desc_`, appended with the service name.

Linker sections for resources should be defined in a linker file. For example, for a service named `my_service`, the linker section shall be defined as follows:

Listing 5: `sections-rom.ld`

```
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_ROM(http_resource_desc_my_service, Z_LINK_ITERABLE_SUBALIGN)
```

Finally, the linker file and linker section have to be added to your application using CMake:

Listing 6: `CMakeLists.txt`

```
zephyr_linker_sources(SECTIONS sections-rom.ld)
zephyr_linker_section(NAME http_resource_desc_my_service
                      KVMA RAM_REGION GROUP RODATA_REGION)
```

Note

You need to define a separate linker section for each HTTP service registered in the system.

Sample Usage

Services The application needs to define an HTTP service (or multiple services), with the same name as used for the linker section with `HTTP_SERVICE_DEFINE` macro:

```
#include <zephyr/net/http/service.h>

static uint16_t http_service_port = 80;

HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10, NULL, NULL,␣
↪NULL);
```

Alternatively, an HTTPS service can be defined with `HTTPS_SERVICE_DEFINE`:

```
#include <zephyr/net/http/service.h>
#include <zephyr/net/tls_credentials.h>

#define HTTP_SERVER_CERTIFICATE_TAG 1

static uint16_t https_service_port = 443;
static const sec_tag_t sec_tag_list[] = {
    HTTP_SERVER_CERTIFICATE_TAG,
};

HTTPS_SERVICE_DEFINE(my_service, "0.0.0.0", &https_service_port, 1, 10,
                     NULL, NULL, NULL, sec_tag_list, sizeof(sec_tag_list));
```

Per-service configuration HTTP services support individual service configuration, for now it includes only socket creation through the `http_service_config` structure. This allows applications to customize socket creation behavior, for example to set specific socket options or use custom socket types.

To use custom socket creation:

```
static int my_socket_create(const struct http_service_desc *svc, int af, int proto)
{
    int fd;

    /* Create socket with custom parameters */
    fd = zsock_socket(af, SOCK_STREAM, proto);
    if (fd < 0) {
        return fd;
    }

    /* Set custom socket options */
    /* Add any other custom socket configuration */

    return fd;
}

static const struct http_service_config my_service_config = {
    .socket_create = my_socket_create,
```

(continues on next page)

(continued from previous page)

```
};

static uint16_t http_service_port = 80;

HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10,
                    NULL, NULL, &my_service_config);
```

The custom socket creation function receives: - `svc`: Pointer to the service descriptor - `af`: Address family (NET_AF_INET or NET_AF_INET6) - `proto`: Protocol (NET_IPPROTO_TCP or NET_IPPROTO_TLS_1_2 for HTTPS)

The function should return the socket file descriptor on success, or a negative error code on failure.

If no custom configuration is needed, simply pass `NULL` for the config parameter:

```
HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10,
                    NULL, NULL, NULL);
```

Fallback Resources The `_res_fallback` parameter can be used when defining an HTTP/HTTPS service to specify a fallback resource which will be used if no other resource matches the URL. This can be used for example to serve an index page for all unknown paths (useful for a single-page app which handles routing in the frontend), or for a customised 404 response.

```
static int default_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
                   const struct http_request_ctx *request_ctx,
                   struct http_response_ctx *response_ctx, void *user_data)
{
    static const char response_404[] = "Oops, page not found!";

    if (status == HTTP_SERVER_REQUEST_DATA_FINAL) {
        response_ctx->status = 404;
        response_ctx->body = response_404;
        response_ctx->body_len = sizeof(response_404) - 1;
        response_ctx->final_chunk = true;
    }

    return 0;
}

static struct http_resource_detail_dynamic default_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_DYNAMIC,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .cb = default_handler,
    .user_data = NULL,
};

/* Register a fallback resource to handle any unknown path */
HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10, NULL, &
↪default_detail, NULL);
```

Note

HTTPS services rely on TLS credentials being registered in the system. See *TLS credentials subsystem* for information on how to configure TLS credentials in the system.

Once HTTP(s) service is defined, resources can be registered for it with `HTTP_RESOURCE_DEFINE` macro.

Application can enable resource wildcard support by enabling `CONFIG_HTTP_SERVER_RESOURCE_WILDCARD` option. When this option is set, then it is possible to match several incoming HTTP requests with just one resource handler. The fnmatch() POSIX API function is used to match the pattern in the URL paths.

Example:

```
HTTP_RESOURCE_DEFINE(my_resource, my_service, "/foo*", &resource_detail);
```

This would match all URLs that start with a string `foo`. See POSIX.2 chapter 2.13 for pattern matching syntax description.

Static resources Static resource content is defined build-time and is immutable. The following example shows how gzip compressed webpage can be defined as a static resource in the application:

```
static const uint8_t index_html_gz[] = {
    #include "index.html.gz.inc"
};

struct http_resource_detail_static index_html_gz_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_STATIC,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
        .content_encoding = "gzip",
    },
    .static_data = index_html_gz,
    .static_data_len = sizeof(index_html_gz),
};

HTTP_RESOURCE_DEFINE(index_html_gz_resource, my_service, "/",
                     &index_html_gz_resource_detail);
```

The resource content and content encoding is application specific. For the above example, a gzip compressed webpage can be generated during build, by adding the following code to the application's `CMakeLists.txt` file:

Listing 7: `CMakeLists.txt`

```
set(gen_dir ${ZEPHYR_BINARY_DIR}/include/generated/)
set(source_file_index src/index.html)
generate_inc_file_for_target(app ${source_file_index} ${gen_dir}/index.html.gz.inc␣
↪--gzip)
```

where `src/index.html` is the location of the webpage to be compressed.

Static filesystem resources Static filesystem resource content is defined build-time and is immutable. Note that only `GET` operation is supported, user is not able to upload files to the filesystem. The following example shows how the path can be defined as a static resource in the application:

```
struct http_resource_detail_static_fs static_fs_resource_detail = {
    .common = {
        .type                                = HTTP_RESOURCE_TYPE_STATIC_FS,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .fs_path = "/lfs1/www",
};

HTTP_RESOURCE_DEFINE(static_fs_resource, my_service, "*", &
↪static_fs_resource_detail);
```

All files located in /lfs1/www are made available to the client. If a file is gzipped, .gz must be appended to the file name (e.g. index.html.gz), then the server delivers index.html.gz when the client requests index.html and adds gzip content-encoding to the HTTP header.

The content type is evaluated based on the file extension. The server supports .html, .js, .css, .jpg, .png and .svg. More content types can be provided with the `HTTP_SERVER_CONTENT_TYPE` macro. All other files are provided with the content type text/html.

```
HTTP_SERVER_CONTENT_TYPE(json, "application/json")
```

When serving files from a static filesystem, the response chunk size can be configured using the `CONFIG_HTTP_SERVER_STATIC_FS_RESPONSE_SIZE` Kconfig option. This determines the size of individual chunks when transmitting file content to clients.

Dynamic resources For dynamic resource, a resource callback is registered to exchange data between the server and the application.

The following example code shows how to register a dynamic resource with a simple resource handler, which echoes received data back to the client:

```
static int dyn_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
                       const struct http_request_ctx *request_ctx,
                       struct http_response_ctx *response_ctx, void *user_data)
{
#define MAX_TEMP_PRINT_LEN 32
    static char print_str[MAX_TEMP_PRINT_LEN];
    enum http_method method = client->method;
    static size_t processed;

    __ASSERT_NO_MSG(request_ctx->data != NULL);

    if (status == HTTP_SERVER_TRANSACTION_ABORTED ||
        status == HTTP_SERVER_TRANSACTION_COMPLETE) {
        if (status == HTTP_SERVER_TRANSACTION_ABORTED) {
            LOG_DBG("Transaction aborted after %zd bytes.", processed);
        }
        processed = 0;
        return 0;
    }

    processed += request_ctx->data_len;

    snprintf(print_str, sizeof(print_str), "%s received (%zd bytes)",
             http_method_str(method), request_ctx->data_len);
    LOG_HEXDUMP_DBG(request_ctx->data, request_ctx->data_len, print_str);
```

(continues on next page)

(continued from previous page)

```
    if (status == HTTP_SERVER_REQUEST_DATA_FINAL) {
        LOG_DBG("All data received (%zd bytes).", processed);
        processed = 0;
    }

    /* Echo data back to client */
    response_ctx->body = request_ctx->data;
    response_ctx->body_len = request_ctx->data_len;
    response_ctx->final_chunk = (status == HTTP_SERVER_REQUEST_DATA_FINAL);

    return 0;
}

struct http_resource_detail_dynamic dyn_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_DYNAMIC,
        .bitmask_of_supported_http_methods =
            BIT(HTTP_GET) | BIT(HTTP_POST),
    },
    .cb = dyn_handler,
    .user_data = NULL,
};

HTTP_RESOURCE_DEFINE(dyn_resource, my_service, "/dynamic",
                     &dyn_resource_detail);
```

The resource callback may be called multiple times for a single request, hence the application should be able to keep track of the received data progress.

The `status` field informs the application about the progress in passing request payload from the server to the application. As long as the status reports `HTTP_SERVER_REQUEST_DATA_MORE`, the application should expect more data to be provided in a consecutive callback calls. Once all request payload has been passed to the application, the server reports `HTTP_SERVER_REQUEST_DATA_FINAL` status. In case of communication errors during request processing (for example client closed the connection before complete payload has been received), the server reports `HTTP_SERVER_TRANSACTION_ABORTED`. When the response has been sent completely to the client, the server reports `HTTP_SERVER_TRANSACTION_COMPLETE` status. Either of the two events indicate that the request processing is finished, and the application shall reset any progress recorded for the resource, and await a new request to come. The server guarantees that the resource can only be accessed by single client at a time.

The `request_ctx` parameter is used to pass request data to the application:

- The `data` and `data_len` fields pass request data to the application.
- The `headers`, `header_count` and `headers_status` fields pass request headers to the application, if `CONFIG_HTTP_SERVER_CAPTURE_HEADERS` is enabled.

The `response_ctx` field is used by the application to pass response data to the HTTP server:

- The `status` field allows the application to send an HTTP response code. If not populated, the response code will be 200 by default.
- The `headers` and `header_count` fields can be used for the application to send any arbitrary HTTP headers. If not populated, only Transfer-Encoding and Content-Type are sent by default. The callback may override the Content-Type if desired.
- The `body` and `body_len` fields are used to send body data.
- The `final_chunk` field is used to indicate that the application has no more response data to send.

Headers and/or response codes may only be sent in the first populated `response_ctx`, after which only further body data is allowed in subsequent callbacks.

The server will call the resource callback until it provided all request data to the application, and the application reports there is no more data to include in the reply.

Websocket resources Websocket resources register an application callback, which is called when a Websocket connection upgrade takes place. The callback is provided with a socket descriptor corresponding to the underlying TCP/TLS connection. Once called, the application takes full control over the socket, i. e. is responsible to release it when done.

```
static int ws_socket;
static uint8_t ws_recv_buffer[1024];

int ws_setup(int sock, struct http_request_ctx *request_ctx, void *user_data)
{
    ws_socket = sock;
    return 0;
}

struct http_resource_detail_websocket ws_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_WEBSOCKET,
        /* We need HTTP/1.1 Get method for upgrading */
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .cb = ws_setup,
    .data_buffer = ws_recv_buffer,
    .data_buffer_len = sizeof(ws_recv_buffer),
    .user_data = NULL, /* Fill this for any user specific data */
};

HTTP_RESOURCE_DEFINE(ws_resource, my_service, "/", &ws_resource_detail);
```

The above minimalistic example shows how to register a Websocket resource with a simple callback, used only to store the socket descriptor provided. Further processing of the Websocket connection is application-specific, hence outside of scope of this guide. See sockets-http-server for an example Websocket-based echo service implementation.

Accessing request headers The application can register an interest in any specific HTTP request headers. These headers are then stored for each incoming request, and can be accessed from within a dynamic resource callback. Request headers are only included in the first callback for a given request, and are not passed to any subsequent callbacks.

This feature must first be enabled with `CONFIG_HTTP_SERVER_CAPTURE_HEADERS` Kconfig option.

Then the application can register headers to be captured, and read the values from within the dynamic resource callback:

```
HTTP_SERVER_REGISTER_HEADER_CAPTURE(capture_user_agent, "User-Agent");

static int dyn_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
                       const struct http_request_ctx *request_ctx,
                       struct http_response_ctx *response_ctx, void *user_data)
{
    size_t header_count = client->header_capture_ctx.count;
    const struct http_header *headers = client->header_capture_ctx.headers;
```

(continues on next page)

(continued from previous page)

```
    LOG_INF("Captured %d headers with request", header_count);

    for (uint32_t i = 0; i < header_count; i++) {
        LOG_INF("Header: '%s: %s'", headers[i].name, headers[i].value);
    }

    return 0;
}
```

Overview Lightweight Machine to Machine (LwM2M) is an application layer protocol designed with device management, data reporting and device actuation in mind. Based on CoAP/UDP, LwM2M is a standard defined by the Open Mobile Alliance and suitable for constrained devices by its use of CoAP packet-size optimization and a simple, stateless flow that supports a REST API.

One of the key differences between LwM2M and CoAP is that an LwM2M client initiates the connection to an LwM2M server. The server can then use the REST API to manage various interfaces with the client.

LwM2M uses a simple resource model with the core set of objects and resources defined in the specification.

The LwM2M library can be enabled with `CONFIG_LWM2M` Kconfig option.

Example LwM2M object and resources: Device *Object definition*

Object ID	Name	Instance	Mandatory
3	Device	Single	Mandatory

Resource definitions

`* R=Read, W=Write, E=Execute`

ID	Name	OP*	Instance	Mandatory	Type
0	Manufacturer	R	Single	Optional	String
1	Model	R	Single	Optional	String
2	Serial number	R	Single	Optional	String
3	Firmware version	R	Single	Optional	String
4	Reboot	E	Single	Mandatory	
5	Factory Reset	E	Single	Optional	
6	Available Power Sources	R	Multiple	Optional	Integer 0-7
7	Power Source Voltage (mV)	R	Multiple	Optional	Integer
8	Power Source Current (mA)	R	Multiple	Optional	Integer
9	Battery Level %	R	Single	Optional	Integer
10	Memory Free (Kb)	R	Single	Optional	Integer
11	Error Code	R	Multiple	Optional	Integer 0-8
12	Reset Error	E	Single	Optional	
13	Current Time	RW	Single	Optional	Time
14	UTC Offset	RW	Single	Optional	String
15	Timezone	RW	Single	Optional	String
16	Supported Binding	R	Single	Mandatory	String
17	Device Type	R	Single	Optional	String
18	Hardware Version	R	Single	Optional	String
19	Software Version	R	Single	Optional	String
20	Battery Status	R	Single	Optional	Integer 0-6
21	Memory Total (Kb)	R	Single	Optional	Integer
22	ExtDevInfo	R	Multiple	Optional	ObjLnk

The server could query the `Manufacturer` resource for `Device` object instance 0 (the default and only instance) by sending a `READ 3/0/0` operation to the client.

The full list of registered objects and resource IDs can be found in the OMA LwM2M registries.

Zephyr's LwM2M library lives in the subsys/net/lib/lwm2m, with a client sample in samples/net/lwm2m_client. For more information about the provided sample see: lwm2m-client. The sample can be configured to use normal insecure network sockets or sockets secured via DTLS.

The Zephyr LwM2M library implements the following items:

- engine to process networking events and core functions
- RD client which performs BOOTSTRAP and REGISTRATION functions
- SenML CBOR, SenML JSON, CBOR, TLV, JSON, and plain text formatting functions
- LwM2M Technical Specification Enabler objects such as Security, Server, Device, Firmware Update, etc.
- Extended IPSO objects such as Light Control, Temperature Sensor, and Timer

By default, the library implements LwM2M specification 1.0.2 and can be set to LwM2M specification 1.1.1 with a Kconfig option.

For more information about LwM2M specification releases visit the OMA LwM2M releases page.

Sample usage To use the LwM2M library, start by creating an LwM2M client context `lwm2m_ctx` structure:

```
/* LwM2M client context */
static struct lwm2m_ctx client;
```

Create callback functions for LwM2M resource executions:

```
static int device_reboot_cb(uint16_t obj_inst_id, uint8_t *args,
                            uint16_t args_len)
{
        LOG_INF("Device rebooting.");
        LOG_PANIC();
        sys_reboot(0);
        return 0; /* won't reach this */
}
```

The LwM2M RD client can send events back to the sample. To receive those events, setup a callback function:

```
static void rd_client_event(struct lwm2m_ctx *client,
                            enum lwm2m_rd_client_event client_event)
{
        switch (client_event) {

        case LWM2M_RD_CLIENT_EVENT_NONE:
                /* do nothing */
                break;

        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_REG_FAILURE:
                LOG_DBG("Bootstrap registration failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_REG_COMPLETE:
                LOG_DBG("Bootstrap registration complete");
                break;
```

(continues on next page)

(continued from previous page)

```
        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_TRANSFER_COMPLETE:
                LOG_DBG("Bootstrap transfer complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_REGISTRATION_FAILURE:
                LOG_DBG("Registration failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_REGISTRATION_COMPLETE:
                LOG_DBG("Registration complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_TIMEOUT:
                LOG_DBG("Registration timeout!");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_UPDATE_COMPLETE:
                LOG_DBG("Registration update complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_DEREGISTER_FAILURE:
                LOG_DBG("Deregister failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_DISCONNECT:
                LOG_DBG("Disconnected");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_UPDATE:
                LOG_DBG("Registration update");
                break;

        case LWM2M_RD_CLIENT_EVENT_DEREGISTER:
                LOG_DBG("Deregistration client");
                break;

        case LWM2M_RD_CLIENT_EVENT_SERVER_DISABLED:
                LOG_DBG("LwM2M server disabled");
          break;
        }
}
```

Next we assign `Security` resource values to let the client know where and how to connect as well as set the `Manufacturer` and `Reboot` resources in the `Device` object with some data and the callback we defined above:

```
/*
 * Server URL of default Security object = 0/0/0
 * Use leshan.eclipse.org server IP (5.39.83.206) for connection
 */
lwm2m_set_string(&LWM2M_OBJ(0, 0, 0), "coap://5.39.83.206");

/*
 * Security Mode of default Security object = 0/0/2
 * 3 = NoSec mode (no security beware!)
 */
```

(continues on next page)

(continued from previous page)

```
lwm2m_set_u8(&LWM2M_OBJ(0, 0, 2), 3);

#define CLIENT_MANUFACTURER "Zephyr Manufacturer"

/*
 * Manufacturer resource of Device object = 3/0/0
 * We use lwm2m_set_res_data() function to set a pointer to the
 * CLIENT_MANUFACTURER string.
 * Note the LWM2M_RES_DATA_FLAG_RO flag which stops the engine from
 * trying to assign a new value to the buffer.
 */
lwm2m_set_res_data(&LWM2M_OBJ(3, 0, 0), CLIENT_MANUFACTURER,
                   sizeof(CLIENT_MANUFACTURER),
                   LWM2M_RES_DATA_FLAG_RO);

/* Reboot resource of Device object = 3/0/4 */
lwm2m_register_exec_callback(&LWM2M_OBJ(3, 0, 4), device_reboot_cb);
```

Lastly, we start the LwM2M RD client (which in turn starts the LwM2M engine). The second parameter of `lwm2m_rd_client_start()` is the client endpoint name. This is important as it needs to be unique per LwM2M server:

```
(void)memset(&client, 0x0, sizeof(client));
lwm2m_rd_client_start(&client, "unique-endpoint-name", 0, rd_client_event);
```

LwM2M security modes The Zephyr LwM2M library can be used either without security or use DTLS to secure the communication channel. When using DTLS with the LwM2M engine, PSK (Pre-Shared Key) and X.509 certificates are the security modes that can be used to secure the communication. The engine uses LwM2M Security object (Id 0) to read the stored credentials and feed keys from the security object into the TLS credential subsystem, see *secure sockets documentation*. Enable the `CONFIG_LWM2M_DTLS_SUPPORT` Kconfig option to use the security.

Depending on the selected mode, the security object must contain following data:

PSK
: Security Mode (Resource ID 2) set to zero (Pre-Shared Key mode). Identity (Resource ID 3) contains PSK ID in binary form. Secret key (Resource ID 5) contains the PSK key in binary form. If the key or identity is provided as a hex string, it must be converted to binary before storing into the security object.

X509
: When X509 certificates are used, set Security Mode (ID 2) to 2 (Certificate mode). Identity (ID 3) is used to store the client certificate and Secret key (ID 5) must have a private key associated with the certificate. Server Public Key resource (ID 4) must contain a server certificate or CA certificate used to sign the certificate chain. If the `CONFIG_MBEDTLS_PEM_PARSE_C` / `CONFIG_MBEDTLS_PEM_WRITE_C` Kconfig options are enabled, certificates and private keys can be entered in PEM format. Otherwise, they must be in binary DER format.

NoSec
: When no security is used, set Security Mode (Resource ID 2) to 3 (NoSec).

In all modes, Server URI resource (ID 0) must contain the full URI for the target server. When DNS names are used, the DNS resolver must be enabled.

When DTLS is used, following options are recommended to reduce DTLS handshake traffic when connection is re-established:

- `CONFIG_LWM2M_DTLS_CID` enables DTLS Connection Identifier support. When server supports it, this completely removes the handshake when device resumes operation after long idle period. Greatly helps when NAT mappings have timed out.

- `CONFIG_LWM2M_TLS_SESSION_CACHING` uses session cache when before falling back to full DTLS handshake. Reduces few packets from handshake, when session is still cached on server side. Most significant effect is to avoid full registration.

LwM2M stack provides callbacks in the `lwm2m_ctx` structure. They are used to feed keys from the LwM2M security object into the TLS credential subsystem. By default, these callbacks can be left as NULL pointers, in which case default callbacks are used. When an external TLS stack, or non-default socket options are required, you can overwrite the `lwm2m_ctx.load_credentials()` or `lwm2m_ctx.set_socketoptions()` callbacks.

An example of setting up the security object for PSK mode:

```
/* "000102030405060708090a0b0c0d0e0f" */
static unsigned char client_psk[] = {
        0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07,
        0x08, 0x09, 0x0a, 0x0b, 0x0c, 0x0d, 0x0e, 0x0f
};

static const char client_identity[] = "Client_identity";

lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 0),
↪"coaps://lwm2m.example.com");
lwm2m_set_u8(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 2), LWM2M_SECURITY_PSK);
/* Set the client identity as a string, but this could be binary as well */
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 3), client_identity);
/* Set the client pre-shared key (PSK) */
lwm2m_set_opaque(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 5), client_psk,␣
↪sizeof(client_psk));
```

An example of setting up the security object for X509 certificate mode:

```
static const char certificate[] = "-----BEGIN CERTIFICATE-----\nMIIB6jCCAY+gAw...";
static const char key[] = "-----BEGIN EC PRIVATE KEY-----\nMHcCAQ...";
static const char root_ca[] = "-----BEGIN CERTIFICATE-----\nMIIBaz...";

lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 0),
↪"coaps://lwm2m.example.com");
lwm2m_set_u8(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 2), LWM2M_SECURITY_CERT);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 3), certificate);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 5), key);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 4), root_ca);
```

Before calling `lwm2m_rd_client_start()` assign the tls_tag # where the LwM2M library should store the DTLS information prior to connection (normally a value of 1 is ok here).

```
(void)memset(&client, 0x0, sizeof(client));
client.tls_tag = 1; /* <---- */
lwm2m_rd_client_start(&client, "endpoint-name", 0, rd_client_event);
```

For a more detailed LwM2M client sample see: lwm2m-client.

Multi-thread usage Writing a value to a resource can be done using functions like lwm2m_set_u8. When writing to multiple resources, the function lwm2m_registry_lock will ensure that the client halts until all writing operations are finished:

```
lwm2m_registry_lock();
lwm2m_set_u32(&LWM2M_OBJ(1, 0, 1), 60);
lwm2m_set_u8(&LWM2M_OBJ(5, 0, 3), 0);
```

(continues on next page)

(continued from previous page)

```
lwm2m_set_f64(&LWM2M_OBJ(3303, 0, 5700), value);
lwm2m_registry_unlock();
```

This is especially useful if the server is composite-observing the resources being written to. Locking will then ensure that the client only updates and sends notifications to the server after all operations are done, resulting in fewer messages in general.

Support for time series data LwM2M version 1.1 adds support for SenML CBOR and SenML JSON data formats. These data formats add support for time series data. Time series formats can be used for READ, NOTIFY and SEND operations. When data cache is enabled for a resource, each write will create a timestamped entry in a cache, and its content is then returned as a content in READ, NOTIFY or SEND operation for a given resource.

Data cache is only supported for resources with a fixed data size.

Supported resource types:

- Signed and unsigned 8-64-bit integers
- Float
- Boolean

Enabling and configuring Enable data cache by selecting `CONFIG_LWM2M_RESOURCE_DATA_CACHE_SUPPORT`. Application needs to allocate an array of `lwm2m_time_series_elem` structures and then enable the cache by calling `lwm2m_enable_cache()` for a given resource. Each resource must be enabled separately and each resource needs their own storage.

```
/* Allocate data cache storage */
static struct lwm2m_time_series_elem temperature_cache[10];
/* Enable data cache */
lwm2m_enable_cache(LWM2M_OBJ(IPSO_OBJECT_TEMP_SENSOR_ID, 0, SENSOR_VALUE_RID),
        temperature_cache, ARRAY_SIZE(temperature_cache));
```

Applications can inspect the available space in a cached resource with `lwm2m_cache_free_slots_get()`, which returns the number of samples that can still be stored or a negative errno value if the query fails.

LwM2M engine have room for four resources that have cache enabled. Limit can be increased by changing `CONFIG_LWM2M_MAX_CACHED_RESOURCES`. This affects a static memory usage of engine.

Data caches depends on one of the SenML data formats `CONFIG_LWM2M_RW_SENML_CBOR_SUPPORT` or `CONFIG_LWM2M_RW_SENML_JSON_SUPPORT` and needs `CONFIG_POSIX_TIMERS` so it can request a timestamp from the system and `CONFIG_RING_BUFFER` for ring buffer.

Read and Write operations Full content of data cache is written into a payload when any READ, SEND or NOTIFY operation internally reads the content of a given resource. This has a side effect that any read callbacks registered for a that resource are ignored when cache is enabled. Data is written into a cache when any of the `lwm2m_set_*` functions are called. Applications can register a cache filter callback with `lwm2m_set_cache_filter()` to drop otherwise valid samples based on application-specific rules.

Limitations Cache size should be manually set so small that the content can fit normal packets sizes. When cache is full, new values are dropped.

Send scheduler helper objects The optional SEND scheduler extension exposes two objects (Send scheduler Control `10523` and Sampling Rules `10524`) that sit on top of cached resources to decide when samples should be kept and when the client should trigger a LWM2M SEND.

Enabling and wiring

- Select CONFIG_LWM2M_SEND_SCHEDULER (requires LwM2M 1.1 SEND support and CONFIG_LWM2M_RESOURCE_DATA_CACHE_SUPPORT).
- Send-scheduler objects register automatically; ensure caches are configured before starting the RD client.
- Attach lwm2m_send_sched_cache_filter() to every cached resource that should be governed by the scheduler using lwm2m_set_cache_filter().
- Call lwm2m_send_sched_handle_registration_event() from the RD client callback when registration or registration-update completes (on LWM2M_RD_CLIENT_EVENT_REGISTRATION_COMPLETE and LWM2M_RD_CLIENT_EVENT_REG_UPDATE_COMPLETE) so cached samples are sent right after the registration exchange.

Scheduler Control object (10523) The single-instance control object configures global behaviour:

- 0: paused – stop accepting samples in cache.
- 1: max-samples – upper limit for cached samples across all resources; a SEND is forced when the limit is reached (0 disables).
- 2: max-age – maximum age in seconds of the oldest cached sample before a SEND is triggered (0 disables).
- 3: flush – Execute resource that immediately triggers a SEND for all configured rule paths.
- 4: flush-on-update – when enabled (default), a successful registration or registration-update event triggers a SEND of cached resources.

Sampling Rules object (10524) Each instance describes one cached resource to watch. /10524/X/0 holds the resource path and /10524/X/1 contains up to four rule strings. Supported attributes:

- gt=<float> – trigger when the sample crosses above the threshold.
- lt=<float> – trigger when the sample crosses below the threshold.
- st=<float> – trigger when the absolute delta from the last reported value is greater than or equal to the threshold.
- pmin=<int> – minimum seconds between accepted samples.
- pmax=<int> – force a cached sample to be kept at least every pmax seconds, even without changes.

When no rules are configured for an instance, every incoming sample is cached. The scheduler also forces a SEND when a cache for a controlled resource runs out of space or when the global max-samples/max-age limits are reached.

LwM2M engine and application events The Zephyr LwM2M engine defines events that can be sent back to the application through callback functions. The engine state machine shows when the events are spawned. Events depicted in the diagram are listed in the table. The events are prefixed with LWM2M_RD_CLIENT_EVENT_.

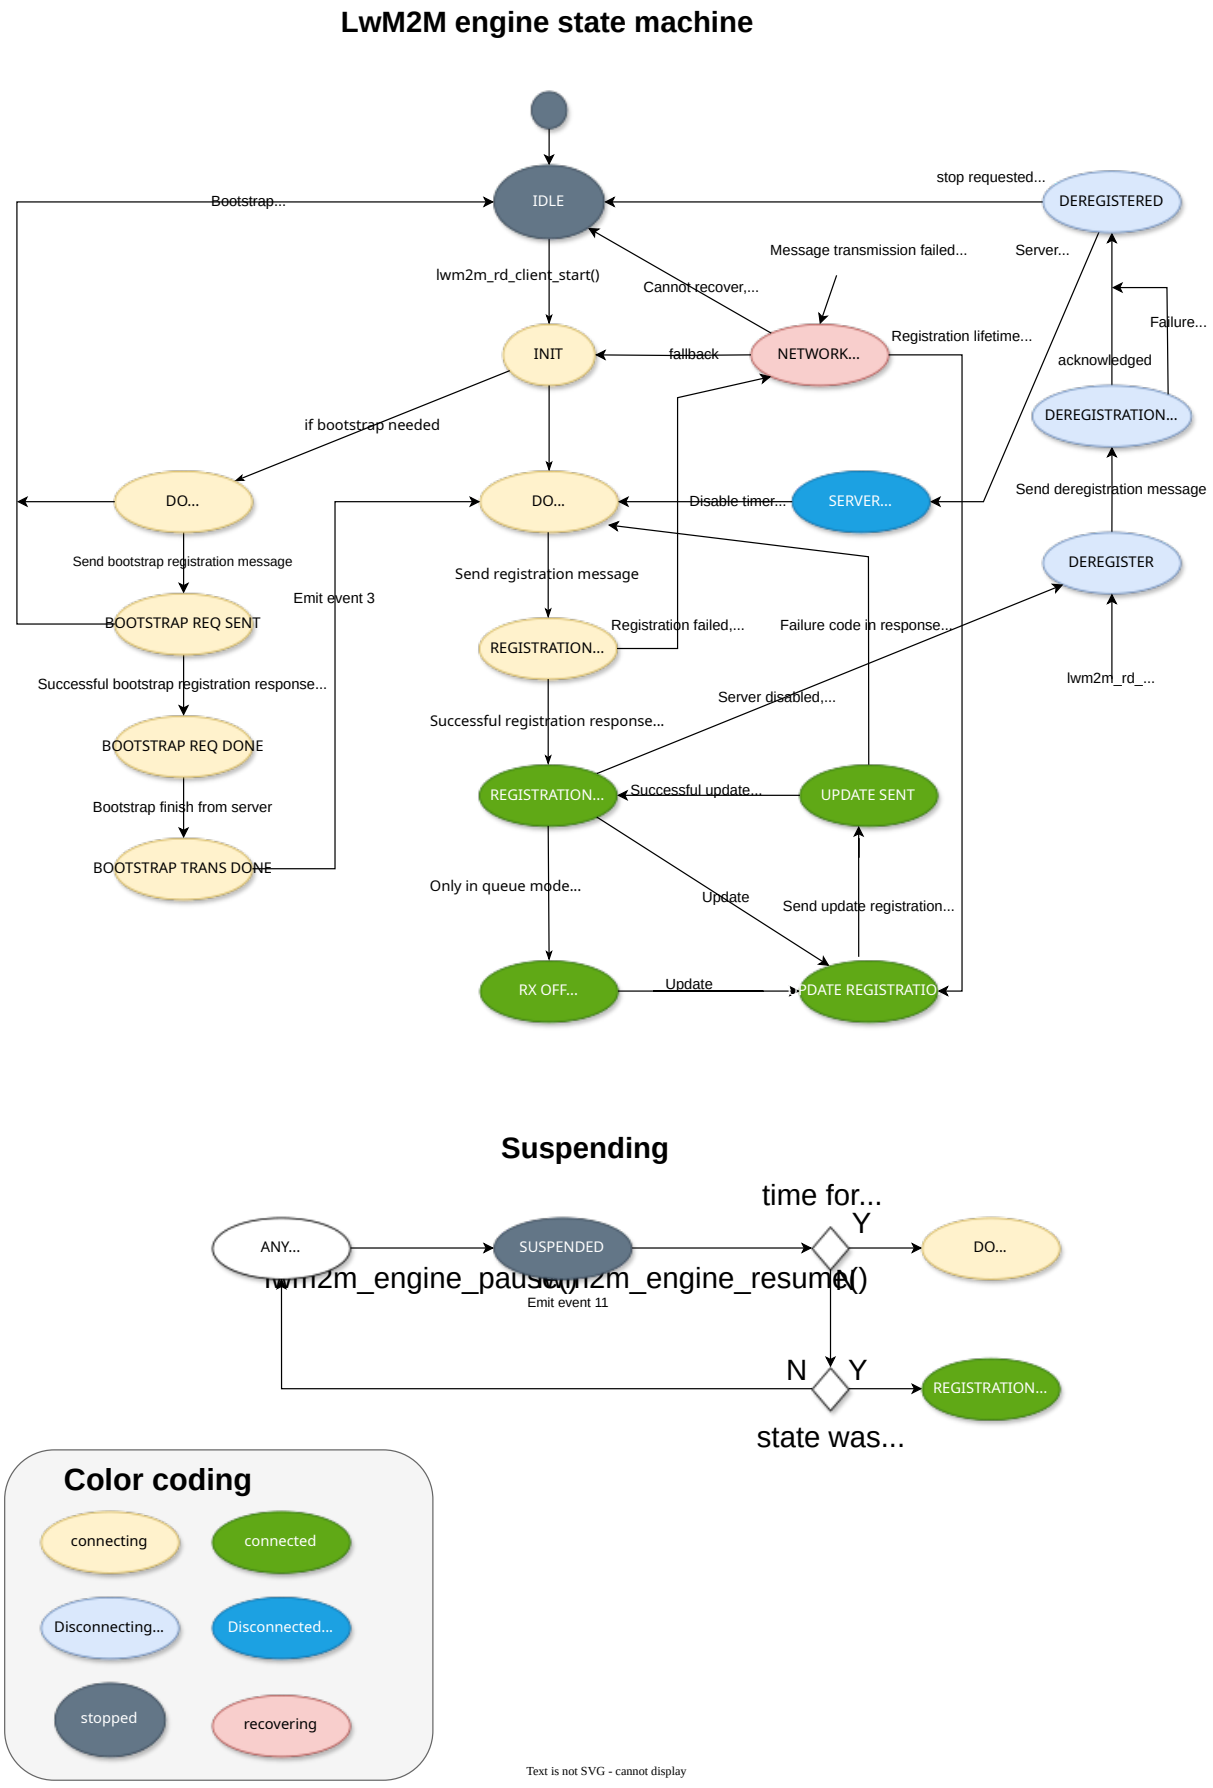

Fig. 15: State machine for the LwM2M engine

Table 33: LwM2M RD Client events

Ever ID	Event Name	Description
0	NONE	No event
1	BOOT-STRAP_REG_F	Bootstrap registration failed. Occurs if there is a timeout or failure in bootstrap registration.
2	BOOT-STRAP_REG_C	Bootstrap registration complete. Occurs after successful bootstrap registration.
3	BOOT-STRAP_TRANS	Bootstrap finish command received from the server.
4	REGISTRA-TION_FAILUR	Registration to LwM2M server failed. Occurs if server rejects the registration attempt.
5	REGISTRA-TION_COMPL	Registration to LwM2M server successful. Occurs after a successful registration reply from the LwM2M server or when session resumption is used.
6	REG_TIMEOU	Registration status lost. Occurs if there is socket errors or message timeouts. Client have lost connection to the server.
7	REG_UPDATE_	Registration update completed. Occurs after successful registration update reply from the LwM2M server.
8	DEREGIS-TER_FAILURE	Deregistration to LwM2M server failed. Occurs if there is a timeout or failure in the deregistration.
9	DISCON-NECT	LwM2M client have de-registered from server and is now stopped. Triggered only if the application have requested the client to stop.
10	QUEUE_MODI	Used only in queue mode, not actively listening for incoming packets. In queue mode the client is not required to actively listen for the incoming packets after a configured time period.
11	EN-GINE_SUSPEN	Indicate that client has now paused as a result of calling `lwm2m_engine_pause()`. State machine is no longer running and the handler thread is suspended. All timers are stopped so notifications are not triggered.
12	SERVER_DISA	Server have executed the disable command. Client will deregister and stay idle for the disable period.
13	NET-WORK_ERROI	Sending messages to the network failed too many times. Client cannot reach any servers or fallback to bootstrap. LwM2M engine cannot recover and have stopped.

The LwM2M client engine handles most of the state transitions automatically. The application needs to handle only the events that indicate that the client have stopped or is in a state where it cannot recover.

Table 34: How application should react to events

Event Name	How application should react
NONE	Ignore the event.
BOOT-STRAP_REG_FAIL	Try to recover network connection. Then restart the client by calling `lwm2m_rd_client_start()`. This might also indicate configuration issue.
BOOT-STRAP_REG_COM	No actions needed
BOOT-STRAP_TRANSFE	No actions needed
REGISTRA-TION_FAILURE	No actions needed. Client proceeds re-registration automatically. Might need a bootstrap or configuration fix. Cannot send or receive data.
REGISTRA-TION_COMPLETI	No actions needed. Application can send or receive data.
REG_TIMEOUT	No actions needed. Client proceeds to re-registration automatically. Cannot send or receive data.
REG_UPDATE_CO	No actions needed Application can send or receive data.
DEREGIS-TER_FAILURE	No actions needed, client proceeds to idle state automatically. Cannot send or receive data.
DISCONNECT	Engine have stopped as a result of calling `lwm2m_rd_client_stop()`. If connection is required, the application should restart the client by calling `lwm2m_rd_client_start()`.
QUEUE_MODE_R	No actions needed. Application can send but cannot receive data. Any data transmission will trigger a registration update.
EN-GINE_SUSPENDE	Engine can be resumed by calling `lwm2m_engine_resume()`. Cannot send or receive data.
SERVER_DISABLI	No actions needed, client will re-register once the disable period is over. Cannot send or receive data.
NET-WORK_ERROR	Try to recover network connection. Then restart the client by calling `lwm2m_rd_client_start()`. This might also indicate configuration issue.

Sending of data in the table above refers to calling `lwm2m_send_cb()` or by writing into one of the observed resources where observation would trigger a notify message. Receiving of data refers to receiving read, write or execute operations from the server. Application can register callbacks for these operations.

Configuring lifetime and activity period In LwM2M engine, there are three Kconfig options and one runtime value that configures how often the client will send LwM2M Update message.

Table 35: Update period variables

Variable	Effect
LwM2M regis-tration lifetime	The lifetime parameter in LwM2M specifies how long a device's registration with an LwM2M server remains valid. Device is expected to send LwM2M Update message before the lifetime exprires.
`CON-FIG_LWM2M_ENGIN`	Default lifetime value, unless set by the bootstrap server. Also defines lower limit that client accepts as a lifetime.
`CON-FIG_LWM2M_UPDAT`	How long the client can stay idle before sending a next update.
`CON-FIG_LWM2M_SECON`	Minimum time margin to send the update message before the registration lifetime expires.

By default, the client uses `CONFIG_LWM2M_SECONDS_TO_UPDATE_EARLY` to calculate how many seconds before the expiration of lifetime it is going to send the registration update. The problem with default mode is when the server changes the lifetime of the registration. This is then affecting the period of updates the client is doing. If this is used with the QUEUE mode, which is

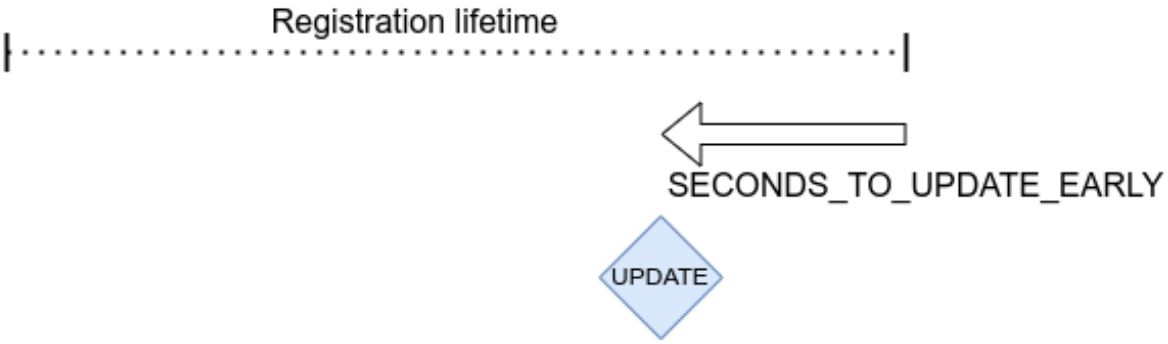

Fig. 16: Default way of calculating when to update registration.

typical in IPv4 networks, it is also affecting the period of when the device is reachable from the server.

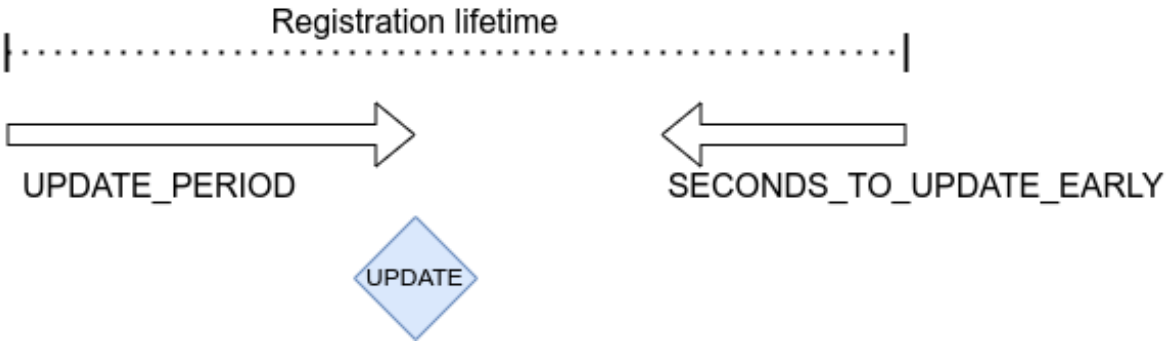

Fig. 17: Update time is controlled by UPDATE_PERIOD.

When also the `CONFIG_LWM2M_UPDATE_PERIOD` is set, time to send the update message is the earliest when any of these values expire. This allows setting long lifetime for the registration and configure the period accurately, even if server changes the lifetime parameter.

In runtime, the update frequency is limited to once in 15 seconds to avoid flooding.

LwM2M shell For testing the client it is possible to enable Zephyr's shell and LwM2M specific commands which support changing the state of the client. Operations supported are read, write and execute resources. Client start, stop, pause and resume are also available. The feature is enabled by selecting `CONFIG_LWM2M_SHELL`. The shell is meant for testing so productions systems should not enable it.

One imaginable scenario, where to use the shell, would be executing client side actions over UART when a server side tests would require those. It is assumed that not all tests are able to trigger required actions from the server side.

```
uart:~$ lwm2m
lwm2m - LwM2M commands
Subcommands:
  send    :send PATHS
          LwM2M SEND operation

  exec    :exec PATH [PARAM]
          Execute a resource

  read    :read PATH [OPTIONS]
          Read value from LwM2M resource
```

(continues on next page)

(continued from previous page)

```
          -x   Read value as hex stream (default)
          -s   Read value as string
          -b   Read value as bool (1/0)
          -uX  Read value as uintX_t
          -sX  Read value as intX_t
          -f   Read value as float
          -t   Read value as time_t

  write   :write PATH [OPTIONS] VALUE
          Write into LwM2M resource
          -s   Write value as string (default)
          -b   Write value as bool

MQTT

- *Overview*
- *Sample usage*
- *Using MQTT with TLS*
- *API Reference*

Overview MQTT (Message Queuing Telemetry Transport) is an application layer protocol which works on top of the TCP/IP stack. It is a lightweight publish/subscribe messaging transport for machine-to-machine communication. For more information about the protocol itself, see https://mqtt.org/.

Zephyr provides an MQTT client library built on top of BSD sockets API. The library can be enabled with `CONFIG_MQTT_LIB` Kconfig option and is configurable at a per-client basis, with support for MQTT versions 3.1.0, 3.1.1 and 5.0. The Zephyr MQTT implementation can be used with either plain sockets communicating over TCP, or with secure sockets communicating over TLS. See *BSD Sockets* for more information about Zephyr sockets.

MQTT clients require an MQTT server to connect to. Such a server, called an MQTT Broker, is responsible for managing client subscriptions and distributing messages published by clients. There are many implementations of MQTT brokers, one of them being Eclipse Mosquitto. See https://mosquitto.org/ for more information about the Eclipse Mosquitto project.

Sample usage To create an MQTT client, a client context structure and buffers need to be defined:

```
/* Buffers for MQTT client. */
static uint8_t rx_buffer[256];
static uint8_t tx_buffer[256];

/* MQTT client context */
static struct mqtt_client client_ctx;
```

Multiple MQTT client instances can be created in the application and managed independently. Additionally, a structure for MQTT Broker address information is needed. This structure must be accessible throughout the lifespan of the MQTT client and can be shared among MQTT clients:

```
/* MQTT Broker address information. */
static struct net_sockaddr_storage broker;
```

An MQTT client library will notify MQTT events to the application through a callback function created to handle respective events:

```
void mqtt_evt_handler(struct mqtt_client *client,
                      const struct mqtt_evt *evt)
{
   switch (evt->type) {
      /* Handle events here. */
   }
}
```

For a list of possible events, see *API Reference*.

The client context structure needs to be initialized and set up before it can be used. An example configuration for TCP transport is shown below:

```
mqtt_client_init(&client_ctx);

/* MQTT client configuration */
client_ctx.broker = &broker;
client_ctx.evt_cb = mqtt_evt_handler;
client_ctx.client_id.utf8 = (uint8_t *)"zephyr_mqtt_client";
client_ctx.client_id.size = sizeof("zephyr_mqtt_client") - 1;
client_ctx.password = NULL;
client_ctx.user_name = NULL;
client_ctx.protocol_version = MQTT_VERSION_3_1_1;
client_ctx.transport.type = MQTT_TRANSPORT_NON_SECURE;

/* MQTT buffers configuration */
client_ctx.rx_buf = rx_buffer;
client_ctx.rx_buf_size = sizeof(rx_buffer);
client_ctx.tx_buf = tx_buffer;
client_ctx.tx_buf_size = sizeof(tx_buffer);
```

After the configuration is set up, the MQTT client can connect to the MQTT broker. Call the `mqtt_connect` function, which will create the appropriate socket, establish a TCP/TLS connection, and send an `MQTT CONNECT` message. When notified, the application should call the `mqtt_input` function to process the response received. Note, that `mqtt_input` is a non-blocking function, therefore the application should use socket `poll` to wait for the response. If the connection was successful, `MQTT_EVT_CONNACK` will be notified to the application through the callback function.

```
rc = mqtt_connect(&client_ctx);
if (rc != 0) {
   return rc;
}

fds[0].fd = client_ctx.transport.tcp.sock;
fds[0].events = ZSOCK_POLLIN;
poll(fds, 1, 5000);

mqtt_input(&client_ctx);

if (!connected) {
   mqtt_abort(&client_ctx);
}
```

In the above code snippet, the MQTT callback function should set the `connected` flag upon a successful connection. If the connection fails at the MQTT level or a timeout occurs, the connection will be aborted, and the underlying socket closed.

After the connection is established, an application needs to call `mqtt_input` and `mqtt_live` functions periodically to process incoming data and upkeep the connection. If an MQTT message is received, an MQTT callback function will be called and an appropriate event notified.

The connection can be closed by calling the `mqtt_disconnect` function.

Zephyr provides sample code utilizing the MQTT client API. See mqtt-publisher for more information.

Using MQTT with TLS The Zephyr MQTT library can be used with TLS transport for secure communication by selecting a secure transport type (`MQTT_TRANSPORT_SECURE`) and some additional configuration information:

```
client_ctx.transport.type = MQTT_TRANSPORT_SECURE;

struct mqtt_sec_config *tls_config = &client_ctx.transport.tls.config;

tls_config->peer_verify = TLS_PEER_VERIFY_REQUIRED;
tls_config->cipher_list = NULL;
tls_config->sec_tag_list = m_sec_tags;
tls_config->sec_tag_count = ARRAY_SIZE(m_sec_tags);
tls_config->hostname = MQTT_BROKER_HOSTNAME;
tls_config->set_native_tls = true;
```

In this sample code, the `m_sec_tags` array holds a list of tags, referencing TLS credentials that the MQTT library should use for authentication. We do not specify `cipher_list`, to allow the use of all cipher suites available in the system. We set `hostname` field to broker hostname, which is required for server authentication. Finally, we enforce peer certificate verification by setting the `peer_verify` field.

Note, that TLS credentials referenced by the `m_sec_tags` array must be registered in the system first. For more information on how to do that, refer to *secure sockets documentation*.

Finally, `set_native_tls` can be optionally set to enable native TLS support instead of offloading TLS operations to an offloaded socket.

An example of how to use TLS with MQTT is also present in mqtt-publisher sample application.

MQTT-SN

- *Overview*
- *Sample usage*
- *Deviations from the standard*
- *API Reference*

Overview MQTT-SN is a variant of the well-known MQTT protocol - see *MQTT*.

In contrast to MQTT, MQTT-SN does not require a TCP transport, but is designed to be used over any message-based transport. Originally, it was mainly created with ZigBee in mind, but others like Bluetooth, UDP or even a UART can be used just as well.

Zephyr provides an MQTT-SN client library built on top of BSD sockets API. The library can be enabled with `CONFIG_MQTT_SN_LIB` Kconfig option and is configurable at a per-client basis, with

support for MQTT-SN version 1.2. The Zephyr MQTT-SN implementation can be used with any message-based transport, but support for UDP is already built-in.

MQTT-SN clients require an MQTT-SN gateway to connect to. These gateways translate between MQTT-SN and MQTT. The Eclipse Paho project offers an implementation of a MQTT-SN gateway, but others are available too. https://www.eclipse.org/paho/index.php?page=components/mqtt-sn-transparent-gateway/index.php

The MQTT-SN spec v1.2 can be found here: https://www.oasis-open.org/committees/download.php/66091/MQTT-SN_spec_v1.2.pdf

Sample usage To create an MQTT-SN client, a client context structure and buffers need to be defined:

```
/* Buffers for MQTT client. */
static uint8_t rx_buffer[256];
static uint8_t tx_buffer[256];

/* MQTT-SN client context */
static struct mqtt_sn_client client;
```

Multiple MQTT-SN client instances can be created in the application and managed independently. Additionally, a structure for the transport is needed as well. The library already comes with an example implementation for UDP.

```
/* MQTT Broker address information. */
static struct mqtt_sn_transport tp;
```

The MQTT-SN library will inform clients about certain events using a callback.

```
static void evt_cb(struct mqtt_sn_client *client,
                   const struct mqtt_sn_evt *evt)
{
   switch(evt->type) {
   {
      /* Handle events here. */
   }
}
```

For a list of possible events, see *API Reference*.

The client context structure needs to be initialized and set up before it can be used. An example configuration for UDP transport is shown below:

```
struct mqtt_sn_data client_id = MQTT_SN_DATA_STRING_LITERAL("ZEPHYR");
struct net_sockaddr_in gateway = {0};

uint8_t tx_buf[256];
uint8_t rx_buf[256];

mqtt_sn_transport_udp_init(&tp, (struct net_sockaddr*)&gateway, sizeof((gateway)));

mqtt_sn_client_init(&client, &client_id, &tp.tp, evt_cb, tx_buf, sizeof(tx_buf),␣
↪rx_buf, sizeof(rx_buf));
```

After the configuration is set up, the network address for the gateway to connect to must be defined. The MQTT-SN protocol offers functionality to discover gateways through an advertisement or a search mechanism. A user should do at least one of the following steps to define a Gateway for the library:

- Call the `mqtt_sn_add_gw()` function to manually define a Gateway address.

- Wait for an MQTT_SN_EVT_ADVERTISE.
- Call the mqtt_sn_search() function and wait for an MQTT_SN_EVT_GWINFO callback. Make sure to call the mqtt_sn_input() function periodically to process incoming messages.

Example mqtt_sn_search() function call:

```
err = mqtt_sn_search(&mqtt_client, 1);
k_sleep(K_SECONDS(10));
err = mqtt_sn_input(&mqtt_client);
__ASSERT(err == 0, "mqtt_sn_search() failed %d", err);
```

After the Gateway address has been defined or found, the MQTT-SN client can connect to the gateway. Call the mqtt_sn_connect() function, which will send a CONNECT MQTT-SN message. The application should periodically call the mqtt_sn_input() function to process the response received. The application does not have to call mqtt_sn_input() if it knows that no data has been received (e.g. when using Bluetooth). Note that mqtt_sn_input() is a non-blocking function, if the transport struct contains a poll() compatible function pointer. If the connection was successful, MQTT_SN_EVT_CONNECTED will be notified to the application through the callback function.

```
err = mqtt_sn_connect(&client, false, true);
__ASSERT(err == 0, "mqtt_sn_connect() failed %d", err);

while (1) {
        mqtt_sn_input(&client);
        if (connected) {
                mqtt_sn_publish(&client, MQTT_SN_QOS_0, &topic_p, false, &pubdata);
        }
        k_sleep(K_MSEC(500));
}
```

In the above code snippet, the gateway is connected to before publishing messages. If the connection fails at the MQTT level or a timeout occurs, the connection will be aborted and an error returned.

After the connection is established, an application needs to call mqtt_input() function periodically to process incoming data. Connection upkeep, on the other hand, is done automatically using a k_work item. If a MQTT message is received, an MQTT callback function will be called and an appropriate event notified.

The connection can be closed by calling the mqtt_sn_disconnect() function. This has no effect on the transport, however. If you want to close the transport (e.g. the socket), call mqtt_sn_client_deinit(), which will deinit the transport as well.

Zephyr provides sample code utilizing the MQTT-SN client API. See mqtt-sn-publisher for more information.

Deviations from the standard Certain parts of the protocol are not yet supported in the library.

Open Charge Point Protocol (OCPP)

- *Overview*
- *Sample usage*
- *API Reference*

Overview Open Charge Point Protocol (OCPP) is an application protocol for communication between Charge Points (Electric vehicle (EV) charging stations) and a central management system, also known as a charging station network. OCPP is a standard defined by The Open Charge Alliance and goal is to offer a uniform solution for the method of communication between charge point and central system. With this protocol it is possible to connect any central system with any charge point, regardless of the vendor.

Zephyr provides an OCPP Charge Point (CP) library built on top of websocket API with payload in json format. The library can be enabled with `CONFIG_OCPP` Kconfig option. Currently OCPP 1.6 with basic core profile is supported.

OCPP charge point (CP) require a Central System (CS) server to connect, an open source SteVe server shall be setup locally for development purpose, See SteVe server for more information about the setup.

The Zephyr OCPP CP library implements the following items:

- engine to process socket connectivity and events
- OCPP core functions to frame/parse payload, user notification for OCPP events, heartbeat notification

Sample usage Init ocpp library with overall CP and CS information. Prior to init an OCPP library, a network interface should be ready using ethernet or wifi or modem. A filled CP, CS structure and user callback needs to be passed in ocpp_init.

```
static int user_notify_cb(ocpp_notify_reason_t reason,
                          ocpp_io_value_t *io,
                          void *user_data)
{

     switch (reason) {
     case OCPP_USR_GET_METER_VALUE:
             ...
             break;

     case OCPP_USR_START_CHARGING:
             ...
             break;

             ...
             ...
}

/* OCPP configuration */
ocpp_cp_info_t cpi = { "basic", "zephyr", .num_of_con = 1};
ocpp_cs_info_t csi =  {"192.168.1.3",   /* ip address */
                       "/steve/websocket/CentralSystemService/zephyr",
                       8180,
                       AF_INET};
```

(continues on next page)

(continued from previous page)

```
ret = ocpp_init(&cpi, &csi, user_notify_cb, NULL);
```

A unique session must open for each physical connector before any ocpp transaction API call.

```
ocpp_session_handle_t sh = NULL;
ret = ocpp_session_open(&sh);
```

idtag is EV user's authentication token which should match with list on CS. Authorize request must call to ensure validity of idtag (if charging request originate from local CP) before start energy transfer to EV.

```
ocpp_auth_status_t status;
ret = ocpp_authorize(sh, idtag, &status, 500);
```

On successful, authorization status is available in status.

Apart from local CP, charging request may originate from CS is notified to user in callback with OCPP_USR_START_CHARGING, here authorize request call is optional. When the CS is ready to provide power to EV, a start transaction is notified to CS with meter reading and connector id using ocpp_start_transaction.

```
const int idcon = 1;
const int mval = 25; //meter reading in wh
ret = ocpp_start_transaction(sh, mval, idcon, 200);
```

Once the start transaction is success, user callback is invoked to get meter readings from the library. callback should be not be hold for longer time.

Latmon Network Service

- *Overview*

- *API Reference*
- *Features*
- *Workflow*
  - *Socket Creation*
  - *Connection Handling*
  - *Monitoring Start*
  - *Monitoring Status*
  - *Thread Management*
- *Enabling the Latmon Service*
- *Example Usage*

Overview Provides the functionality required for network-based latency monitoring, including socket management, client-server communication, and data exchange with the Latmus service running on the System Under Test (SUT).

The Latmon network service is responsible for establishing and managing network communication between the Latmon application (running on a Zephyr-based board) and the Latmus service (running on the SUT).

It uses TCP sockets for reliable communication and UDP sockets for broadcasting the IP address of the Latmon device.

API Reference

Latency Monitor

Related code samples

- Latmon ClientMeasures delta time between GPIO events and reports the latency metrics via latmon to the latmus service executing on the SUT.

Features

- **Socket Management**: Creates and manages TCP and UDP sockets for communication.
- **Client-Server Communication**: Handles incoming connections from the Latmus service.
- **Data Exchange**: Sends latency metrics and histogram data to the Latmus service.
- **IP Address Broadcasting**: Broadcasts the IP address of the Latmon device to facilitate discovery by the Latmus service.
- **Thread-Safe Design**: Uses Zephyr's kernel primitives (e.g., message queues and semaphores) for synchronization.

Workflow

Socket Creation The `net_latmon_get_socket()` function is called to create and configure a TCP socket to communicate with the Latmus service. A connection address can be specified as a parameter to bind the socket to a specific interface and port.

Connection Handling The `net_latmon_connect()` function waits for a connection from the Latmus service. If no connection is received within the timeout period, the service broadcasts its IP address using UDP and returns `-EAGAIN`. If the broadcast request cannot be sent, the function returns `-1`, and the client should quit.

Monitoring Start Once a connection is established, the `net_latmon_start()` function is called to start the monitoring process. This function uses a callback to calculate latency deltas and sends the data to the Latmus service.

Monitoring Status The `net_latmon_running()` function can be used to check if the monitoring process is active.

Thread Management The service uses Zephyr threads to handle incoming connections and manage the monitoring process.

Enabling the Latmon Service The following configuration option must be enabled in the `prj.conf` file.

- `CONFIG_NET_LATMON`

The following options may be configured to customize the Latmon service:

- `CONFIG_NET_LATMON_PORT` - Port number for the Latmon service.
- `CONFIG_NET_LATMON_XFER_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_XFER_THREAD_PRIORITY`
- `CONFIG_NET_LATMON_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_THREAD_PRIORITY`
- `CONFIG_NET_LATMON_MONITOR_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_MONITOR_THREAD_PRIORITY`

Example Usage

```
#include <zephyr/net/latmon.h>
#include <zephyr/net/socket.h>

void main(void)
{
    struct in_addr ip;
    int server_socket, client_socket;

    /* Create and configure the server socket */
    server_socket = net_latmon_get_socket(NULL);

    while (1) {
        /* Wait for a connection from the Latmus service */
        client_socket = net_latmon_connect(server_socket, &ip);
        if (client_socket < 0) {
            if (client_socket == -EAGAIN) {
                continue;
            }
            goto out;
        }

        /* Start the latency monitoring process */
```

(continues on next page)

(continued from previous page)

```
        net_latmon_start(client_socket, measure_latency_cycles);
    }
out:
    close(server_socket);
}
```

Network System Management

Network Configuration Library

- *Overview*
- *Sample usage*
- *API Reference*

Overview The network configuration library sets up networking devices in a semi-automatic way during the system boot, based on user-supplied Kconfig options.

The following Kconfig options affect how configuration library will setup the system:

Table 36: Kconfig options for network configuration library

Option name	Description
CONFIG_NET_CONFIG_SETTINGS	This option controls whether the network system is configured or initialized at all. If not set, then the config library is not used for initialization and the application needs to do all the network related configuration itself. If this option is set, then the user can optionally configure static IP addresses to be set to the first network interface in the system. Typically setting static IP addresses is only usable in testing and should not be used in production code. See the config library Kconfig file subsys/net/lib/config/Kconfig for specific options to set the static IP addresses.
CONFIG_NET_CONFIG_AUTO_INIT	The networking system is automatically configured when the device is started.
CONFIG_NET_CONFIG_INIT_TIMEOUT	This tells how long to wait for the networking to be ready and available. If for example IPv4 address from DHCPv4 is not received within this limit, then a call to net_config_init() will return error during the device startup.
CONFIG_NET_CONFIG_NEED_IPV4	The network application needs IPv4 support to function properly. This option makes sure the network application is initialized properly in order to use IPv4. If CONFIG_NET_IPV4 is not enabled, then setting this option will automatically enable IPv4.
CONFIG_NET_CONFIG_NEED_IPV6	The network application needs IPv6 support to function properly. This option makes sure the network application is initialized properly in order to use IPv6. If CONFIG_NET_IPV6 is not enabled, then setting this option will automatically enable IPv6.
CONFIG_NET_CONFIG_NEED_IPV6_ROUTER	If IPv6 is enabled, then this option tells that the network application needs IPv6 router to exists before continuing. This means in practice that the application wants to wait until it receives IPv6 router advertisement message before continuing.
CONFIG_NET_CONFIG_MY_IPV6_ADDR	Local static IPv6 address assigned to the default network interface.
CONFIG_NET_CONFIG_PEER_IPV6_ADDR	Peer static IPv6 address. This is mainly useful in testing setups where the application can connect to a pre-defined host.
CONFIG_NET_CONFIG_MY_IPV4_ADDR	Local static IPv4 address assigned to the default network interface.
CONFIG_NET_CONFIG_MY_IPV4_NETMASK	Static IPv4 netmask assigned to the IPv4 address.
CONFIG_NET_CONFIG_MY_IPV4_GW	Static IPv4 gateway address assigned to the default network interface.
CONFIG_NET_CONFIG_PEER_IPV4_ADDR	Peer static IPv4 address. This is mainly useful in testing setups where the application can connect to a pre-defined host.

Sample usage If CONFIG_NET_CONFIG_AUTO_INIT is set, then the configuration library is automatically enabled and run during the device boot. In this case, the library will call net_config_init() automatically and the application does not need to do any network configuration.

If you want to use the network configuration library but without automatic initialization, you can

call `net_config_init()` manually. The `flags` parameter can be used to give hints to the library about what kind of functionality the application wishes to have before the actual application starts.

Overview The Dynamic Host Configuration Protocol (DHCP) for IPv6 is a network management protocol used on IPv6 based networks. A DHCPv6 server dynamically assigns an IPv6 address and other network configuration parameters to each device on a network so they can communicate with other IP networks. See this DHCPv6 Wikipedia article for a detailed overview of how DHCPv6 works.

Note that Zephyr only supports DHCPv6 client functionality.

API Reference
DHCPv6

Hostname Configuration

- *Overview*
- *API Reference*

Overview A networked device might need a hostname, for example, if the device is configured to be a mDNS responder (see *DNS Resolve* for details) and needs to respond to `<hostname>.local` DNS queries.

The `CONFIG_NET_HOSTNAME_ENABLE` must be set in order to store the hostname and enable the relevant APIs. If the option is enabled, then the default hostname is set to be `zephyr` by `CONFIG_NET_HOSTNAME` option.

If the same firmware image is used to flash multiple boards, then it is not practical to use the same hostname in all of the boards. In that case, one can enable `CONFIG_NET_HOSTNAME_UNIQUE` which will add a unique postfix to the hostname. By default the link local address of the first network interface is used as a postfix. In Ethernet networks, the link local address refers to MAC address. For example, if the link local address is `01:02:03:04:05:06`, then the unique hostname could be `zephyr010203040506`. If you want to set the prefix yourself, then call `net_hostname_set_postfix_str()` before the network interfaces are created. Alternatively, if you prefer a hexadecimal conversion for the prefix, then call `net_hostname_set_postfix()`. For example for the Ethernet networks, the initialization priority is set by `CONFIG_ETH_INIT_PRIORITY` so you would need to set the postfix before that. The postfix can be set only once.

API Reference
Network Hostname Library

Network Core Helpers

- *Overview*
- *API Reference*

Overview The network subsystem contains two functions for sending and receiving data from the network. The `net_recv_data()` is typically used by network device driver when the received network data needs to be pushed up in the network stack for further processing. All the data is received via a network interface which is typically created by the device driver.

For sending, the `net_send_data()` can be used. Typically applications do not call this function directly as there is the *BSD Sockets* API for sending and receiving network data.

API Reference
Network Core Library

Network Interface

- *Overview*
- *Network interface state management*
- *API Reference*

Overview The network interface is a nexus that ties the network device drivers and the upper part of the network stack together. All the sent and received data is transferred via a network interface. The network interfaces cannot be created at runtime. A special linker section will contain information about them and that section is populated at linking time.

Network interfaces are created by `NET_DEVICE_INIT()` macro. For Ethernet network, a macro called `ETH_NET_DEVICE_INIT()` should be used instead as it will create VLAN interfaces automatically if `CONFIG_NET_VLAN` is enabled. These macros are typically used in network device driver source code.

The network interface can be turned ON by calling `net_if_up()` and OFF by calling `net_if_down()`. When the device is powered ON, the network interface is also turned ON by default.

The network interfaces can be referenced either by a `struct net_if *` pointer or by a network interface index. The network interface can be resolved from its index by calling `net_if_get_by_index()` and from interface pointer by calling `net_if_get_by_iface()`.

The IP address for network devices must be set for them to be connectable. In a typical dynamic network environment, IP addresses are set automatically by DHCPv4, for example. If needed though, the application can set a device's IP address manually. See the API documentation below for functions such as `net_if_ipv4_addr_add()` that do that.

The `net_if_get_default()` returns a *default* network interface. What this default interface means can be configured via options like `CONFIG_NET_DEFAULT_IF_FIRST` and `CONFIG_NET_DEFAULT_IF_ETHERNET`. See Kconfig file subsys/net/ip/Kconfig what options are available for selecting the default network interface.

The transmitted and received network packets can be classified via a network packet priority. This is typically done in Ethernet networks when virtual LANs (VLANs) are used. Higher priority packets can be sent or received earlier than lower priority packets. The traffic class setup can be configured by `CONFIG_NET_TC_TX_COUNT` and `CONFIG_NET_TC_RX_COUNT` options.

If the `CONFIG_NET_PROMISCUOUS_MODE` is enabled and if the underlying network technology supports promiscuous mode, then it is possible to receive all the network packets that the network device driver is able to receive. See *Promiscuous Mode* API for more details.

Network interface state management Zephyr distinguishes between two interface states: administrative state and operational state, as described in RFC 2863. The administrative state indicate whether an interface is turned ON or OFF. This state is represented by `NET_IF_UP` flag and is controlled by the application. It can be changed by calling `net_if_up()` or `net_if_down()` functions. Network drivers or L2 implementations should not change administrative state on their own.

Bringing an interface up however not always means that the interface is ready to transmit packets. Because of that, operational state, which represents the internal interface status, was implemented. The operational state is updated whenever one of the following conditions take place:

- The interface is brought up/down by the application (administrative state changes).
- The interface is notified by the driver/L2 that PHY status has changed.
- The interface is notified by the driver/L2 that it joined/left a network.

The PHY status is represented with `NET_IF_LOWER_UP` flag and can be changed with `net_if_carrier_on()` and `net_if_carrier_off()`. By default, the flag is set on a newly initialized interface. An example of an event that changes the carrier state is Ethernet cable being plugged in or out.

The network association status is represented with `NET_IF_DORMANT` flag and can be changed with `net_if_dormant_on()` and `net_if_dormant_off()`. By default, the flag is cleared on a newly initialized interface. An example of an event that changes the dormant state is a Wi-Fi driver successfully connecting to an access point. In this scenario, driver should set the dormant state to ON during initialization, and once it detects that it connected to a Wi-Fi network, the dormant state should be set to OFF.

The operational state of an interface is updated as follows:

- `!net_if_is_admin_up()`

  Interface is in `NET_IF_OPER_DOWN`.

- `net_if_is_admin_up() && !net_if_is_carrier_ok()`

  Interface is in `NET_IF_OPER_DOWN` or `NET_IF_OPER_LOWERLAYERDOWN` if the interface is stacked (virtual).

- `net_if_is_admin_up() && net_if_is_carrier_ok() && net_if_is_dormant()`

  Interface is in `NET_IF_OPER_DORMANT`.

- `net_if_is_admin_up() && net_if_is_carrier_ok() && !net_if_is_dormant()`

  Interface is in `NET_IF_OPER_UP`.

Only after an interface enters `NET_IF_OPER_UP` state the `NET_IF_RUNNING` flag is set on the interface indicating that the interface is ready to be used by the application.

L2 Layer Management

- *Overview*
- *L2 layer API*

- *Network Device drivers*
  - *Ethernet device driver*
  - *IEEE 802.15.4 device driver*
- *API Reference*

Overview The L2 stack is designed to hide the whole networking link-layer part and the related device drivers from the upper network stack. This is made through a `net_if` declared in include/zephyr/net/net_if.h.

The upper layers are unaware of implementation details beyond the net_if object and the generic API provided by the L2 layer in include/zephyr/net/net_l2.h as `net_l2`.

Only the L2 layer can talk to the device driver, linked to the net_if object. The L2 layer dictates the API provided by the device driver, specific for that device, and optimized for working together.

Currently, there are L2 layers for *Ethernet*, *IEEE 802.15.4 Soft-MAC*, *CANBUS*, *OpenThread*, Wi-Fi, and a dummy layer example that can be used as a template for writing a new one.

L2 layer API In order to create an L2 layer, or a driver for a specific L2 layer, one needs to understand how the L3 layer interacts with it and how the L2 layer is supposed to behave. See also *network stack architecture* for more details. The generic L2 API has these functions:

- `recv()`: All device drivers, once they receive a packet which they put into a `net_pkt`, will push this buffer to the network stack via `net_recv_data()`. At this point, the network stack does not know what to do with it. Instead, it passes the buffer along to the L2 stack's `recv()` function for handling. The L2 stack does what it needs to do with the packet, for example, parsing the link layer header, or handling link-layer only packets. The `recv()` function will return `NET_DROP` in case of an erroneous packet, `NET_OK` if the packet was fully consumed by the L2, or `NET_CONTINUE` if the network stack should then handle it.
- `send()`: Similar to receive function, the network stack will call this function to actually send a network packet. All relevant link-layer content will be generated and added by this function. The `send()` function returns the number of bytes sent, or a negative error code if there was a failure sending the network packet.
- `enable()`: This function is used to enable/disable traffic over a network interface. The function returns `<0` if error and `>=0` if no error.
- `get_flags()`: This function will return the capabilities of an L2 driver, for example whether the L2 supports multicast or promiscuous mode.

Network Device drivers Network device drivers fully follows Zephyr device driver model as a basis. Please refer to *Device Driver Model*.

There are, however, two differences:

- The driver_api pointer must point to a valid `net_if_api` pointer.
- The network device driver must use `NET_DEVICE_INIT_INSTANCE()` or `ETH_NET_DEVICE_INIT()` for Ethernet devices. These macros will call the `DEVICE_DEFINE()` macro, and also instantiate a unique `net_if` related to the created device driver instance.

Implementing a network device driver depends on the L2 stack it belongs to: *Ethernet*, *IEEE 802.15.4*, etc. In the next section, we will describe how a device driver should behave when receiving or sending a network packet. The rest is hardware dependent and is not detailed here.

Ethernet device driver On reception, it is up to the device driver to fill-in the network packet with as many data buffers as required. The network packet itself is a `net_pkt` and should be allocated through `net_pkt_rx_alloc_with_buffer()`. Then all data buffers will be automatically allocated and filled by `net_pkt_write()`.

After all the network data has been received, the device driver needs to call `net_recv_data()`. If that call fails, it will be up to the device driver to unreference the buffer via `net_pkt_unref()`.

On sending, the device driver send function will be called, and it is up to the device driver to send the network packet all at once, with all the buffers.

Each Ethernet device driver will need, in the end, to call `ETH_NET_DEVICE_INIT()` like this:

```
ETH_NET_DEVICE_INIT(..., CONFIG_ETH_INIT_PRIORITY,
                    &the_valid_net_if_api_instance, 1500);
```

IEEE 802.15.4 device driver Device drivers for IEEE 802.15.4 L2 work basically the same as for Ethernet. What has been described above, especially for `recv()`, applies here as well. There are two specific differences however:

- It requires a dedicated device driver API: `ieee802154_radio_api`, which overloads `net_if_api`. This is because 802.15.4 L2 needs more from the device driver than just `send()` and `recv()` functions. This dedicated API is declared in include/zephyr/net/ieee802154_radio.h. Each and every IEEE 802.15.4 device driver must provide a valid pointer on such relevantly filled-in API structure.
- Sending a packet is slightly different than in Ethernet. Most IEEE 802.15.4 PHYs support relatively small frames only, 127 bytes all inclusive: frame header, payload and frame checksum. Buffers to be sent over the radio will often not fit this frame size limitation, e.g. a buffer containing an IPv6 packet will often have to be split into several fragments and IP6 packet headers and fragments need to be compressed using a protocol like 6LoWPAN before being passed on to the radio driver. Additionally the IEEE 802.15.4 standard defines medium access (e.g. CSMA/CA), frame retransmission, encryption and other preprocessing procedures (e.g. addition of information elements) that individual radio drivers should not have to care about. This is why the `ieee802154_radio_api` requires a tx function pointer which differs from the `net_if_api` send function pointer. Zephyr's native IEEE 802.15.4 L2 implementation provides a generic `ieee802154_send()` instead, meant to be given as `net_if` send function. The implementation of `ieee802154_send()` takes care of IEEE 802.15.4 standard packet preparation procedures, splitting the packet into possibly compressed, encrypted and otherwise pre-processed fragment buffers, sending one buffer at a time through `ieee802154_radio_api` tx function and unreferencing the network packet only when the transmission as a whole was either successful or failed.

Interaction between IEEE 802.15.4 radio device drivers and L2 is bidirectional:

- L2 -> L1: Methods as `ieee802154_send()` and several IEEE 802.15.4 net management calls will call into the driver, e.g. to send a packet over the radio link or re-configure the driver at runtime. These incoming calls will all be handled by the methods in the `ieee802154_radio_api`.
- L1 -> L2: There are several situations in which the driver needs to initiate calls into the L2/MAC layer. Zephyr's IEEE 802.15.4 L1 -> L2 adaptation API employs an "inversion-of-control" pattern in such cases avoids duplication of complex logic across independent driver implementations and ensures implementation agnostic loose coupling and clean separation of concerns between MAC (L2) and PHY (L1) whenever reverse information transfer or close co-operation between hardware and L2 is required. During driver initialization, for example, the driver calls `ieee802154_init()` to pass the interface's MAC address as well as other hardware-related configuration to L2. Similarly, drivers may indicate performance or timing critical radio events to L2 that require close integration with the hardware (e.g. `ieee802154_handle_ack()`). Calls from L1 into L2 are not implemented as methods in `ieee802154_radio_api` but are standalone functions declared and documented

as such in include/zephyr/net/ieee802154_radio.h. The API documentation will clearly state which functions must be implemented by all L2 stacks as part of the L1 -> L2 "inversion-of-control" adaptation API.

Note: Standalone functions in include/zephyr/net/ieee802154_radio.h that are not explicitly documented as callbacks are considered to be helper functions within the PHY (L1) layer implemented independently of any specific L2 stack, see for example `ieee802154_is_ar_flag_set()`.

As all net interfaces, IEEE 802.15.4 device driver implementations will have to call `NET_DEVICE_INIT_INSTANCE()` in the end:

```
NET_DEVICE_INIT_INSTANCE(...,
                         the_device_init_prio,
                         &the_valid_ieee802154_radio_api_instance,
                         IEEE802154_L2,
                         NET_L2_GET_CTX_TYPE(IEEE802154_L2), 125);
```

Network Traffic Offloading

- *Network Offloading*
  - *Overview*
  - *API Reference*
- *Socket Offloading*
  - *Overview*

Network Offloading

Overview The network offloading API provides hooks that a device vendor can use to provide an alternate implementation for an IP stack. This means that the actual network connection creation, data transfer, etc., is done in the vendor HAL instead of the Zephyr network stack.

API Reference
Network Offloading Interface

Socket Offloading

Overview In addition to the network offloading API, Zephyr allows offloading of networking functionality at the socket API level. With this approach, vendors who provide an alternate implementation of the networking stack, exposing socket API for their networking devices, can easily integrate it with Zephyr.

See drivers/wifi/simplelink/simplelink_sockets.c for a sample implementation on how to integrate network offloading at socket level.

Link Layer Address Handling

- *Overview*
- *API Reference*

Overview The link layer addresses are set for network interfaces so that L2 connectivity works correctly in the network stack. Typically the link layer addresses are 6 bytes long like in Ethernet but for IEEE 802.15.4 the link layer address length is 8 bytes.

API Reference
Network Link Address Library

Ethernet Management

- *Overview*
- *API Reference*

Overview Ethernet management API provides functions to manage the Ethernet network interface low level status. The caller of these functions can:

- raise `carrier ON` or `carrier OFF` management events
- raise `VLAN enabled` or `VLAN disabled` management events

Typically the `carrier OFF` event would be generated by the Ethernet device driver when it notices that the Ethernet cable is disconnected. The `carrier ON` event would be generated if the Ethernet device driver notices that the Ethernet cable is re-connected.

Currently the VLAN events are generated by the Ethernet L2 layer when a specific VLAN tag is either enabled or disabled.

The user application can monitor these events if it needs to act when the corresponding status changes.

API Reference
Ethernet Library

Traffic Classification

Overview Traffic classification is an automated process that categorizes computer network traffic according to various parameters. For Zephyr, the VLAN priority code point (PCP) is used to classify both received and sent network packets. See more information about VLAN priority at IEEE 802.1Q.

By default, all network traffic is treated equal in Zephyr. If desired, the option `CONFIG_NET_TC_TX_COUNT` can be used to set the number of transmit queues. The option `CONFIG_NET_TC_RX_COUNT` can be used to set the number of receive queues. Each traffic class queue corresponds to a specific kernel work queue. Each kernel work queue has a priority. The VLAN

priority is mapped to a certain traffic class according to rules specified in IEEE 802.1Q spec chapter I.3, chapter 8.6.6 table 8-4, and chapter 34.5 table 34-1. Each traffic class is in turn mapped to a certain kernel work queue. The maximum number of traffic classes for both Rx and Tx is 8.

See subsys/net/ip/net_tc.c for details of how various mappings are done.

Network Packet Filtering

- *Overview*
- *Examples*
- *API Reference*

Overview The Network Packet Filtering facility provides the infrastructure to construct custom rules for accepting and/or denying packet transmission and reception. It also allows to modify the priority of incoming network packets. This can be used to create a basic firewall, control network traffic, etc.

The `CONFIG_NET_PKT_FILTER` must be set in order to enable the relevant APIs.

Both the transmission and reception paths may have a list of filter rules. Each rule is made of a set of conditions and a packet outcome. Every packet is subjected to the conditions attached to a rule. When all the conditions for a given rule are true then the packet outcome is immediately determined as specified by the current rule and no more rules are considered. If one condition is false then the next rule in the list is considered.

Packet outcome is either `NET_OK` to accept the packet, `NET_DROP` to drop it or `NET_CONTINUE` to modify its priority on the fly.

When the outcome is `NET_CONTINUE` the priority is updated but the final outcome is not yet determined and processing continues. If all conditions of multiple rules are true, then the packet gets the priority of the rule last considered.

A rule is represented by a `npf_rule` object. It can be inserted to, appended to or removed from a rule list contained in a `npf_rule_list` object using `npf_insert_rule()`, `npf_append_rule()`, and `npf_remove_rule()`.

There are different sets of rules for different layers in the network stack. Some of the rules are applied for L2 layer like Ethernet, and some for L3 layer where IPv4 or IPv6 protocol is handled. The `local_in` rules are for matching incoming protocol types like UDP or TCP packets that are run on top of IPv4 or IPv6. The rule support for different layers can be controlled by relevant Kconfig options mentioned below.

- `npf_send_rules` is a rule list applied to outgoing packets in L2 layer
- `npf_recv_rules` is a rule list applied to incoming packets in L2 layer
- `npf_ipv4_recv_rules` is a rule list applied for incoming IPv4 packets. Can be enabled or disabled by `CONFIG_NET_PKT_FILTER_IPV4_HOOK` option.
- `npf_ipv6_recv_rules` is a rule list applied for incoming IPv6 packets. Can be enabled or disabled by `CONFIG_NET_PKT_FILTER_IPV6_HOOK` option.
- `npf_local_in_recv_rules` is a rule list applied for incoming UDP or TCP packets. Can be enabled or disabled by `CONFIG_NET_PKT_FILTER_LOCAL_IN_HOOK` option.

If a filter rule list is empty then `NET_OK` is assumed. If a non-empty rule list runs to the end then `NET_DROP` is assumed. However it is recommended to always terminate a non-empty rule list with an explicit default termination rule, either `npf_default_ok` or `npf_default_drop`.

Rule conditions are represented by a `npf_test`. This structure can be embedded into a larger structure when a specific condition requires extra test data. It is up to the test function for such conditions to retrieve the outer structure from the provided `npf_test` structure pointer.

Convenience macros are provided in include/zephyr/net/net_pkt_filter.h to statically define condition instances for various conditions, and `NPF_RULE()` and `NPF_PRIORITY()` to create a rule instance with an immediate outcome or a priority change.

See also net-pkt-filter sample for an example of how to create and manage packet filters. The network shell has a `net filter` command that can be used to see the installed rules at runtime.

Examples Here's an example usage:

```
static NPF_SIZE_MAX(maxsize_200, 200);
static NPF_ETH_TYPE_MATCH(ip_packet, NET_ETH_PTYPE_IP);

static NPF_RULE(small_ip_pkt, NET_OK, ip_packet, maxsize_200);

void install_my_filter(void)
{
    npf_insert_recv_rule(&npf_default_drop);
    npf_insert_recv_rule(&small_ip_pkt);
}
```

The above would accept IP packets that are 200 bytes or smaller, and drop all other packets.

Another (less efficient) way to achieve the same result could be:

```
static NPF_SIZE_MIN(minsize_201, 201);
static NPF_ETH_TYPE_UNMATCH(not_ip_packet, NET_ETH_PTYPE_IP);

static NPF_RULE(reject_big_pkts, NET_DROP, minsize_201);
static NPF_RULE(reject_non_ip, NET_DROP, not_ip_packet);

void install_my_filter(void) {
    npf_append_recv_rule(&reject_big_pkts);
    npf_append_recv_rule(&reject_non_ip);
    npf_append_recv_rule(&npf_default_ok);
}
```

This example assigns priorities to different network traffic. It gives network control priority (`NET_PRIORITY_NC`) to the `ptp` packets, critical applications priority (`NET_PRIORITY_CA`) to the internet traffic of version 6, excellent effort (`NET_PRIORITY_EE`) for internet protocol version 4 traffic, and the lowest background priority (`NET_PRIORITY_BK`) to `lldp` and `arp`.

Priority rules are only really useful if multiple traffic class queues are enabled in the project configuration `CONFIG_NET_TC_RX_COUNT`. The mapping from the priority of the packet to the traffic class queue is in accordance with the standard 802.1Q and depends on the `CONFIG_NET_TC_RX_COUNT`.

```
static NPF_ETH_TYPE_MATCH(is_arp, NET_ETH_PTYPE_ARP);
static NPF_ETH_TYPE_MATCH(is_lldp, NET_ETH_PTYPE_LLDP);
static NPF_ETH_TYPE_MATCH(is_ptp, NET_ETH_PTYPE_PTP);
static NPF_ETH_TYPE_MATCH(is_ipv4, NET_ETH_PTYPE_IP);
static NPF_ETH_TYPE_MATCH(is_ipv6, NET_ETH_PTYPE_IPV6);

static NPF_PRIORITY(priority_bk, NET_PRIORITY_BK, is_arp, is_lldp);
static NPF_PRIORITY(priority_ee, NET_PRIORITY_EE, is_ipv4);
static NPF_PRIORITY(priority_ca, NET_PRIORITY_CA, is_ipv6);
static NPF_PRIORITY(priority_nc, NET_PRIORITY_NC, is_ptp);
```

(continues on next page)

(continued from previous page)

```
void install_my_filter(void) {
    npf_append_recv_rule(&priority_bk);
    npf_append_recv_rule(&priority_ee);
    npf_append_recv_rule(&priority_ca);
    npf_append_recv_rule(&priority_nc);
    npf_append_recv_rule(&npf_default_ok);
}
```

Basic Filter Conditions

Ethernet Filter Conditions

Network Shell Network shell provides helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. Note that `net-shell` should probably not be used in production code as it will require extra memory. See also *generic shell* for detailed shell information.

The following net-shell commands are implemented:

Table 37: net-shell commands

Command	Description
net allocs	Print network memory allocations. Only available if CONFIG_NET_DEBUG_NET_PKT_ALLOC is set.
net arp	Print information about IPv4 ARP cache. Only available if CONFIG_NET_ARP is set in IPv4 enabled networks.
net capture	Monitor network traffic See *Monitor Network Traffic* for details.
net conn	Print information about network connections.
net dns	Show how DNS is configured. The command can also be used to resolve a DNS name. Only available if CONFIG_DNS_RESOLVER is set.
net events	Enable network event monitoring. Only available if CONFIG_NET_MGMT_EVENT_MONITOR is set.
net filter	View network packet filter rules. Only available if CONFIG_NET_PKT_FILTER is set.
net gptp	Print information about gPTP support. Only available if CONFIG_NET_GPTP is set.
net iface	Print information about network interfaces.
net ipv6	Print IPv6 specific information and configuration. Only available if CONFIG_NET_IPV6 is set.
net mem	Print information about network memory usage. The command will print more information if CONFIG_NET_BUF_POOL_USAGE is set.
net nbr	Print neighbor information. Only available if CONFIG_NET_IPV6 is set.
net ping	Ping a network host.
net qbv	Show and configure IEEE 802.1Qbv Time-Aware Shaper (TAS) information. Only available if CONFIG_NET_QBV is set.
net route	Show IPv6 network routes. Only available if CONFIG_NET_ROUTE is set.
net sockets	Show network socket information and statistics. Only available if CONFIG_NET_SOCKETS_OBJ_CORE and CONFIG_OBJ_CORE are set.
net stats	Show network statistics.
net tcp	Connect/send data/close TCP connection. Only available if CONFIG_NET_TCP is set.
net vlan	Show Ethernet virtual LAN information. Only available if CONFIG_NET_VLAN is set.

TLS Credentials Shell The TLS Credentials shell provides a command-line interface for managing installed TLS credentials.

Commands

Buffer Credential (buf) Buffer data incrementally into the credential buffer so that it can be added using the *Add Credential (add)* command.

Alternatively:

- Clear the credential buffer.
- Load credential directly to the credential buffer, ending with `Ctrl + c`.

Usage To append <DATA> to the credential buffer, use:

```
cred buf <DATA>
```

Use this as many times as needed to load the full credential into the credential buffer, then use the *Add Credential (add)* command to store it.

To load <DATA> directly to the credential buffer, use:

```
cred buf load
<DATA>
Ctrl + c
```

To clear the credential buffer, use:

```
cred buf clear
```

Arguments

Argument	Description
<DATA>	Text data to be appended to credential buffer. It can be either text, or base64-encoded binary. See *Add Credential (add)* and *Storage/Retrieval Formats* for details.

Add Credential (add) Add a TLS credential to the TLS Credential store.

Credential contents can be provided in-line with the call to `cred add`, or will otherwise be sourced from the credential buffer.

Usage To add a TLS credential using the data from the credential buffer, use:

```
cred add <SECTAG> <TYPE> <BACKEND> <FORMAT>
```

To add a TLS credential using data provided with the same command, use:

```
cred add <SECTAG> <TYPE> <BACKEND> <FORMAT> <DATA>
```

Arguments

Argument	Description
<SECTAG>	The sectag to use for the new credential. Can be any non-negative integer.
<TYPE>	The type of credential to add. See *Credential Types* for valid values.
<BACKEND>	Reserved. Must always be `DEFAULT` (case-insensitive).
<FORMAT>	Specifies the storage format of the provided credential. See *Storage/Retrieval Formats* for valid values.
<DATA>	If provided, this argument will be used as the credential data, instead of any data in the credential buffer. Can be either text, or base64-encoded binary.

Delete Credential (del) Delete a specified credential from the credential store.

Usage To delete a credential matching a specified sectag and credential type (if it exists), use:

```
cred del <SECTAG> <TYPE>
```

Arguments

Argument	Description
<SECTAG>	The sectag of the credential to delete. Can be any non-negative integer.
<TYPE>	The type of credential to delete. See *Credential Types* for valid values.

Get Credential Contents (get) Retrieve and print the contents of a specified credential.

Usage To retrieve and print a credential matching a specified sectag and credential type (if it exists), use:

```
cred get <SECTAG> <TYPE> <FORMAT>
```

Arguments

Argument	Description
<SECTAG>	The sectag of the credential to get. Can be any non-negative integer.
<TYPE>	The type of credential to get. See *Credential Types* for valid values.
<FORMAT>	Specifies the retrieval format for the provided credential. See *Storage/Retrieval Formats* for valid values.

List Credentials (`list`) List TLS credentials in the credential store.

Usage To list all available credentials, use:

```
cred list
```

To list all credentials with a specified sectag, use:

```
cred list <SECTAG>
```

To list all credentials with a specified credential type, use:

```
cred list any <TYPE>
```

To list all credentials with a specified credential type and sectag, use:

```
cred list <SECTAG> <TYPE>
```

Arguments

Argument	Description
<SECTAG>	Optional. If provided, only list credentials with this sectag. Pass any or omit to allow any sectag. Otherwise, can be any non-negative integer.
<TYPE>	Optional. If provided, only list credentials with this credential type. Pass any or omit to allow any credential type. Otherwise, see *Credential Types* for valid values.

Output The command outputs all matching credentials in the following (CSV-compliant) format:

```
<SECTAG>,<TYPE>,<DIGEST>,<STATUS>
```

Where:

Symbol	Value
<SECTAG>	The sectag of the listed credential. A non-negative integer.
<TYPE>	Credential type short-code (see *Credential Types* for details) of the listed credential.
<DIGEST>	A string digest representing the credential contents. The exact nature of this digest may vary depending on credentials storage backend, but currently for all backends this is a base64 encoded SHA256 hash of the raw credential contents (so different storage formats for essentially identical credentials will have different digests).
<STATUS>	Status code indicating success or failure with generating a digest of the listed credential. 0 if successful, negative error code specific to the storage backend otherwise. Lines for which status is not zero will be printed with error formatting.

After the list is printed, a final summary of the found credentials will be printed in the form:

```
<N> credentials found.
```

Where <N> is the number of credentials found, and is zero if none are found.

Credential Types The following keywords (case-insensitive) may be used to specify a credential type:

Keyword(s)	Meaning
CA_CERT, CA	A trusted CA certificate.
SERVER_CERT, SELF_CERT, CLIENT_CERT, CLIENT, SELF, SERV	Self or server certificate.
PRIVATE_KEY, PK	A private key.
PRE_SHARED_KEY, PSK	A pre-shared key.
PRE_SHARED_KEY_ID, PSK_ID	ID for pre-shared key.

Storage/Retrieval Formats The *tls_credentials* module treats stored credentials as arbitrary binary buffers.

For convenience, the TLS credentials shell offers four formats for providing and later retrieving these buffers using the shell.

These formats and their (case-insensitive) keywords are as follows:

Kw	Meaning	Behavior during storage (cred add)	Behavior during retrieval (cred get)
BI	Credential is handled by shell as base64 and stored without NULL termination.	Data entered into shell will be decoded from base64 into raw binary before storage. No terminator will be appended.	Stored data will be encoded into base64 before being printed.
BI	Credential is handled by shell as base64 and stored with NULL termination.	Data entered into shell will be decoded from base64 into raw binary and a NULL terminator will be appended before storage.	NULL terminator will be truncated from stored data before said data is encoded into base64 and then printed.
ST	Credential is handled by shell as literal string and stored without NULL termination.	Text data entered into shell will be passed into storage as-written, without a NULL terminator.	Stored data will be printed as text. Non-printable characters will be printed as ?
ST	Credential is handled by shell as literal string and stored with NULL-termination.	Text data entered into shell will be passed into storage as-written, with a NULL terminator.	NULL terminator will be truncated from stored data before said data is printed as text. Non-printable characters will be printed as ?

The `BIN` format can be used to install credentials of any type, since base64 can be used to encode any concievable binary buffer. The remaining three formats are provided for convenience in special use-cases.

For example:

- To install printable pre-shared-keys, use `STR` to enter the PSK without first encoding it. This ensures it is stored without a NULL terminator.
- To install DER-formatted X.509 certificates (or other raw-binary credentials, such as non-printable PSKs) base64-encode the binary and use the `BIN` format.
- To install PEM-formatted X.509 certificates or certificate chains, base64 encode the full PEM string (including new-lines and `----BEGIN X ----` / `----END X----` markers), and then use the `BINT` format to make sure the stored string is NULL-terminated. This is required because Zephyr does not support multi-line strings in the shell. Otherwise, the `STRT` format could be used for this purpose without base64 encoding. It is possible to use `BIN` instead if you manually encode a NULL terminator into the base64.

Time Sensitive Networking

generic Precision Time Protocol (gPTP)

- *Overview*
- *Supported features*
- *Supported hardware*
- *Enabling the stack*
- *Application interfaces*
- *Testing*
- *API Reference*

Overview This gPTP stack supports the protocol and procedures as defined in the IEEE 802.1AS-2011 standard (Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks).

Supported features The stack handles communications and state machines defined in the IEEE 802.1AS-2011 standard. Mandatory requirements for a full-duplex point-to-point link end-point, as defined in Annex A of the standard, are supported.

The stack is in principle capable of handling communications on multiple network interfaces (also defined as "ports" in the standard) and thus act as a 802.1AS bridge. However, this mode of operation has not been validated on the Zephyr OS.

Supported hardware Although the stack itself is hardware independent, Ethernet frame timestamping support must be enabled in ethernet drivers.

Boards supported:

- frdm_k64f
- nucleo_h743zi
- nucleo_h745zi_q
- nucleo_f767zi
- sam_e70_xplained
- native_sim (only usable for simple testing, limited capabilities due to lack of hardware clock)
- qemu_x86 (emulated, limited capabilities due to lack of hardware clock)

Enabling the stack The following configuration option must me enabled in `prj.conf` file.

- `CONFIG_NET_GPTP`

Application interfaces The following Application Interfaces as defined in section 9 of the standard are available:

- `ClockSourceTime` interface (`gptp_clk_src_time_invoke()`)
- `ClockTargetPhaseDiscontinuity` interface (`gptp_register_phase_dis_cb()`)
- `ClockTargetEventCapture` interface (`gptp_event_capture()`)

Testing The stack has been informally tested using the OpenAVnu gPTP and Linux ptp4l daemons. The gPTP sample application from the Zephyr source distribution can be used for testing.

Precision Time Protocol (PTP)

- *Overview*
- *Supported features*
- *Supported Management messages*
- *Enabling the stack*
- *Testing*
- *API Reference*

Overview PTP is a network protocol implemented in the application layer, used to synchronize clocks in a computer network. It's accurate up to less than a microsecond. The stack supports the protocol and procedures as defined in the IEEE 1588-2019 standard (IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems). It has multiple profiles, and can be implemented on top of L2 (Ethernet) or L3 (UDP/IPv4 or UDP/IPv6). Its accuracy is achieved by using hardware timestamping of the protocol packets.

Zephyr's implementation of PTP stack consist following items:

- PTP stack thread that handles incoming messages and events
- Integration with ptp_clock driver
- PTP stack initialization executed during system init

The implementation automatically creates PTP Ports (each PTP Port corresponds to unique interface).

Supported features Implementation of the stack doesn't support all features specified in the standard. In the table below all supported features are listed.

Table 38: Supported features

Feature	Supported
Ordinary Clock	yes
Boundary Clock	yes
Transparent Clock	
Management Node	
End to end delay mechanism	yes
Peer to peer delay mechanism	
Multicast operation mode	
Hybrid operation mode	
Unicast operation mode	
Non-volatile storage	
UDP IPv4 transport protocol	yes
UDP IPv6 transport protocol	yes
IEEE 802.3 (Ethernet) transport protocol	
Hardware timestamping	yes
Software timestamping	
TIME_RECEIVER_ONLY PTP Instance	yes
TIME_TRANSMITTER_ONLY PTP Instance	

Supported Management messages Based on Table 59 from section 15.5.2.3 of the IEEE 1588-2019 following management TLVs are supported:

Table 39: Supported management message's IDs

Manage-ment_ID	Management_ID name	Allowed actions
0x0000	NULL_PTP_MANAGEMENT	GET SET COMMAND

zperf: Network Traffic Generator

- *Overview*
- *Sample Usage*
- *Session Management*
- *Custom Data Upload*
- *Raw TX Mode*

Overview zperf is a shell utility which allows to generate network traffic in Zephyr. The tool may be used to evaluate network bandwidth.

zperf is compatible with iPerf 2.0.10 and newer. For compatibility with older versions, enable `CONFIG_NET_ZPERF_LEGACY_HEADER_COMPAT`.

zperf can be enabled in any application, a dedicated sample is also present in Zephyr. See zperf sample application for details.

Sample Usage If Zephyr acts as a client, iPerf must be executed in server mode. For example, the following command line must be used for UDP testing:

```
$ iperf -s -l 1K -u -V -B 2001:db8::2
```

For TCP testing, the command line would look like this:

```
$ iperf -s -l 1K -V -B 2001:db8::2
```

In the Zephyr console, zperf can be executed as follows:

```
zperf udp upload 2001:db8::2 5001 10 1K 1M
```

For TCP the zperf command would look like this:

```
zperf tcp upload 2001:db8::2 5001 10 1K 1M
```

If the IP addresses of Zephyr and the host machine are specified in the config file, zperf can be started as follows:

```
zperf udp upload2 v6 10 1K 1M
```

or like this if you want to test TCP:

```
zperf tcp upload2 v6 10 1K 1M
```

If Zephyr is acting as a server, set the download mode as follows for UDP:

```
zperf udp download 5001
```

or like this for TCP:

```
zperf tcp download 5001
```

and in the host side, iPerf must be executed with the following command line if you are testing UDP:

```
$ iperf -l 1K -u -V -c 2001:db8::1 -p 5001
```

and this if you are testing TCP:

```
$ iperf -l 1K -V -c 2001:db8::1 -p 5001
```

iPerf output can be limited by using the -b option if Zephyr is not able to receive all the packets in orderly manner.

Session Management If `CONFIG_ZPERF_SESSION_PER_THREAD` option is set, then multiple upload sessions can be done at the same time if user supplies `-a` option when starting the upload. Each session will have their own work queue to run the test. The session test results can be viewed also after the tests have finished. The sessions can be started with `-w` option which then lets the worker threads to wait a start signal so that all the threads can be started at the same time. This will prevent the case where the zperf shell cannot run because it is running in lower

priority than the already started session thread. If you have only one upload session, then the `-w` is not really needed.

Following zperf shell commands are available for session management:

zperf shell command	Description
`jobs`	Show currently active or finished sessions
`jobs all`	Show statistics of finished sessions
`jobs clear`	Clear finished session statistics
`jobs start`	Start all the waiting sessions

Example:

```
uart:~$ zperf udp upload -a -t 5 192.0.2.2 5001 10 1K 1M
Remote port is 5001
Connecting to 192.0.2.2

Num errors:             0 (retry or fail)
Rate:                   12.38 Mbps
Thread priority:        6
Protocol:               TCP
Session id:             0
Total 2 sessions done
```

Custom Data Upload zperf supports more advanced data upload profiling by setting a custom data source through `zperf_upload_params.data_loader`. This enables the generation of custom packet contents instead of sending a constant packet consisting solely of the `z` character. An example use case would be determining the maximum throughput of uploading data from an external flash memory chip.

Raw TX Mode zperf supports raw packet transmission mode for testing custom L2 frames or vendor-specific protocols. This mode bypasses UDP/TCP and sends raw packets directly using packet sockets.

To enable raw TX mode, set the following Kconfig options:

```
CONFIG_NET_SOCKETS_PACKET=y
CONFIG_NET_ZPERF_RAW_TX=y
```

The maximum header size can be configured with `CONFIG_NET_ZPERF_RAW_TX_MAX_HDR_SIZE` (default: 64 bytes).

Before using raw TX mode, TX injection mode must be enabled on the network interface:

```
uart:~$ net iface txinjection 1 on
```

The raw TX upload command syntax is:

```
zperf raw upload [-a] <if_index> <header_hex> [<duration_sec>] [<packet_size>]␣
↪[<rate_kbps>]
```

Where:

- `-a`: Optional async mode flag
- `if_index`: Network interface index (e.g., 1)
- `header_hex`: User-provided header as hex string (vendor metadata + frame header)
- `duration_sec`: Test duration in seconds (default: 1)
- `packet_size`: Total packet size including header (default: 256)
- `rate_kbps`: Target rate in Kbps, supports K/M suffixes (default: 10)

Example for sending raw 802.11 frames with vendor metadata:

```
uart:~$ zperf raw upload 1␣
↪123456780004000300000000880000000ffffffffffa06960e35215a06960e3521500000000aaaa030000000800␣
↪10 1024 50M
```

The header hex string contains:

- Vendor metadata (first 12 bytes in this example)
- 802.11 QoS Data header with LLC/SNAP

The payload (filled with z characters) is automatically appended to reach the specified packet size.

6.3.8 Connection Manager

Overview

Connection Manager is a collection of optional Zephyr features that aim to allow applications to monitor and control connectivity (access to IP-capable networks) with minimal concern for the specifics of underlying network technologies.

Using Connection Manager, applications can use a single abstract API to control network association and monitor Internet access, and avoid excessive use of technology-specific boilerplate.

This allows an application to potentially support several very different connectivity technologies (for example, Wi-Fi and LTE) with a single codebase.

Applications can also use Connection Manager to generically manage and use multiple connectivity technologies simultaneously.

Structure Connection Manager is split into the following two subsystems:

- *Connectivity monitoring* (header file `include/zephyr/net/conn_mgr_monitoring.h`) monitors all available *Zephyr network interfaces (ifaces)* and triggers *network management* events indicating when IP connectivity is gained or lost.
- *Connectivity control* (header file `include/zephyr/net/conn_mgr_connectivity.h`) provides an abstract API for controlling iface network association.

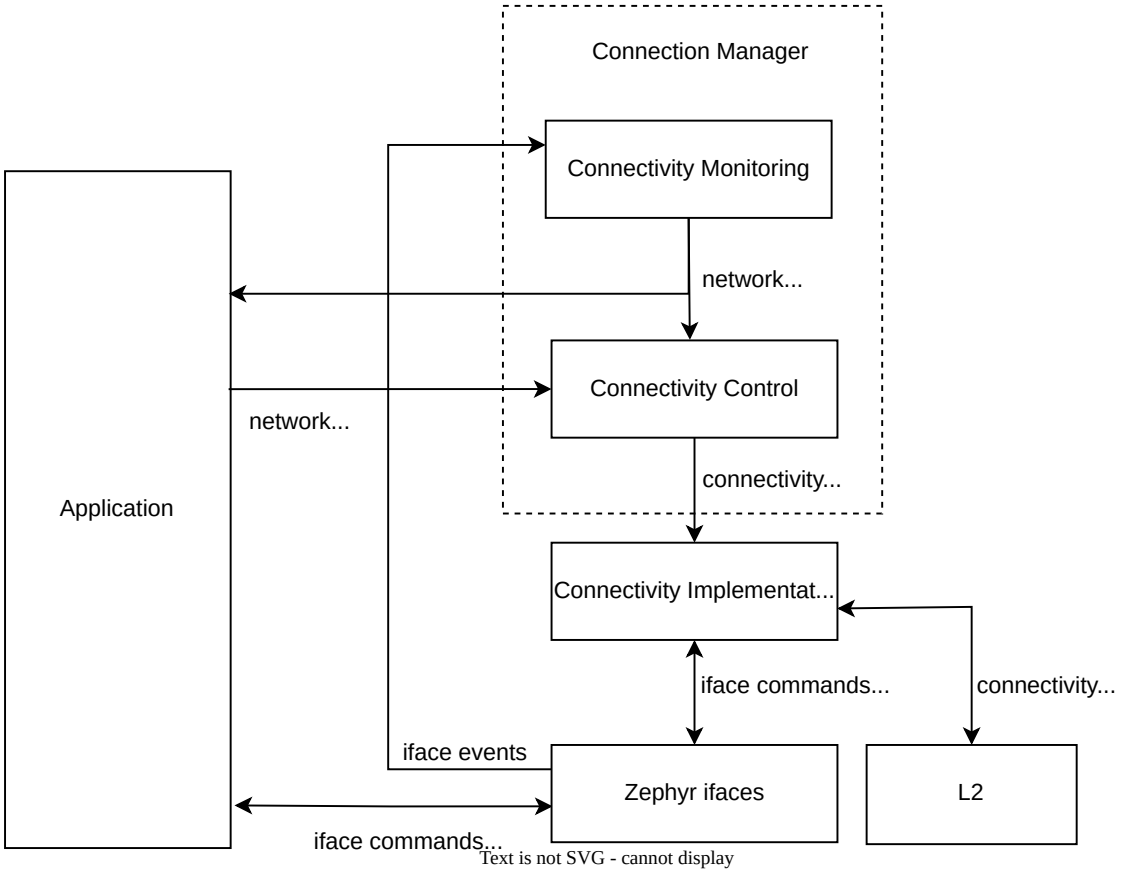

Fig. 18: A simplified view of how Connection Manager integrates with Zephyr and the application.

See *here* for a more detailed version.

Connectivity monitoring

Connectivity monitoring tracks all available ifaces (whether or not they support *Connectivity control*) as they transition through various *operational states* and acquire or lose assigned IP addresses.

Each available iface is considered ready if it meets the following criteria:

- The iface is admin-up
  - This means the iface has been instructed to become operational-up (ready for use). This is done by a call to `net_if_up()`.
- The iface is oper-up
  - This means the interface is completely ready for use; It is online, and if applicable, has associated with a network.
  - See *Network interface state management* for details.
- The iface has at least one assigned IP address
  - Both IPv4 and IPv6 addresses are acceptable. This condition is met as soon as one or both of these is assigned.
  - See *Network Interface* for details on iface IP assignment.
- The iface has not been ignored
  - Ignored ifaces are always treated as unready.
  - See *Ignoring ifaces* for more details.

Note

Typically, iface state and IP assignment are updated either by the iface's *L2 implementation* or bound *connectivity implementation*.

See *Implement iface state reporting* for details.

A ready iface ceases to be ready the moment any of the above conditions is lost.

When at least one iface is ready, the `NET_EVENT_L4_CONNECTED` *network management* event is triggered, and IP connectivity is said to be ready.

Afterwards, ifaces can become ready or unready without firing additional events, so long as there always remains at least one ready iface.

When there are no longer any ready ifaces left, the `NET_EVENT_L4_DISCONNECTED` *network management* event is triggered, and IP connectivity is said to be unready.

Note

Connection Manager also fires the following more specific `CONNECTED` / `DISCONNECTED` events:

- `NET_EVENT_L4_IPV4_CONNECTED`
- `NET_EVENT_L4_IPV4_DISCONNECTED`
- `NET_EVENT_L4_IPV6_CONNECTED`
- `NET_EVENT_L4_IPV6_DISCONNECTED`

These are similar to `NET_EVENT_L4_CONNECTED` and `NET_EVENT_L4_DISCONNECTED`, but specifically track whether IPv4- and IPv6-capable ifaces are ready.

Usage Connectivity monitoring is enabled if the CONFIG_NET_CONNECTION_MANAGER Kconfig option is enabled.

To receive connectivity updates, create and register a listener for the NET_EVENT_L4_CONNECTED and NET_EVENT_L4_DISCONNECTED *network management* events:

```
/* Callback struct where the callback will be stored */
struct net_mgmt_event_callback l4_callback;

/* Callback handler */
static void l4_event_handler(struct net_mgmt_event_callback *cb,
                             uint32_t event, struct net_if *iface)
{
        if (event == NET_EVENT_L4_CONNECTED) {
                LOG_INF("Network connectivity gained!");
        } else if (event == NET_EVENT_L4_DISCONNECTED) {
                LOG_INF("Network connectivity lost!");
        }

        /* Otherwise, it's some other event type we didn't register for. */
}

/* Call this before Connection Manager monitoring initializes */
static void my_application_setup(void)
{
        /* Configure the callback struct to respond to (at least) the L4_CONNECTED
         * and L4_DISCONNECTED events.
         *
         *
         * Note that the callback may also be triggered for events other than
↪those specified here!
         * (See the net_mgmt documentation)
         */
        net_mgmt_init_event_callback(
                &l4_callback, l4_event_handler,
                NET_EVENT_L4_CONNECTED | NET_EVENT_L4_DISCONNECTED
        );

        /* Register the callback */
        net_mgmt_add_event_callback(&l4_callback);
}
```

See *Listening to network events* for more details on listening for net_mgmt events.

Note

To avoid missing initial connectivity events, you should register your listener(s) before Connection Manager monitoring initializes. See *Avoiding missed notifications* for strategies to ensure this.

Avoiding missed notifications Connectivity monitoring may trigger events immediately upon initialization.

If your application registers its event listeners after connectivity monitoring initializes, it is possible to miss this first wave of events, and not be informed the first time network connectivity is gained.

If this is a concern, your application should *register its event listeners* before connectivity monitoring initializes.

Connectivity monitoring initializes using the SYS_INIT APPLICATION initialization priority specified by the CONFIG_NET_CONNECTION_MANAGER_MONITOR_PRIORITY Kconfig option.

You can register your callbacks before this initialization by using SYS_INIT with an earlier initialization priority than this value, for instance priority 0:

```
static int my_application_setup(void)
{
        /* Register callbacks here */
        return 0;
}

SYS_INIT(my_application_setup, APPLICATION, 0);
```

If this is not feasible, you can instead request that connectivity monitoring resend the latest connectivity events at any time by calling conn_mgr_mon_resend_status():

```
static void my_late_application_setup(void)
{
  /* Register callbacks here */

  /* Once done, request that events be re-triggered */
  conn_mgr_mon_resend_status();
}
```

Ignoring ifaces Applications can request that ifaces be ignored by Connection Manager by calling conn_mgr_ignore_iface() with the iface to be ignored.

Alternatively, an entire *L2 implementation* can be ignored by calling conn_mgr_ignore_l2().

This has the effect of individually ignoring all the ifaces using that *L2 implementation*.

While ignored, the iface is treated by Connection Manager as though it were unready for network traffic, no matter its actual state.

This may be useful, for instance, if your application has configured one or more ifaces that cannot (or for whatever reason should not) be used to contact the wider Internet.

Bulk convenience functions optionally skip ignored ifaces.

See conn_mgr_ignore_iface() and conn_mgr_watch_iface() for more details.

Connectivity monitoring API Include header file include/zephyr/net/conn_mgr_monitoring.h to access these.

Connection Manager API

Connectivity control

Many network interfaces require a network association procedure to be completed before being usable.

For such ifaces, connectivity control can provide a generic API to request network association (conn_mgr_if_connect()) and disassociation (conn_mgr_if_disconnect()). Network interfaces implement support for this API by *binding themselves to a connectivity implementation*.

Using this API, applications can associate with networks with minimal technology-specific boilerplate.

Connectivity control also provides the following additional features:

- Standardized *persistence and timeout* behaviors during association.

- *Bulk functions* for controlling the admin state and network association of all available ifaces simultaneously.
- Optional *convenience automations* for common connectivity actions.

Basic operation The following sections outline the basic operation of Connection Manager's connectivity control.

Binding Before an iface can be commanded to associate or disassociate using Connection Manager, it must first be bound to a *connectivity implementation*. Binding is performed by the provider of the iface, not by the application (see *Binding an iface to an implementation*), and can be thought of as an extension of the iface declaration.

Once an iface is bound, all connectivity commands passed to it (such as `conn_mgr_if_connect()` or `conn_mgr_if_disconnect()`) will be routed to the corresponding implementation function in the connectivity implementation.

> **Note**
>
> To avoid inconsistent behavior, all connectivity implementations must adhere to the *implementation guidelines*.

Connecting Once a bound iface is admin-up (see *Network interface state management*), `conn_mgr_if_connect()` can be called to cause it to associate with a network.

If association succeeds, the connectivity implementation will mark the iface as operational-up (see *Network interface state management*).

If association fails unrecoverably, the *fatal error event* will be triggered.

You can configure an optional *timeout* for this process.

> **Note**
>
> The `conn_mgr_if_connect()` function is intentionally minimalistic, and does not take any kind of configuration. Each connectivity implementation should provide a way to pre-configure or automatically configure any required association settings or credentials. See *Allow connectivity pre-configuration* for details.

Connection loss If connectivity is lost due to external factors, the connectivity implementation will mark the iface as operational-down.

Depending on whether *persistence* is set, the iface may then attempt to reconnect.

Manual disconnection The application can also request that connectivity be intentionally abandoned by calling `conn_mgr_if_disconnect()`.

In this case, the connectivity implementation will disassociate the iface from its network and mark the iface as operational-down (see *Network interface state management*). A new connection attempt will not be initiated, regardless of whether persistence is enabled.

Timeouts and Persistence Connection Manager requires that all connectivity implementations support the following standard key features:

- *Connection timeouts*
- *Connection persistence*

These features describe how ifaces should behave during connect and disconnect events. You can individually set them for each iface.

> **Note**
>
> It is left to connectivity implementations to successfully and accurately implement these two features as described below. See *Implementing timeouts and persistence* for more details from the connectivity implementation perspective.

The Connection Manager also implements the following optional feature:

- *Interface idle timeouts*

> **Note**
>
> The only requirement on the connectivity implementation to implement idle timeouts is to call `conn_mgr_if_used()` each time the interface is used.

Connection Timeouts When `conn_mgr_if_connect()` is called on an iface, a connection attempt begins.

The connection attempt continues indefinitely until it succeeds, unless a timeout has been specified for the iface (using `conn_mgr_if_set_timeout()`).

In that case, the connection attempt will be abandoned if the timeout elapses before it succeeds. If this happens, the *timeout event* is raised.

Interface Idle Timeout The connection manager enables users to apply an inactivity timeout on an interface (`conn_mgr_if_set_idle_timeout()`). Once connected, if the interface goes for the configured number of seconds without any activity, the interface is automatically disconnected. If this happens, the *idle timeout event* is raised. An idle timeout is considered an unintentional connection loss for the purposes of *Connection persistence*.

Connection Persistence Each iface also has a connection persistence setting that you can enable or disable by setting the `CONN_MGR_IF_PERSISTENT` flag with `conn_mgr_binding_set_flag()`.

This setting specifies how the iface should handle unintentional connection loss.

If persistence is enabled, any unintentional connection loss will initiate a new connection attempt, with a new timeout if applicable.

Otherwise, the iface will not attempt to reconnect.

> **Note**
>
> Persistence not does affect connection attempt behavior. Only the timeout setting affects this.
>
> For instance, if a connection attempt on an iface times out, the iface will not attempt to reconnect, even if it is persistent.
>
> Conversely, if there is not a specified timeout, the iface will try to connect forever until it succeeds, even if it is not persistent.
>
> See *Persistence during connection attempts* for the equivalent implementation guideline.

Control events Connectivity control triggers *network management* events to inform the application of important state changes.

See *Trigger connectivity control events* for the corresponding connectivity implementation guideline.

Fatal Error The NET_EVENT_CONN_IF_FATAL_ERROR event is raised when an iface encounters an error from which it cannot recover (meaning any subsequent attempts to associate are guaranteed to fail, and all such attempts should be abandoned).

Handlers of this event will be passed a pointer to the iface for which the fatal error occurred. Individual connectivity implementations may also pass an application-specific data pointer.

Timeout The NET_EVENT_CONN_IF_TIMEOUT event is raised when an *iface association* attempt *times out*.

Handlers of this event will be passed a pointer to the iface that timed out attempting to associate.

Idle Timeout The NET_EVENT_CONN_IF_IDLE_TIMEOUT event is raised when an interface is considered *inactive*.

Handlers of this event will be passed a pointer to the iface that timed out attempting to associate.

Listening for control events You can listen for control events as follows:

```
/* Declare a net_mgmt callback struct to store the callback */
struct net_mgmt_event_callback my_conn_evt_callback;

/* Declare a handler to receive control events */
static void my_conn_evt_handler(struct net_mgmt_event_callback *cb,
                                uint32_t event, struct net_if *iface)
{
        if (event == NET_EVENT_CONN_IF_TIMEOUT) {
                /* Timeout occurred, handle it */
        } else if (event == NET_EVENT_CONN_IF_FATAL_ERROR) {
                /* Fatal error occurred, handle it */
        }

        /* Otherwise, it's some other event type we didn't register for. */
}

int main()
{
        /* Configure the callback struct to respond to (at least) the␣
↪CONN_IF_TIMEOUT
         * and CONN_IF_FATAL_ERROR events.
         *
         * Note that the callback may also be triggered for events other than␣
↪those specified here!
         * (See the net_mgmt documentation)
         */

        net_mgmt_init_event_callback(
                &conn_mgr_conn_callback, conn_mgr_conn_handler,
                    NET_EVENT_CONN_IF_TIMEOUT | NET_EVENT_CONN_IF_FATAL_ERROR
        );

        /* Register the callback */
```

(continues on next page)

(continued from previous page)

```
        net_mgmt_add_event_callback(&conn_mgr_conn_callback);
        return 0;
}
```

See *Listening to network events* for more details on listening for net_mgmt events.

Automated behaviors There are a few actions related to connectivity that are (by default at least) performed automatically for the user.

Automatic admin-up

In Zephyr, ifaces are automatically taken admin-up (see *Network interface state management* for details on iface states) during initialization.

Applications can disable this behavior by setting the `NET_IF_NO_AUTO_START` interface flag with `net_if_flag_set()`.

Automatic connect

By default, Connection Manager will automatically connect any *bound* iface that becomes admin-up.

Applications can disable this by setting the `CONN_MGR_IF_NO_AUTO_CONNECT` connectivity flag with `conn_mgr_if_set_flag()`.

Automatic admin-down

By default, Connection Manager will automatically take any bound iface admin-down if it has given up on associating.

Applications can disable this for all ifaces by disabling the `CONFIG_NET_CONNECTION_MANAGER_AUTO_IF_DOWN` Kconfig option, or for individual ifaces by setting the `CONN_MGR_IF_NO_AUTO_DOWN` connectivity flag with `conn_mgr_if_set_flag()`.

Connectivity control API Include header file `include/zephyr/net/conn_mgr_connectivity.h` to access these.

Connection Manager Connectivity API

Bulk API Connectivity control provides several bulk functions allowing all ifaces to be controlled at once.

You can restrict these functions to operate only on non-*ignored* ifaces if desired.

Include header file `include/zephyr/net/conn_mgr_connectivity.h` to access these.

Connection Manager Connectivity Bulk API

Connectivity Implementations

Overview Connectivity implementations are technology-specific modules that allow specific Zephyr ifaces to support *Connectivity Control*. They are responsible for translating generic *connectivity control API* calls into hardware-specific operations. They are also responsible for implementing standardized *persistence and timeout* behaviors.

See the *implementation guidelines* for details on writing conformant connectivity implementations.

Architecture The *implementation API* allows connectivity implementations to be *defined* at build time using `CONN_MGR_CONN_DEFINE`.

This creates a static instance of the `conn_mgr_conn_impl` struct, which then stores a reference to the passed in `conn_mgr_conn_api` struct (which should be populated with implementation callbacks).

Once defined, you can reference implementations by name and bind them to any unbound iface using `CONN_MGR_BIND_CONN`. Make sure not to accidentally bind two connectivity implementations to a single iface.

Once the iface is bound, *connectivity control API* functions can be called on the iface, and they will be translated to the corresponding implementation functions in `conn_mgr_conn_api`.

Binding an iface does not directly modify its `iface struct`.

Instead, an instance of `conn_mgr_conn_binding` is created and appended an internal *iterable section*.

This binding structure will contain a reference to the bound iface, the connectivity implementation it is bound to, as well as a pointer to a per-iface *context pointer*.

This iterable section can then be iterated over to find out what (if any) connectivity implementation has been bound to a given iface. This search process is used by most of the functions in the *connectivity control API*. As such, these functions should be called sparingly, due to their relatively high search cost.

A single connectivity implementation may be bound to multiple ifaces. See *Do not instance implementations* for more details.

Context Pointer Since a single connectivity implementation may be shared by several Zephyr ifaces, each binding instantiates a context container (of *configurable type*) unique to that binding. Each binding is then instantiated with a reference to that container, which implementations can then use to access per-iface state information.

See also *Do not access bindings without locking them* and *Do not instance implementations*.

Defining an implementation A connectivity implementation may be defined as follows:

```
/* Create the API implementation functions */
int my_connect_impl(struct conn_mgr_conn_binding *const binding) {
        /* Cause your underlying technology to associate */
}
int my_disconnect_impl(struct conn_mgr_conn_binding *const binding) {
        /* Cause your underlying technology to disassociate */
}
void my_init_impl(struct conn_mgr_conn_binding *const binding) {
        /* Perform any required initialization for your underlying technology */
}

/* Declare the API struct */
static struct conn_mgr_conn_api my_impl_api = {
        .connect = my_connect_impl,
        .disconnect = my_disconnect_impl,
        .init = my_init_impl,
        /* ... so on */
};
```

(continues on next page)

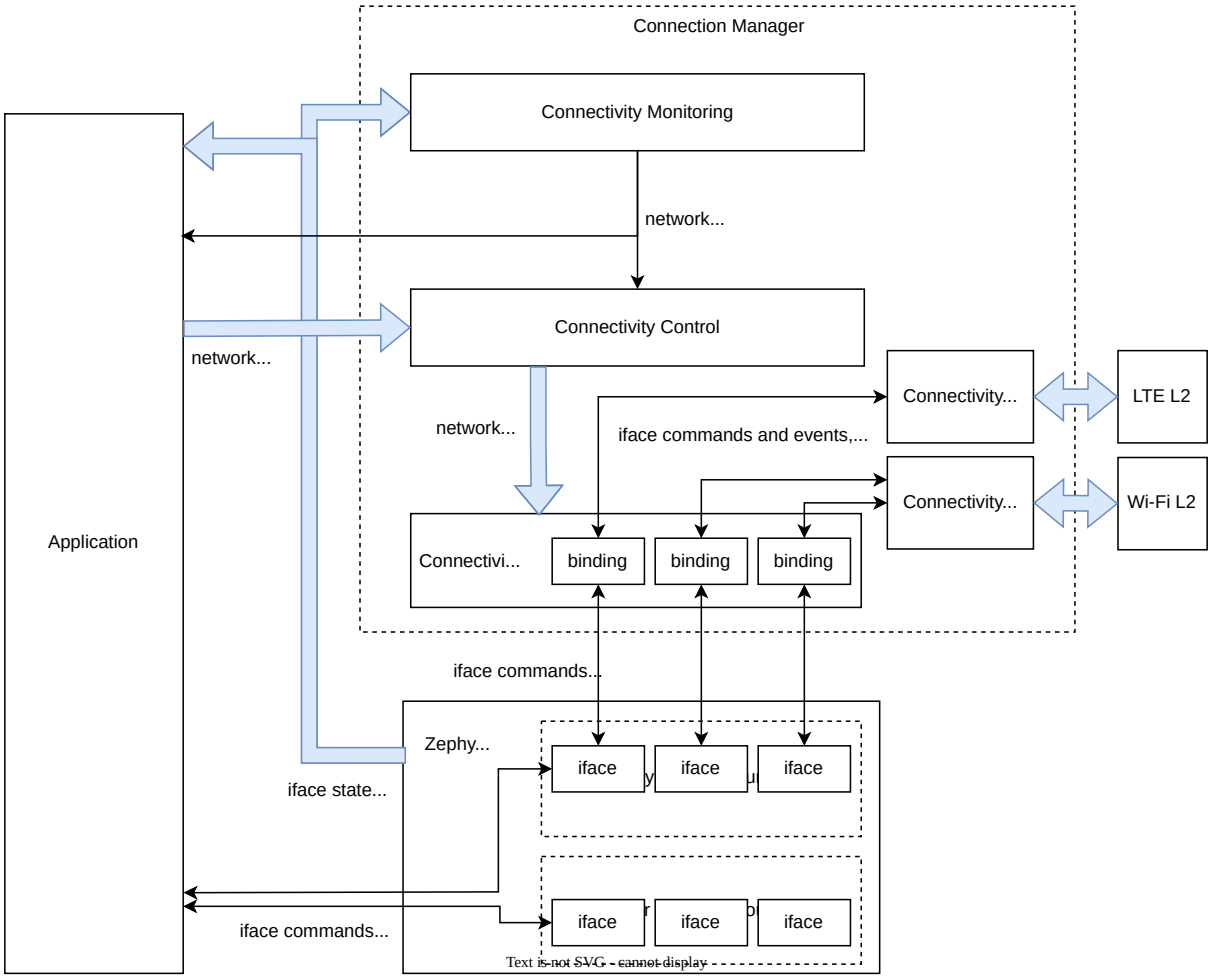

Fig. 19: A detailed view of how Connection Manager integrates with Zephyr and the application.
See *here* for a simplified version.

(continued from previous page)

```
/* Define the implementation (named MY_CONNECTIVITY_IMPL) */
CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Note

This does not work unless you also *declare the context pointer type*.

Declaring an implementation publicly Once defined, you can make a connectivity implementation available to other compilation units by declaring it (in a header file) as follows:

Listing 8: `my_connectivity_header.h`

```
CONN_MGR_CONN_DECLARE_PUBLIC(MY_CONNECTIVITY_IMPL);
```

The header file that contains this declaration must be included in any compilation units that need to reference the implementation.

Declaring a context type For `CONN_MGR_CONN_DEFINE` to work, you must declare a corresponding context pointer type. This is because all connectivity bindings contain a *Context Pointer* of their associated context pointer type.

If you are using `CONN_MGR_CONN_DECLARE_PUBLIC`, declare this type alongside the declaration:

Listing 9: `my_connectivity_impl.h`

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE struct my_context_type *
CONN_MGR_CONN_DECLARE_PUBLIC(MY_CONNECTIVITY_IMPL);
```

Then, make sure to include the header file before calling `CONN_MGR_CONN_DEFINE`:

Listing 10: `my_connectivity_impl.c`

```
#include "my_connectivity_impl.h"

CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Otherwise, it is sufficient to simply declare the context pointer type immediately before the call to `CONN_MGR_CONN_DEFINE`:

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE struct my_context_type *
CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Note

Naming is important. Your context pointer type declaration must use the same name as your implementation declaration, but with `_CTX_TYPE` appended.

In the previous example, the context type is named `MY_CONNECTIVITY_IMPL_CTX_TYPE`, because `MY_CONNECTIVITY_IMPL` was used as the connectivity implementation name.

If your connectivity implementation does not need a context pointer, simply declare the type as void:

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE void *
```

Binding an iface to an implementation A defined connectivity implementation may be bound to an iface by calling `CONN_MGR_BIND_CONN` anywhere after the iface's device definition:

```
/* Define an iface */
NET_DEVICE_INIT(my_iface,
        /* ... the specifics here don't matter ... */
);

/* Now bind MY_CONNECTIVITY_IMPL to that iface --
 * the name used should match with the above
 */
CONN_MGR_BIND_CONN(my_iface, MY_CONNECTIVITY_IMPL);
```

Connectivity implementation guidelines Rather than implement all features centrally, Connection Manager relies on each connectivity implementation to implement many behaviors and features individually.

This approach allows Connection Manager to remain lean, and allows each connectivity implementation to choose the most appropriate approach to these behaviors for itself. However, it relies on trust that all connectivity implementations will faithfully implement the features that have been delegated to them.

To maintain consistency between all connectivity implementations, observe the following guidelines when writing your own implementation:

Completely implement timeout and persistence All connectivity implementations must offer complete support for *timeout and persistence*, such that a user can disable or enable these features, regardless of the inherent behavior of the underlying technology. In other words, no matter how the underlying technology behaves, your implementation must make it appear to the end user to behave exactly as specified in the *Timeouts and Persistence* section.

See *Implementing timeouts and persistence* for a detailed technical discussion on implementing timeouts and persistence.

Conform to API specifications Each `implementation API function` you implement should behave as-described in the corresponding connectivity control API function.

For example, your implementation of `conn_mgr_conn_api.connect` should conform to the behavior described for `conn_mgr_if_connect()`.

Allow connectivity pre-configuration Connectivity implementations should provide means for applications to pre-configure all necessary connection parameters (for example, network SSID, or PSK, if applicable), before the call to `conn_mgr_if_connect()`. It should not be necessary to provide this information as part of, or following the `conn_mgr_if_connect()` call, although implementations *should await this information if it is not provided*.

Await valid connectivity configuration If network association fails because the application pre-configured invalid connection parameters, or did not configure connection parameters at all, this should be treated as a network failure.

In other words, the connectivity implementation should not give up on the connection attempt, even if valid connection parameters have not been configured.

Instead, the connectivity implementation should asynchronously wait for valid connection parameters to be configured, either indefinitely, or until the configured *connectivity timeout* elapses.

Implement iface state reporting All connectivity implementations must keep bound iface state up to date.

To be specific:

- Set the iface to dormant, carrier-down, or both during `binding init`.
  - See *Network interface state management* for details regarding iface carrier and dormant states.
- Update dormancy and carrier state so that the iface is non-dormant and carrier-up whenever (and only when) association is complete and connectivity is ready.
- Set the iface either to dormant or to carrier-down as soon as interruption of service is detected.
  - It is acceptable to gate this behind a small timeout (separate from the connection timeout) for network technologies where service is commonly intermittent.
- If the technology also handles IP assignment, ensure those IP addresses are *assigned to the iface*.

Note

iface state updates do not necessarily need to be performed directly by connectivity implementations.

For instance:

- IP assignment is not necessary if *DHCP* is used for the iface.
- The connectivity implementation does not need to update iface dormancy if the underlying *L2 implementation* already does so.

Do not use iface state as implementation state Zephyr ifaces may be accessed from other threads without respecting the binding mutex. As such, Zephyr iface state may change unpredictably during connectivity implementation callbacks.

Therefore, do not base implementation behaviors on iface state.

Keep iface state updated to reflect network availability, but do not read iface state for any purpose.

If you need to keep track of dormancy or IP assignment, use a separate state variable stored in the *context pointer*.

Remain non-interferent Connectivity implementations should not prevent applications from interacting directly with associated technology-specific APIs.

In other words, it should be possible for an application to directly use your underlying technology without breaking your connectivity implementation.

If exceptions to this are absolutely necessary, they should be constrained to specific API calls and should be documented.

Note

While connectivity implementations must not break, it is acceptable for implementations to have potentially unexpected behavior if applications attempt to directly control the association state.

For instance, if an application directly instructs an underlying technology to disassociate, it would be acceptable for the connectivity implementation to interpret this as an unexpected connection loss and immediately attempt to re-associate.

Remain non-blocking All connectivity implementation callbacks should be non-blocking.

For instance, calls to `conn_mgr_conn_api.connect` should initiate a connection process and return immediately.

One exception is `conn_mgr_conn_api.init`, whose implementations are permitted to block.

However, bear in mind that blocking during this callback will delay system init, so still consider offloading time-consuming tasks to a background thread.

Make API immediately ready Connectivity implementations must be ready to receive API calls immediately after `conn_mgr_conn_api.init`.

For instance, a call to `conn_mgr_conn_api.connect` must eventually lead to an association attempt, even if called immediately after `conn_mgr_conn_api.init`.

If the underlying technology cannot be made ready for connect commands immediately when `conn_mgr_conn_api.init` is called, calls to `conn_mgr_conn_api.connect` must be queued in a non-blocking fashion, and then executed later when ready.

Do not store state information outside the context pointer Connection Manager provides a context pointer to each binding.

Connectivity implementations should store all state information in this context pointer.

The only exception is connectivity implementations that are meant to be bound to only a single iface. Such implementations may use statically declared state instead.

See also *Do not instance implementations*.

Access ifaces only through binding structs Do not use statically declared ifaces or externally acquire references to ifaces.

For example, do not use `net_if_get_default()` under the assumption that the bound iface will be the default iface.

Instead, always use the `iface pointer` provided by the relevant `binding struct`. See also *Do not access bindings without locking them*.

Make implementations optional at compile-time Connectivity implementations should provide a Kconfig option to enable or disable the implementation without affecting bound iface availability.

In other words, it should be possible to configure builds that include Connectivity Manager, as well as the iface that would have been bound to the implementation, but not the implementation itself, nor its binding.

Do not instance implementations Do not declare a separate connectivity implementation for every iface you are going to bind to.

Instead, bind one global connectivity implementation to all of your ifaces, and use the context pointer to store state relevant to individual ifaces.

See also *Do not access bindings without locking them* and *Access ifaces only through binding structs*.

Do not access bindings without locking them Bindings may be accessed and modified at random by multiple threads, so modifying or reading from a binding without first `locking it` may lead to unpredictable behavior.

This applies to all descendents of the binding, including anything in the *context container*.

Make sure to `unlock` the binding when you are done accessing it.

Note

A possible exception to this rule is if the resource in question is inherently thread-safe.

However, be careful taking advantage of this exception. It may still be possible to create a race condition, for instance when accessing multiple thread-safe resources simultaneously.

Therefore, it is recommended to simply always lock the binding, whether or not the resource being accessed is inherently thread-safe.

Do not disable built-in features Do not attempt to prevent the use of built-in features (such as *Timeouts and Persistence* or *Automated behaviors*).

All connectivity implementations must fully support these features. Implementations must not attempt to force certain features to be always enabled or always disabled.

Trigger connectivity control events Connectivity control *network management* events are not triggered automatically by Connection Manager.

Connectivity implementations must trigger these events themselves.

Trigger `NET_EVENT_CONN_CMD_IF_TIMEOUT` when a connection *timeout* occurs. See *Timeout* for details.

Trigger `NET_EVENT_CONN_IF_FATAL_ERROR` when a fatal (non-recoverable) connection error occurs. See *Fatal Error* for details.

See *Network Management* for details on firing network management events.

Implementing timeouts and persistence First, see *Timeouts and Persistence* for a high-level description of the expected behavior of timeouts and persistence.

Connectivity implementations must fully conform to that description, regardless of the behavior of the underlying connectivity technology.

Sometimes this means writing extra logic in the connectivity implementation to fake certain behaviors. The following sections discuss various common edge-cases and nuances and how to handle them.

Inherently persistent technologies If the underlying technology automatically attempts to reconnect or retry connection after connection loss or failure, the connectivity implementation must manually cancel such attempts when they are in conflict with timeout or persistence settings.

For example:

- If the underlying technology automatically attempts to reconnect after losing connection, and persistence is disabled for the iface, the connectivity implementation should immediately cancel this reconnection attempt.
- If a connection attempt times out on an iface whose underlying technology does not have a built-in timeout, the connectivity implementation must simulate a timeout by cancelling the connection attempt manually.

Technologiess that give up on connection attempts If the underlying technology has no mechanism to retry connection attempts, or would give up on them before the user-configured timeout, or would not reconnect after connection loss, the connectivity implementation must manually re-request connection to counteract these deviances.

- If your underlying technology is not persistent, you must manually trigger reconnect attempts when persistence is enabled.
- If your underlying technology does not support a timeout, you must manually cancel connection attempts if the timeout is enabled.
- If your underlying technology forces a timeout, you must manually trigger a new connection attempts if that timeout is shorter than the Connection Manager timeout.

Technologies with association retry Many underlying technologies do not usually associate in a single attempt.

Instead, these underlying technologies may need to make multiple back-to-back association attempts in a row, usually with a small delay.

In these situations, the connectivity implementation should treat this series of back-to-back association sub-attempts as a single unified connection attempt.

For instance, after a sub-attempt failure, persistence being disabled should not prevent further sub-attempts, since they all count as one single overall connection attempt. See also *Persistence during connection attempts*.

At which point a series of failed sub-attempts should be considered a failure of the connection attempt as a whole is up to each implementation to decide.

If the connection attempt crosses this threshold, but the configured timeout has not yet elapsed, or there is no timeout, sub-attempts should continue.

Persistence during connection attempts Persistence should not affect any aspect of implementation behavior during a connection attempt. Persistence should only affect whether or not connection attempts are automatically triggered after a connection loss.

The configured timeout should fully determine whether connection retry should be performed.

Implementation API Include header file `include/zephyr/net/conn_mgr_connectivity_impl.h` to access these.

Only for use by connectivity implementations.

Connection Manager Connectivity Implementation API

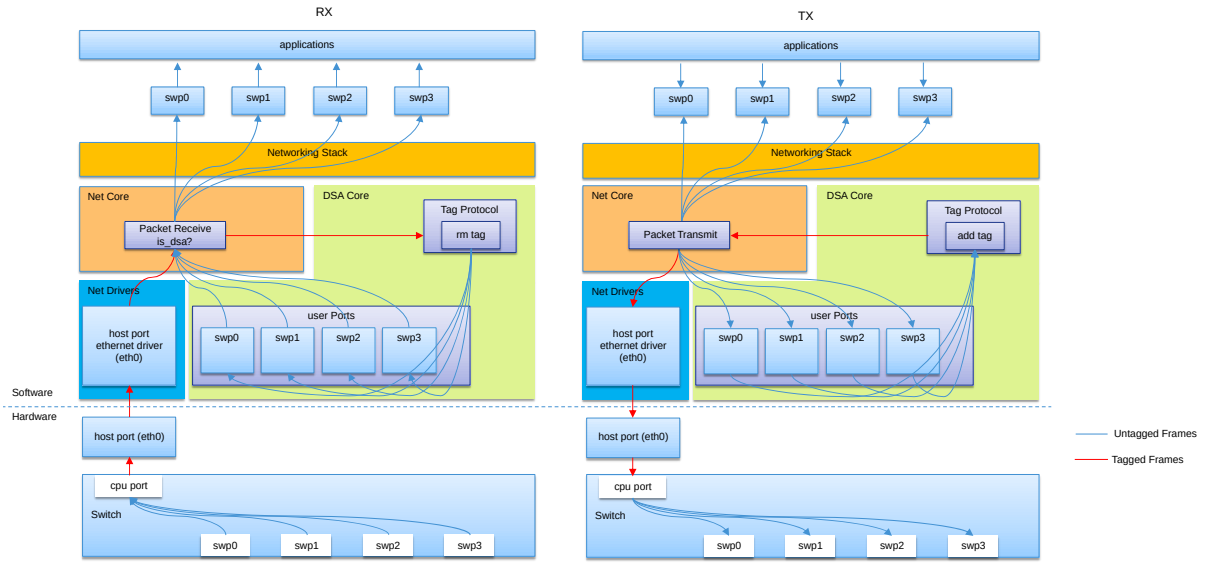
6.3.9 Distributed Switch Architecture (DSA)

- *DSA switch TX/RX process*
- *Host interface*
- *Switch interface*
- *Switch tagging protocols*
- *Networking stack process*
- *DSA device driver support*
- *Common pitfalls using DSA setups*
- *TODO work*

Distributed Switch Architecture (DSA) is not something new. It has been a mature subsystem in Linux for many years. This document just skips the background, terms and any knowledge related description, as user may find all of these in Linux DSA documentation.

DSA switch TX/RX process

The DSA switch TX/RX process is as below.



Host interface

Host interface network devices use regular and unmodified ethernet driver working as DSA conduit port, which manages the switch through processor.

Switch interface

The switch interfaces are also exposed as standard ethernet interfaces in zephyr. The one connected to conduit port work as CPU port, and the others for user purpose work as user ports.

Switch tagging protocols

Generally, switch tagging protocols are vendor specific. They all contain something which:

- identifies which port the Ethernet frame came from/should be sent to
- provides a reason why this frame was forwarded to the management interface

And tag on the packets to give them a switch frame header. But there are also tag-less case. It depends on the vendor.

Networking stack process

In order to have the DSA subsystem process the Ethernet switch specific tagging protocol via conduit port.

For RX path, put `dsa_recv()` at beginning of `net_recv_data()` in `subsys/net/ip/net_core.c` to handle first for untagging and re-directing interface.

For TX path, the switch interfaces register as standard ethernet devices with `dsa_xmit()` as `ethernet_api->send`. The `dsa_xmit()` processes the tagging and re-directing to conduit port work.

DSA device driver support

As the DSA core driver interacts with subsystems/drivers including MDIO, PHY and device tree to to support the common DSA setup and working process. The device driver support is much easy.

For device tree, the switch description should be following the `dts/bindings/dsa/dsa.yaml`.

For device driver, all needed to prepare are `dsa_api`, private data if has, and `dsa_port_config`. The macro functions could be utilized. And below is an example of i.MX NETC.

- `DSA_SWITCH_INST_INIT`
- `DSA_PORT_INST_INIT`

```
#define DSA_NETC_PORT_INST_INIT(port, n)                                        ␣
↪         \
        COND_CODE_1(DT_NUM_PINCTRL_STATES(port),                                ␣
↪         \
                        (PINCTRL_DT_DEFINE(port);), (EMPTY))                    ␣
↪         \
        struct dsa_netc_port_config dsa_netc_##n##_##port##_config = {          ␣
↪         \
                .pincfg = COND_CODE_1(DT_NUM_PINCTRL_STATES(port),              ␣
↪         \
                                (PINCTRL_DT_DEV_CONFIG_GET(port)), NULL),       ␣
↪         \
                .phy_mode = NETC_PHY_MODE(port),                                ␣
↪         \
        };                                                                      ␣
↪         \
        struct dsa_port_config dsa_##n##_##port##_config = {                    ␣
↪         \
                .use_random_mac_addr = DT_PROP(port, zephyr_random_mac_address),␣
↪         \
                .mac_addr = DT_PROP_OR(port, local_mac_address, {0}),           ␣
↪         \
                .port_idx = DT_REG_ADDR(port),                                  ␣
↪         \
                .phy_dev = DEVICE_DT_GET_OR_NULL(DT_PHANDLE(port, phy_handle)), ␣
↪         \
                .phy_mode = DT_PROP_OR(port, phy_connection_type, ""),          ␣
↪         \
                .ethernet_connection = DEVICE_DT_GET_OR_NULL(DT_PHANDLE(port,␣
↪ethernet)),    \
                .prv_config = &dsa_netc_##n##_##port##_config,                  ␣
↪         \
        };                                                                      ␣
↪         \
        DSA_PORT_INST_INIT(port, n, &dsa_##n##_##port##_config)

#define DSA_NETC_DEVICE(n)                                                      ␣
↪         \
        AT_NONCACHEABLE_SECTION_ALIGN(static netc_cmd_bd_t␣
↪dsa_netc_##n##_cmd_bd[8],        \
```

(continues on next page)

(continued from previous page)

```
                                        NETC_BD_ALIGN);
↪          \
        static struct dsa_netc_data dsa_netc_data_##n = {
↪          \
                .cmd_bd = dsa_netc_##n##_cmd_bd,
↪          \
        };
↪          \
        DSA_SWITCH_INST_INIT(n, &dsa_netc_api, &dsa_netc_data_##n,
↪DSA_NETC_PORT_INST_INIT);
```

Common pitfalls using DSA setups

This is copied from Linux DSA documentation. It applies to zephyr too. Although conduit port and cpu port exposed as ethernet device in zephyr, they are not able to be used.

> **Note**
>
> Once a conduit network device is configured to use DSA (dev->dsa_ptr becomes non-NULL), and the switch behind it expects a tagging protocol, this network interface can only exclusively be used as a conduit interface. Sending packets directly through this interface (e.g.: opening a socket using this interface) will not make us go through the switch tagging protocol transmit function, so the Ethernet switch on the other end, expecting a tag will typically drop this frame.

TODO work

Comparing to Linux, there are too much features to support in/based on zephyr DSA. But basically bridge layer should be supported. Then DSA could provide two options for users to use switch ports.

- Standalone mode: all user ports work as regular ethernet devices. No switching.
- Bridge mode: switch mode enabled with adding user ports into virtual bridge device. IP address could be assigned to the bridge.

6.4 LoRa and LoRaWAN

6.4.1 Overview

LoRa (abbrev. for Long Range) is a proprietary low-power wireless communication protocol developed by the Semtech Corporation.

LoRa acts as the physical layer (PHY) based on the chirp spread spectrum (CSS) modulation technique.

LoRaWAN (for Long Range Wide Area Network) defines a networking layer on top of the LoRa PHY.

Zephyr provides APIs for LoRa to send raw data packets directly over the wireless interface as well as APIs for LoRaWAN to connect the end device to the internet through a gateway.

The Zephyr implementation is based on Semtech's LoRaMac-node library, which is included as a Zephyr module.

Note

LoRaMac-node has been deprecated by Semtech in favor of LoRa Basics Modem. Porting the Zephyr API's to use LoRa Basics Modem as the backend is in progress.

Currently, only the base LoRa API is supported for the SX1261, SX1262, SX1272 and SX1276 chipsets through CONFIG_LORA_MODULE_BACKEND_LORA_BASICS_MODEM.

The LoRaWAN specification is published by the LoRa Alliance.

6.4.2 Configuration Options

LoRa PHY

Related configuration options can be found under drivers/lora/Kconfig.

- CONFIG_LORA
- CONFIG_LORA_SHELL
- CONFIG_LORA_INIT_PRIORITY

LoRaWAN

Related configuration options can be found under subsys/lorawan/Kconfig.

- CONFIG_LORAWAN
- CONFIG_LORAWAN_SYSTEM_MAX_RX_ERROR
- CONFIG_LORAWAN_REGION_AS923
- CONFIG_LORAWAN_REGION_AU915
- CONFIG_LORAWAN_REGION_CN470
- CONFIG_LORAWAN_REGION_CN779
- CONFIG_LORAWAN_REGION_EU433
- CONFIG_LORAWAN_REGION_EU868
- CONFIG_LORAWAN_REGION_KR920
- CONFIG_LORAWAN_REGION_IN865
- CONFIG_LORAWAN_REGION_US915
- CONFIG_LORAWAN_REGION_RU864

Overview

The USB device stack is a hardware independent interface between USB device controller driver and USB device class drivers or customer applications. It is a port of the LPCUSB device stack and has been modified and expanded over time. It provides the following functionalities:

- Uses the *USB device controller driver API (deprecated)* provided by the device controller drivers to interact with the USB device controller.
- Responds to standard device requests and returns standard descriptors, essentially handling 'Chapter 9' processing, specifically the standard device requests in table 9-3 from the universal serial bus specification revision 2.0.

- Provides a programming interface to be used by USB device classes or customer applications. The APIs is described in include/zephyr/usb/usb_device.h

> **Note**
>
> All APIs listed in *USB device support APIs (deprecated)* and the functions that depend on them are deprecated and will be remove in v4.4.0. Please use the new USB device support represented by the APIs in *USB device support APIs*.

Supported USB classes

Audio There is an experimental implementation of the Audio class. It follows specification version 1.00 (`bcdADC 0x0100`) and supports synchronous synchronisation type only. See usb-audio-headphones-microphone and usb-audio-headset samples for reference.

Bluetooth HCI USB transport layer Bluetooth HCI USB transport layer implementation uses *HCI RAW channel* to expose HCI interface to the host. It is not fully in line with the description in the Bluetooth specification and consists only of an interface with the endpoint configuration:

- HCI commands through control endpoint (host-to-device only)
- HCI events through interrupt IN endpoint
- ACL data through one bulk IN and one bulk OUT endpoints

A second interface for the voice channels has not been implemented as there is no support for this type in *Bluetooth*. It is not a big problem under Linux if HCI USB transport layer is the only interface that appears in the configuration, the btusb driver would not try to claim a second (isochronous) interface. The consequence is that if HCI USB is used in a composite configuration and is the first interface, then the Linux btusb driver will claim both the first and the next interface, preventing other composite functions from working. Because of this problem, HCI USB should not be used in a composite configuration. This problem is fixed in the implementation for new USB support.

See bluetooth_hci_usb sample for reference.

CDC ACM The CDC ACM class is used as backend for different subsystems in Zephyr. However, its configuration may not be easy for the inexperienced user. Below is a description of the different use cases and some pitfalls.

The interface for CDC ACM user is *Universal Asynchronous Receiver-Transmitter (UART)* driver API. But there are two important differences in behavior to a real UART controller:

- Data transfer is only possible after the USB device stack has been initialized and started, until then any data is discarded
- If device is connected to the host, it still needs an application on the host side which requests the data
- The CDC ACM poll out implementation follows the API and blocks when the TX ring buffer is full only if the hw-flow-control property is enabled and called from a non-ISR context.

The devicetree compatible property for CDC ACM UART is `zephyr,cdc-acm-uart`. CDC ACM support is automatically selected when USB device support is enabled and a compatible node in the devicetree sources is present. If necessary, CDC ACM support can be explicitly disabled by `CONFIG_USB_CDC_ACM`. About four CDC ACM UART instances can be defined and used, limited by the maximum number of supported endpoints on the controller.

CDC ACM UART node is supposed to be child of a USB device controller node. Since the designation of the controller nodes varies from vendor to vendor, and our samples and application should be as generic as possible, the default USB device controller is usually assigned an

zephyr_udc0 node label. Often, CDC ACM UART is described in a devicetree overlay file and looks like this:

```
&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Sample usb-cdc-acm has similar overlay files. And since no special properties are present, it may seem overkill to use devicetree to describe CDC ACM UART. The motivation behind using devicetree is the easy interchangeability of a real UART controller and CDC ACM UART in applications.

Console over CDC ACM UART With the CDC ACM UART node from above and `zephyr,console` property of the chosen node, we can describe that CDC ACM UART is to be used with the console. A similar overlay file is used by the usb-cdc-acm-console sample.

```
/ {
        chosen {
                zephyr,console = &cdc_acm_uart0;
        };
};

&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Before the application uses the console, it is recommended to wait for the DTR signal:

```
const struct device *const dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_console));
uint32_t dtr = 0;

if (usb_enable(NULL)) {
        return;
}

while (!dtr) {
        uart_line_ctrl_get(dev, UART_LINE_CTRL_DTR, &dtr);
        k_sleep(K_MSEC(100));
}

printk("nuqneH\n");
```

CDC ACM UART as backend As for the console sample, it is possible to configure CDC ACM UART as backend for other subsystems by setting *Chosen nodes* properties.

List of few Zephyr specific chosen properties which can be used to select CDC ACM UART as backend for a subsystem or application:

- `zephyr,bt-c2h-uart` used in Bluetooth, for example see bluetooth_hci_uart
- `zephyr,ot-uart` used in OpenThread, for example see openthread-coprocessor
- `zephyr,shell-uart` used by shell for serial backend, for example see samples/subsys/shell/shell_module

- `zephyr,uart-mcumgr` used by smp-svr sample

POSIX default tty ECHO mitigation POSIX systems, like Linux, default to enabling ECHO on tty devices. Host side application can disable ECHO by calling `open()` on the tty device and issuing `ioctl()` (preferably via `tcsetattr()`) to disable echo if it is not desired. Unfortunately, there is an inherent race between the `open()` and `ioctl()` where the ECHO is enabled and any characters received (even if host application does not call `read()`) will be echoed back. This issue is especially visible when the CDC ACM port is used without any real UART on the other side because there is no arbitrary delay due to baud rate.

To mitigate the issue, Zephyr CDC ACM implementation arms IN endpoint with ZLP after device is configured. When the host reads the ZLP, which is pretty much the best indication that host application has opened the tty device, Zephyr will force `CONFIG_CDC_ACM_TX_DELAY_MS` millisecond delay before real payload is sent. This should allow sufficient time for first, and only first, application that opens the tty device to disable ECHO if ECHO is not desired. If ECHO is not desired at all from CDC ACM device it is best to set up udev rule to disable ECHO as soon as device is connected.

ECHO is particurarly unwanted when CDC ACM instance is used for Zephyr shell, because the control characters to set color sent back to shell are interpreted as (invalid) command and user will see garbage as a result. While minicom does disable ECHO by default, on exit with reset it will restore the termios settings to whatever was set on entry. Therefore, if minicom is the first application to open the tty device, the exit with reset will enable ECHO back and thus set up a problem for the next application (which cannot be mitigated at Zephyr side). To prevent the issue it is recommended either to leave minicom without reset or to disable ECHO before minicom is started.

DFU USB DFU class implementation is tightly coupled to *Device Firmware Upgrade* and *MCUBoot API*. This means that the target platform must support the *Flash Image* API.

See legacy-usb-dfu sample for reference.

USB Human Interface Devices (HID) support HID support abuses *Device Driver Model* simply to allow applications to use the `device_get_binding()`. Note that there is no HID device API as such, instead the interface is provided by `hid_ops`. The default instance name is `HID_n`, where n can be {0, 1, 2, ...} depending on the `CONFIG_USB_HID_DEVICE_COUNT`.

Each HID instance requires a HID report descriptor. The interface to the core and the report descriptor must be registered using `usb_hid_register_device()`.

As the USB HID specification is not only used by the USB subsystem, the USB HID API reference is split into two parts, *Human Interface Devices (HID)* and *USB HID Class API (deprecated)*. HID helper macros from *Human Interface Devices (HID)* should be used to compose a HID report descriptor. Macro names correspond to those used in the USB HID specification.

For the HID class interface, an IN interrupt endpoint is required for each instance, an OUT interrupt endpoint is optional. Thus, the minimum implementation requirement for `hid_ops` is to provide `int_in_ready` callback.

```
#define REPORT_ID               1
static bool configured;
static const struct device *hdev;

static void int_in_ready_cb(const struct device *dev)
{
        static uint8_t report[2] = {REPORT_ID, 0};

        if (hid_int_ep_write(hdev, report, sizeof(report), NULL)) {
                LOG_ERR("Failed to submit report");
```

(continues on next page)

(continued from previous page)

```
        } else {
                report[1]++;
        }
}

static void status_cb(enum usb_dc_status_code status, const uint8_t *param)
{
        if (status == USB_DC_RESET) {
                configured = false;
        }

        if (status == USB_DC_CONFIGURED && !configured) {
                int_in_ready_cb(hdev);
                configured = true;
        }
}

static const uint8_t hid_report_desc[] = {
        HID_USAGE_PAGE(HID_USAGE_GEN_DESKTOP),
        HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
        HID_COLLECTION(HID_COLLECTION_APPLICATION),
        HID_LOGICAL_MIN8(0x00),
        HID_LOGICAL_MAX16(0xFF, 0x00),
        HID_REPORT_ID(REPORT_ID),
        HID_REPORT_SIZE(8),
        HID_REPORT_COUNT(1),
        HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
        HID_INPUT(0x02),
        HID_END_COLLECTION,
};

static const struct hid_ops my_ops = {
        .int_in_ready = int_in_ready_cb,
};

int main(void)
{
        int ret;

        hdev = device_get_binding("HID_0");
        if (hdev == NULL) {
                return -ENODEV;
        }

        usb_hid_register_device(hdev, hid_report_desc, sizeof(hid_report_desc),
                                &my_ops);

        ret = usb_hid_init(hdev);
        if (ret) {
                return ret;
        }

        return usb_enable(status_cb);
}
```

If the application wishes to receive output reports via the OUT interrupt endpoint, it must enable `CONFIG_ENABLE_HID_INT_OUT_EP` and provide `int_out_ready` callback. The dis-

advantage of this is that Kconfig options such as CONFIG_ENABLE_HID_INT_OUT_EP or CONFIG_HID_INTERRUPT_EP_MPS apply to all instances. This design issue will be fixed in the HID class implementation for the new USB support.

See usb-hid-mouse sample for reference.

Mass Storage Class MSC follows Bulk-Only Transport specification and uses *Disk Access* to access and expose a RAM disk, emulated block device on a flash partition, or SD Card to the host. Only one disk instance can be exported at a time.

The disc to be used by the implementation is set by the CONFIG_MASS_STORAGE_DISK_NAME and should be the same as the name used by the disc access driver that the application wants to expose to the host. Flash, RAM, and SDMMC/MMC disk drivers use node property disk-name to set the disk name.

For the emulated block device on a flash partition, the flash partition and flash disk to be used must be described in the devicetree. If a storage partition is already described at the board level, application devicetree overlay must also delete storage_partition node first. CONFIG_MASS_STORAGE_DISK_NAME should be the same as disk-name property.

```
/delete-node/ &storage_partition;

&mx25r64 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                storage_partition: partition@0 {
                        label = "storage";
                        reg = <0x00000000 0x00020000>;
                };
        };
};

/ {
        msc_disk0 {
                compatible = "zephyr,flash-disk";
                partition = <&storage_partition>;
                disk-name = "NAND";
                cache-size = <4096>;
        };
};
```

The disk-property “NAND” may be confusing, but it is simply how some file systems identifies the disc. Therefore, if the application also accesses the file system on the exposed disc, default names should be used, see usb-mass sample for reference.

Networking There are three implementations that work in a similar way, providing a virtual Ethernet connection between the remote (USB host) and Zephyr network support.

- CDC ECM class, enabled with CONFIG_USB_DEVICE_NETWORK_ECM
- CDC EEM class, enabled with CONFIG_USB_DEVICE_NETWORK_EEM
- RNDIS support, enabled with CONFIG_USB_DEVICE_NETWORK_RNDIS

See legacy-netusb sample for reference.

Applications using RNDIS support should enable CONFIG_USB_DEVICE_OS_DESC for a better user experience on a host running Microsoft Windows OS.

Binary Device Object Store (BOS) support

BOS handling can be enabled with Kconfig option CONFIG_USB_DEVICE_BOS. This option also has the effect of changing device descriptor bcdUSB to 0210. The application should register descriptors such as Capability Descriptor using usb_bos_register_cap(). Registered descriptors are added to the root BOS descriptor and handled by the stack.

See legacy-webusb sample for reference.

Interface number and endpoint address assignment

In USB terminology, a function is a device that provides a capability to the host, such as a HID class device that implements a keyboard. A function contains a collection of interfaces; at least one interface is required. An interface may contain device endpoints; for example, at least one input endpoint is required to implement a HID class device, and no endpoints are required to implement a USB DFU class. A USB device that combines functions is a multifunction USB device, for example, a combination of a HID class device and a CDC ACM device.

With Zephyr RTOS USB support, various combinations are possible with built-in USB classes/functions or custom user implementations. The limitation is the number of available device endpoints. Each device endpoint is uniquely addressable. The endpoint address is a combination of endpoint direction and endpoint number, a four-bit value. Endpoint number zero is used for the default control method to initialize and configure a USB device. By specification, a maximum of 15 IN and 15 OUT device endpoints are also available for use in functions. The actual number depends on the device controller used. Not all controllers support the maximum number of endpoints and all endpoint types. For example, a device controller might support one IN and one OUT isochronous endpoint, but only for endpoint number 8, resulting in endpoint addresses 0x88 and 0x08. Also, one controller may be able to have IN/OUT endpoints on the same endpoint number, interrupt IN endpoint 0x81 and bulk OUT endpoint 0x01, while the other may only be able to handle one endpoint per endpoint number. Information about the number of interfaces, interface associations, endpoint types, and addresses is provided to the host by the interface, interface specific, and endpoint descriptors.

Host driver for specific function, uses interface and endpoint descriptor to obtain endpoint addresses, types, and other properties. This allows function host drivers to be generic, for example, a multi-function device consisting of one or more CDC ACM and one or more CDC ECM class implementations is possible and no specific drivers are required.

Interface and endpoint descriptors of built-in USB class/function implementations in Zephyr RTOS typically have default interface numbers and endpoint addresses assigned in ascending order. During initialization, default interface numbers may be reassigned based on the number of interfaces in a given configuration. Endpoint addresses are reassigned based on controller capabilities, since certain endpoint combinations are not possible with every controller, and the number of interfaces in a given configuration. This also means that the device side class/function in the Zephyr RTOS must check the actual interface and endpoint descriptor values at runtime. This mechanism also allows as to provide generic samples and generic multifunction samples that are limited only by the resources provided by the controller, such as the number of endpoints and the size of the endpoint FIFOs.

There may be host drivers for a specific function, for example in the Linux Kernel, where the function driver does not read interface and endpoint descriptors to check interface numbers or endpoint addresses, but instead uses hardcoded values. Therefore, the host driver cannot be used in a generic way, meaning it cannot be used with different device controllers and different device configurations in combination with other functions. This may also be because the driver is designed for a specific hardware and is not intended to be used with a clone of this specific hardware. On the contrary, if the driver is generic in nature and should work with different hardware variants, then it must not use hardcoded interface numbers and endpoint addresses. It is not possible to disable endpoint reassignment in Zephyr RTOS, which may prevent you from implementing a hardware-clone firmware. Instead, if possible, the host driver implementation should be fixed to use values from the interface and endpoint descriptor.

Testing over USBIP in native_sim

A virtual USB controller implemented through USBIP might be used to test the USB device stack. Follow the general build procedure to build the USB sample for the native_sim configuration.

Run built sample with:

```
west build -t run
```

In a terminal window, run the following command to list USB devices:

```
$ usbip list -r localhost
Exportable USB devices
======================
 - 127.0.0.1
        1-1: unknown vendor : unknown product (2fe3:0100)
           : /sys/devices/pci0000:00/0000:00:01.2/usb1/1-1
           : (Defined at Interface level) (00/00/00)
           :  0 - Vendor Specific Class / unknown subclass / unknown protocol␣
↪(ff/00/00)
```

In a terminal window, run the following command to attach the USB device:

```
$ sudo usbip attach -r localhost -b 1-1
```

The USB device should be connected to your Linux host, and verified with the following commands:

```
$ sudo usbip port
Imported USB devices
====================
Port 00: <Port in Use> at Full Speed(12Mbps)
       unknown vendor : unknown product (2fe3:0100)
       7-1 -> usbip://localhost:3240/1-1
           -> remote bus/dev 001/002
$ lsusb -d 2fe3:0100
Bus 007 Device 004: ID 2fe3:0100
```

USB Vendor and Product identifiers

The USB Vendor ID for the Zephyr project is `0x2FE3`. This USB Vendor ID must not be used when a vendor integrates Zephyr USB device support into its own product.

Each USB sample has its own unique Product ID. The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

The following Product IDs are currently used:

Sample	PID
usb-cdc-acm	0x0001
Reserved (previously: usb-cdc-acm-composite)	0x0002
Reserved (previously: usb-hid-cdc)	0x0003
usb-cdc-acm-console	0x0004
usb-dfu (Run-Time)	0x0005
Reserved (previously: usb-hid)	0x0006
usb-hid-mouse	0x0007
usb-mass	0x0008
testusb-app	0x0009
webusb	0x000A
bluetooth_hci_usb	0x000B
Reserved (previously: bluetooth_hci_usb_h4)	0x000C
Reserved (previously: wpan-usb)	0x000D
uac2-explicit-feedback	0x000E
uac2-implicit-feedback	0x000F
uvc	0x0011
usb-dfu (DFU Mode)	0xFFFF

The USB device descriptor field `bcdDevice` (Device Release Number) represents the Zephyr kernel major and minor versions as a binary coded decimal value.

6.5.2 USB device support APIs (deprecated)

USB device controller driver API (deprecated)

The USB device controller driver API is described in include/zephyr/drivers/usb/usb_dc.h and sometimes referred to as the `usb_dc` API.

This API has some limitations by design, it does not follow *Device Driver Model* and is being replaced by *USB device controller (UDC) driver API*.

API reference

USB Device Controller API

USB device stack API (deprecated)

API reference There are two ways to transmit data, using the 'low' level read/write API or the 'high' level transfer API.

Low level API
: To transmit data to the host, the class driver should call usb_write(). Upon completion the registered endpoint callback will be called. Before sending another packet the class driver should wait for the completion of the previous write. When data is received, the registered endpoint callback is called. usb_read() should be used for retrieving the received data. For CDC ACM sample driver this happens via the OUT bulk endpoint handler (cdc_acm_bulk_out) mentioned in the endpoint array (cdc_acm_ep_data).

High level API
: The usb_transfer method can be used to transfer data to/from the host. The transfer API will automatically split the data transmission into one or more USB transaction(s), depending endpoint max packet size. The class driver does not have to implement endpoint callback and should set this callback to the generic usb_transfer_ep_callback.

USB support

6.5.3 USB device support

Overview

USB device support consists of the USB device controller (UDC) drivers , *USB device controller (UDC) driver API*, and USB device stack, *USB device stack API*. The *USB device controller (UDC) driver API* provides a generic and vendor independent interface to USB device controllers, and although, there a is clear separation between these layers, the purpose of *USB device controller (UDC) driver API* is to serve Zephyr’s USB device stack exclusively.

The device stack supports multiple device controllers, meaning that if a SoC has multiple controllers, they can be used simultaneously. Full and high-speed device controllers are supported. It also provides support for registering multiple function or class instances to a configuration at runtime, or changing the configuration later. It has built-in support for several USB classes and provides an API to implement custom USB functions.

Samples

- usb-hid-keyboard
- uac2-explicit-feedback
- uac2-implicit-feedback
- uvc
- bluetooth_hci_usb
- usb-cdc-acm
- usb-cdc-acm-console
- usb-mass
- usb-hid-mouse
- zperf To build the sample for the device support, set the configuration overlay file `-DEXTRA_CONF_FILE=overlay-usbd_next_ecm.conf` and devicetree overlay file `-DDTC_OVERLAY_FILE="usbd_next_ecm.overlay` either directly or via `west`.

How to configure and enable USB device support

For the USB device support samples in the Zephyr project repository, we have a common file for instantiation, configuration and initialization, samples/subsys/usb/common/sample_usbd_init.c. The following code snippets from this file are used as examples. USB Samples Kconfig options used in the USB samples and prefixed with `SAMPLE_USBD_` have default values specific to the Zephyr project and the scope is limited to the project samples. In the examples below, you will need to replace these Kconfig options and other defaults with values appropriate for your application or hardware.

The USB device stack requires a context structure to manage its properties and runtime data. The preferred way to define a device context is to use the `USBD_DEVICE_DEFINE` macro. This creates a static `usbd_context` variable with a given name. Any number of contexts may be instantiated. A USB controller device can be assigned to multiple contexts, but only one context can be initialized and used at a time. Context properties must not be directly accessed or manipulated by the application.

```
/*
 * Instantiate a context named sample_usbd using the default USB device
 * controller, the Zephyr project vendor ID, and the sample product ID.
 * Zephyr project vendor ID must not be used outside of Zephyr samples.
 */
USBD_DEVICE_DEFINE(sample_usbd,
                   DEVICE_DT_GET(DT_NODELABEL(zephyr_udc0)),
                   CONFIG_SAMPLE_USBD_VID, CONFIG_SAMPLE_USBD_PID);
```

Your USB device may have manufacturer, product, and serial number string descriptors. To instantiate these string descriptors, the application should use the appropriate `USBD_DESC_MANUFACTURER_DEFINE`, `USBD_DESC_PRODUCT_DEFINE`, and `USBD_DESC_SERIAL_NUMBER_DEFINE` macros. String descriptors also require a single instantiation of the language descriptor using the `USBD_DESC_LANG_DEFINE` macro.

```
USBD_DESC_LANG_DEFINE(sample_lang);
USBD_DESC_MANUFACTURER_DEFINE(sample_mfr, CONFIG_SAMPLE_USBD_MANUFACTURER);
USBD_DESC_PRODUCT_DEFINE(sample_product, CONFIG_SAMPLE_USBD_PRODUCT);
IF_ENABLED(CONFIG_HWINFO, (USBD_DESC_SERIAL_NUMBER_DEFINE(sample_sn)));
```

String descriptors must be added to the device context at runtime before initializing the USB device with `usbd_add_descriptor()`.

```
err = usbd_add_descriptor(&sample_usbd, &sample_lang);
if (err) {
        LOG_ERR("Failed to initialize language descriptor (%d)", err);
        return NULL;
}

err = usbd_add_descriptor(&sample_usbd, &sample_mfr);
if (err) {
        LOG_ERR("Failed to initialize manufacturer descriptor (%d)", err);
        return NULL;
}

err = usbd_add_descriptor(&sample_usbd, &sample_product);
if (err) {
        LOG_ERR("Failed to initialize product descriptor (%d)", err);
        return NULL;
}

IF_ENABLED(CONFIG_HWINFO, (
        err = usbd_add_descriptor(&sample_usbd, &sample_sn);
))
if (err) {
        LOG_ERR("Failed to initialize SN descriptor (%d)", err);
        return NULL;
}
```

USB device requires at least one configuration instance per supported speed. The application should use USBD_CONFIGURATION_DEFINE to instantiate a configuration. Later, USB device functions are assigned to a configuration.

```
static const uint8_t attributes = (IS_ENABLED(CONFIG_SAMPLE_USBD_SELF_POWERED) ?
                                   USB_SCD_SELF_POWERED : 0) |
                                  (IS_ENABLED(CONFIG_SAMPLE_USBD_REMOTE_WAKEUP) ?
                                   USB_SCD_REMOTE_WAKEUP : 0);

/* Full speed configuration */
USBD_CONFIGURATION_DEFINE(sample_fs_config,
                          attributes,
                          CONFIG_SAMPLE_USBD_MAX_POWER, &fs_cfg_desc);

/* High speed configuration */
USBD_CONFIGURATION_DEFINE(sample_hs_config,
                          attributes,
                          CONFIG_SAMPLE_USBD_MAX_POWER, &hs_cfg_desc);
```

Each configuration instance for a specific speed must be added to the device context at runtime before the USB device is initialized using usbd_add_configuration(). Note USBD_SPEED_FS and USBD_SPEED_HS. The first full-speed or high-speed configuration will get bConfigurationValue one, and then further upward.

```
err = usbd_add_configuration(&sample_usbd, USBD_SPEED_FS,
                             &sample_fs_config);
if (err) {
        LOG_ERR("Failed to add Full-Speed configuration");
        return NULL;
}
```

Although we have already done a lot, this USB device has no function. A device can have mul-

tiple configurations with different set of functions at different speeds. A function or class can be registered on a USB device before it is initialized using `usbd_register_class()`. The desired configuration is specified using `USBD_SPEED_FS` or `USBD_SPEED_HS` and the configuration number. For simple cases, `usbd_register_all_classes()` can be used to register all available instances.

```
err = usbd_register_all_classes(&sample_usbd, USBD_SPEED_FS, 1, blocklist);
if (err) {
        LOG_ERR("Failed to add register classes");
        return NULL;
}
```

The last step in the preparation is to initialize the device with `usbd_init()`. After this, the configuration of the device cannot be changed. A device can be deinitialized with `usbd_shutdown()` and all instances can be reused, but the previous steps must be repeated. So it is possible to shutdown a device, register another type of configuration or function, and initialize it again. At the USB controller level, `usbd_init()` does only what is necessary to detect VBUS changes. There are controller types where the next step is only possible if a VBUS signal is present.

A function or class implementation may require its own specific configuration steps, which should be performed prior to initializing the USB device.

```
err = usbd_init(&sample_usbd);
if (err) {
        LOG_ERR("Failed to initialize device support");
        return NULL;
}
```

The final step to enable the USB device is `usbd_enable()`, after that, if the USB device is connected to a USB host controller, the host can start enumerating the device. The application can disable the USB device using `usbd_disable()`.

```
ret = usbd_enable(sample_usbd);
if (ret) {
        LOG_ERR("Failed to enable device support");
        return ret;
}
```

USB Message notifications The application can register a callback using `usbd_msg_register_cb()` to receive message notification from the USB device support subsystem. The messages are mostly about the common device state changes, and a few specific types from the USB CDC ACM implementation.

```
err = usbd_msg_register_cb(&sample_usbd, msg_cb);
if (err) {
        LOG_ERR("Failed to register message callback");
        return NULL;
}
```

The helper function `usbd_msg_type_string()` can be used to convert `usbd_msg_type` to a human readable form for logging.

If the controller supports VBUS state change detection, the battery-powered application may want to enable the USB device only when it is connected to a host. A generic application should use `usbd_can_detect_vbus()` to check for this capability.

```
static void msg_cb(struct usbd_context *const usbd_ctx,
                   const struct usbd_msg *const msg)
{
        LOG_INF("USBD message: %s", usbd_msg_type_string(msg->type));
```

(continues on next page)

(continued from previous page)

```
        if (msg->type == USBD_MSG_CONFIGURATION) {
                LOG_INF("\tConfiguration value %d", msg->status);
        }

        if (usbd_can_detect_vbus(usbd_ctx)) {
                if (msg->type == USBD_MSG_VBUS_READY) {
                        if (usbd_enable(usbd_ctx)) {
                                LOG_ERR("Failed to enable device support");
                        }
                }

                if (msg->type == USBD_MSG_VBUS_REMOVED) {
                        if (usbd_disable(usbd_ctx)) {
                                LOG_ERR("Failed to disable device support");
                        }
                }
        }
}
```

Built-in functions

The USB device stack has built-in USB functions. Some can be used directly in the user application through a special API, such as HID or Audio class devices, while others use a general Zephyr RTOS driver API, such as MSC and CDC class implementations. The *Identification string* identifies a class or function instance (`n`) and is used as an argument to the `usbd_register_class()`.

Class or function	User API (if any)	Identification string
USB Audio 2 class	*Audio Class 2 device API*	`uac2_n`
USB CDC ACM class	*Universal Asynchronous Receiver-Transmitter (UART)*	`cdc_acm_n`
USB CDC ECM class	Ethernet device	`cdc_ecm_n`
USB Mass Storage Class (MSC)	*USB Mass Storage Class device API*	`msc_n`
USB Human Interface Devices (HID)	*HID device API*	`hid_n`
Bluetooth HCI USB transport layer	*HCI RAW channel*	`bt_hci_n`
USB Video Class (UVC)	Video device	`uvc_n`

6.5.4 USB Vendor and Product identifiers

The USB Vendor ID for the Zephyr project is `0x2FE3`. Zephyr USB Vendor ID must not be used when a vendor integrates Zephyr USB device support into its own product.

Each USB sample has its own unique Product ID. The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

The following Product IDs are currently used:

Sample	PID
usb-cdc-acm	0x0001
Reserved (previously: usb-cdc-acm-composite)	0x0002
Reserved (previously: usb-hid-cdc)	0x0003
usb-cdc-acm-console	0x0004
usb-dfu (Run-Time)	0x0005
Reserved (previously: usb-hid)	0x0006
usb-hid-mouse	0x0007
usb-mass	0x0008
testusb-app	0x0009
webusb	0x000A
bluetooth_hci_usb	0x000B
Reserved (previously: bluetooth_hci_usb_h4)	0x000C
Reserved (previously: wpan-usb)	0x000D
uac2-explicit-feedback	0x000E
uac2-implicit-feedback	0x000F
uvc	0x0011
usb-dfu (DFU Mode)	0xFFFF

6.5.5 USB device CDC ACM

The CDC ACM function provided by the USB device stack only implements Abstract Control Model Serial Emulation. Its sole purpose is to emulate serial lines, as its name suggests. Most modern operating systems should provide support for it out of the box.

The CDC ACM function is represented as a serial interface on both the host and device sides, while the user or application interface is the *Universal Asynchronous Receiver-Transmitter (UART)* driver API. This allows applications that already use the UART API to use the serial interface provided by the CDC ACM function without changing the code responsible for data communication. Only additional configuration and USB device stack initialization are required.

CDC ACM UART configuration

Like the real UART controller, the virtual CDC ACM UART is described in the device tree. The devicetree compatible property for CDC ACM UART is `zephyr,cdc-acm-uart`.

CDC ACM support is automatically selected when USB device support is enabled and a compatible node in the devicetree sources is present. If necessary, CDC ACM support can be explicitly disabled by `CONFIG_USBD_CDC_ACM_CLASS`. The number of possible CDC ACM instances depends on the number of supported endpoints on the USB device controller. Each CDC ACM instance requires three endpoints: two bulk endpoints (one IN, one OUT) and one interrupt IN with a MaxPacketSize of 16. The CDC ACM node can use the `label` property to distinguish different interfaces on the host side. Below is an example of the devicetree overlay file.

```
&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Before the application uses CDC ACM UART, it may want to wait for the DTR signal. Please refer to usb-cdc-acm on how to implement this functionality.

Note

To communicate with the host, beside the UART configuration, the application must enable USB device stack, for that please refer to *How to configure and enable USB device support* and read carefully the next chapter. For users and applications migrating from the legacy stack, this is the only part they need to adapt.

CDC ACM UART as serial backend

Using the example above and the `zephyr,console` chosen node property, you can configure the CDC ACM UART as the console device.

```
/ {
        chosen {
                zephyr,console = &cdc_acm_uart0;
        };
};

&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

In the same way that the console in the above example is configured to use the CDC ACM UART, `zephyr,shell-uart` chosen node property can be used to configure the shell to use the CDC ACM UART as the serial backend. See sample shell-module and *chosen nodes documentation*.

Since the use case as a serial backend is very common and no configuration is necessary at runtime for the CDC ACM UART, the stack offers a helper that performs the steps described in *How to configure and enable USB device support*. The helper is enabled by the `CONFIG_CDC_ACM_SERIAL_INITIALIZE_AT_BOOT` and initializes the USB device stack with a single CDC ACM instance. Sample usb-cdc-acm-console demonstrates how to use it.

`CONFIG_CDC_ACM_SERIAL_INITIALIZE_AT_BOOT` should also be used by the boards like nrf52840dongle, which do not have a debug adapter but a USB device controller, and want to use CDC ACM UART as default serial backend for logging and shell. As the configuration would be identical for any board, there are common devicetree file and Kconfig file that must be included in the board's devicetree and Kconfig.defconfig files.

Using CDC ACM UART in the application

CDC ACM implements a virtual UART controller and provides Interrupt-driven UART API and Polling UART API. The ASYNC API is not supported yet. If the application wants to communicate over CDC ACM UART, the preferable way is to use Interrupt-driven UART API. It is essential to understand API documentation, nevertheless, some notes below.

Interrupt-driven UART API Internally the CDC ACM UART implementation uses two ring-buffers. These take over the function of the TX/RX FIFOs (TX/RX buffers) from the *Interrupt-driven API*.

As described in the *Interrupt-driven API*, the functions `uart_irq_update()`, `uart_irq_is_pending()`, `uart_irq_rx_ready()`, `uart_irq_tx_ready()` `uart_fifo_read()`, and `uart_fifo_fill()` should be called from the interrupt handler, see `uart_irq_callback_user_data_set()`. To prevent undefined behavior, the implementation of these functions checks in what context they are called and fails if it is not an interrupt handler.

Also, as described in the UART API, `uart_irq_is_pending()` `uart_irq_rx_ready()`, and `uart_irq_tx_ready()` can only be called after `uart_irq_update()`.

Simplified, application interrupt handler should look something like:

```
static void interrupt_handler(const struct device *dev, void *user_data)
{
        while (uart_irq_update(dev) && uart_irq_is_pending(dev)) {
                if (uart_irq_rx_ready(dev)) {
                        int len;
                        int n;

                        /* ... */
                        n = uart_fifo_read(dev, buffer, len);
                        /* ... */
                }

                if (uart_irq_tx_ready(dev)) {
                        int len;
                        int n;

                        /* ... */
                        n = uart_fifo_fill(dev, buffer, len);
                  /* ... */
                }
        }
}
```

All these functions are not directly dependent on the status of the USB device. Filling the TX FIFO does not mean that data is being sent to the host. And successfully reading the RX FIFO does not mean that the device is still connected to the host. If there is space in the TX FIFO, and the TX interrupt is enabled, `uart_irq_tx_ready()` will succeed. If there is data in the RX FIFO, and the RX interrupt is enabled, `uart_irq_rx_ready()` will succeed. Function `uart_irq_tx_complete()` is not implemented yet.

Polling UART API The CDC ACM poll out implementation follows *Polling API* and blocks when the TX FIFO is full only if the hw-flow-control property is enabled and called from a non-ISR context.

6.5.6 USB device support APIs

USB device controller (UDC) driver API

The USB device controller driver API is described in include/zephyr/drivers/usb/udc.h and referred to as the `UDC driver` API.

UDC driver API is unstable and is subject to change without notice. It is a replacement for *USB device controller driver API (deprecated)*. If you wish to port an existing driver to UDC driver API, or add a new driver, please use drivers/usb/udc/udc_skeleton.c as a starting point.

6.5.8 USB/IP protocol support

Overview

New USB support includes initial support for the USB/IP protocol. It is still under development and is currently limited to supporting only one device connected to the host controller being exported.

USB/IP uses TCP/IP. Both of the underlying connectivity stacks, USB and networking, require significant memory resources, which must be considered when choosing a platform.

In the USB/IP protocol, a server exports the USB devices and a client imports them. USB/IP support in the Zephyr RTOS implements server functionality and exports a device connected to a host controller on a device running the Zephyr RTOS. A client, typically running the Linux kernel, imports this device. The USB/IP protocol is described in USB/IP protocol documentation.

To use USB/IP support, make sure the required modules are loaded on the client side.

```
modprobe vhci_hcd
modprobe usbip-core
modprobe usbip-host
```

On the client side, you will also need the **usbip** user tool. It can be installed using your Linux distribution's package management system or built from Linux kernel sources.

There are a few basic commands for everyday use. To list exported USB devices, run the following command:

```
$ usbip list -r 192.0.2.1
Exportable USB devices
======================
 - 192.0.2.1
        1-1: NordicSemiconductor : unknown product (2fe3:0001)
           : /sys/bus/usb/devices/usb1/1-1
           : Miscellaneous Device / ? / Interface Association (ef/02/01)
           :  0 - Communications / Abstract (modem) / None (02/02/00)
           :  1 - CDC Data / Unused / unknown protocol (0a/00/00)
```

To attach an exported device with busid 1-1:

```
$ sudo usbip attach -r 192.0.2.1 -b 1-1
```

To detach an exported device on port 0:

```
$ sudo usbip detach -p 0
```

USB/IP with native_sim

The preferred method to develop with USB/IP support enabled is to use native_sim. Use on real hardware is not really tested yet. USB/IP requires a network connection, see *Networking with native_sim board* for how to set up the interface on the client side.

Building and running a sample with USB/IP requires extensive configuration, you can use usbip-native-sim snippet to configure host and USB/IP support.

```
# From the root of the zephyr repository
west build -b native_sim/native/64 samples/subsys/usb/cdc_acm -- -
↪DSNIPPET=usbip-native-sim -DEXTRA_DTC_OVERLAY_FILE=app.overlay
```

USB Power Delivery support

6.5.9 USB-C device stack

The USB-C device stack is a hardware independent interface between a Type-C Port Controller (TCPC) and customer applications. It is a port of the Google ChromeOS Type-C Port Manager (TCPM) stack. It provides the following functionalities:

- Uses the APIs provided by the Type-C Port Controller drivers to interact with the Type-C Port Controller.
- Provides a programming interface that's used by a customer applications. The APIs is described in include/zephyr/usb_c/usbc.h

Currently the device stack supports implementation of Sink only and Source only devices. Dual Role Power (DRP) devices are not yet supported.

List of samples for different purposes.

Implementing a Sink Type-C and Power Delivery USB-C device

The configuration of a USB-C Device is done in the stack layer and devicetree.

The following devicetree, structures and callbacks need to be defined:

- Devicetree usb-c-connector node referencing a TCPC
- Devicetree vbus node referencing a VBUS measurement device
- User defined structure that encapsulates application specific data
- Policy callbacks

For example, for the Sample USB-C Sink application:

Each Physical Type-C port is represented in the devicetree by a usb-c-connector compatible node:

```
port1: usbc-port@1 {
        compatible = "usb-c-connector";
        reg = <1>;
        tcpc = <&ucpd1>;
        vbus = <&vbus1>;
        power-role = "sink";
        sink-pdos = <PDO_FIXED(5000, 100, 0)>;
};
```

VBUS is measured by a device that's referenced in the devicetree by a usb-c-vbus-adc compatible node:

```
        vbus1: vbus {
                compatible = "zephyr,usb-c-vbus-adc";
                io-channels = <&adc2 8>;
                output-ohms = <49900>;
                full-ohms = <(330000 + 49900)>;
        };
```

A user defined structure is defined and later registered with the subsystem and can be accessed from callback through an API:

```
/**
 * @brief A structure that encapsulates Port data.
 */
static struct port0_data_t {
        /** Sink Capabilities */
        uint32_t snk_caps[DT_PROP_LEN(USBC_PORT0_NODE, sink_pdos)];
        /** Number of Sink Capabilities */
        int snk_cap_cnt;
        /** Source Capabilities */
        uint32_t src_caps[PDO_MAX_DATA_OBJECTS];
        /** Number of Source Capabilities */
        int src_cap_cnt;
        /* Power Supply Ready flag */
        atomic_t ps_ready;
} port0_data = {
        .snk_caps = {DT_FOREACH_PROP_ELEM(USBC_PORT0_NODE, sink_pdos, SINK_PDO)},
        .snk_cap_cnt = DT_PROP_LEN(USBC_PORT0_NODE, sink_pdos),
        .src_caps = {0},
        .src_cap_cnt = 0,
        .ps_ready = 0
};

```

These callbacks are used by the subsystem to set or get application specific data:

```
static int port0_policy_cb_get_snk_cap(const struct device *dev,
                                       uint32_t **pdos,
                                       int *num_pdos)
{

{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        return build_rdo(dpm_data);
}
```

This callback is used by the subsystem to query if a certain action can be taken:

```
bool port0_policy_check(const struct device *dev,
                        const enum usbc_policy_check_t policy_check)
{
        switch (policy_check) {
        case CHECK_POWER_ROLE_SWAP:
                /* Reject power role swaps */
                return false;
        case CHECK_DATA_ROLE_SWAP_TO_DFP:
                /* Reject data role swap to DFP */
                return false;
        case CHECK_DATA_ROLE_SWAP_TO_UFP:
                /* Accept data role swap to UFP */
                return true;
        case CHECK_SNK_AT_DEFAULT_LEVEL:
                /* This device is always at the default power level */
                return true;
        default:
                /* Reject all other policy checks */
                return false;

        }
}
```

This callback is used by the subsystem to notify the application of an event:

```
static void port0_notify(const struct device *dev,
                         const enum usbc_policy_notify_t policy_notify)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        switch (policy_notify) {
        case PROTOCOL_ERROR:
                break;
        case MSG_DISCARDED:
                break;
        case MSG_ACCEPT_RECEIVED:
```

(continues on next page)

(continued from previous page)

```
                break;
        case MSG_REJECTED_RECEIVED:
                break;
        case MSG_NOT_SUPPORTED_RECEIVED:
                break;
        case TRANSITION_PS:
                atomic_set_bit(&dpm_data->ps_ready, 0);
                break;
        case PD_CONNECTED:
                break;
        case NOT_PD_CONNECTED:
                break;
        case POWER_CHANGE_0A0:
                LOG_INF("PWR 0A");
                break;
        case POWER_CHANGE_DEF:
                LOG_INF("PWR DEF");
                break;
        case POWER_CHANGE_1A5:
                LOG_INF("PWR 1A5");
                break;
        case POWER_CHANGE_3A0:
                LOG_INF("PWR 3A0");
                break;
        case DATA_ROLE_IS_UFP:
                break;
        case DATA_ROLE_IS_DFP:
                break;
        case PORT_PARTNER_NOT_RESPONSIVE:
                LOG_INF("Port Partner not PD Capable");
                break;
        case SNK_TRANSITION_TO_DEFAULT:
                break;
        case HARD_RESET_RECEIVED:
                break;
        case SENDER_RESPONSE_TIMEOUT:
                break;
        case SOURCE_CAPABILITIES_RECEIVED:
                break;
        }
}
```

Registering the callbacks:

```
        /* Register USB-C Callbacks */

        /* Register Policy Check callback */
        usbc_set_policy_cb_check(usbc_port0, port0_policy_check);
        /* Register Policy Notify callback */
        usbc_set_policy_cb_notify(usbc_port0, port0_notify);
        /* Register Policy Get Sink Capabilities callback */
        usbc_set_policy_cb_get_snk_cap(usbc_port0, port0_policy_cb_get_snk_cap);
        /* Register Policy Set Source Capabilities callback */
        usbc_set_policy_cb_set_src_cap(usbc_port0, port0_policy_cb_set_src_cap);
        /* Register Policy Get Request Data Object callback */
        usbc_set_policy_cb_get_rdo(usbc_port0, port0_policy_cb_get_rdo);
```

Register the user defined structure:

```
        /* Set Application port data object. This object is passed to the policy␣
↪callbacks */
        port0_data.ps_ready = ATOMIC_INIT(0);
        usbc_set_dpm_data(usbc_port0, &port0_data);
```

Start the USB-C subsystem:

```
        /* Start the USB-C Subsystem */
        usbc_start(usbc_port0);
```

Implementing a Source Type-C and Power Delivery USB-C device

The configuration of a USB-C Device is done in the stack layer and devicetree.

Define the following devicetree, structures and callbacks:

- Devicetree `usb-c-connector` node referencing a TCPC
- Devicetree `vbus` node referencing a VBUS measurement device
- User defined structure that encapsulates application specific data
- Policy callbacks

For example, for the Sample USB-C Source application:

Each Physical Type-C port is represented in the devicetree by a `usb-c-connector` compatible node:

```
                port1: usbc-port@1 {
                        compatible = "usb-c-connector";
                        reg = <1>;
                        tcpc = <&ucpd1>;
                        vbus = <&vbus1>;
                        power-role = "source";
                        typec-power-opmode = "3.0A";
                        source-pdos = <PDO_FIXED(5000, 100, 0) PDO_FIXED(9000, 100,
↪ 0)
                                       PDO_FIXED(15000, 100, 0)>;
                };
```

VBUS is measured by a device that's referenced in the devicetree by a `usb-c-vbus-adc` compatible node:

```
        vbus1: vbus {
                compatible = "zephyr,usb-c-vbus-adc";
                io-channels = <&adc1 9>;
                output-ohms = <49900>;
                full-ohms = <(330000 + 49900)>;

                /* Pin B13 is used to control VBUS Discharge for Port1 */
                discharge-gpios = <&gpiob 13 GPIO_ACTIVE_HIGH>;
        };
```

A user defined structure is defined and later registered with the subsystem and can be accessed from callback through an API:

```
/**
 * @brief A structure that encapsulates Port data.
```

(continues on next page)

(continued from previous page)

```
 */
static struct port0_data_t {
        /** Source Capabilities */
        uint32_t src_caps[DT_PROP_LEN(USBC_PORT0_NODE, source_pdos)];
        /** Number of Source Capabilities */
        int src_cap_cnt;
        /** CC Rp value */
        int rp;
        /** Sink Request RDO */
        union pd_rdo sink_request;
        /** Requested Object Pos */
        int obj_pos;
        /** VCONN CC line*/
        enum tc_cc_polarity vconn_pol;
        /** True if power supply is ready */
        bool ps_ready;
        /** True if power supply should transition to a new level */
        bool ps_tran_start;
        /** Log Sink Requested RDO to console */
        atomic_t show_sink_request;
} port0_data = {
        .rp = DT_ENUM_IDX(USBC_PORT0_NODE, typec_power_opmode),
        .src_caps = {DT_FOREACH_PROP_ELEM(USBC_PORT0_NODE, source_pdos,␣
↪SOURCE_PDO)},
        .src_cap_cnt = DT_PROP_LEN(USBC_PORT0_NODE, source_pdos),
};

```

These callbacks are used by the subsystem to set or get application specific data:

```
/**
 * @brief PE calls this function when it needs to set the Rp on CC
 */
int port0_policy_cb_get_src_rp(const struct device *dev,
                               enum tc_rp_value *rp)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        *rp = dpm_data->rp;

        return 0;
}

/**
 * @brief PE calls this function to Enable (5V) or Disable (0V) the
 *          Power Supply
 */
int port0_policy_cb_src_en(const struct device *dev, bool en)
{
        source_ctrl_set(en ? SOURCE_5V : SOURCE_0V);

        return 0;
}

/**
 * @brief PE calls this function to Enable or Disable VCONN
```

(continues on next page)

(continued from previous page)

```
 */
int port0_policy_cb_vconn_en(const struct device *dev, enum tc_cc_polarity pol,␣
↪bool en)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

↪port0_policy_cb_check_sink_request);
        /* Register Policy callback to check if the power supply is ready */
        usbc_set_policy_cb_is_ps_ready(usbc_port0, port0_policy_cb_is_ps_ready);
        /* Register Policy callback to check if Present Contract is still valid */
        usbc_set_policy_cb_present_contract_is_valid(usbc_port0,
                                port0_policy_cb_present_contract_is_valid);

```

Register the user defined structure:

```
        /* Set Application port data object. This object is passed to the policy␣
↪callbacks */
        usbc_set_dpm_data(usbc_port0, &port0_data);
```

Start the USB-C subsystem:

```
        /* Start the USB-C Subsystem */
        usbc_start(usbc_port0);
```

6.6 Modbus

Modbus is an industrial messaging protocol. The protocol is specified for different types of networks or buses. Zephyr OS implementation supports communication over serial line and may be used with different physical interfaces, like RS485 or RS232. TCP support is not implemented directly, but there are helper functions to realize TCP support according to the application's needs.

Modbus communication is based on client/server model. Only one client may be present on the bus. Client can communicate with several server devices. Server devices themselves are passive and must not send requests or unsolicited responses. Services requested by the client are specified by function codes (FCxx), and can be found in the specification or documentation of the API below.

Zephyr RTOS implementation supports both client and server roles.

More information about Modbus and Modbus RTU can be found on the website MODBUS Protocol Specifications.

Hardware Support

7.1 Architecture-related Guides

7.1.1 Zephyr support status on ARC processors

Overview

This page describes current state of Zephyr for ARC processors and some future plans. Please note that

- plans are given without exact deadlines
- software features require corresponding hardware to be present and configured the proper way
- not all the features can be enabled at the same time

Support status

Legend: **Y** - yes, supported; **N** - no, not supported; **WIP** - Work In Progress; **TBD** - to be decided

	Processor families				
	EM	**HS3x/4x**	**VPX**	**HS5x**	**HS6x**
Port status	up-streamed	up-streamed	up-streamed	up-streamed	up-streamed
Features					
Closely coupled memories (ICCM, DCCM)[1]	Y	Y	Y	TBD	TBD
Execution with caches - Instruction/Data, L1/L2 caches	Y	Y	Y	Y	Y
Hardware-assisted unaligned memory access	Y[2]	Y	Y	Y	Y
Regular interrupts with multiple priority levels, direct interrupts	Y	Y	Y	Y	Y

Notes

VPX Vector Registers Zephyr supports a limited form sharing of the VPX vector registers known as cooperative sharing. Threads that use these registers must bookend the relevant sections with calls to `arc_vpx_lock()` and `arc_vpx_unlock()` to control access to this resource.

> **Note**
>
> If the system has multiple CPUs, then it is the responsibility of the application developer to both pin the thread to a single CPU before it attempts to get the cooperative lock, and not modify the CPU affinity while it is waiting for or holding that cooperative lock.

[6] currently only ARC VPX scalar port is supported. The support of VPX vector pipeline, VCCM, STU is not included in this port, and require additional development and / or other runtime integration.

[1] usage of CCMs is limited on SMP systems

[2] except the systems with secure features (SecureShield) due to HW limitation

[3] We only support save/restore ACCL/ACCH registers in task's context. Rest of DSP/AGU registers save/restore isn't implemented but kernel itself does not use these registers. This allows single task per core to use DSP/AGU safely.

[5] Single-thread kernel is support only for single core targets

[4] QEMU doesn't support all the ARC processor's HW features. For the detailed info please check the ARC QEMU documentation

Configuration Options The cooperative sharing of the VPX vector registers is selected when configuration option `CONFIG_ARC_VPX_COOPERATIVE_SHARING` is enabled.

7.1.2 Arm Cortex-M Developer Guide

Overview

This page contains detailed information about the status of the Arm Cortex-M architecture porting in the Zephyr RTOS and describes key aspects when developing Zephyr applications for Arm Cortex-M-based platforms.

Key supported features

The table below summarizes the status of key OS features in the different Arm Cortex-M implementation variants.

Architecture variant		Arm v6-M		Arm v7-M
		M0/M1	**M0+**	**M3**
OS Features				
Programmable fault IRQ priorities		N	N	Y
Single-thread kernel support		Y	Y	Y
Thread local storage support		Y	Y	Y
Interrupt handling				
	Regular interrupts	Y	Y	Y
	Dynamic interrupts	Y	Y	Y

	Direct interrupts	Y	Y	Y
	Zero Latency interrupts	N	N	Y
CPU idling		Y	Y	Y
Native system timer (SysTick)		N[1]	Y	Y
Memory protection				
	User mode	N	Y	Y
	HW stack protection (MPU)	N	N	Y
	HW-assisted stack limit checking	N	N	N
	Privileged Execute Never[3]	N	N	N
HW-assisted Control Flow integrity	PACBTI	N	N	N

HW-assisted null-pointer dereference detection		N	N	Y
HW-assisted atomic operations		N	N	Y
Support for non-cacheable regions		N	N	Y
Execute SRAM functions		N	N	Y
Floating Point Services		N	N	N
DSP ISA		N	N	N
Trusted Execution				
	Native TrustZone M support	N	N	N
	TF-M integration	N	N	N
Code relocation		Y	Y	Y
SW-based vector table relaying		Y	Y	Y

HW-assisted timing functions	N		N	Y

Notes

OS features

Threads

Thread stack alignment Each Zephyr thread is defined with its own stack memory. By default, Cortex-M enforces a double word thread stack alignment, see `CONFIG_STACK_ALIGN_DOUBLE_WORD`. If MPU-based HW-assisted stack overflow detection (`CONFIG_MPU_STACK_GUARD`) is enabled, thread stacks need to be aligned with a larger value, reflected by `CONFIG_ARM_MPU_REGION_MIN_ALIGN_AND_SIZE`. In Arm v6-M and Arm v7-M architecture variants, thread stacks are additionally required to align with a value equal to their size, in applications that need to support user mode (`CONFIG_USERSPACE`). The thread stack sizes in that case need to be a power of two. This is all reflected by `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT`, that is enforced in Arm v6-M and Arm v7-M builds with user mode support.

Stack pointers While executing in thread mode the processor is using the Process Stack Pointer (PSP). The processor uses the Main Stack Pointer (MSP) while executing in handler mode, that is, while servicing exceptions and HW interrupts. Using PSP in thread mode *facilitates thread stack pointer manipulation* during thread context switching, without affecting the current execution context flow in handler mode.

In Arm Cortex-M builds a single interrupt stack memory is shared among exceptions and interrupts. The size of the interrupt stack needs to be selected taking into consideration nested interrupts, each pushing an additional stack frame. Developers can modify the interrupt stack size using `CONFIG_ISR_STACK_SIZE`.

The interrupt stack is also used during early boot so the kernel can initialize the main thread's stack before switching to the main thread.

Thread context switching In Arm Cortex-M builds, the PendSV exception is used in order to trigger a context switch to a different thread. PendSV exception is always present in Cortex-M implementations. PendSV is configured with the lowest possible interrupt priority level, in all Cortex-M variants. The main reasons for that design are

- to utilize the tail chaining feature of Cortex-M processors, and thus limit the number of context switch operations that occur.
- to not impact the interrupt latency observed by HW interrupts.

As a result, context switch in Cortex-M is non-atomic, i.e. it may be *preempted* by HW interrupts, however, a context-switch operation must be completed before a new thread context-switch may start.

Typically a thread context-switch will perform the following operations

[1] SysTick is optional in Cortex-M1
[2] Stack limit checking only in Secure builds in Cortex-M23
[3] https://developer.arm.com/documentation/107655/100/RTOS-and-Secure-software-design-considerations/Secure-software-development-design-considerations/Security-and-privilege-combination/Using-PXN-bit?lang=en

- When switching-out the current thread, the processor stores
  - the callee-saved registers (R4 - R11) in the thread's container for callee-saved registers, which is located in kernel memory
  - the thread's current operation *mode*
    - user or privileged execution mode
    - presence of an active floating point context
    - the EXC_RETURN value of the current handler context (PendSV)
  - the floating point callee-saved registers (S16 - S31) in the thread's container for FP callee-saved registers, if the current thread has an active FP context
  - the PSP of the current thread which points to the beginning of the current thread's exception stack frame. The latter contains the caller-saved context and the return address of the switched-out thread.
- When switching-in a new thread the processor
  - restores the new thread's callee-saved registers from the thread's container for callee-saved registers
  - restores the new thread's operation *mode*
  - restores the FP callee-saved registers if the switched-in thread had an active FP context before being switched-out
  - re-programs the dynamic MPU regions to allow a user thread access its stack and application memories, and/or programs a stack-overflow MPU guard at the bottom of the thread's privileged stack
  - restores the PSP for the incoming thread and re-programs the stack pointer limit register (if applicable, see `CONFIG_BUILTIN_STACK_GUARD`)
  - optionally does a stack limit checking for the switched-in thread, if sentinel-based stack limit checking is enabled (see `CONFIG_STACK_SENTINEL`).

PendSV exception return sequence restores the new thread's caller-saved registers and the return address, as part of unstacking the exception stack frame.

The implementation of the context-switch mechanism is present in `arch/arm/core/cortex_m/swap_helper.S`.

Stack limit checking (Arm v8-M) Armv8-M and Armv8.1-M variants support stack limit checking using the MSPLIM and PSPLIM core registers. The feature is enabled when `CONFIG_BUILTIN_STACK_GUARD` is set. When stack limit checking is enabled, both the thread's privileged or user stack, as well as the interrupt stack are guarded by PSPLIM and MSPLIM registers, respectively. MSPLIM is configured *once* during kernel boot, while PSLIM is re-programmed during every thread context-switch or during system calls, when the thread switches from using its default stack to using its privileged stack, and vice versa. PSPLIM re-programming

- has a relatively low runtime overhead (programming is done with MSR instructions)
- does not impact interrupt latency
- does not require any memory areas to be reserved for stack guards
- does not make use of MPU regions

It is, therefore, considered as a lightweight but very efficient stack overflow detection mechanism in Cortex-M applications.

Stack overflows trigger the dedicated UsageFault exception provided by Arm v8-M.

Interrupt handling features This section describes certain aspects around exception and interrupt handling in Arm Cortex-M.

Interrupt priority levels The number of available (configurable) interrupt priority levels is determined by the number of implemented interrupt priority bits in NVIC; this needs to be described for each Cortex-M platform using DeviceTree:

```
&nvic {
        arm,num-irq-priority-bits = <#priority-bits>;
};
```

Reserved priority levels A number of interrupt priority levels are reserved for the OS.

By design, system fault exceptions have the highest priority level. In *Baseline* Cortex-M, this is actually enforced by hardware, as HardFault is the only available processor fault exception, and its priority is higher than any configurable exception priority.

In *Mainline* Cortex-M, the available fault exceptions (e.g. MemManageFault, UsageFault, etc.) are assigned the highest *configurable* priority level. (`CONFIG_CPU_CORTEX_M_HAS_PROGRAMMABLE_FAULT_PRIOS` signifies explicitly that the Cortex-M implementation supports configurable fault priorities.)

This priority level is never shared with HW interrupts (an exception to this rule is described below). As a result, processor faults occurring in regular ISRs will be handled by the corresponding fault handler and will not escalate to a HardFault, *similar to processor faults occurring in thread mode*.

SVC exception is normally configured with the highest configurable priority level (an exception to this rule will be described below). SVCs are used by the Zephyr kernel to dispatch system calls, trigger runtime system errors (e.g. Kernel oops or panic), or implement IRQ offloading.

In Baseline Cortex-M the priority level of SVC may be shared with other exceptions or HW interrupts that are also given the highest configurable priority level (As a result of this, kernel runtime errors during interrupt handling will escalate to HardFault. Additional logic in the fault handling routines ensures that such runtime errors are detected successfully).

In Mainline Cortex-M, however, the SVC priority level is *reserved*, thus normally it is only shared with the fault exceptions of configurable priority. This simplifies the fault handling routines in Mainline Cortex-M architecture, since runtime kernel errors are serviced by the SVC handler (i.e no HardFault escalation, even if the kernel errors occur in ISR context).

HW interrupts in Mainline Cortex-M builds are allocated a priority level lower than the SVC.

One exception to the above rules is when Zephyr applications support Zero Latency Interrupts (ZLIs). Such interrupts are designed to have a priority level higher than any HW or system interrupt. If the ZLI feature is enabled in Mainline Cortex-M builds (see `CONFIG_ZERO_LATENCY_IRQS`), then

- ZLIs are assigned the highest configurable priority level
- SVCs are assigned the second highest configurable priority level
- Regular HW interrupts are assigned priority levels lower than SVC.

The priority level configuration in Cortex-M is implemented in `include/zephyr/arch/arm/cortex_m/exception.h`.

Locking and unlocking IRQs In Baseline Cortex-M locking interrupts is implemented using the PRIMASK register.

```
arch_irq_lock()
```

will set the PRIMASK register to 1, eventually, masking all IRQs with configurable priority. While this fulfils the OS requirement of locking interrupts, the consequence is that kernel runtime errors (triggering SVCs) will escalate to HardFault.

In Mainline Cortex-M locking interrupts is implemented using the BASEPRI register (Mainline Cortex-M builds select `CONFIG_CPU_CORTEX_M_HAS_BASEPRI` to signify that BASEPRI register is implemented.). By modifying BASEPRI (or BASEPRI_MAX) arch_irq_lock() masks all system and HW interrupts with the exception of

- SVCs
- processor faults
- ZLIs

This allows zero latency interrupts to be triggered inside OS critical sections. Additionally, this allows system (processor and kernel) faults to be handled by Zephyr in *exactly the same way*, regardless of whether IRQs have been locked or not when the error occurs. It also allows for system calls to be dispatched while IRQs are locked.

Note

Mainline Cortex-M fault handling is designed and configured in a way that all processor and kernel faults are handled by the corresponding exception handlers and never result in HardFault escalation. In other words, a HardFault may only occur in Zephyr applications that have modified the default fault handling configurations. The main reason for this design was to reserve the HardFault exception for handling exceptional error conditions in safety critical applications.

Dynamic direct interrupts Cortex-M builds support the installation of direct interrupt service routines during runtime. Direct interrupts are designed for performance-critical interrupt handling and do not go through all of the common Zephyr interrupt handling code.

Direct dynamic interrupts are enabled via switching on `CONFIG_DYNAMIC_DIRECT_INTERRUPTS`.

Note that enabling direct dynamic interrupts requires enabling support for dynamic interrupts in the kernel, as well (see `CONFIG_DYNAMIC_INTERRUPTS`).

Zero Latency interrupts As described above, in Mainline Cortex-M applications, the Zephyr kernel reserves the highest configurable interrupt priority level for its own use (SVC). SVCs will not be masked by interrupt locking. Zero-latency interrupt can be used to set up an interrupt at the highest interrupt priority which will not be blocked by interrupt locking. To use the ZLI feature `CONFIG_ZERO_LATENCY_IRQS` needs to be enabled.

Zero latency IRQs have minimal interrupt latency, as they will always preempt regular HW or system interrupts.

Note, however, that since ZLI ISRs will run at a priority level higher than the kernel exceptions they **cannot use** any kernel functionality. Additionally, since the ZLI interrupt priority level is equal to processor fault priority level, faults occurring in ZLI ISRs will escalate to HardFault and will not be handled in the same way as regular processor faults. Developers need to be aware of this limitation.

CPU Idling The Cortex-M architecture port implements both k_cpu_idle() and k_cpu_atomic_idle(). The implementation is present in `arch/arm/core/cortex_m/cpu_idle.c`.

In both implementations, the processor will attempt to put the core to low power mode. In k_cpu_idle() the processor ends up executing WFI (Wait For Interrupt) instruction, while in k_cpu_atomic_idle() the processor will execute a WFE (Wait For Event) instruction.

When using the CPU idling API in Cortex-M it is important to note the following:

- Both k_cpu_idle() and k_cpu_atomic_idle() are *assumed* to be invoked with interrupts locked. This is taken care of by the kernel if the APIs are called by the idle thread.
- After waking up from low power mode, both functions will *restore* interrupts unconditionally, that is, regardless of the interrupt lock status before the CPU idle API was called.

The Zephyr CPU Idling mechanism is detailed in *CPU Idling*.

Memory protection features This section describes certain aspects around memory protection features in Arm Cortex-M applications.

User mode system calls User mode is supported in Cortex-M platforms that implement the standard (Arm) MPU or a similar core peripheral logic for memory access policy configuration and control, such as the NXP MPU for Kinetis platforms. (Currently, `CONFIG_ARCH_HAS_USERSPACE` is selected if `CONFIG_ARM_MPU` is enabled by the user in the board default Kconfig settings).

A thread performs a system call by triggering a (synchronous) SVC exception, where

- up to 5 arguments are placed on registers R1 - R5
- system call ID is placed on register R6.

The SVC Handler will branch to the system call preparation logic, which will perform the following operations

- switch the thread's PSP to point to the beginning of the thread's privileged stack area, optionally reprogramming the PSPLIM if stack limit checking is enabled
- modify CONTROL register to switch to privileged mode
- modify the return address in the SVC exception stack frame, so that after exception return the system call dispatcher is executed (in thread privileged mode)

Once the system call execution is completed the system call dispatcher will restore the user's original PSP and PSPLIM and switch the CONTROL register back to unprivileged mode before returning back to the caller of the system call.

System calls execute in thread mode and can be preempted by interrupts at any time. A thread may also be context-switched-out while doing a system call; the system call will resume as soon as the thread is switched-in again.

The system call dispatcher executes at SVC priority, therefore it cannot be preempted by HW interrupts (with the exception of ZLIs), which may observe some additional interrupt latency if they occur during a system call preparation.

MPU-assisted stack overflow detection Cortex-M platforms with MPU may enable `CONFIG_MPU_STACK_GUARD` to enable the MPU-based stack overflow detection mechanism. The following points need to be considered when enabling the MPU stack guards

- stack overflows are triggering processor faults as soon as they occur
- the mechanism is essential for detecting stack overflows in supervisor threads, or user threads in privileged mode; stack overflows in threads in user mode will always be detected regardless of `CONFIG_MPU_STACK_GUARD` being set.
- stack overflows are always detected, however, the mechanism does not guarantee that no memory corruption occurs when supervisor threads overflow their stack memory
- `CONFIG_MPU_STACK_GUARD` will normally reserve one MPU region for programming the stack guard (in certain Arm v8-M configurations with `CONFIG_MPU_GAP_FILLING` enabled 2 MPU regions are required to implement the guard feature)
- MPU guards are re-programmed at every context-switch, adding a small overhead to the thread swap routine. Compared, however, to the `CONFIG_BUILTIN_STACK_GUARD` feature, no re-programming occurs during system calls.

- When CONFIG_HW_STACK_PROTECTION is enabled on Arm v8-M platforms the native stack limit checking mechanism is used by default instead of the MPU-based stack overflow detection mechanism; users may override this setting by manually enabling CONFIG_MPU_STACK_GUARD in these scenarios.

Pointer Authentication and Branch Target Identification (PACBTI) The Armv8.1-M Pointer Authentication and Branch Target Identification (PACBTI) extension is an optional extension for the Armv8.1-M architecture profile and consists of the implementation of the following control-flow integrity approaches:

- Return address signing and authentication (PAC-RET) as a mitigation for Return Oriented Programming (ROP) style attack.
- BTI instruction placement (BTI) as a mitigation for Jump Oriented Programming (JOP) style attacks.

When hardware support is present (e.g., Cortex-M85) and compiler support is available, PACBTI can be enabled at build time in Zephyr by selecting one of the below configs:

- CONFIG_ARM_PACBTI_STANDARD
- CONFIG_ARM_PACBTI_PACRET
- CONFIG_ARM_PACBTI_PACRET_LEAF
- CONFIG_ARM_PACBTI_BTI
- CONFIG_ARM_PACBTI_PACRET_BTI
- CONFIG_ARM_PACBTI_PACRET_LEAF_BTI
- CONFIG_ARM_PACBTI_NONE

The config options ensures that compiler flags enabling PACBTI instructions are added to the build, specifically:

- -mbranch-protection= for GCC toolchains.

Further, CONFIG_ARM_PAC and CONFIG_ARM_BTI are automatically selected based on the branch protection option chosen for CONFIG_ARM_PACBTI. These configuration options enforce PACBTI by enabling corresponding PACBTI bits in CONTROL register and in the FVP.

To further enhance pointer authentication, Zephyr supports using cryptographically secure, per-thread PAC keys by enabling CONFIG_ARM_PAC_PER_THREAD. For more details on key generation sources and configuration, refer to the Kconfig help for CONFIG_ARM_PAC_PER_THREAD.

Limitations:

- Only builds targeting Armv8.1-M Mainline processors with PACBTI hardware support (e.g., Cortex-M85) are able to fully use this feature.
- Zephyr's integrated SDK currently includes GCC 12.2 which does not support PACBTI so external GCC toolchains (14.3 or later recommended) must be used for PACBTI support. Refer to this document on how to set up toolchains.

For more information about PACBTI, refer to the official Arm documentation and also Arm community blog

Memory map and MPU considerations

Fixed MPU regions By default, when CONFIG_ARM_MPU is enabled a set of *fixed* MPU regions are programmed during system boot.

- One MPU region programs the entire flash area as read-execute. User can override this setting by enabling CONFIG_MPU_ALLOW_FLASH_WRITE, which programs the flash with RWX

permissions. If CONFIG_USERSPACE is enabled unprivileged access on the entire flash area is allowed.

- One MPU region programs the entire SRAM area with privileged-only RW permissions. That is, an MPU region is utilized to disallow execute permissions on SRAM. (An exception to this setting is when CONFIG_MPU_GAP_FILLING is disabled (Arm v8-M only); in that case no SRAM MPU programming is done so the access is determined by the default Arm memory map policies, allowing for privileged-only RWX permissions on SRAM).
- All the memory regions defined in the devicetree with the property zephyr,memory-attr defining the MPU permissions for the memory region. See the next section for more details.

The above MPU regions are defined in arch/arm/core/mpu/arm_mpu_regions.c. Alternative MPU configurations are allowed by enabling CONFIG_CPU_HAS_CUSTOM_FIXED_SOC_MPU_REGIONS. When enabled, this option signifies that the Cortex-M SoC will define and configure its own fixed MPU regions in the SoC definition.

Fixed MPU regions defined in devicetree When the property zephyr,memory-attr is present in a memory node, a new MPU region will be allocated and programmed during system boot. When used with the zephyr,memory-region devicetree compatible, it will result in a linker section being generated associated to that MPU region.

For example, to define a new non-cacheable memory region in devicetree:

```
sram_no_cache: memory@20300000 {
     compatible = "zephyr,memory-region", "mmio-sram";
     reg = <0x20300000 0x100000>;
     zephyr,memory-region = "SRAM_NO_CACHE";
     zephyr,memory-attr = <DT_MEM_ARM_MPU_RAM_NOCACHE>;
};
```

This will automatically create a new MPU entry in with the correct name, base, size and attributes gathered directly from the devicetree. See *Caching Basics* and *Memory Attributes* for more details.

Static MPU regions Additional *static* MPU regions may be programmed once during system boot. These regions are required to enable certain features. See *Caching Basics* for more details.

- a RX region to allow execution from SRAM, when CONFIG_ARCH_HAS_RAMFUNC_SUPPORT is enabled and users have defined functions to execute from SRAM.
- a RX region for relocating text sections to SRAM, when CONFIG_CODE_DATA_RELOCATION_SRAM is enabled
- a nocache region to allow for a non-cacheable SRAM area, when CONFIG_NOCACHE_MEMORY is enabled
- a possibly unprivileged RW region for GCOV code coverage accounting area, when CONFIG_COVERAGE_GCOV is enabled
- a no-access region to implement null pointer dereference detection, when CONFIG_NULL_POINTER_EXCEPTION_DETECTION_MPU is enabled

The boundaries of these static MPU regions are derived from symbols exposed by the linker, in include/linker/linker-defs.h.

Dynamic MPU regions Certain thread-specific MPU regions may be re-programmed dynamically, at each thread context switch:

- an unprivileged RW region for the current thread's stack area (for user threads)
- a read-only region for the MPU stack guard

- unprivileged RW regions for the partitions of the current thread's application memory domain.

Considerations The number of available MPU regions for a Cortex-M platform is a limited resource. Most platforms have 8 MPU regions, while some Cortex-M33 or Cortex-M7 platforms may have up to 16 MPU regions. Therefore there is a relatively strict limitation on how many fixed, static and dynamic MPU regions may be programmed simultaneously. For platforms with 8 available MPU regions it might not be possible to enable all the aforementioned features that require MPU region programming. In most practical applications, however, only a certain set of features is required and 8 MPU regions are, in many cases, sufficient.

In Arm v8-M processors the MPU architecture does not allow programmed MPU regions to overlap. `CONFIG_MPU_GAP_FILLING` controls whether the fixed MPU region covering the entire SRAM is programmed. When it does, a full SRAM area partitioning is required, in order to program the static and the dynamic MPU regions. This increases the total number of required MPU regions. When `CONFIG_MPU_GAP_FILLING` is not enabled the fixed MPU region covering the entire SRAM is not programmed, thus, the static and dynamic regions are simply programmed on top of the always-existing background region (full-SRAM partitioning is not required). Note, however, that the background SRAM region allows execution from SRAM, so when `CONFIG_MPU_GAP_FILLING` is not set Zephyr is not protected against attacks that attempt to execute malicious code from SRAM.

Floating point Services Both unshared and shared FP registers mode are supported in Cortex-M (see *Floating Point Services* for more details).

When FPU support is enabled in the build (`CONFIG_FPU` is enabled), the sharing FP registers mode (`CONFIG_FPU_SHARING`) is enabled by default. This is done as some compiler configurations may activate a floating point context by generating FP instructions for any thread, regardless of whether floating point calculations are performed, and that context must be preserved when switching such threads in and out.

The developers can still disable the FP sharing mode in their application projects, and switch to Unshared FP registers mode, if it is guaranteed that the image code does not generate FP instructions outside the single thread context that is allowed (and supposed) to do so.

Under FPU sharing mode, the callee-saved FPU registers are saved and restored in context-switch, if the corresponding threads have an active FP context. This adds some runtime overhead on the swap routine. In addition to the runtime overhead, the sharing FPU mode

- requires additional memory for each thread to save the callee-saved FP registers
- requires additional stack memory for each thread, to stack the caller-saved FP registers, upon exception entry, if an FP context is active. Note, however, that since lazy stacking is enabled, there is no runtime overhead of FP context stacking in regular interrupts (FP state preservation is only activated in the swap routine in PendSV interrupt).

Misc

Chain-loadable images Cortex-M applications may either be standalone images or chain-loadable, for instance, by a bootloader. Application images chain-loadable by bootloaders (or other applications) normally occupy a specific area in the flash denoted as their *code partition*. `CONFIG_USE_DT_CODE_PARTITION` will ensure that a Zephyr chain-loadable image will be linked into its code partition, specified in DeviceTree.

HW initialization at boot In order to boot properly, chain-loaded applications may require that the core Arm hardware registers and peripherals are initialized in their reset values. Enabling `CONFIG_INIT_ARCH_HW_AT_BOOT` Zephyr to force the initialization of the internal Cortex-M architectural state during boot to the reset values as specified by the corresponding Arm architecture manual.

Software vector relaying In Cortex-M platforms that implement the VTOR register (see CONFIG_CPU_CORTEX_M_HAS_VTOR), chain-loadable images relocate the Cortex-M vector table by updating the VTOR register with the offset of the image vector table.

Baseline Cortex-M platforms without VTOR register might not be able to relocate their vector table which remains at a fixed location. Therefore, a chain-loadable image will require an alternative way to route HW interrupts and system exceptions to its own vector table; this is achieved with software vector relaying.

When a bootloader image enables CONFIG_SW_VECTOR_RELAY it is able to relay exceptions and interrupts based on a vector table pointer that is set by the chain-loadable application. The latter sets the CONFIG_SW_VECTOR_RELAY_CLIENT option to instruct the boot sequence to set the vector table pointer in SRAM so that the bootloader can forward the exceptions and interrupts to the chain-loadable image's software vector table.

While this feature is intended for processors without VTOR register, it may also be used in Mainline Cortex-M platforms.

Code relocation Cortex-M support the code relocation feature. When CONFIG_CODE_DATA_RELOCATION_SRAM is selected, Zephyr will relocate .text, data and .bss sections from the specified files and place it in SRAM. It is possible to relocate only parts of the code sections into SRAM, without relocating the whole image text and data sections. More details on the code relocation feature can be found in *Code And Data Relocation*.

Linking Cortex-M applications

Most Cortex-M platforms make use of the default Cortex-M GCC linker script in include/zephyr/arch/arm/cortex_m/scripts/linker.ld, although it is possible for platforms to use a custom linker script as well.

CMSIS

Cortex-M CMSIS headers are provided through standalone module repositories:

- **CMSIS 5**: zephyrproject-rtos/cmsis
- **CMSIS 6**: zephyrproject-rtos/CMSIS_6

Zephyr has begun transitioning to **CMSIS 6** as the default source for Cortex-M core headers. However, at present, Zephyr includes headers from **both** the CMSIS 6 and legacy CMSIS 5 modules.

The legacy CMSIS 5 headers remain available primarily for compatibility with vendor HALs, while all new architecture-level development should use **CMSIS 6** headers whenever possible.

CONFIG_CPU_CORTEX_M selects CONFIG_HAS_CMSIS_CORE to signify that CMSIS headers are available for all supported Cortex-M variants.

Testing

A list of unit tests for the Cortex-M porting and miscellaneous features is present in tests/arch/arm/. The tests suites are continuously extended and new test suites are added, in an effort to increase the coverage of the Cortex-M architecture support in Zephyr.

QEMU

We use QEMU to verify the implemented features of the Cortex-M architecture port in Zephyr. Adequate coverage is achieved by defining and utilizing a list of QEMU targets, each with a specific architecture variant and Arm peripheral support list.

The table below lists the QEMU platform targets defined in Zephyr along with the corresponding Cortex-M implementation variant and the peripherals these targets emulate.

	QEMU target				
Architecture variant	Arm v6-M	Arm v7-M		Arm v8-M	Arm v8.1-M
	qemu_cortex	qemu_cortex	mps2/an3	mps2/an521/c	mps3/corstone300/an547
Emulated features					
NVIC	Y	Y	Y	Y	Y
BASEPRI	N	Y	Y	Y	Y
SysTick	N	Y	Y	Y	Y
MPU	N	N	Y	Y	Y
FPU	N	N	N	Y	N
SPLIM	N	N	N	Y	Y
TrustZone-M	N	N	N	Y	N

Maintainers & Collaborators

The status of the Arm Cortex-M architecture port in Zephyr is: *maintained*. The updated list of maintainers and collaborators for Cortex-M can be found in `MAINTAINERS.yml`.

7.1.3 Zephyr support status on RISC-V processors

Overview

This page describes current state of Zephyr for RISC-V processors. Currently, there's support for some boards, as well as Qemu support and support for some FPGA implementations such as neorv32 and litex_vexriscv.

Zephyr support includes PMP, *user mode*, several ISA extensions as well as *semihosting*.

User mode and PMP support

When the platform has Physical Memory Protection (PMP) support, enabling it on Zephyr allows user space support and stack protection to be selected.

ISA extensions

It's possible to set in Zephyr which ISA extensions (RV32/64I(E)MAFD(G)QC) are available on a given platform, by setting the appropriate `CONFIG_RISCV_ISA_*` kconfig. Look at `arch/riscv/Kconfig.isa` for more information.

Note that Zephyr SDK toolchain support may not be defined for all combinations.

SMP support

SMP is supported on RISC-V for both QEMU-virtualized and hardware-based platforms. In order to test the SMP support, one can use qemu_riscv32 or qemu_riscv64 for QEMU-based platforms, or beaglev_fire or mpfs_icicle for hardware-based platforms.

7.1.4 Semihosting Guide

Overview

Semihosting is a mechanism that enables code running on ARM, RISC-V and Xtensa targets to communicate and use the Input/Output facilities on a host computer that is running a debugger or emulator.

More complete documentation on the available functionality is available at the ARM Github documentation.

The RISC-V functionality borrows from the ARM definitions, as described at the RISC-V Github documentation.

Semihosting implementation on Xtensa supports GDB File-I/O extension, which is explained in GDB File-I/O Remote Protocol.

File Operations

Semihosting enables files on the host computer to be opened, read, and modified by an application. This can be useful when attempting to validate the behaviour of code across datasets that are larger than what can fit into ROM of an emulated platform. File paths can be either absolute, or relative to the directory of the running process.

```
const char *path = "./data.bin";
long file_len, bytes_read, fd;
uint8_t buffer[16];

/* Open the data file for reading */
fd = semihost_open(path, SEMIHOST_OPEN_RB);
if (fd < 0) {
   return -ENOENT;
}
/* Read all data from the file */
file_len = semihost_flen(fd);
while(file_len > 0) {
   bytes_read = semihost_read(fd, buffer, MIN(file_len, sizeof(buffer)));
   if (bytes_read < 0) {
      break;
   }
   /* Process read data */
   do_data_processing(buffer, bytes_read);
   /* Update remaining length */
   file_len -= bytes_read;
}
/* Close the file */
semihost_close(fd);
```

Additional Functionality

Additional functionality is available by running semihosting instructions directly with `semihost_exec()` with one of the instructions defined in `semihost_instr`. For complete documentation on the required arguments and return codes, see the ARM Github documentation.

API Reference

Semihosting APIs

7.1.5 x86 Developer Guide

Overview

This page contains information on certain aspects when developing for x86-based platforms.

Virtual Memory

During very early boot, page tables are loaded so technically the kernel is executing in virtual address space. By default, physical and virtual memory are identity mapped and thus giving the appearance of execution taking place in physical address space. The physical address space

is marked by kconfig CONFIG_SRAM_BASE_ADDRESS and CONFIG_SRAM_SIZE while the virtual address space is marked by CONFIG_KERNEL_VM_BASE and CONFIG_KERNEL_VM_SIZE. Note that CONFIG_SRAM_OFFSET controls where the Zephyr kernel is being placed in the memory, and its counterpart CONFIG_KERNEL_VM_OFFSET.

Separate Virtual Address Space from Physical Address Space On 32-bit x86, it is possible to have separate physical and virtual address space. Code and data are linked in virtual address space, but are still loaded in physical memory. However, during boot, code and data must be available and also addressable in physical address space before vm_enter inside arch/x86/core/ia32/crt0.S. After vm_enter, code execution is done via virtual addresses and data can be referred via their virtual addresses. This is possible as the page table generation script (arch/x86/gen_mmu.py) identity maps the physical addresses at the page directory level, in addition to mapping virtual addresses to the physical memory. Later in the boot process, the entries for identity mapping at the page directory level are cleared in z_x86_mmu_init(), effectively removing the identity mapping of physical memory. This unmapping must be done for userspace isolation or else they would be able to access restricted memory via physical addresses. Since the identity mapping is done at the page directory level, there is no need to allocate additional space for the page table. However, additional space may still be required for additional page directory table.

There are restrictions on where virtual address space can be:

- Physical and virtual address spaces must be disjoint. This is required as the entries in page directory table will be cleared. If they are not disjoint, it would clear the entries needed for virtual addresses.
  - If CONFIG_X86_PAE is enabled (=y), each address space must reside in their own 1GB region, due to each entry of PDP (Page Directory Pointer) covers 1GB of memory. For example:
    - Assuming CONFIG_SRAM_OFFSET and CONFIG_KERNEL_VM_OFFSET are both 0x0.
    - CONFIG_SRAM_BASE_ADDRESS == 0x00000000 and CONFIG_KERNEL_VM_BASE = 0x40000000 is valid, while
    - CONFIG_SRAM_BASE_ADDRESS == 0x00000000 and CONFIG_KERNEL_VM_BASE = 0x20000000 is not.
  - If CONFIG_X86_PAE is disabled (=n), each address space must reside in their own 4MB region, due to each entry of PD (Page Directory) covers 4MB of memory.
  - Both CONFIG_SRAM_BASE_ADDRESS and CONFIG_KERNEL_VM_BASE must also align with the starting addresses of targeted regions.

Specifying Additional Memory Mappings at Build Time

The page table generation script (arch/x86/gen_mmu.py) generates the necessary multi-level page tables for code execution and data access using the kernel image produced by the first linker pass. Additional command line arguments can be passed to the script to generate additional memory mappings. This is useful for static mappings and/or device MMIO access during very early boot. To pass extra command line arguments to the script, populate a CMake list named X86_EXTRA_GEN_MMU_ARGUMENTS in the board configuration file. Here is an example:

```
set(X86_EXTRA_GEN_MMU_ARGUMENTS
    --map 0xA0000000,0x2000
    --map 0x80000000,0x400000,LWUX,0xB0000000)
```

The argument --map takes the following value: <physical address>,<size>[,<flags:LUWX>[,<virtual address>]], where:

- <physical address> is the physical address of the mapping. (Required)
- <size> is the size of the region to be mapped. (Required)

- <flags> is the flag associated with the mapping: (Optional)
  - L: Large page at the page directory level.
  - U: Allow userspace access.
  - W: Read/write.
  - X: Allow execution.
  - D: Cache disabled.
    - Default is small page (4KB), supervisor only, read only, and execution disabled.
- <virtual address is the virtual address of the mapping. (Optional)

Note that specifying additional memory mappings requires larger storage space for the pre-allocated page tables (both kernel and per-domain tables). CONFIG_X86_EXTRA_PAGE_TABLE_PAGES is needed to specify how many more memory pages to be reserved for the page tables. If the needed space is not exactly the same as required space, the gen_mmu.py script will print out a message indicating what needs to be the value for the kconfig.

7.1.6 Xtensa Developer Guide

Overview

This page contains information on certain aspects when developing for Xtensa-based platforms.

HiFi Audio Engine DSP

The kernel allows threads to use the HiFi Audio Engine DSP registers on boards that support these registers. The kernel only supports the use of the HiFi registers by threads and not ISRs.

> **Note**
>
> Presently, only the Intel ADSP ACE hardware platforms are configured for HiFi support by default.

Concepts The kernel can be configured for an application to leverage the services provided by the Xtensa HiFi Audio Engine DSP. Three modes of operation are supported, which are described below.

No HiFi registers mode This mode is used when the application has no threads that use the HiFi registers. It is the kernel's default HiFi services mode.

Unshared HiFi registers mode This mode is used when the application has only a single thread that uses the HiFi registers. The HiFi registers are left unchanged whenever a context switch occurs.

> **Note**
>
> The behavior is undefined, if two or more threads attempt to use the HiFi registers, as the kernel does not attempt to detect (nor prevent) multiple threads from using these registers.

Shared HiFi registers mode This mode is used when the application has two or more threads that use HiFi registers. When enabled, the kernel automatically allows all threads to use the HiFi registers. Conceptually, it can be sub-divided into two sub-modes–eager mode and lazy mode. They will both save and restore the HiFi registers, but they differ in when the registers are saved and restored, as well as to where they are saved and from where they are restored.

In the eager sharing model, the HiFi registers are saved and restored during every thread context switch, regardless of whether the thread used them or not. Additional stack space may be required for each thread to account for the extra registers that must be saved. This is default of the two models.

In the lazy sharing model, the kernel tracks the thread that 'owns' the coprocessor. If the 'owning' thread is switched out, the HiFi registers will not be saved until a new thread attempts to use the HiFi, after which that new thread becomes the new owner and its HiFi registers are loaded.

Note

If an SMP system detects that the owner-to-be is still an owner on another CPU, an IPI will be sent to that CPU to initiate the saving of its HiFi registers to memory. The current processor will then spin until the HiFi registers are saved. This spinning may result in sporadically longer delays. For the best performance, it is recommended that a thread using HiFi be pinned to a single CPU.

Configuration Options The unshared HiFi registers mode is selected when configuration option `CONFIG_XTENSA_HIFI_SHARING` is disabled but configuration options `CONFIG_XTENSA_HIFI3` and/or `CONFIG_XTENSA_HIFI4` are enabled.

The shared HiFi registers mode is selected when the configuration option `CONFIG_XTENSA_HIFI_SHARING` is enabled in addition to configuration options `CONFIG_XTENSA_HIFI3` and/or `CONFIG_XTENSA_HIFI4`. Threads must have sufficient stack space for saving the HiFi register values during context switches as described above.

Both eager and lazy HiFi sharing modes require the configuration option `CONFIG_XTENSA_HIFI_SHARING` to be enabled. Although eager HiFi sharing is the default, it can be explicitly selected by enabling the configuration option `CONFIG_XTENSA_EAGER_HIFI_SHARING`. To select lazy HiFi sharing instead, enable the configuration option `CONFIG_XTENSA_LAZY_HIFI_SHARING`.

7.1.7 ARM System Control and Management Interface

Overview

What is SCMI? System Control and Management Interface (SCMI) is a specification developed by ARM, which describes a set of OS-agnostic software interfaces used to perform system management (e.g: clock control, pinctrl, etc...).

Agent, platform, protocol and transport The SCMI specification defines **four** key terms, which will also be used throughout this documentation:

1. **Agent**
   Entity that performs SCMI requests (e.g: gating a clock or configuring a pin). In this context, Zephyr itself is an agent.
2. **Platform**
   This refers to a set of hardware components that handle the requests from agents and provide the necessary functionality. In some cases, the requests are handled by a firmware, running on a core dedicated to performing system management tasks.

3. **Protocol**
   A protocol is a set of messages grouped by functionality. Intuitively, a message can be thought of as a remote procedure call.

   The SCMI specification defines ten standard protocols:

   1. **Base** (0x10)
   2. **Power domain management** (0x11)
   3. **System power management** (0x12)
   4. **Performance domain management** (0x13)
   5. **Clock management** (0x14)
   6. **Sensor management** (0x15)
   7. **Reset domain management** (0x16)
   8. **Voltage domain management** (0x17)
   9. **Power capping and monitoring** (0x18)
   10. **Pin Control** (0x19)

   where each of these protocols is identified by an unique protocol ID (listed between brackets).

   Apart from the standard protocols, the SCMI specification reserves the **0x80-0xFF** protocol ID range for vendor-specific protocols.

4. **Transport**
   This describes how messages are exchanged between agents and the platform. The communication itself happens through channels.

> **Note**
>
> A system may have more than one agent.

Channels A **channel** is the medium through which agents and the platform exchange messages. The structure of a channel and the way it works is solely dependent on the transport.

Each agent has its own distinct set of channels, meaning some channel A cannot be used by two different agents for example.

Channels are **bidirectional** (exception: FastChannels), and, depending on which entity initiates the communication, can be one of **two** types:

1. **A2P (agent to platform)**
   The agent is the initiator/requester. The messages passed through these channels are known as **commands**.
2. **P2A (platform to agent)**
   The platform is the initiator/requester.

Messages The SCMI specification defines **four** types of messages:

1. **Synchronous**
   These are commands that block until the platform has completed the requested work and are sent over A2P channels.
2. **Asynchronous**
   For these commands, the platform schedules the requested work to be performed at a later time. As such, they return almost immediately. These commands are sent over A2P channels.

3. **Delayed response**
   These messages indicate the completion of the work associated with an asynchronous command. These are sent over P2A channels.
4. **Notification**
   These messages are used to notify agents of events that take place on the platform. These are sent over P2A channels.

The Zephyr support for SCMI is based on the documentation provided by ARM: DEN0056E. For more details on the specification, the readers are encouraged to have a look at it.

SCMI support in Zephyr

Shared memory and doorbell-based transport This form of transport uses shared memory for reading/writing messages and doorbells for signaling. The interaction with the shared memory area is performed using a driver (`drivers/firmware/scmi/shmem.c`), which offers a set of functions for this exact purpose. Furthermore, signaling is performed using the Zephyr MBOX API (signaling mode only, no message passing).

Interacting with the shared memory area and signaling are abstracted by the transport API, which is implemented by the shared memory and doorbell-based transport driver (`drivers/firmware/scmi/mailbox.c`).

The steps below exemplify how the communication between the Zephyr agent and the platform may happen using this transport:

1. Write message to the shared memory area.
2. Zephyr rings request doorbell. If in `PRE_KERNEL_1` or `PRE_KERNEL_2` phase start polling for reply, otherwise wait for reply doorbell ring.
3. Platform reads message from shared memory area, processes it, writes the reply back to the same area and rings the reply doorbell.
4. Zephyr reads reply from the shared memory area.

In the context of this transport, a channel is comprised of a **single** shared memory area and one or more mailbox channels. This is because users may need/want to use different mailbox channels for the request/reply doorbells.

Protocols Currently, Zephyr has support for the following standard protocols:

1. **Power domain management**
2. **System power management**
3. **Clock management**
4. **Pin Control**

NXP-specific protocols:

1. **CPU domain management**

Power domain management This protocol is intended for management of power states of power domains. This is done via a set of functions implementing various commands, for example, `POWER_STATE_GET` and `POWER_STATE_SET`.

> **Note**
>
> This driver is vendor-agnostic. As such, it may be used on any system that uses SCMI for power domain management operations.

Power Domain Protocol

System power management This protocol is intended for system power management. This is done via a set of functions implementing various commands, for example, `SYSTEM_POWER_STATE_SET`.

> **Note**
>
> This driver is vendor-agnostic. As such, it may be used on any system that uses SCMI for system power management operations.

System Power Protocol

Clock management This protocol is used to perform clock management operations. This is done via a driver (`drivers/clock_control/clock_control_arm_scmi.c`), which implements the Zephyr clock control subsystem API. As such, from the user's perspective, using this driver is no different than using any other clock management driver.

> **Note**
>
> This driver is vendor-agnostic. As such, it may be used on any system that uses SCMI for clock management operations.

Pin Control This protocol is used to perform pin configuration operations. This is done via a set of functions implementing various commands. Currently, the only supported command is `PINCTRL_SETTINGS_CONFIGURE`.

> **Note**
>
> The support for this protocol **does not** include a definition for the `pinctrl_configure_pins` function. Each vendor should use their own definition of `pinctrl_configure_pins`, which should call into the SCMI pin control protocol function implementing the `PINCTRL_SETTINGS_CONFIGURE` command.

Pin Control Protocol

NXP - CPU domain management This protocol is intended for management of cpu states. This is done via a set of functions implementing various commands, for example, `CPU_SLEEP_MODE_SET`.

> **Note**
>
> This driver is NXP-specific. As such, it may only be used on NXP system that uses SCMI for cpu domain management operations.

Enabling the SCMI support

To use the SCMI support, each vendor is required to add an `scmi` DT node (used for transport driver binding) and a `protocol` node under the `scmi` node for each supported protocol.

Note

Zephyr has no support for protocol discovery. As such, if users add a DT node for a certain protocol it's assumed the platform supports said protocol.

The example below shows how a DT may be configured in order to use the SCMI support. It's assumed that the only protocol required is the clock management protocol.

```
#include <mem.h>

#define MY_CLOCK_CONSUMER_CLK_ID 123

scmi_res0: memory@cafebabe {
        /* mandatory to use shared memory driver */
        compatible = "arm,scmi-shmem";
        reg = <0xcafebabe DT_SIZE_K(1)>;
};

scmi {
        /* compatible for shared memory and doorbell-based transport */
        compatible = "arm,scmi";

        /* one SCMI channel => A2P/transmit channel */
        shmem = <&scmi_res0>;

        /* two mailbox channels */
        mboxes = <&my_mbox_ip 0>, <&my_mbox_ip 1>;
        mbox-names = "tx", "tx_reply";

        scmi_clk: protocol@14 {
                compatible = "arm,scmi-clock";

                /* matches the clock management protocol ID */
                reg = <0x14>;

                /* vendor-agnostic - always 1 */
                #clock-cells = <1>;
        };
};

my_mbox_ip: mailbox@deadbeef {
        compatible = "vnd,mbox-ip";
        reg = <0xdeadbeef DT_SIZE_K(1)>;
        #mbox-cells = <1>;
};

my_clock_consumer_ip: serial@12345678 {
        compatible = "vnd,consumer-ip";
        reg = <0x12345678 DT_SIZE_K(1)>;
        /* clock ID is vendor specific */
        clocks = <&scmi_clk MY_CLOCK_CONSUMER_CLK_ID>;
};
```

Finally, all that's left to do is enable `CONFIG_ARM_SCMI`.

7.2 Barriers API

Barrier Services APIs

7.3 Caching

7.3.1 Cache Control Configuration

This is a high-level guide to Zephyr's cache interface and Kconfig options related to cache controllers. See *Cache API* for API reference material.

Zephyr has different Kconfig options to control how the cache controller is implemented and controlled.

- `CONFIG_CPU_HAS_DCACHE` / `CONFIG_CPU_HAS_ICACHE`: these hidden options should be selected at SoC / platform level when the CPU actually supports a data or instruction cache. The cache controller can be in the core or can be an external cache controller for which a driver is provided.

  These options have the goal to document an available hardware feature and should be set whether we plan to support and use the cache control in Zephyr or not.

- `CONFIG_DCACHE` / `CONFIG_ICACHE`: these options must be selected when support for data or instruction cache is present and working in zephyr. Note that if these options are disabled, caching may still be enabled depending on the hardware defaults.

  All the code paths related to cache control must be conditionally enabled depending on these symbols. When the symbol is set the cache is considered enabled and used.

  These symbols say nothing about the actual API interface exposed to the user. For example a platform using the data cache can enable the `CONFIG_DCACHE` symbol and use some HAL exported function in some platform-specific code to enable and manage the d-cache.

- `CONFIG_CACHE_MANAGEMENT`: this option must be selected when the cache operations are exposed to the user through a standard API (see *Cache API*).

  When this option is enabled we assume that all the cache functions are implemented in the architectural code or in an external cache controller driver.

- `CONFIG_MEM_ATTR`: this option allows the user to specify (using *memory region attributes*) a fixed region in memory that will have caching disabled once the kernel has initialized.

- `CONFIG_NOCACHE_MEMORY`: this option allows the user to specify individual global variables as uncached using `__nocache`. This will instruct the linker to place any marked variables into a special `nocache` region in memory and the MPU driver will configure that region as uncached.

- `CONFIG_ARCH_CACHE`/`CONFIG_EXTERNAL_CACHE`: mutually exclusive options for `CACHE_TYPE` used to define whether the cache operations are implemented at arch level or using an external cache controller with a provided driver.
  - `CONFIG_ARCH_CACHE`: the cache API is implemented by the arch code
  - `CONFIG_EXTERNAL_CACHE`: the cache API is implemented by a driver that supports the external cache controller. In this case the driver must be located as usual in the `drivers/cache/` directory

Cache API

Cache Interface

7.3.2 Caching Basics

This section discusses the basics of cache coherency and under what situations a user needs to explicitly deal with caching. For more detailed info on Zephyr's caching tools, see *Cache Control Configuration* for Zephyr Kconfig options or *Cache API* for the API reference. This section primarily focuses on the data cache though there is typically also an instruction cache for systems with cache support.

Note

The information here assumes that the architecture-specific MPU support is enabled. See the architecture-specific documentation for details.

Note

While cache coherence can be a concern for data shared between SMP cores, Zephyr in general ensures that memory will be seen in a coherent state from multiple cores. Most applications will only need to use the cache APIs for interaction with external hardware like DMA controllers or foreign CPUs running a different OS image. For more information on cache coherence between SMP cores, see `CONFIG_KERNEL_COHERENCE`.

When dealing with memory shared between a processor core and other bus masters, cache coherency needs to be considered. Typically processor caches exist as close to each processor core as possible to maximize performance gain. Because of this, data moved into and out of memory by DMA engines will be stale in the processor's cache, resulting in what appears to be corrupt data. If you are moving data using DMA and the processor doesn't see the data you expect, cache coherency may be the issue.

There are multiple approaches to ensuring that the data seen by the processor core and peripherals is coherent. The simplest is just to disable caching, but this defeats the purpose of having a hardware cache in the first place and results in a significant performance hit. Many architectures provide methods for disabling caching for only a portion of memory. This can be useful when cache coherence is more important than performance, such as when using DMA with SPI. Finally, there is the option to flush or invalidate the cache for regions of memory at runtime.

Globally Disabling the Data Cache

As mentioned above, globally disabling data caching can have a significant performance impact but can be useful for debugging.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_CACHE_MANAGEMENT`: cache API enabled.
- Call `sys_cache_data_disable()` to globally disable the data cache.

Disabling Caching for a Memory Region

Disabling caching for only a portion of memory can be a good performance compromise if performance on the uncached memory is not critical to the application. This is a good option if the application requires many small unrelated buffers that are smaller than a cache line.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_MEM_ATTR`: enable the `mem-attr` library for handling memory attributes in the device tree.

- Annotate your device tree according to *Memory Attributes*.

Assuming the MPU driver is enabled, it will configure the specified regions according to the memory attributes specified during kernel initialization. When using a dedicated uncached region of memory, the linker needs to be instructed to place buffers into that region. This can be accomplished by specifying the memory region explicitly using `Z_GENERIC_SECTION`:

```
/* SRAM4 marked as uncached in device tree */
uint8_t buffer[BUF_SIZE] Z_GENERIC_SECTION("SRAM4");
```

Note

Configuring a distinct memory region with separate caching rules requires the use of an MPU region which may be a limited resource on some architectures. MPU regions may be needed by other memory protection features such as *userspace*, *stack protection*, or *memory domains*.

Automatically Disabling Caching by Variable

Zephyr has the ability to automatically define an uncached region in memory and allocate variables to it using `__nocache`. Any variables marked with this attribute will be placed in a special `nocache` linker region in memory. This region will be configured as uncached by the MPU driver during initialization. This is a simpler option than explicitly declaring a region of memory uncached but provides less control over the placement of these variables, as the linker may allocate this region anywhere in RAM.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_NOCACHE_MEMORY`: enable allocation of the `nocache` linker region and configure it as uncached.
- Add the `__nocache` attribute at the end of any uncached buffer definition:

```
uint8_t buffer[BUF_SIZE] __nocache;
```

Note

See note above regarding possible limitations on MPU regions. The `nocache` region is still a distinct MPU region even though it is automatically created by Zephyr instead of being explicitly defined by the user.

Runtime Cache Control

The most performant but most complex option is to control data caching at runtime. The two most relevant cache operations in this case are **flushing** and **invalidating**. Both of these operations operate on the smallest unit of cacheable memory, the cache line. Data cache lines are typically 16 to 128 bytes. See `CONFIG_DCACHE_LINE_SIZE`. Cache line sizes are typically fixed in hardware and not configurable, but Zephyr does need to know the size of cache lines in order to correctly and efficiently manage the cache. If the buffers in question are smaller than the data cache line size, it may be more efficient to place them in an uncached region, as unrelated data packed into the same cache line may be destroyed when invalidating.

Flushing the cache involves writing all modified cache lines in a specified region back to shared memory. Flush the cache associated with a buffer after the processor has written to it and before a remote bus master reads from that region.

Note

Some architectures support a cache configuration called **write-through** caching in which data writes from the processor core propagate through to shared memory. While this solves the cache coherence problem for CPU writes, it also results in more traffic to main memory which may result in performance degradation.

Invalidating the cache works similarly but in the other direction. It marks cache lines in the specified region as stale, ensuring that the cache line will be refreshed from main memory when the processor next reads from the specified region. Invalidate the data cache of a buffer that a peripheral has written to before reading from that region.

In some cases, the same buffer may be reused for e.g. DMA reads and DMA writes. In that case it is possible to first flush the cache associated with a buffer and then invalidate it, ensuring that the cache will be refreshed the next time the processor reads from the buffer.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_CACHE_MANAGEMENT`: cache API enabled.
- Call `sys_cache_data_flush_range()` to flush a memory region.
- Call `sys_cache_data_invd_range()` to invalidate a memory region.
- Call `sys_cache_data_flush_and_invd_range()` to flush and invalidate.

Alignment

As mentioned in `sys_cache_data_invd_range()` and associated functions, buffers should be aligned to the cache line size. This can be accomplished by using `__aligned`:

```
uint8_t buffer[BUF_SIZE] __aligned(CONFIG_DCACHE_LINE_SIZE);
```

7.4 Zephyr's device emulators/simulators

7.4.1 Overview

Zephyr includes in its codebase a set of device emulators/simulators. With this we refer to SW components which are built together with the embedded SW and present themselves as devices of a given class to the rest of the system.

These device emulators/simulators can be built for any target which has sufficient RAM and flash, even if some may have extra functionality which is only available in some targets.

Note

Zephyr also includes and uses many other types of simulators/emulators, including CPU and platform simulators, radio simulators, and several build targets which allow running the embedded code in the development host.

Some of Zephyr communication controllers/drivers include also either loopback modes or loopback devices.

This page does not cover any of these.

Note

Drivers which are specific to some platform, like for example the native_sim specific drivers which emulate a peripheral class by connecting to host APIs are not covered by this page.

7.4.2 Available Emulators

ADC emulator

- A fake driver which pretends to be actual ADC, and can be used for testing higher-level API for ADC devices.
- Main Kconfig option: `CONFIG_ADC_EMUL`
- DT binding: `zephyr,adc-emul`

DMA emulator

- Emulated DMA controller
- Main Kconfig option: `CONFIG_DMA_EMUL`
- DT binding: `zephyr,dma-emul`

EEPROM emulator

- Emulate an EEPROM on a flash partition
- Main Kconfig option: `CONFIG_EEPROM_EMULATOR`
- DT binding: `zephyr,emu-eeprom`

EEPROM simulator

- Emulate an EEPROM on RAM
- Main Kconfig option: `CONFIG_EEPROM_SIMULATOR`
- DT binding: `zephyr,sim-eeprom`
- Note: For native targets it is also possible to keep the content as a file on the host filesystem.

External bus and bus connected peripheral emulators

- *Documentation*
- Allow emulating external buses like I2C or SPI and peripherals connected to them.

Flash simulator

- Emulate a flash on RAM
- Main Kconfig option: `CONFIG_FLASH_SIMULATOR`
- DT binding: `zephyr,sim-flash`
- Note: For native targets it is also possible to keep the content as a file on the host filesystem. Check the native_sim flash simulator section.

GPIO emulator

- Emulated GPIO controllers which can be driven from SW
- Main Kconfig option: `CONFIG_GPIO_EMUL`
- DT binding: `zephyr,gpio-emul`

I2C emulator

- Emulated I2C bus. See *bus emulators*.

- Main Kconfig option: `CONFIG_I2C_EMUL`
- DT binding: `zephyr,i2c-emul-controller`

RTC emulator

- Emulated RTC peripheral. See *RTC emulated device section*
- Main Kconfig option: `CONFIG_RTC_EMUL`
- DT binding: `zephyr,rtc-emul`

SPI emulator

- Emulated SPI bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_SPI_EMUL`
- DT binding: `zephyr,spi-emul-controller`

MSPI emulator

- Emulated MSPI bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_MSPI_EMUL`
- DT binding: `zephyr,mspi-emul-controller`

UART emulator

- Emulated UART bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_UART_EMUL`
- DT binding: `zephyr,uart-emul`

7.5 External Bus and Bus Connected Peripherals Emulators

7.5.1 Overview

Zephyr supports a simple emulator framework to support testing of external peripheral drivers without requiring real hardware.

Emulators are used to emulate external hardware devices, to support testing of various subsystems. For example, it is possible to write an emulator for an I2C compass such that it appears on the I2C bus and can be used just like a real hardware device.

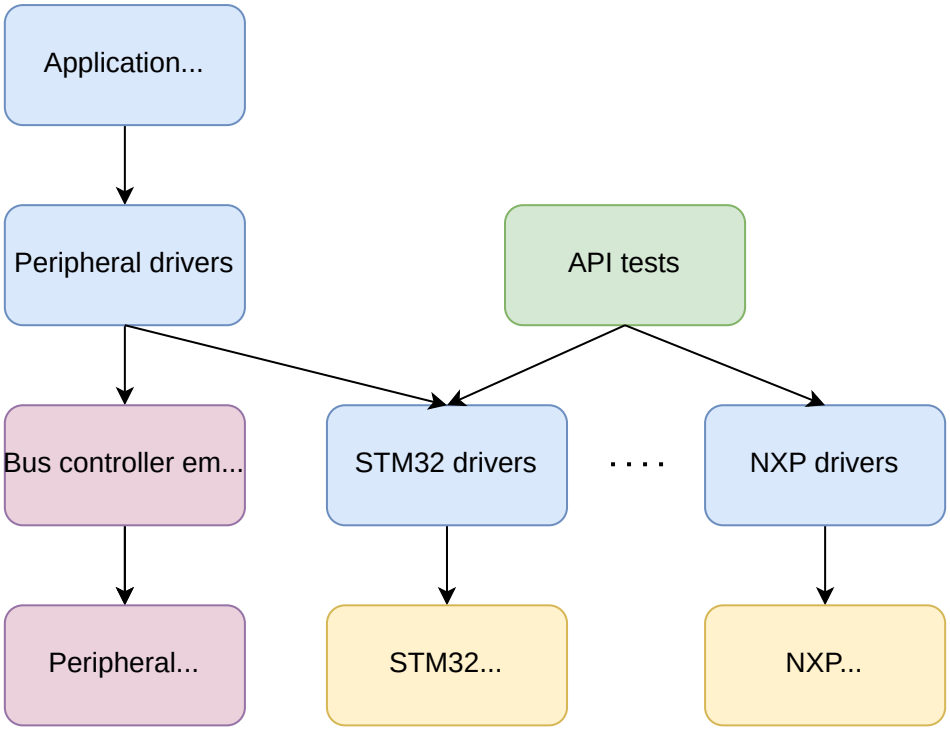
Emulators often implement special features for testing. For example a compass may support returning bogus data if the I2C bus speed is too high, or may return invalid measurements if calibration has not yet been completed. This allows for testing that high-level code can handle these situations correctly. Test coverage can therefore approach 100% if all failure conditions are emulated.

7.5.2 Concept

The diagram below shows application code / high-level tests at the top. This is the ultimate application we want to run.

Below that are peripheral drivers, such as the AT24 EEPROM driver. We can test peripheral drivers using an emulation driver connected via a emulated I2C controller/emulator which passes I2C traffic from the AT24 driver to the AT24 simulator.

Separately we can test the STM32 and NXP I2C drivers on real hardware using API tests. These require some sort of device attached to the bus, but with this, we can validate much of the driver functionality.



Putting the two together, we can test the application and peripheral code entirely on native_sim. Since we know that the I2C driver on the real hardware works, we should expect the application and peripheral drivers to work on the real hardware also.

Using the above framework we can test an entire application (e.g. Embedded Controller) on native_sim using emulators for all non-chip drivers.

With this approach we can:

- Write individual tests for each driver (green), covering all failure modes, error conditions, etc.
- Ensure 100% test coverage for drivers (green)
- Write tests for combinations of drivers, such as GPIOs provided by an I2C GPIO expander driver talking over an I2C bus, with the GPIOs controlling a charger. All of this can work in the emulated environment or on real hardware.
- Write a complex application that ties together all of these pieces and runs on native_sim. We can develop on a host, use source-level debugging, etc.
- Transfer the application to any board which provides the required features (e.g. I2C, enough GPIOs), by adding Kconfig and devicetree fragments.

7.5.3 Creating a Device Driver Emulator

The emulator subsystem is modeled on the *Device Driver Model*. You create an emulator instance using one of the `EMUL_DT_DEFINE()` or `EMUL_DT_INST_DEFINE()` APIs.

Emulators for peripheral devices reuse the same devicetree node as the real device driver. This means that your emulator defines `DT_DRV_COMPAT` using the same `compat` value from the real driver.

```
/* From drivers/sensor/bm160/bm160.c */
#define DT_DRV_COMPAT bosch_bmi160
```

(continues on next page)

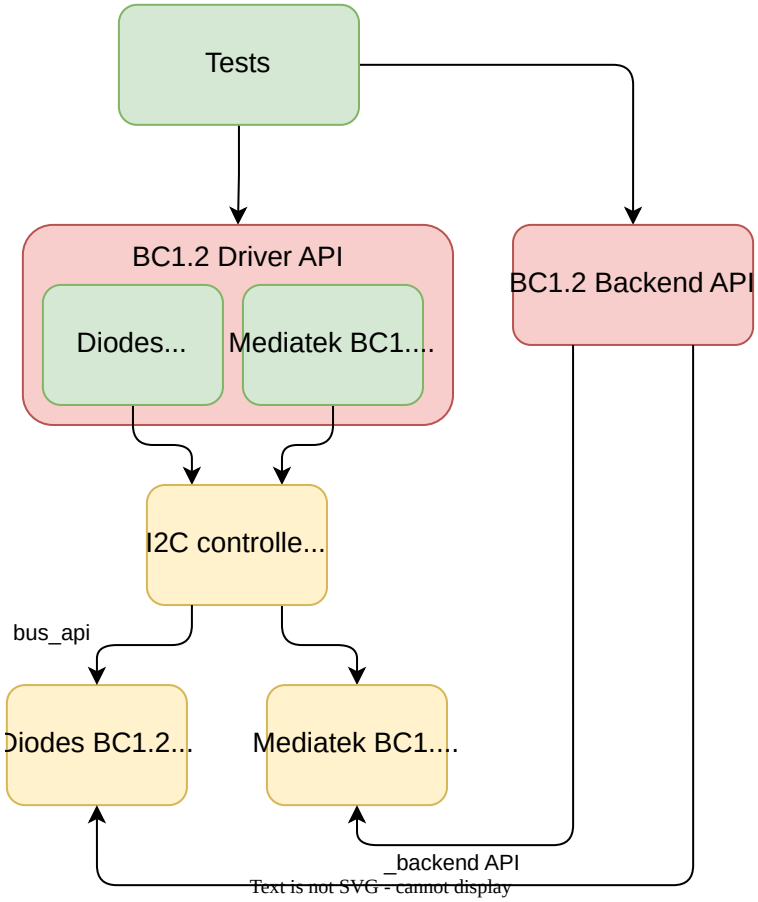
(continued from previous page)

```
/* From drivers/sensor/bmi160/emul_bmi160.c */
#define DT_DRV_COMPAT bosch_bmi160
```

The `EMUL_DT_DEFINE()` function accepts two API types:

1. `bus_api` - This points to the API for the upstream bus that the emulator connects to. The `bus_api` parameter is required. The supported emulated bus types include I2C, SPI, eSPI, and MSPI.
2. `_backend_api` - This points to the device-class specific backend API for the emulator. The `_backend_api` parameter is optional.

The diagram below demonstrates the logical organization of the `bus_api` and `_backend_api` using the BC1.2 charging detector driver as the model device-class.



The real code is shown in green, while the emulator code is shown in yellow.

The `bus_api` connects the BC1.2 emulators to the `native_sim` I2C controller. The real BC1.2 drivers are unchanged and operate exactly as if there was a physical I2C controller present in the system. The `native_sim` I2C controller uses the `bus_api` to initiate register reads and writes to the emulator.

The `_backend_api` provides a mechanism for tests to manipulate the emulator out of band. Each device class defines it's own API functions. The backend API functions focus on high-level behavior and do not provide hooks for specific emulators.

In the case of the BC1.2 charging detector the backend API provides functions to simulate connecting and disconnecting a charger to the emulated BC1.2 device. Each emulator is responsible for updating the correct vendor specific registers and potentially signalling an interrupt.

Example test flow:

1. Test registers BC1.2 detection callback using the Zephyr BC1.2 driver API.
2. Test connects a charger using the BC1.2 emulator backend.
3. Test verifies B1.2 detection callback invoked with correct charger type.
4. Test disconnects a charger using the BC1.2 emulator backend.

With this architecture, the same test can be used will all supported drivers in the same driver class.

7.5.4 Available Emulators

Zephyr includes the following emulators:

- I2C emulator driver, allowing drivers to be connected to an emulator so that tests can be performed without access to the real hardware
- SPI emulator driver, which does the same for SPI
- eSPI emulator driver, which does the same for eSPI. The emulator is being developed to support more functionalities.
- MSPI emulator driver, allowing drivers to be connected to an emulator so that tests can be performed without access to the real hardware.

I2C Emulation features

In the binding of the I2C emulated bus, there's a custom property for address based forwarding. Given the following devicetree node:

```
i2c0: i2c@100 {
  status = "okay";
  compatible = "zephyr,i2c-emul-controller";
  clock-frequency = <I2C_BITRATE_STANDARD>;
  #address-cells = <1>;
  #size-cells = <0>;
  #forward-cells = <1>;
  reg = <0x100 4>;
  forwards = <&i2c1 0x20>;
};
```

The final property, `forwards` indicates that any read/write requests sent to address `0x20` should be sent to `i2c1` with the same address. This allows us to test both the controller and the target end of the communication on the same image.

Note

The `#forward-cells` attribute should always be 1. Each entry in the `forwards` attribute consists of the phandle followed by the address. In the example above, `<&i2c1 0x20>` will forward all read/write operations made to `i2c0` at port `0x20` to `i2c1` on the same port. Since no additional cells are used by the emulated controller, the number of cells should remain 1.

7.5.5 Samples

Here are some examples present in Zephyr:

1. Bosch BMI160 sensor driver connected via both I2C and SPI to an emulator:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/sensor/bmi160
```

2. The same test can be built with a second EEPROM which is an Atmel AT24 EEPROM driver connected via I2C an emulator:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/eeprom/api -- -
↪DDTC_OVERLAY_FILE=at2x_emul.overlay -DEXTRA_CONF_FILE=at2x_emul.conf
```

7.5.6 API Reference

Emulator interfaces

7.6 Peripherals

7.6.1 1-Wire Bus

Overview

1-Wire is a low speed half-duplex serial bus using only a single wire plus ground for both data transmission and device power supply. Similarly to I2C, 1-Wire uses a bidirectional open-collector data line, and is a single master multidrop bus. This means one master initiates all data exchanges with the slave devices. The 1-Wire bus supports longer bus lines than I2C, while it reaches speeds of up to 15.4 kbps in standard mode and up to 125 kbps in overdrive mode. Reliable communication in standard speed configuration is possible with 10 nodes over a bus length of 100 meters. Using overdrive speed, 3 nodes on a bus of 10 meters length are expected to work solid. Optimized timing parameters and fewer nodes on the bus may allow to reach larger bus extents.

The implementation details are specified in the BOOK OF IBUTTON STANDARDS.

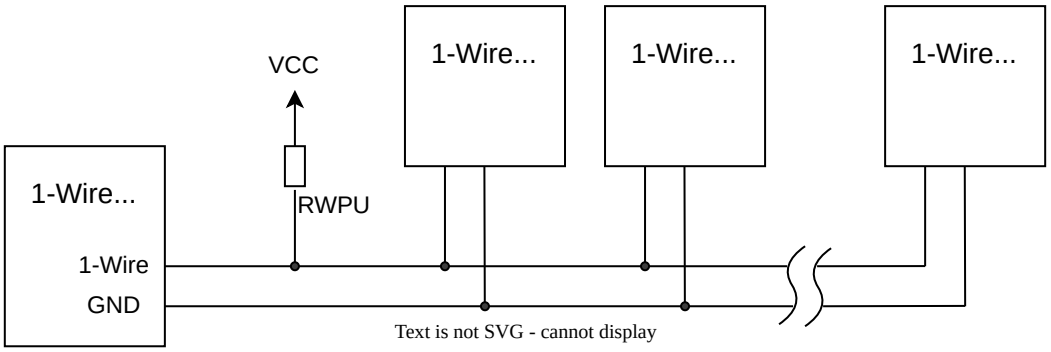


Fig. 1: A typical 1-Wire bus topology

W1 Master API Zephyr's 1-Wire Master API is used to interact with 1-Wire slave devices like temperature sensors and serial memories.

In Zephyr this API is split into the following layers.

- The link layer handles basic communication functions such as bus reset, presence detect and bit transfer operations. It is the only hardware-dependent layer in Zephyr. This layer is supported by a driver using the Zephyr *Universal Asynchronous Receiver-Transmitter (UART)* interface, which should work on most Zephyr platforms. In the future, a GPIO/Timer based driver and hardware specific drivers might be added.
- The 1-Wire network layer handles all means for slave identification and bus arbitration. This includes ROM commands like Match ROM, or Search ROM.
  - All slave devices have a unique 64-bit identification number, which includes a 8-bit 1-Wire Family Code and a 8-bit CRC.

  - In order to find slaves on the bus, the standard specifies an search algorithm which successively detects all slaves on the bus. This algorithm is described in the 1-Wire Search Algorithm Application Note.

- Transport layer and Presentation layer functions are not implemented in the generic 1-Wire driver and therefore must be handled in individual slave drivers.

The 1-Wire API is considered experimental.

Configuration Options

Related configuration options:

- `CONFIG_W1`
- `CONFIG_W1_NET`

W1 Serial Driver

The `zephyr,w1-serial` driver implements the 1-Wire interface using a UART peripheral. Individual 1-Wire bits are encoded as bytes sent over the UART. For standard speed, it uses 115200 Baud for data and 9600 Baud for reset/presence detection. For overdrive speed, it uses configurable baud rates with a default of 1000000 Baud for data and 115200 Baud for reset/presence.

7.6.3 Auxiliary Display (auxdisplay)

Overview

Auxiliary Displays are text-based displays that have simple interfaces for displaying textual, numeric or alphanumeric data, as opposed to the *Display*, auxiliary displays do not support custom graphical output to displays (and most often monochrome), the most advanced custom feature supported is generation of custom characters. These inexpensive displays are commonly found with various configurations and sizes, a common display size is 16 characters by 2 lines.

This API is unstable and subject to change.

7.6.5 Battery Backed RAM (BBRAM)

The BBRAM APIs allow interfacing with the unique properties of this memory region. The following common types of BBRAM properties are easily accessed via this API:

- IBBR (invalid) state - check that the BBRAM is not corrupt.
- VSBY (voltage standby) state - check if the BBRAM is using standby voltage.
- VCC (active power) state - check if the BBRAM is on normal power.

- Size - get the size (in bytes) of the BBRAM region.

Along with these, the API provides a means for reading and writing to the memory region via `bbram_read()` and `bbram_write()` respectively. Both functions are expected to only succeed if the BBRAM is in a valid state and the operation is bounded to the memory region.

API Reference

BBRAM

7.6.6 BC1.2 Devices (Experimental)

The Battery Charging specification, currently at revision 1.2, is commonly referred to as just BC1.2. BC1.2 defines limits and detection mechanisms for USB devices to draw current exceeding the USB 2.0 specification limit of 0.5A, 2.5W.

The BC1.2 specification uses the term Charging Port for the device that supplies VBUS on the USB connection and the term Portable Device for the device that sinks current from the USB connection.

Note that the BC1.2 Specification uses the acronym PD for Portable Device. This should not be confused with the USB-C Power Delivery, which also uses the acronym PD.

On many devices, BC1.2 is the fallback mechanism to determine the connected charger capability on USB type C ports when the attached type-C partner does not support Power Delivery.

Key parameters from the BC1.2 Specification include:

Parameter	Symbol	Range
Allowed PD (portable device) Current Draw from Charging Port	IDEV_CHG	1.5 A
Charging Downstream Port Rated Current	ICDP	1.5 - 5.0 A
Maximum Configured Current when connected to a SDP	ICFG_MAX	500 mA
Dedicated Charging Port Rated Current	IDCP	1.5 - 5.0 A
Suspend current	ISUSP	2.5 mA
Unit load current	IUNIT	100 mA

While the ICDP and IDCP rated currents go up to 5.0 A, the BC1.2 current is limited by the IDEV_CHG parameter. So the BC1.2 support is capped at 1.5 A in the Zephyr implementation when using portable-device mode.

Basic Operation

The BC1.2 device driver provides only two APIs, `bc12_set_role()` and `bc12_set_result_cb()`.

The application calls `bc12_set_role()` to transition the BC1.2 device to either a disconnected, portable-device, or charging port mode.

For the disconnected state, the BC1.2 driver powers down the detection chip. The power down operation is vendor specific.

The application calls `bc12_set_role()` with the type set to BC12_PORTABLE_DEVICE when both the following conditions are true:

- The application configured the port as an upstream facing port, i.e. a USB device port.
- The application detects VBUS on the USB connection.

For portable-device mode, the BC1.2 driver powers up the detection chip and starts charger detection. At completion of the charger detection, the BC1.2 driver notifies the callback registered with `bc12_set_result_cb()`. By default, the BC1.2 driver clamps the current to 1.5A to comply with the BC1.2 specification.

To comply with the USB 2.0 specification, when the driver detects a SDP (Standard Downstream Port) charging partner or if BC1.2 detection fails, the driver reports the available current as ISUSP (2.5 mA). The application may increase the current draw to IUNIT (100 mA) when the connected USB host resumes the USB bus and may increase the current draw to ICFG_MAX (500 mA) when the USB host configures the USB device.

Charging port mode is used by the application when the USB port is configured as a downstream facing port, i.e. a USB host port. For charging port mode, the BC1.2 driver powers up the detection chip and configures the charger type specified by a devicetree property. If the driver supports detection of plug and unplug events, the BC1.2 driver notifies the callback registered with `bc12_set_result_cb()` to indicate the current connection state of the portable device partner.

7.6.7 Biometrics

Overview

The biometrics API provides a unified interface for biometric sensors such as fingerprint scanners, iris scanners, and face recognition modules. These sensors are commonly used for secure authentication in embedded systems, access control devices, and IoT applications.

The API supports the full lifecycle of biometric operations including enrollment, template management, and matching. Sensors can store templates on-device or on the host system depending on hardware capabilities.

A typical fingerprint enrollment process requires capturing multiple samples of the same finger to create a reliable template. The matching process compares a captured sample against stored templates to verify identity.

7.6.9 Controller Area Network (CAN)

CAN Controller

- *Overview*
- *Sending*
- *Receiving*
- *Setting the bitrate*
- *SocketCAN*
- *Samples*
- *CAN Controller API Reference*

Overview Controller Area Network is a two-wire serial bus specified by the Bosch CAN Specification, Bosch CAN with Flexible Data-Rate specification and the ISO 11898-1:2003 standard. CAN is mostly known for its application in the automotive domain. However, it is also used in home and industrial automation and other products.

Warning

CAN controllers can only initialize when the bus is in the idle (recessive) state for at least 11 recessive bits. Therefore you have to make sure that CAN RX is high, at least for a short time. This is also necessary for loopback mode.

The bit-timing as defined in ISO 11898-1:2003 looks as following:

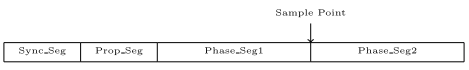

Figure 2: CAN Timing. ©Alexander Wachter

A single bit is split into four segments.

- Sync_Seg: The nodes synchronize at the edge of the Sync_Seg. It is always one time quantum in length.
- Prop_Seg: The signal propagation delay of the bus and other delays of the transceiver and node.
- Phase_Seg1 and Phase_Seg2 :Define the sampling point. The bit is sampled at the end of Phase_Seg1.

The bit-rate is calculated from the time of a time quantum and the values defined above. A bit has the length of Sync_Seg plus Prop_Seg plus Phase_Seg1 plus Phase_Seg2 multiplied by the time of single time quantum. The bit-rate is the inverse of the length of a single bit.

A bit is sampled at the sampling point. The sample point is between Phase_Seg1 and PhaseSeg2 and therefore is a parameter that the user needs to choose. The CiA recommends setting the sample point to 87.5% of the bit.

The resynchronization jump width (SJW) defines the amount of time quantum the sample point can be moved. The sample point is moved when resynchronization is needed.

The timing parameters (SJW, bitrate and sampling point, or bitrate, Prop_Seg, Phase_Seg1and Phase_Seg2) are initially set from the device-tree and can be changed at run-time from the timing-API.

CAN uses so-called identifiers to identify the frame instead of addresses to identify a node. This identifier can either have 11-bit width (Standard or Basic Frame) or 29-bit in case of an Extended Frame. The Zephyr CAN API supports both Standard and Extended identifiers concurrently. A CAN frame starts with a dominant Start Of Frame bit. After that, the identifiers follow. This phase is called the arbitration phase. During the arbitration phase, write collisions are allowed. They resolve by the fact that dominant bits override recessive bits. Nodes monitor the bus and notice when their transmission is being overridden and in case, abort their transmission. This effectively gives lower number identifiers priority over higher number identifiers.

Filters are used to allowlist identifiers that are of interest for the specific node. An identifier that doesn't match any filter is ignored. Filters can either match exactly or a specified part of the identifier. This method is called masking. As an example, a mask with 11 bits set for standard or 29 bits set for extended identifiers must match perfectly. Bits that are set to zero in the mask are ignored when matching an identifier. Most CAN controllers implement a limited number of filters in hardware. The number of filters is also limited in Kconfig to save memory.

Errors may occur during transmission. In case a node detects an erroneous frame, it partially overrides the current frame with an error-frame. Error-frames can either be error passive or error active, depending on the state of the controller. In case the controller is in error active state, it sends six consecutive dominant bits, which is a violation of the stuffing rule that all nodes can detect. The sender may resend the frame right after.

An initialized node can be in one of the following states:

- Error-active
- Error-passive
- Bus-off

After initialization, the node is in the error-active state. In this state, the node is allowed to send active error frames, ACK, and overload frames. Every node has a receive- and transmit-error counter. If either the receive- or the transmit-error counter exceeds 127, the node changes to error-passive state. In this state, the node is not allowed to send error-active frames anymore. If the transmit-error counter increases further to 255, the node changes to the bus-off state. In this state, the node is not allowed to send any dominant bits to the bus. Nodes in the bus-off state may recover after receiving 128 occurrences of 11 concurrent recessive bits.

You can read more about CAN bus in this CAN Wikipedia article.

Zephyr supports following CAN features:

- Standard and Extended Identifiers
- Filters with Masking
- Loopback and Silent mode
- Remote Request

Sending The following code snippets show how to send data.

This basic sample sends a CAN frame with standard identifier 0x123 and eight bytes of data. When passing NULL as the callback, as shown in this example, the send function blocks until the frame is sent and acknowledged by at least one other node or an error occurred. The timeout only takes effect on acquiring a mailbox. When a transmitting mailbox is assigned, sending cannot be canceled.

```
struct can_frame frame = {
        .flags = 0,
        .id = 0x123,
        .dlc = 8,
        .data = {1,2,3,4,5,6,7,8}
};
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));
int ret;

ret = can_send(can_dev, &frame, K_MSEC(100), NULL, NULL);
if (ret != 0) {
        LOG_ERR("Sending failed [%d]", ret);
}
```

This example shows how to send a frame with extended identifier 0x1234567 and two bytes of data. The provided callback is called when the message is sent, or an error occurred. Passing `K_FOREVER` to the timeout causes the function to block until a transfer mailbox is assigned to the frame or an error occurred. It does not block until the message is sent like the example above.

```
void tx_callback(const struct device *dev, int error, void *user_data)
{
        char *sender = (char *)user_data;

        if (error != 0) {
                LOG_ERR("Sending failed [%d]\nSender: %s\n", error, sender);
        }
}

int send_function(const struct device *can_dev)
{
        struct can_frame frame = {
                .flags = CAN_FRAME_IDE,
                .id = 0x1234567,
                .dlc = 2
        };

        frame.data[0] = 1;
        frame.data[1] = 2;

        return can_send(can_dev, &frame, K_FOREVER, tx_callback, "Sender 1");
}
```

Receiving Frames are only received when they match a filter. The following code snippets show how to receive frames by adding filters.

Here we have an example for a receiving callback as used for `can_add_rx_filter()`. The user data argument is passed when the filter is added.

```
void rx_callback_function(const struct device *dev, struct can_frame *frame, void␣
↪*user_data)
{
        ... do something with the frame ...
}
```

The following snippet shows how to add a filter with a callback function. It is the most efficient but also the most critical way to receive messages. The callback function is called from an interrupt context, which means that the callback function should be as short as possible and must not block. Adding callback functions is not allowed from userspace context.

The filter for this example is configured to match the identifier 0x123 exactly.

```
const struct can_filter my_filter = {
        .flags = 0U,
        .id = 0x123,
        .mask = CAN_STD_ID_MASK
};
int filter_id;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));

filter_id = can_add_rx_filter(can_dev, rx_callback_function, callback_arg, &
↪my_filter);
if (filter_id < 0) {
  LOG_ERR("Unable to add rx filter [%d]", filter_id);
}
```

Here an example for `can_add_rx_filter_msgq()` is shown. With this function, it is possible to receive frames synchronously. This function can be called from userspace context. The size of the message queue should be as big as the expected backlog.

The filter for this example is configured to match the extended identifier 0x1234567 exactly.

```
const struct can_filter my_filter = {
        .flags = CAN_FILTER_IDE,
        .id = 0x1234567,
        .mask = CAN_EXT_ID_MASK
};
CAN_MSGQ_DEFINE(my_can_msgq, 2);
struct can_frame rx_frame;
int filter_id;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));

filter_id = can_add_rx_filter_msgq(can_dev, &my_can_msgq, &my_filter);
if (filter_id < 0) {
  LOG_ERR("Unable to add rx msgq [%d]", filter_id);
  return;
}

while (true) {
  k_msgq_get(&my_can_msgq, &rx_frame, K_FOREVER);
  ... do something with the frame ...
}
```

`can_remove_rx_filter()` removes the given filter.

```
can_remove_rx_filter(can_dev, filter_id);
```

Setting the bitrate The bitrate and sampling point is initially set at runtime. To change it from the application, one can use the `can_set_timing()` API. The `can_calc_timing()` function can calculate timing from a bitrate and sampling point in permille. The following example sets the bitrate to 250k baud with the sampling point at 87.5%.

```
struct can_timing timing;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));
int ret;

ret = can_calc_timing(can_dev, &timing, 250000, 875);
if (ret > 0) {
  LOG_INF("Sample-Point error: %d", ret);
}

if (ret < 0) {
  LOG_ERR("Failed to calc a valid timing");
  return;
}

ret = can_stop(can_dev);
if (ret != 0) {
  LOG_ERR("Failed to stop CAN controller");
}

ret = can_set_timing(can_dev, &timing);
if (ret != 0) {
  LOG_ERR("Failed to set timing");
}

ret = can_start(can_dev);
if (ret != 0) {
  LOG_ERR("Failed to start CAN controller");
}
```

A similar API exists for calculating and setting the timing for the data phase for CAN FD capable controllers. See `can_set_timing_data()` and `can_calc_timing_data()`.

SocketCAN Zephyr additionally supports SocketCAN, a BSD socket implementation of the Zephyr CAN API. SocketCAN brings the convenience of the well-known BSD Socket API to Controller Area Networks. It is compatible with the Linux SocketCAN implementation, where many other high-level CAN projects build on top. Note that frames are routed to the network stack instead of passed directly, which adds some computation and memory overhead.

Samples We have two ready-to-build samples demonstrating use of the Zephyr CAN API: Zephyr CAN counter sample and SocketCAN sample.

CAN Transceiver

- *Overview*
- *CAN Transceiver API Reference*

Overview A CAN transceiver is an external device that converts the logic level signals from the CAN controller to the bus-levels. The bus lines are called CAN High (CAN H) and CAN Low (CAN L). The transmit wire from the controller to the transceiver is called CAN TX, and the receive wire is called CAN RX. These wires use the logic levels whereas the bus-level is interpreted differentially between CAN H and CAN L. The bus can be either in the recessive (logical one) or dominant (logical zero) state. The recessive state is when both lines, CAN H and CAN L, are roughly at the same voltage level. This state is also the idle state. To write a dominant bit to the bus, open-drain transistors tie CAN H to Vdd and CAN L to ground. The first and last node use a 120-ohm resistor between CAN H and CAN L to terminate the bus. The dominant state always overrides the recessive state. This structure is called a wired-AND.

CAN Transceiver

CAN Shell

- *Overview*
- *Inspection*
- *Configuration*
- *Receiving*
- *Sending*
- *Bus Recovery*

Overview The CAN shell provides a `can` command with a set of subcommands for the *shell* module. It allows for testing and exploring the *CAN Controller* driver API through an interactive

interface without having to write a dedicated application. The CAN shell can also be enabled in existing applications to aid in interactive debugging of CAN issues.

The CAN shell provides access to most CAN controller features, including inspection, configuration, sending and receiving of CAN frames, and bus recovery.

In order to enable the CAN shell, the following *Kconfig* options must be enabled:

- CONFIG_SHELL
- CONFIG_CAN
- CONFIG_CAN_SHELL

The following *Kconfig* options enable additional subcommands and features of the can command:

- CONFIG_CAN_FD_MODE enables CAN FD specific subcommands (e.g. for setting the timing for the CAN FD data phase).
- CONFIG_CAN_RX_TIMESTAMP enables printing of timestamps for received CAN frames.
- CONFIG_CAN_STATS enables printing of various statistics for the CAN controller in the can show subcommand. This depends on CONFIG_STATS being enabled as well.
- CONFIG_CAN_MANUAL_RECOVERY_MODE enables the can recover subcommand.

For example, building the hello_world sample for the frdm_k64f with the CAN shell and CAN statistics enabled:

```
# From the root of the zephyr repository
west build -b frdm_k64f samples/hello_world -- -DCONFIG_SHELL=y -DCONFIG_CAN=y -
↪DCONFIG_CAN_SHELL=y -DCONFIG_STATS=y -DCONFIG_CAN_STATS=y
```

See the *shell* documentation for general instructions on how to connect and interact with the shell. The CAN shell comes with built-in help (unless CONFIG_SHELL_HELP is disabled). The built-in help messages can be printed by passing -h or --help to the can command or any of its subcommands. All subcommands also support tab-completion of their arguments.

Tip

All of the CAN shell subcommands take the name of a CAN controller as their first argument, which also supports tab-completion. A list of all devices available can be obtained using the device list shell command when CONFIG_DEVICE_SHELL is enabled. The examples below all use the device name can@0.

Inspection The properties of a given CAN controller can be inspected using the can show subcommand as shown below. The properties include the core CAN clock rate, the maximum supported bitrate, the number of RX filters supported, capabilities, current mode, current state, error counters, timing limits, and more:

```
uart:~$ can show can@0
core clock:      144000000 Hz
max bitrate:     5000000 bps
max std filters: 15
max ext filters: 15
capabilities:    normal loopback listen-only fd
mode:            normal
state:           stopped
rx errors:       0
tx errors:       0
timing:          sjw 1..128, prop_seg 0..0, phase_seg1 2..256, phase_seg2 2..128,␣
```

(continues on next page)

(continued from previous page)

```
↪prescaler 1..512
timing data:     sjw 1..16, prop_seg 0..0, phase_seg1 1..32, phase_seg2 1..16,␣
↪prescaler 1..32
transceiver:     passive/none
statistics:
  bit errors:    0
    bit0 errors: 0
    bit1 errors: 0
  stuff errors:  0
  crc errors:    0
  form errors:   0
  ack errors:    0
  rx overruns:   0
```

Note

The statistics are only printed if `CONFIG_CAN_STATS` is enabled.

Configuration The CAN shell allows for configuring the CAN controller mode and timing, along with starting and stopping the processing of CAN frames.

Note

The CAN controller mode and timing can only be changed while the CAN controller is stopped, which is the initial setting upon boot-up. The initial CAN controller mode is set to `normal` and the initial timing is set according to the `bitrate`, `sample-point`, `bitrate-data`, and `sample-point-data` *Devicetree* properties.

Timing The classic CAN bitrate/CAN FD arbitration phase bitrate can be configured using the `can bitrate` subcommand as shown below. The bitrate is specified in bits per second.

```
uart:~$ can bitrate can@0 125000
setting bitrate to 125000 bps
```

If `CONFIG_CAN_FD_MODE` is enabled, the data phase bitrate can be configured using the `can dbitrate` subcommand as shown below. The bitrate is specified in bits per second.

```
uart:~$ can dbitrate can@0 1000000
setting data bitrate to 1000000 bps
```

Both of these subcommands allow specifying an optional sample point in per mille and a (Re)Synchronization Jump Width (SJW) in Time Quanta as positional arguments. Refer to the interactive help of the subcommands for more details.

It is also possible to configure the raw bit timing using the `can timing` and `can dtiming` subcommands. Refer to the interactive help output for these subcommands for details on the required arguments.

Mode The CAN shell allows for setting the mode of the CAN controller using the `can mode` subcommand. An example for enabling loopback mode is shown below.

```
uart:~$ can mode can@0 loopback
setting mode 0x00000001
```

The subcommand accepts multiple modes given on the same command line (e.g. `can mode can@0 fd loopback` for setting CAN FD and loopback mode). Vendor-specific modes can be specified in hexadecimal.

Starting and Stopping After the timing and mode has been configured as needed, the CAN controller can be started using the `can start` subcommand as shown below. This will enable reception and transmission of CAN frames.

```
uart:~$ can start can@0
starting can@0
```

Prior to reconfiguring the timing or mode, the CAN controller needs to be stopped using the `can stop` subcommand as shown below:

```
uart:~$ can stop can@0
stopping can@0
```

Receiving In order to receive CAN frames, one or more CAN RX filters need to be configured. CAN RX filters are added using the `can filter add` subcommand as shown below. The subcommand accepts a CAN ID in hexadecimal format along with an optional CAN ID mask, also in hexadecimal format, for setting which bits in the CAN ID are to be matched. Refer to the interactive help output for this subcommand for further details on the supported arguments.

```
uart:~$ can filter add can@0 010
adding filter with standard (11-bit) CAN ID 0x010, CAN ID mask 0x7ff, data frames␣
↪1, RTR frames 0, CAN FD frames 0
filter ID: 0
```

The filter ID (0 in the example above) returned is to be used when removing the CAN RX filter.

Received CAN frames matching the added filter(s) are printed to the shell. A few examples are shown below:

```
# Dev Flags    ID   Size  Data bytes
can0  --       010   [8]  01 02 03 04 05 06 07 08
can0  B-       010  [08]  01 02 03 04 05 06 07 08
can0  BP       010  [03]  01 aa bb
can0  --  00000010   [0]
can0  --       010   [1]  20
can0  --       010   [8]  remote transmission request
```

The columns have the following meaning:

- Dev
  - Name of the device receiving the frame.
- Flags
  - `B`: The frame has the CAN FD Baud Rate Switch (BRS) flag set.
  - `P`: The frame has the CAN FD Error State Indicator (ESI) flag set. The transmitting node is in error-passive state.
  - `-`: Unset flag.
- ID
  - `010`: The standard (11-bit) CAN ID of the frame in hexadecimal format, here 10h.
  - `00000010`: The extended (29-bit) CAN ID of the frame in hexadecimal format, here 10h.
- Size

  - `[8]`: The number of frame data bytes in decimal format, here a classic CAN frame with 8 data bytes.
  - `[08]`: The number of frame data bytes in decimal format, here a CAN FD frame with 8 data bytes.
- Data bytes
  - `01 02 03 04 05 06 07 08`: The frame data bytes in hexadecimal format, here the numbers from 1 through 8.
  - `remote transmission request`: The frame is a Remote Transmission Request (RTR) frame and thus carries no data bytes.

Tip

If `CONFIG_CAN_RX_TIMESTAMP` is enabled, each line will be prepended with a timestamp from the free-running timestamp counter in the CAN controller.

Configured CAN RX filters can be removed again using the `can filter remove` subcommand as shown below. The filter ID is the ID returned by the `can filter add` subcommand (0 in the example below).

```
uart:~$ can filter remove can@0 0
removing filter with ID 0
```

Another option is to use the `can dump` subcommand, which adds standard (11-bit) and extended (29-bit) CAN filters matching any RX frame, starts the CAN controller, and prints all received CAN frames to the shell:

```
uart:~$ can dump can@0
dumping CAN RX frames on device can@0, press Ctrl+C to exit
```

After exiting the `can dump` subcommand by pressing Ctrl+C, the added filters are automatically removed and the CAN controller stopped again.

Sending CAN frames can be queued for transmission using the `can send` subcommand as shown below. The subcommand accepts a CAN ID in hexadecimal format and optionally a number of data bytes, also specified in hexadecimal. Refer to the interactive help output for this subcommand for further details on the supported arguments.

```
uart:~$ can send can@0 010 1 2 3 4 5 6 7 8
enqueuing CAN frame #2 with standard (11-bit) CAN ID 0x010, RTR 0, CAN FD 0, BRS␣
↪0, DLC 8
CAN frame #2 successfully sent
```

Bus Recovery The `can recover` subcommand can be used for initiating manual recovery from a CAN bus-off event as shown below:

```
uart:~$ can recover can@0
recovering, no timeout
```

The subcommand accepts an optional bus recovery timeout in milliseconds. If no timeout is specified, the command will wait indefinitely for the bus recovery to succeed.

Note

The `recover` subcommand is only available if `CONFIG_CAN_MANUAL_RECOVERY_MODE` is enabled.

7.6.10 Chargers

The charger subsystem exposes an API to uniformly access battery charger devices.

A charger device, or charger peripheral, is a device used to take external power provided to the system as an input and provide power as an output downstream to the battery pack(s) and system. The charger device can exist as a module, an integrated circuit, or as a functional block in a power management integrated circuit (PMIC).

The action of charging a battery pack is referred to as a charge cycle. When the charge cycle is executed the battery pack is charged according to the charge profile configured on the charger device. The charge profile is defined in the battery pack's specification that is provided by the manufacturer. On charger devices with a control port, the charge profile can be configured by the host controller by setting the relevant properties, and can be adjusted at runtime to respond to environmental changes.

Basic Operation

Initiating a Charge Cycle A charge cycle is initiated or terminated using `charger_charge_enable()`.

Properties Fundamentally, a property is a configurable setting, state, or quantity that a charger device can measure.

Chargers typically support multiple properties, such as temperature readings of the battery-pack or present-time current/voltage.

Properties are fetched by the client one at a time using `charger_get_prop()`. Properties are set by the client one at a time using `charger_set_prop()`.

7.6.11 Comparator

Overview

An analog comparator compares the voltages of two analog signals connected to its negative and positive inputs. If the voltage at the positive input is higher than the negative input, the comparator's output will be high, otherwise, it will be low.

Comparators can typically set a trigger which triggers on output changes. This trigger can either invoke a callback, or its status can be polled.

Related configuration options:

- `CONFIG_COMPARATOR`

Configuration

Embedded comparators can typically be configured at runtime. When enabled, an initial configuration must be provided using the devicetree. At runtime, comparators can have their configuration updated using device driver specific APIs. The configuration will be applied when the comparator is resumed.

Power management

Comparators are enabled using power management. When resumed, the comparator will actively compare its inputs, producing an output and detecting edges. When suspended, the comparator will be inactive.

Comparator shell

The comparator shell provides the `comp` command with a set of subcommands for the *shell* module.

The `comp` shell command provides the following subcommands:

- `get_output` See `comparator_get_output()`
- `set_trigger` See `comparator_set_trigger()`
- `await_trigger` Awaits trigger using the following flow:
  - Set trigger callback using `comparator_set_trigger_callback()`
  - Await callback or time out after default or optionally provided timeout
  - Clear trigger callback using `comparator_set_trigger_callback()`
- `trigger_is_pending` See `comparator_trigger_is_pending()`

Related configuration options:

- `CONFIG_SHELL`
- `CONFIG_COMPARATOR_SHELL`
- `CONFIG_COMPARATOR_SHELL_AWAIT_TRIGGER_DEFAULT_TIMEOUT`
- `CONFIG_COMPARATOR_SHELL_AWAIT_TRIGGER_MAX_TIMEOUT`

Note

The power management shell can optionally be enabled alongside the comparator shell.

7.6.12 Coredump Device

Overview

The coredump device is a pseudo-device driver with two types.A COREDUMP_TYPE_MEMCPY type exposes device tree bindings for memory address/size values to be included in any dump. And the driver exposes an API to add/remove dump memory regions at runtime. A COREDUMP_TYPE_CALLBACK device requires exactly one entry in the memory-regions array with a size of 0 and a desired size. The driver will statically allocate memory of the desired size and provide an API to register a callback function to fill that memory when a dump occurs.

7.6.16 Direct Memory Access (DMA)

Overview

Direct Memory Access (Controller) is a commonly provided type of co-processor that can typically offload transferring data to and from peripherals and memory.

The DMA API is not a portable API and really cannot be as each DMA has unique memory requirements, peripheral interactions, and features. The API in effect provides a union of all useful DMA functionality drivers have needed in the tree. It can still be a good abstraction, with care, for peripheral devices for vendors where the DMA IP might be very similar but have slight variances.

The DMA drivers in general do not handle cache coherency; this is left up to the developer as requirements vary dramatically depending on the application. See *Caching Basics* for an overview of cache management in Zephyr.

Driver Implementation Expectations

Synchronization and Ownership From an API point of view, a DMA channel is a single-owner object, meaning the drivers should not attempt to wrap a channel with kernel synchronization primitives such as mutexes or semaphores. If DMA channels require mutating shared registers, those register updates should be wrapped in a spin lock.

This enables the entire API to be low-cost and callable from any call context, including ISRs where it may be very useful to start/stop/suspend/resume/reload a channel transfer.

Transfer Descriptor Memory Management Drivers should not attempt to use heap allocations of any kind. If object pools are needed for transfer descriptors then those should be setup in a way that does not break the promise of ISR-allowable calls. Many drivers choose to create a simple static descriptor array per channel with the size of the descriptor array adjustable using Kconfig.

Channel State Machine Expectations DMA channels should be viewed as state machines that the DMA API provides transition events for in the form of API calls. Every driver is expected to maintain its own channel state tracking. The busy state of the channel should be inspectable at any time with `dma_get_status()`.

A diagram, showing those expected possible state transitions and their API calls is provided here for reference.

API Reference

DMA

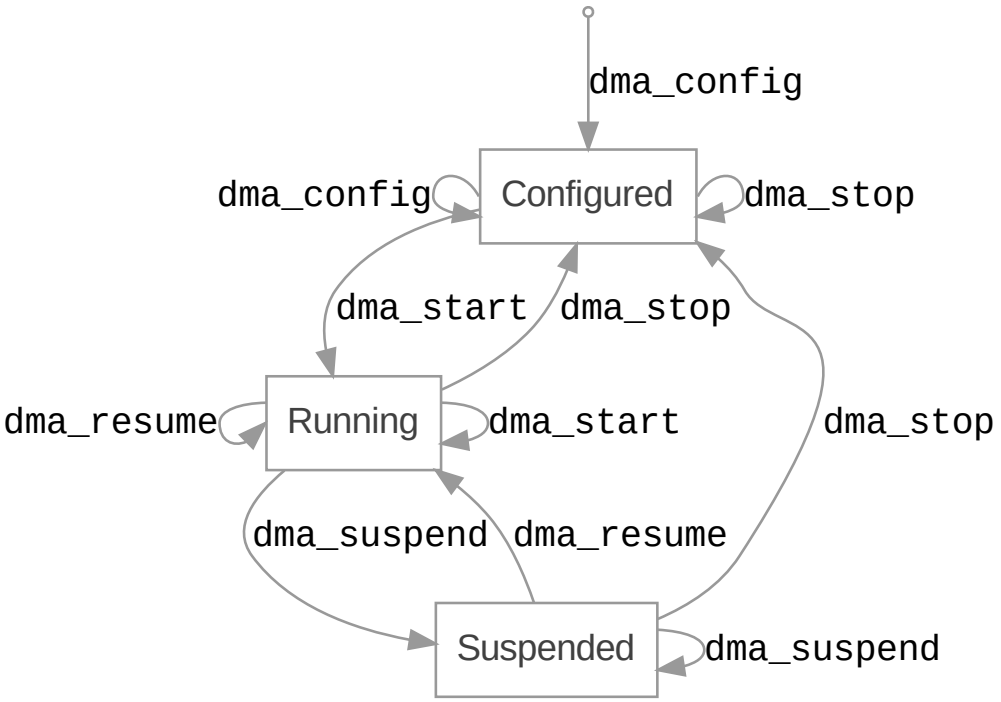

Fig. 2: DMA state finite state machine

7.6.17 Display

The Display subsystem in Zephyr provides a unified way to interact with a wide range of display devices. The Display API is transport-agnostic: it describes what you want the display to do, without exposing how the data moves over the wire.

MIPI Display Bus Interface (DBI)

The **MIPI DBI** specification defines several parallel and serial buses for connecting a host to a display controller. In Zephyr, DBI support provides bus-level primitives for command writes, reads, pixel transfers, reset, and related operations that a driver uses internally to implement the generic API.

Applications do not use DBI functions directly. Instead, they call the generic Display API (e.g., to write pixels), and the display driver handles the DBI protocol under the hood.

MIPI-DBI defines 3 interface types:

- Type A: Motorola 6800 parallel bus
- Type B: Intel 8080 parallel bus
- Type C: SPI Type serial bit bus with 3 options:
  1. 9 write clocks per byte, final bit is command/data selection bit
  2. Same as above, but 16 write clocks per byte
  3. 8 write clocks per byte. Command/data selected via GPIO pin

Currently, the API does not support Type C controllers with 16 write clocks (option 2).

MIPI Display Serial Interface (DSI)

The **MIPI DSI** standard is a high-speed differential serial bus designed for modern color TFT panels. Zephyr's DSI support provides the primitives needed by drivers to implement the generic Display API on top of a DSI link.

As with DBI, applications never call DSI functions directly. They remain portable by using the generic Display API, while the driver handles the DSI transactions internally.

7.6.18 Electrically Erasable Programmable Read-Only Memory (EEPROM)

Overview

EEPROMs have an erase block size of 1 byte, a long lifetime, and allow overwriting data on byte-by-byte access.

EEPROM API

Overview The EEPROM API provides read and write access to Electrically Erasable Programmable Read-Only Memory (EEPROM) devices.

Configuration Options Related configuration options:

- `CONFIG_EEPROM`

API Reference
EEPROM

Related code samples

- EEPROMStore a boot count value in EEPROM.

EEPROM Shell

- *Overview*
- *EEPROM Size*
- *Writing Data*
- *Reading Data*

Overview The EEPROM shell provides an `eeprom` command with a set of subcommands for the *shell* module. It allows testing and exploring the *EEPROM* driver API through an interactive interface without having to write a dedicated application. The EEPROM shell can also be enabled in existing applications to aid in interactive debugging of EEPROM issues.

In order to enable the EEPROM shell, the following *Kconfig* options must be enabled:

- `CONFIG_SHELL`
- `CONFIG_EEPROM`
- `CONFIG_EEPROM_SHELL`

For example, building the hello_world sample for the native_sim with the EEPROM shell:

```
# From the root of the zephyr repository
west build -b native_sim samples/hello_world -- -DCONFIG_SHELL=y -DCONFIG_EEPROM=y␣
↪-DCONFIG_EEPROM_SHELL=y
```

See the *shell* documentation for general instructions on how to connect and interact with the shell. The EEPROM shell comes with built-in help (unless `CONFIG_SHELL_HELP` is disabled). The built-in help messages can be printed by passing `-h` or `--help` to the `eeprom` command or any of its subcommands. All subcommands also support tab-completion of their arguments.

Tip

All of the EEPROM shell subcommands take the name of an EEPROM peripheral as their first argument, which also supports tab-completion. A list of all devices available can be obtained using the `device list` shell command when `CONFIG_DEVICE_SHELL` is enabled. The examples below all use the device name `eeprom@0`.

EEPROM Size The size of an EEPROM can be inspected using the `eeprom size` subcommand as shown below:

```
uart:~$ eeprom size eeprom@0
32768 bytes
```

Writing Data Data can be written to an EEPROM using the `eeprom write` subcommand. This subcommand takes at least three arguments; the EEPROM device name, the offset to start writing to, and at least one data byte. In the following example, the hexadecimal sequence of bytes `0x0d 0x0e 0x0a 0x0d 0x0b 0x0e 0x0e 0x0f` is written to offset `0x0`:

```
uart:~$ eeprom write eeprom@0 0x0 0x0d 0x0e 0x0a 0x0d 0x0b 0x0e 0x0e 0x0f
Writing 8 bytes to EEPROM...
Verifying...
Verify OK
```

It is also possible to fill a portion of the EEPROM with the same pattern using the `eeprom fill` subcommand. In the following example, the pattern `0xaa` is written to 16 bytes starting at offset `0x8`:

```
uart:~$ eeprom fill eeprom@0 0x8 16 0xaa
Writing 16 bytes of 0xaa to EEPROM...
Verifying...
Verify OK
```

Reading Data Data can be read from an EEPROM using the `eeprom read` subcommand. This subcommand takes three arguments; the EEPROM device name, the offset to start reading from, and the number of bytes to read:

```
uart:~$ eeprom read eeprom@0 0x0 8
Reading 8 bytes from EEPROM, offset 0...
00000000: 0d 0e 0a 0d 0b 0e 0e 0f                          |........        |
```

7.6.19 Enhanced Serial Peripheral Interface (eSPI) Bus

Overview

The eSPI (enhanced serial peripheral interface) is a serial bus that is based on SPI. It also features a four-wire interface (receive, transmit, clock and target select) and three configurations: single IO, dual IO and quad IO.

The technical advancements include lower voltage signal levels (1.8V vs. 3.3V), lower pin count, and the frequency is twice as fast (66MHz vs. 33MHz) Because of its enhancements, the eSPI is used to replace the LPC (lower pin count) interface, SPI, SMBus and sideband signals.

See eSPI interface specification for additional details.

7.6.21 Error Detection And Correction (EDAC)

Error Detection And Correction is a mechanism used to detect and correct errors while storing or reading data.

In Band Error Correction Code (IBECC)

Overview The mechanism initially found in Intel Elkhart Lake SOCs and later boards is an integrated memory controller with IBECC.

The In-Band Error Correction Code (IBECC) improves reliability by providing error detection and correction. IBECC can work for all or for specific regions of physical memory space. The IBECC is useful for memory technologies that do not support the out-of-band ECC.

IBECC adds memory overhead of 1/32 of the memory. This memory is not accessible and used to store ECC syndrome data. IBECC converts read / write transactions to two separate transactions: one for actual data and another for cache line containing ECC value.

There is a debug feature IBECC Error Injection which helps to debug and verify IBECC functionality. ECC errors are injected on the write path and cause ECC errors on the read path.

IBECC Configuration There are three IBECC operation modes which can be selected by Bootloader. They are listed below:

- OPERATION_MODE = 0x0 sets functional mode to protect requests based on address range
- OPERATION_MODE = 0x1 sets functional mode to all requests not be protected and to ignore range checks
- OPERATION_MODE = 0x2 sets functional mode to protect all requests and ignore range checks

IBECC operational mode is configured through BIOS or Bootloader. For operation mode 0 there are more BIOS configuration options such as memory regions.

Due to high security risk Error Injection capability should not be enabled for production. Error Injection is only enabled for tests.

IBECC Logging IBECC logs the following fields:

- Error Address
- Error Syndrome
- Error Type
  - Correctable Error (CE) - error is detected and corrected by IBECC module.
  - Uncorrectable Error (UE) - error is detected by IBECC module and not automatically corrected.

The IBECC driver provides error type for the higher-level application to implement desired policy with respect for handling those memory errors. Error syndrome is not used in the IBECC driver but provided to higher-level application.

Usage notes Exceptional care needs to be taken with Non Maskable Interrupt (NMI). NMI will arrive at any time, even if the local CPU has disabled interrupts. That means that no locking mechanism can protect code against an NMI happening. Zephyr's IPC mechanisms universally use local IRQ locking as the base layer for all higher-level synchronization primitives. So, you cannot share anything that is "protected" by a lock with an NMI, because the protection does not work. The only tool you have available for synchronization in the Zephyr API that works against an NMI is the atomic layer. This also applies to callback function which is called by NMI handler.

7.6.22 Flash

Overview

Flash offset concept

Offsets used by the user API are expressed in relation to the flash memory beginning address. This rule shall be applied to all flash controller regular memory that layout is accessible via API for retrieving the layout of pages (see CONFIG_FLASH_PAGE_LAYOUT).

An exception from the rule may be applied to a vendor-specific flash dedicated-purpose region (such a region obviously can't be covered under API for retrieving the layout of pages).

7.6.23 Fuel Gauge

The fuel gauge subsystem exposes an API to uniformly access battery fuel gauge devices.

Basic Operation

Properties Fundamentally, a property is a quantity that a fuel gauge device can measure.

Fuel gauges typically support multiple properties, such as temperature readings of the battery-pack or present-time current/voltage.

Properties are fetched by the client one at a time using `fuel_gauge_get_prop()`, or fetched in a batch using `fuel_gauge_get_props()`. Buffer properties, e.g. device name, are fetched by using `fuel_gauge_get_buffer_prop()`.

Properties are set by the client one at a time using `fuel_gauge_set_prop()`, or set in a batch using `fuel_gauge_set_props()`.

Battery Cutoff Many fuel gauges embedded within battery packs expose a register address that when written to with a specific payload will do a battery cutoff. This battery cutoff is often referred to as ship, shelf, or sleep mode due to its utility in reducing battery drain while devices are stored or shipped.

The fuel gauge API exposes battery cutoff with the `fuel_gauge_battery_cutoff()` function.

Caching The Fuel Gauge API explicitly provides no caching for its clients.

7.6.24 GNSS (Global Navigation Satellite System)

Overview

GNSS is a general term which covers satellite systems used for navigation, like GPS (Global Positioning System). GNSS services are usually accessed through GNSS modems which receive and process GNSS signals to determine their position, or more specifically, their antennas position. They usually additionally provide a precise time synchronization mechanism, commonly named PPS (Pulse-Per-Second).

Subsystem support

The GNSS subsystem is based on the *Modem modules*. The GNSS subsystem covers everything from sending and receiving commands to and from the modem, to parsing, creating and processing NMEA0183 messages.

Adding support for additional NMEA0183 based GNSS modems requires little more than implementing power management and configuration for the specific GNSS modem.

Adding support for GNSS modems which use other protocols and/or buses than the usual NMEA0183 over UART is possible, but will require a bit more work from the driver developer.

7.6.25 General-Purpose Input/Output (GPIO)

Overview

A General-Purpose Input/Output (GPIO) is a digital signal pin that does not have a specific function but can be controlled by software to function as an input or an output.

The GPIO API provides a generic method to interact with General Purpose Input/Output (GPIO) pins. It allows applications to configure pins as inputs or outputs, read and write their state, and manage interrupts. Key features include:

Pin Configuration
: Configure pins as input, output, or disconnected. Support for internal pull-up/pull-down resistors and drive strength configuration.

Data Access
: Read input values and write output values.

Interrupts
: Configure interrupts on pin state changes (rising edge, falling edge, level low, level high) and register callbacks to handle these interrupts.

Devicetree Integration
: GPIOs are typically defined in the Devicetree, allowing drivers and applications to reference them in a hardware-agnostic way using `gpio_dt_spec`.

Devicetree Configuration

GPIO controllers are defined in the Devicetree as nodes with the `gpio-controller` property. The `#gpio-cells` property typically specifies that 2 cells are used to describe a GPIO: the pin number and the flags.

Example of a GPIO controller definition:

```
gpio0: gpio@40022000 {
    compatible = "ti,cc13xx-cc26xx-gpio";
    reg = <0x40022000 0x400>;
    interrupts = <0 0>;
```

(continues on next page)

(continued from previous page)

```
    gpio-controller;
    #gpio-cells = <2>;
};
```

Example of referencing a GPIO:

```
leds {
    compatible = "gpio-leds";
    led0: led_0 {
        gpios = <&gpio0 25 GPIO_ACTIVE_HIGH>;
        label = "Green LED";
    };
};
```

Basic Operation

GPIO operations are usually performed on a `gpio_dt_spec` structure, which is a container for the GPIO pin information specified in the Devicetree.

This structure is typically populated using `GPIO_DT_SPEC_GET` macro (or any of its variants).

Listing 1: Populating a gpio_dt_spec structure for a GPIO pin defined as alias `led0`

```
#define LED0_NODE DT_ALIAS(led0)
static const struct gpio_dt_spec led = GPIO_DT_SPEC_GET(LED0_NODE, gpios);
```

The `gpio_dt_spec` structure can then be used to perform GPIO operations.

Listing 2: Configure a GPIO pin (`led` from the previous snippet) as output, initially inactive, and then set it to its active level.

```
int ret;

ret = gpio_pin_configure_dt(&led, GPIO_OUTPUT_INACTIVE);
if (ret < 0) {
    return ret;
}

ret = gpio_pin_set_dt(&led, 1);
if (ret < 0) {
    return ret;
}
```

Refer to blinky for a complete example of basic operations on GPIOs using the `gpio_dt_spec` structure.

GPIO operations can also be performed directly on a GPIO controller device, in which case you will use the GPIO API functions that take a device pointer as an argument. For example `gpio_pin_configure()` instead of `gpio_pin_configure_dt()`.

GPIO Hogs

GPIO hogs provide a mechanism to automatically configure GPIO pins during system initialization. This is useful for pins that need to be set to a specific state (e.g., reset lines, power enables) and don't require runtime control by an application.

Hogs are defined in the Devicetree as children of a GPIO controller node.

- The `gpio-hog` property marks the node as a hog.
- The `gpios` property specifies the pin and its active state.
- One of `input`, `output-low`, or `output-high` properties specifies the configuration.

Example Devicetree overlay:

```
&gpio0 {
    hog1 {
        gpio-hog;
        gpios = <1 GPIO_ACTIVE_LOW>;
        output-high;
    };

    hog2 {
        gpio-hog;
        gpios = <2 GPIO_ACTIVE_HIGH>;
        output-low;
    };
};
```

If you need runtime control of a pin configured as a hog beyond the initial state being automatically set during system initialization, you may consider using the *Regulators* instead, with a `regulator-fixed` Devicetree node.

Configuration Options

Main configuration options:

7.6.26 Haptics

Overview

The haptics API allows for the control of haptic driver devices for the purposes of performing haptic feedback events.

During a haptic feedback event the haptic device drives a signal to an actuator. The source of the haptic event signal varies depending on the capabilities of the haptic device.

Some examples of haptic signal sources are analog signals, preprogrammed (ROM) wavetables, synthesized (RAM) wavetables, and digital audio streams.

Additionally, haptic driver devices often offer controls for adjusting and tuning the drive signal to meet the electrical requirements of their respective actuators.

7.6.30 Improved Inter-Integrated Circuit (I3C) Bus

I3C (Improved Inter-Integrated Circuit) is a two-signal shared peripheral interface bus. Devices on the bus can operate in two roles: as a "controller" that initiates transactions and controls the clock, or as a "target" that responds to transaction commands.

Currently, the API is based on I3C Specification version 1.1.1.

- *I3C Controller API*
  - *In-Band Interrupt (IBI)*
  - *Device Tree*
  - *Device Drivers for I3C Devices*
  - *I^2C Devices under I3C Bus*
- *Configuration Options*
- *API Reference*

I3C Controller API

Zephyr's I3C controller API is used when an I3C controller controls the bus, particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I3C target devices such as sensors.

Due to the nature of the I3C, there are devices on the bus where they may not have addresses when powered on. Therefore, an additional dynamic address assignment needs to be carried out by the I3C controller. Because of this, the controller needs to maintain separate structures to keep track of device status. This can be done at build time, for example, by creating arrays of device descriptors for both I3C and I^2C devices:

```
static struct i3c_device_desc i3c_device_array[] = I3C_DEVICE_ARRAY_DT_INST(inst);
static struct i3c_i2c_device_desc i2c_device_array[] =␣
↪I3C_I2C_DEVICE_ARRAY_DT_INST(inst);
```

The macros `I3C_DEVICE_ARRAY_DT_INST` and `I3C_I2C_DEVICE_ARRAY_DT_INST` are helper macros to aid in create arrays of device descriptors corresponding to the devicetree nodes under the I3C controller.

Here is a list of generic steps for initializing the I3C controller and the I3C bus inside the device driver initialization function:

1. Initialize the data structure of the I3C controller device driver instance. The usual device defining macros such as `DEVICE_DT_INST_DEFINE` can be used, and the initialization function provided as a parameter to the macro.
   - The `i3c_addr_slots` and `i3c_dev_list` are structures to aid in address assignments and device list management. If this is being used, this struct needs to be initialized by calling `i3c_addr_slots_init()`. These two structures can also be used with various helper functions.
   - Initialize the device descriptors if needed by the controller driver.
2. Initialize the hardware, including but not limited to:
   - Setup pin mux and directions.
   - Setup the clock for the controller.
   - Power on the hardware.
   - Configure the hardware (e.g. SCL clock frequency).
3. Perform bus initialization. There is a generic helper function, `i3c_bus_init()`, which performs the following steps. This function can be used if the controller does not require any special handling during bus initialization.
   1. Do `RSTDAA` to reset dynamic addresses of connected devices. If any connected devices have already been assigned an address, the bookkeeping data structures do not have records of these, for example, at power-on. So it is a good idea to reset and assign them new addresses.
   2. Do `DISEC` to disable any events from devices.
   3. Do `SETDASA` to assign a dynamic address using the static address of the device if so desired.
      - `SETAASA` may not be supported for all connected devices to assign static addresses as dynamic addresses.
      - BCR and DCR need to be obtained separately to populate the relevant fields in the I3C target device descriptor struct.
   4. Do `ENTDAA` to start dynamic address assignment, if there are still devices without addresses.
      - If there is a device waiting for address, it will send its Provisioned ID, BCR, and DCR back. Match the received Provisioned ID to the list of registered I3C devices.
        - If there is a match, assign an address (either from the stated static address if `SETDASA` has not been done, or use a free address).
          * Also, set the BCR and DCR fields in the device descriptor struct.
        - If there is no match, depending on policy, it can be assigned a free address, or the device driver can stop the assignment process and errors out.
          * Note that the I3C API requires device descriptor to function. A device without a device descriptor cannot be accessed through the API.
      - This step can be skipped if there is no connected devices requiring DAA.
   5. These are optional but highly recommended:
      - Do `GETMRL` and `GETMWL` to get maximum read/write length.
      - Do `GETMXDS` to get maximum read/write speed and maximum read turnaround time.

- The helper function, `i3c_bus_init()`, would retrieve basic device information such as BCR, DCR, MRL and MWL.

6. Do `ENEC` to re-enable events from devices.
   - The helper function, `i3c_bus_init()`, only re-enables hot-join events. IBI event should only be enabled when enabling IBI of a device.

In-Band Interrupt (IBI) If a target device can generate In-Band Interrupt (IBI), the controller needs to be made aware of it.

- `i3c_ibi_enable()` to enable IBI of a target device.
  - Some controller hardware have IBI slots which need to be programmed so that the controller can recognize incoming IBIs from a particular target device.
    - If the hardware has IBI slots, `i3c_ibi_enable()` needs to program those IBI slots.
    - Note that there are usually limited IBI slots on the controller so this operation may fail.
  - The implementation in driver should also send the `ENEC` command to enable interrupt of this target device.
- `i3c_ibi_disable()` to disable IBI of a target device.
  - If controller hardware makes use of IBI slots, this will remove description of the target device from the slots.
  - The implementation in driver should also send the `DISEC` command to disable interrupt of this target device.

Device Tree Here is an example for defining a I3C controller in device tree:

```
i3c0: i3c@10000 {
        compatible = "vendor,i3c";

        #address-cells = < 0x3 >;
        #size-cells = < 0x0 >;

        reg = < 0x10000 0x1000 >;
        interrupts = < 0x1F 0x0 >;

        pinctrl-0 = < &pinmux-i3c >;
        pinctrl-names = "default";

        i2c-scl-hz = < 400000 >;

        i3c-scl-hz = < 12000000 >;

        status = "okay";

        i3c-dev0: i3c-dev0@420000ABCD12345678 {
                compatible = "vendor,i3c-dev";

                reg = < 0x42 0xABCD 0x12345678 >;

                status = "okay";
        };

        i2c-dev0: i2c-dev0@380000000000000050 {
                compatible = "vendor-i2c-dev";
```

(continues on next page)

(continued from previous page)

```
                reg = < 0x38 0x0 0x50 >;

                status = "okay";
        };
};
```

I3C Devices For I3C devices, the `reg` property has 3 elements:

- The first one is the static address of the device.
  - Can be zero if static address is not used. Address will be assigned during DAA (Dynamic Address Assignment).
  - If non-zero and property `assigned-address` is not set, this will be the address of the device after SETDASA (Set Dynamic Address from Static Address) is issued.
- Second element is the upper 16-bit of the Provisioned ID (PID) which contains the manufacturer ID left-shifted by 1. This is the bits 33-47 (zero-based) of the 48-bit Provisioned ID.
- Third element contains the lower 32-bit of the Provisioned ID which is a combination of the part ID (left-shifted by 16, bits 16-31 of the PID) and the instance ID (left-shifted by 12, bits 12-15 of the PID).

Note that the unit-address (the part after `@`) must match the `reg` property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer. This is required for properly generating device tree macros.

I²C Devices For I²C devices where the device driver has support for working under I3C bus, the device node can be described as a child of the I3C controller. If the device driver is written to only work with I²C controllers, define the node under the I²C virtual controller as described below. Otherwise, the `reg` property, similar to I3C devices, has 3 elements:

- The first one is the static address of the device. This must be a valid address as I²C devices do not support dynamic address assignment.
- Second element is always zero.
  - This is used by various helper macros to determine whether the device tree entry corresponds to a I²C device.
- Third element is the LVR (Legacy Virtual Register):
  - bit[31:8] are unused.
  - bit[7:5] are the I²C device index:
    - Index `0`
      - I3C device has a 50 ns spike filter where it is not affected by high frequency on SCL.
    - Index 1
      - I²C device does not have a 50 ns spike filter but can work with high frequency on SCL.
    - Index 2
      - I3C device does not have a 50 ns spike filter and cannot work with high frequency on SCL.
  - bit[4] is the I²C mode indicator:

* `0` is FM+ mode.
* 1 is FM mode.

Similar to I3C devices, the unit-address must match the `reg` property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer.

Device Drivers for I3C Devices All of the transfer functions of I3C controller API require the use of device descriptors, `i3c_device_desc`. This struct contains runtime information about a I3C device, such as, its dynamic address, BCR, DCR, MRL and MWL. Therefore, the device driver of a I3C device should grab a pointer to this device descriptor from the controller using `i3c_device_find()`. This function takes an ID parameter of type `i3c_device_id` for matching. The returned pointer can then be used in subsequent API calls to the controller.

I²C Devices under I3C Bus Since I3C is backward compatible with I²C, the I3C controller API can accommodate I2C API calls without modifications if the controller device driver implements the I2C API. This has the advantage of using existing I2C devices without any modifications to their device drivers. However, since the I3C controller API works on device descriptors, any calls to I2C API will need to look up the corresponding device descriptor from the I2C device address. This adds a bit of processing cost to any I2C API calls.

On the other hand, a device driver can be extended to utilize native I2C device support via the I3C controller API. During device initialization, `i3c_i2c_device_find()` needs to be called to retrieve the pointer to the device descriptor. This pointer can be used in subsequent API calls.

Note that, with either methods mentioned above, the devicetree node of the I2C device must be declared according to I3C standard:

The I²C virtual controller device driver provides a way to interface I²C devices on the I3C bus where the associated device drivers can be used as-is without modifications. This requires adding an intermediate node in the device tree:

```
i3c0: i3c@10000 {
        <... I3C controller related properties ...>
        <... Nodes of I3C devices, if any ...>

        i2c-dev0: i2c-dev0@42000000000000050 {
                compatible = "vendor-i2c-dev";

                reg = < 0x42 0x0 0x50 >;

                status = "okay";
        };
};
```

7.6.31 Inter-Integrated Circuit (I2C) Bus

Overview

> **Note**
>
> The terminology used in Zephyr I2C APIs follows that of the NXP I2C Bus Specification Rev 7.0. These changed from previous revisions as of its release October 1, 2021.

I2C (Inter-Integrated Circuit, pronounced "eye squared see") is a commonly-used two-signal shared peripheral interface bus. Many system-on-chip solutions provide controllers that communicate on an I2C bus. Devices on the bus can operate in two roles: as a "controller" that initiates transactions and controls the clock, or as a "target" that responds to transaction commands. A I2C controller on a given SoC will generally support the controller role, and some will also support the target mode. Zephyr has API for both roles.

I2C Controller API Zephyr's I2C controller API is used when an I2C peripheral controls the bus, particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I2C devices like sensors and serial memory.

This API is supported in all in-tree I2C peripheral drivers and is considered stable.

I2C Target API Zephyr's I2C target API is used when an I2C peripheral responds to transactions initiated by a different controller on the bus. It might be used for a Zephyr application with transducer roles that are controlled by another device such as a host processor.

This API is supported in very few in-tree I2C peripheral drivers. The API is considered experimental, as it is not compatible with the capabilities of all I2C peripherals supported in controller mode.

7.6.34 Management Data Input/Output (MDIO)

Overview

MDIO is a bus that is commonly used to communicate with ethernet PHY devices. Many ethernet MAC controllers also provide hardware to communicate over MDIO bus with a peripheral device.

This API is intended to be used primarily by PHY drivers but can also be used by user firmware.

API Reference

MDIO

7.6.35 Multi-bit SPI Bus

The MSPI (multi-bit SPI) is provided as a generic API to accommodate advanced SPI peripherals and devices that typically require command, address and data phases, and multiple signal lines during these phases. While the API supports advanced features such as *XIP* and scrambling, it is also compatible with generic SPI.

- *MSPI Controller API*
  - *Transceive*
  - *Device Tree*

  - *Multi Peripheral*
- *Configuration Options*
- *API Reference*

MSPI Controller API

Zephyr's MSPI controller API may be used when a multi-bit SPI controller is present. E.g. Ambiq MSPI, QSPI, OSPI, Flexspi, etc. The API supports single to hex SDR/DDR IO with variable latency and advanced features such as *XIP* and scrambling. Applicable devices include but not limited to high-speed, high density flash/psram memory devices, displays and sensors.

The MSPI interface contains controller drivers that are SoC platform specific and implement the MSPI APIs, and device drivers that reference these APIs. The relationship between the controller and device drivers is many-to-many to allow for easy switching between platforms.

Here is a list of generic steps for initializing the MSPI controller and the MSPI bus inside the device driver initialization function:

1. Initialize the data structure of the MSPI controller driver instance. The usual device defining macros such as `DEVICE_DT_INST_DEFINE` can be used, and the initialization function, config and data provided as a parameter to the macro.
2. Initialize the hardware, including but not limited to:
   - Check `mspi_cfg` against hardware's own capabilities to prevent incorrect usages.
   - Setup default pinmux.
   - Setup the clock for the controller.
   - Power on the hardware.
   - Configure the hardware using `mspi_cfg` and possibly more platform specific settings.
   - Usually, the `mspi_cfg` is filled from device tree and contains static, boot time parameters. However, if needed, one can use `mspi_config()` to re-initialize the hardware with new parameters during runtime.
   - Release any lock if applicable.
3. Perform device driver initialization. As usually, `DEVICE_DT_INST_DEFINE` can be used. Inside device driver initialization function, perform the following required steps.
   1. Call `mspi_dev_config()` with device specific hardware settings obtained from device datasheets.
      - The `mspi_dev_cfg` should be filled by device tree and helper macro `MSPI_DEVICE_CONFIG_DT` can be used.
      - The controller driver should then validate the members of `mspi_dev_cfg` to prevent incorrect usage.
      - The controller driver should implement a mutex to protect from accidental access.
      - The controller driver may also switch between different devices based on `mspi_dev_id`.
   2. Call API for additional setups if supported by hardware
      - `mspi_xip_config()` for *XIP* feature
      - `mspi_scramble_config()` for scrambling feature
      - `mspi_timing_config()` for platform specific timing setup.
   3. Register any callback with `mspi_register_callback()` if needed.

4. Release the controller mutex lock.

Transceive The transceive request is of type `mspi_xfer` which allows dynamic change to the transfer related settings once the mode of operation is determined and configured by `mspi_dev_config()`.

The API also supports bulk transfers with different starting addresses and sizes with `mspi_xfer_packet`. However, it is up to the controller implementation whether to support scatter IO and callback management. The controller can determine which user callback to trigger based on `mspi_bus_event_cb_mask` upon completion of each async/sync transfer if the callback had been registered using `mspi_register_callback()`. Or not to trigger any callback at all with `MSPI_BUS_NO_CB` even if the callbacks are already registered. If the implemented driver support it, the API supports `MSPI_BUS_XFER_COMPLETE_CB` to signal when a transfer finishes and `MSPI_BUS_TIMEOUT_CB` to signal when a transfer or request has timed-out. In which case that a controller supports hardware command queue, user could take full advantage of the hardware performance if scatter IO and callback management are supported by the driver implementation.

Device Tree Here is an example for defining an MSPI controller in device tree: The mspi controller's bindings should reference mspi-controller.yaml as one of the base.

```
mspi0: mspi@400 {
         status = "okay";
         compatible = "zephyr,mspi-emul-controller";

         reg = < 0x400 0x4 >;
         #address-cells = < 0x1 >;
         #size-cells = < 0x0 >;

         clock-frequency = < 0x17d7840 >;
         op-mode = "MSPI_CONTROLLER";
         duplex = "MSPI_HALF_DUPLEX";
         ce-gpios = < &gpio0 0x5 0x1 >, < &gpio0 0x12 0x1 >;
         dqs-support;

         pinctrl-0 = < &pinmux-mspi0 >;
         pinctrl-names = "default";
};
```

Here is an example for defining an MSPI device in device tree: The mspi device's bindings should reference mspi-device.yaml as one of the base.

```
&mspi0 {

         mspi_dev0: mspi_dev0@0 {
                  status = "okay";
                  compatible = "zephyr,mspi-emul-device";

                  reg = < 0x0 >;
                  size = < 0x10000 >;

                  mspi-max-frequency = < 0x2dc6c00 >;
                  mspi-io-mode = "MSPI_IO_MODE_QUAD";
                  mspi-data-rate = "MSPI_DATA_RATE_SINGLE";
                  mspi-hardware-ce-num = < 0x0 >;
                  read-instruction = < 0xb >;
                  write-instruction = < 0x2 >;
```

(continues on next page)

(continued from previous page)

```
                instruction-length = "INSTR_1_BYTE";
                address-length = "ADDR_4_BYTE";
                rx-dummy = < 0x8 >;
                tx-dummy = < 0x0 >;
                xip-config = < 0x0 0x0 0x0 0x0 >;
                ce-break-config = < 0x0 0x0 >;
        };

};
```

User should specify target operating parameters in the DTS such as `mspi-max-frequency`, `mspi-io-mode` and `mspi-data-rate` even though they may subject to change during runtime. It should represent the typical configuration of the device during normal operations.

Multi Peripheral With `mspi_dev_id` defined as collection of the device index and CE GPIO from device tree, the API supports multiple devices on the same controller instance. The controller driver implementation may or may not support device switching, which can be performed either by software or by hardware. If the switching is handled by software, it should be performed in `mspi_dev_config()` call.

The device driver should record the current operating conditions of the device to support software controlled device switching by saving and updating `mspi_dev_cfg` and other relevant mspi struct or private data structures. In particular, `mspi_dev_id` which contains the identity of the device needs to be used for every API call.

7.6.44 Real-Time Clock (RTC)

Overview

Table 2: **Glossary**

Word	Definition
Real-time clock	Low power device tracking time using broken-down time
Real-time counter	Low power counter which can be used to track time
RTC	Acronym for real-time clock

An RTC is a low power device which tracks time using broken-down time. It should not be confused with low-power counters which sometimes share the same name, acronym, or both.

RTCs are usually optimized for low energy consumption and are usually kept running even when the system is in a low power state.

RTCs usually contain one or more alarms which can be configured to trigger at a given time. These alarms are commonly used to wake up the system from a low power state.

Devicetree bindings

RTC bindings must include the `rtc-device.yaml` binding, which includes the `base.yaml` binding and the required `alarms-count` property.

```
include: rtc-device.yaml
```

Device driver design

Driver init RTCs are never powered off by the system. On init, drivers should expect the RTC is either:

- Powered, configured, and running.
- Powered, unconfigured, and stopped.

On init, drivers shall ensure the RTC is configured correctly, while preserving the time, alarms, and running status.

Time is set by calling `rtc_set_time()`, at which point the RTC will start running. Alarms pending status is cleared by `rtc_alarm_is_pending()` or by an alarm callback resulting from `rtc_alarm_set_callback()`.

GPIO routed interrupts RTCs with connected interrupt output pins shall configure and enable them on init. The host may enable and disable interrupts for its GPIOs, but RTC interrupt output pins must remain enabled.

This ensures consistent behavior between internally and externally connected RTCs, and allows for system wakeup through GPIO on any enabled RTC event like alarms or update.

Note

RTCs with unconnected interrupt output pins are not allowed to periodically poll the RTC to emulate it being connected. `rtc_alarm_set_callback()` and `rtc_update_set_callback()` shall return `-ENOTSUP` in this case.

Clock output If supported, the clock output configuration is defined in the devicetree. The output is configured by the driver on init.

Related code samples

- Real-Time Clock (RTC)Set and read the date/time from a Real-Time Clock.

RTC device driver test suite

The test suite validates the behavior of the RTC device driver. It is designed to be portable between boards. It uses the device tree alias `rtc` to designate the RTC device to test.

This test suite tests the following:

- Setting and getting the time.
- RTC Time incrementing correctly.
- Alarms if supported by hardware, with and without callback enabled
- Calibration if supported by hardware.

The calibration test tests a range of values which are printed to the console to be manually compared. The user must review the set and gotten values to ensure they are valid.

By default, only the mandatory setting and getting of time is enabled for testing. To test the optional alarms, update event callback and clock calibration, these must be enabled by selecting `CONFIG_RTC_ALARM`, `CONFIG_RTC_UPDATE` and `CONFIG_RTC_CALIBRATION`.

The following examples build the test suite for the `native_sim` board. To build the test suite for a different board, replace the `native_sim` board with your board.

To build the test application with the default configuration, testing only the mandatory features, the following command can be used for reference:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
```

To build the test with additional RTC features enabled, use menuconfig to enable the additional features by updating the configuration. The following command can be used for reference:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
west build -t menuconfig
```

Then build the test application using the following command:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
```

To run the test suite, flash and run the application on your board, the output will be printed to the console.

Note

The tests take up to 30 seconds each if they are testing real hardware.

RTC emulated device

The emulated RTC device fully implements the RTC API, and will behave like a real RTC device, with the following limitations:

- RTC time is not persistent across application initialization.
- RTC alarms are not persistent across application initialization.
- RTC time will drift over time.

Every time an application is initialized, the RTC's time and alarms are reset. Reading the time using `rtc_get_time()` will return `-ENODATA`, until the time is set using `rtc_set_time()`. The RTC will then behave as a real RTC, until the application is reset.

The emulated RTC device driver is built for the compatible `zephyr,rtc-emul` and will be included if `CONFIG_RTC` is selected.

History of RTCs in Zephyr

RTCs have been supported before this API was created, using the *Counter* API. The unix timestamp was used to convert between broken-down time and the unix timestamp within the RTC drivers, which internally used the broken-down time representation.

The disadvantages of this approach were that hardware counters could not be set to a specific count, requiring all RTCs to use device specific APIs to set the time, converting from unix time to broken-down time, unnecessarily in some cases, and some common features missing, like input clock calibration and the update callback.

7.6.45 Regulators

This subsystem provides control of voltage and current regulators. A common example is a GPIO that controls a transistor that supplies current to a device that is not always needed. Another example is a PMIC, typically a much more complex device.

The `*-supply` devicetree properties are used to identify the regulator(s) that a devicetree node directly depends on. Within the driver for the node the regulator API is used to issue requests for power when the device is to be active, and release the power request when the device shuts down.

The simplest case where a regulator is needed is one where there is only one client. For those situations the cost of using the regulator device infrastructure is not justified, and `*-gpios` devicetree properties should be used. There is no device interface to these regulators as they are entirely controlled within the driver for the corresponding node, e.g. a sensor.

API Reference

Regulator

7.6.46 Reset Controller

Overview

Reset controllers are units that control the reset signals to multiple peripherals. The reset controller API allows peripheral drivers to request control over their reset input signals, including the ability to assert, deassert and toggle those signals. Also, the reset status of the reset input signal can be checked.

Mainly, the line_assert and line_deassert API functions are optional because in most cases we want to toggle the reset signals.

Configuration Options

Related configuration options:

- `CONFIG_RESET`

API Reference

Reset Controller

7.6.47 Retained Memory

Overview

The retained memory driver API provides a way of reading from/writing to memory areas whereby the contents of the memory is retained whilst the device is powered (data may be lost in low power modes).

Configuration Options

Related configuration options:

- `CONFIG_RETAINED_MEM`
- `CONFIG_RETAINED_MEM_INIT_PRIORITY`
- `CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE`

Mutex protection

Mutex protection of retained memory drivers is enabled by default when applications are compiled with multithreading support. This means that different threads can safely call the retained memory functions without clashing with other concurrent thread function usage, but means that retained memory functions cannot be used from ISRs. It is possible to disable mutex protection globally on all retained memory drivers by enabling `CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE` - users are then responsible for ensuring that the function calls do not conflict with each other.

API Reference

Retained memory

7.6.48 Secure Digital (SD card) interface

Zephyr can communicate with an attached SD card either using a system's native SD card interface or over SPI (Serial Peripheral Interface). Some devices can also communicate with MMC (MultiMediaCard) devices.

Applications can use Zephyr's *the disk access API* to use SD cards as storage devices, or Zephyr's SD card subsystem to directly read from and write to a card.

SD Host Controller (SDHC)

An SD host controller (SDHC) is a device capable of sending commands to an SD card. These commands can be sent using a system's native SD card interface, or over SPI.

Applications should generally not use the SD host controller API directly, instead they should use Zephyr's SD card subsystem.

Requests The core of the SD host controller (SDHC) API is the `sdhc_request()` API. Requests contain a `sdhc_command` command structure, and an optional `sdhc_data` data structure. The caller may check the return code, or the `response` field of the SD command structure to determine if the SDHC request succeeded. The data structure allows the caller to specify a number of blocks to transfer, and a buffer location to read or write them from. Whether the provided buffer is used for sending or reading data depends on the command opcode provided.

Host Controller I/O The `sdhc_set_io()` API allows the user to change I/O settings of the SD host controller, such as clock frequency, I/O voltage, and card power. Not all controllers will support applying all I/O settings. For example, SPI mode controllers typically cannot toggle power to the SD card.

Related configuration options:

- `CONFIG_SDHC`

API Reference

SDHC

7.6.49 Sensors

The sensor driver API provides functionality to uniformly read, configure, and setup event handling for devices that take real world measurements in meaningful units.

Sensors range from very simple temperature-reading devices that must be polled with a fixed scale to complex devices taking in readings from multitudes of sensors and themselves producing new inferred sensor data such as step counts, presence detection, orientation, and more.

Supporting this wide breadth of devices is a demanding task and the sensor API attempts to provide a uniform interface to them.

Using Sensors

Using sensors from an application there are some APIs and terms that are helpful to understand. Sensors in Zephyr are composed of *Sensor Channels*, *Sensor Attributes*, and *Sensor Triggers*. Attributes and triggers may be device or channel specific.

> **Note**
>
> Getting samples from sensors using the sensor API today can be done in one of two ways. A stable and long-lived API *Fetch and Get*, or a newer but rapidly stabilizing API *Read and Decode*. It's expected that in the near future *Fetch and Get* will be deprecated in favor of *Read and Decode*. Triggers are handled entirely differently for *Fetch and Get* or *Read and Decode* and the differences are noted in each of those sections.

Sensor Attributes *Attributes*, enumerated in `sensor_attribute`, are immutable and mutable properties of a sensor and its channels.

Attributes allow for obtaining metadata and changing configuration of a sensor. Common configuration parameters like channel scale, sampling frequency, adjusting channel offsets, signal filtering, power modes, on chip buffers, and event handling options are very common. Attributes provide a flexible API for inspecting and manipulating such device properties.

Attributes are specified using `sensor_attribute` which can be used with `sensor_attr_get()` and `sensor_attr_set()` to get and set a sensors attributes.

A quick example...

```
const struct device *accel_dev = DEVICE_DT_GET(DT_ALIAS(accel0));
struct sensor_value accel_sample_rate;
int rc;

rc = sensor_attr_get(accel_dev, SENSOR_CHAN_ACCEL_XYZ,␣
↪SENSOR_ATTR_SAMPLING_FREQUENCY, &accel_sample_rate);
if (rc != 0) {
            printk("Failed to get sampling frequency\n");
}

printk("Sample rate for accel %p is %d.06%d\n", accel_dev, accel_sample_rate.val1,␣
↪accel_sample_rate.val2*1000000);

accel_sample_rate.val1 = 2000;

rc = sensor_attr_set(accel_dev, SENSOR_CHAN_ACCEL_XYZ,␣
↪SENSOR_ATTR_SAMPLING_FREQUENCY, accel_sample_rate);
if (rc != 0) {
            printk("Failed to set sampling frequency\n");
}
```

Sensor Channels *Channels*, enumerated in `sensor_channel`, are quantities that a sensor device can measure.

Sensors may have multiple channels, either to represent different axes of the same physical property (e.g. acceleration); or because they can measure different properties altogether (ambient temperature, pressure and humidity). Sensors may have multiple channels of the same measurement type to enable measuring many readings of perhaps temperature, light intensity, amperage, voltage, or capacitance for example.

A channel is specified in Zephyr using a `sensor_chan_spec` which is a pair containing both the channel type (`sensor_channel`) and channel index. At times only `sensor_channel` is used but this should be considered historical since the introduction of `sensor_chan_spec` for Zephyr 3.7.

Sensor Triggers *Triggers*, enumerated in `sensor_trigger_type`, are sensor generated events. Typically sensors allow setting up these events to cause digital line signaling for easy capture by a microcontroller. The events can then commonly be inspected by reading registers to determine which event caused the digital line signaling to occur.

There are many kinds of triggers sensors provide, from informative ones such as data ready to physical events such as taps or steps.

Power Management Power management of sensors is often a non-trivial task as sensors may have multiple power states for various channels. Some sensors may allow for low noise, low power, or suspending channels potentially saving quite a bit of power at the cost of noise or sampling speed performance. In very low power states sensors may lose their state, turning off even the digital logic portion of the device.

All this is to say that power management of sensors is typically application specific! Often the channel states are mutable using *Sensor Attributes*. While total device suspending and resume can be done using the power management ref counting APIs if the device implements the necessary functionality.

Most likely the API sensors should use for their fully suspended/resume power states is *Device Runtime Power Management* using explicit calls at an application level to `pm_device_runtime_get()` and `pm_device_runtime_put()`.

In the future, with *Read and Decode* its possible that automatic management of device power management would be possible in the streaming case as the application informs the driver of usage at all times through requests to read on given events.

Device Tree In the context of sensors device tree provides the initial hardware configuration for sensors on a per device level. Each device must specify a device tree binding in Zephyr, and ideally, a set of hardware configuration options for things such as channel power modes, data rates, filters, decimation, and scales. These can then be used in a boards devicetree to configure a sensor to its initial state.

        gyro-fs = <ICM42688_GYRO_FS_16>; /* 16G scale */
    };
};
```

Fetch and Get The stable and long existing APIs for reading sensor data and handling triggers are:

- `sensor_sample_fetch()`
- `sensor_sample_fetch_chan()`
- `sensor_channel_get()`
- `sensor_trigger_set()`

These functions work together. The fetch APIs block the calling context which must be a thread until the requested `sensor_channel` (or all channels) has been obtained and stored into the driver instance's private data.

The channel data most recently fetched can then be obtained as a `sensor_value` by calling `sensor_channel_get()` for each channel type.

Warning

It should be noted that calling fetch and get from multiple contexts without a locking mechanism is undefined and most sensor drivers do not attempt to internally provide exclusive access to the device during or between these calls.

Polling Using fetch and get sensor can be read in a polling manner from software threads.

#include <zephyr/sys/printk.h>
#include <stdio.h>

int main(void)
{
        const struct device *const dev = DEVICE_DT_GET(DT_ALIAS(magn0));
        struct sensor_value value_x, value_y, value_z;
        int ret;

        if (!device_is_ready(dev)) {
                printk("sensor: device not ready.\n");
                return 0;
        }

        printk("Polling magnetometer data from %s.\n", dev->name);

        while (1) {
                ret = sensor_sample_fetch(dev);
                if (ret) {
                        printk("sensor_sample_fetch failed ret %d\n", ret);
                        return 0;
                }

                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_X, &value_x);
                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_Y, &value_y);
                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_Z, &value_z);
                printf("( x y z ) = ( %f  %f  %f )\n",
                       sensor_value_to_double(&value_x),
                       sensor_value_to_double(&value_y),
                       sensor_value_to_double(&value_z));

                k_sleep(K_MSEC(500));
        }
        return 0;
}
```

Triggers Triggers in the stable API require enabling triggers with a device specific Kconfig. The device specific Kconfig typically allows selecting the context the trigger runs. The application then needs to register a callback with a function signature matching `sensor_trigger_handler_t` using `sensor_trigger_set()` for the specific triggers (events) to listen for.

Note

Triggers may not be set from user mode threads, and the callback is not run in a user mode context.

There are typically two options provided for each driver where to run trigger handlers. Either the trigger handler is run using the system work queue thread (*Workqueue Threads*) or a dedicated thread. A great example can be found in the BMI160 driver which has Kconfig options for selecting a trigger mode. See `CONFIG_BMI160_TRIGGER_NONE`, `CONFIG_BMI160_TRIGGER_GLOBAL_THREAD` (work queue), `CONFIG_BMI160_TRIGGER_OWN_THREAD` (dedicated thread).

Some notable attributes of using a driver dedicated thread vs the system work queue.

- Driver dedicated threads have dedicated stack (RAM) which only gets used for that single trigger handler function.
- Driver dedicated threads *do* get their own priority typically which lets you prioritize trigger handling among other threads.
- Driver dedicated threads will not have head of line blocking if the driver needs time to handle the trigger.

Note

In all cases it's very likely there will be variable delays from the actual interrupt to your callback function being run. In the work queue (GLOBAL_THREAD) case the work queue itself can be the source of variable latency!

                return rc;
        }

        return rc;
}
```

Read and Decode The quickly stabilizing APIs for reading sensor data are:

- `sensor_read()`
- `sensor_read_async_mempool()`
- `sensor_get_decoder()`
- `sensor_decode()`

Benefits over *Fetch and Get* These APIs allow for a wider usage of sensors, sensor types, and data flows with sensors. These are the future looking APIs in Zephyr and solve many issues that have been run into with *Fetch and Get*.

`sensor_read()` and similar functions acquire sensor encoded data into a buffer provided by the caller. Decode (`sensor_decode()`) then decodes the sensor specific encoded data into fixed point `q31_t` values as vectors per channel. This allows further processing using fixed point DSP functions that work on vectors of data to be done (e.g. low-pass filters, FFT, fusion, etc).

Reading is by default asynchronous in its implementation and takes advantage of *Real Time I/O (RTIO)* to enable chaining asynchronous requests, or starting requests against many sensors simultaneously from a single call context.

This enables incredibly useful code flows when working with sensors such as:

- Obtaining the raw sensor data, decoding never, later, or on a separate processor (e.g. a phone).
- Starting a read for sensors directly from an interrupt handler. No dedicated thread needed saving precious stack space. No work queue needed introducing variable latency. Starting a read for multiple sensors simultaneously from a single call context (interrupt/thread/work queue).
- Requesting multiple reads to the same device for Ping-Pong (double buffering) setups.
- Creating entire pipelines of data flow from sensors allowing for software defined virtual sensors (*Sensing Subsystem*) all from a single thread with DAG process ordering.
- Potentially pre-programming DMAs to trigger on GPIO events, leaving the CPU entirely out of the loop in handling sensor events like FIFO watermarks.

Additionally, other shortcomings of *Fetch and Get* related to memory and trigger handling are solved.

- Triggers result in enqueued events, not callbacks.
- Triggers can be setup to automatically fetch data. Potentially enabling pre-programmed DMA transfers on GPIO interrupts.
- Far less likely triggers are missed due to long held interrupt masks from callbacks and context swapping.
- Sensor FIFOs supported by wiring up FIFO triggers to read data into mempool allocated buffers.
- All sensor processing can be done in user mode (memory protected) threads.
- Multiple sensor channels of the same type are better supported.

Note

For *Read and Decode* benefits to be fully realized requires *Real Time I/O (RTIO)* compliant communication access to the sensor. Typically this means an *Real Time I/O (RTIO)* enabled bus driver for SPI or I2C.

Polling Read Polling reads with *Read and Decode* can be accomplished by instantiating a polling I/O device (akin to a file descriptor) for the sensor with the desired channels to poll. Requesting either blocking or non-blocking reads, then optionally decoding the data into fixed point values.

Polling a temperature sensor and printing its readout is likely the simplest sample to show how this all works.

```

 */

#include <zephyr/drivers/sensor.h>

#define TEMP_CHANNEL {SENSOR_CHAN_AMBIENT_TEMP, 0}

const struct device *const temp0 = DEVICE_DT_GET(DT_ALIAS(temp0));

SENSOR_DT_READ_IODEV(temp_iodev, DT_ALIAS(temp0), TEMP_CHANNEL);
RTIO_DEFINE(temp_ctx, 1, 1);

int main(void)
{
        int rc;
        uint8_t buf[8];
        struct sensor_q31_data temp_data = {0};
        struct sensor_decode_context temp_decoder = SENSOR_DECODE_CONTEXT_INIT(
                SENSOR_DECODER_DT_GET(DT_ALIAS(temp0)), buf,␣
↪SENSOR_CHAN_AMBIENT_TEMP, 0);

        while (1) {
                /* Blocking read */
                rc = sensor_read(temp_iodev, &temp_ctx, buf, sizeof(buf));
```

(continues on next page)

(continued from previous page)

```
                if (rc != 0) {
                        printk("sensor_read() failed %d\n", rc);
                }

                /* Decode the data into a single q31 */
                sensor_decode(&temp_decoder, &temp_data, 1);

                printk("Temperature " PRIsensor_q31_data "\n",
                       PRIsensor_q31_data_arg(temp_data, 0));

                k_msleep(1);
        }
}
```

Polling Read with Multiple Sensors One of the benefits of Read and Decode is the ability to concurrently read many sensors with many channels in one thread. Effectively read requests are started asynchronously for all sensors and their channels. When each read completes we then decode the sensor data. Examples speak loudly and so a sample showing how this might work with multiple temperature sensors with multiple temperature channels:

                               dev->name,
                               PRIsensor_three_axis_data_arg(accel_data, 0));
                }

                rtio_release_buffer(&accel_ctx, buf, buf_len);
        }
}
```

Implementing Sensor Drivers

> **Note**
>
> Implementing the driver side of the sensor API requires an understanding how the sensor APIs are used. Please read through *Using Sensors* first!

Implementing Attributes

- SHOULD implement attribute setting in a blocking manner.
- SHOULD provide the ability to get and set channel scale if supported by the device.
- SHOULD provide the ability to get and set channel sampling rate if supported by the device.

Implementing Fetch and Get

- SHOULD implement `sensor_sample_fetch_t` as a blocking call that stashes the specified channels (or all sensor channels) as driver instance data.
- SHOULD implement `sensor_channel_get_t` without side effects manipulating driver state returning stashed sensor readings.
- SHOULD implement `sensor_trigger_set_t` storing the address of the `sensor_trigger` rather than copying the contents. This is so `CONTAINER_OF` may be used for trigger callback context.

Implementing Read and Decode

- MUST implement `sensor_submit_t` as a non-blocking call.
- SHOULD implement `sensor_submit_t` using *Real Time I/O (RTIO)* to do non-blocking bus transfers if possible.
- MAY implement `sensor_submit_t` using a work queue if *Real Time I/O (RTIO)* is unsupported by the bus.
- SHOULD implement `sensor_submit_t` checking the `rtio_sqe` is of type `RTIO_SQE_RX` (read request).
- SHOULD implement `sensor_submit_t` checking all requested channels supported or respond with an error if not.
- SHOULD implement `sensor_submit_t` checking the provided buffer is large enough for the requested channels.

- SHOULD implement `sensor_submit_t` in a way that directly reads into the provided buffer avoiding copying of any kind, with few exceptions.
- MUST implement `sensor_decoder_api` with pure stateless functions. All state needed to convert the raw sensor readings into fixed point SI united values must be in the provided buffer.
- MUST implement `sensor_get_decoder_t` returning the `sensor_decoder_api` for that device type.

- HCI SPIExpose a Bluetooth controller to another device or CPU over SPI.
- SPI bitbangUse the bitbang SPI driver for communicating with a slave.
- SPIS wake upReduce current consumption by handling the wake line while using an SPIS.

7.6.52 Steppers

The stepper driver subsystem consists of two device driver APIs:

Stepper API

The stepper driver API provides a common interface for stepper drivers.

- Configure **micro-stepping resolution** using `stepper_set_micro_step_res()` and `stepper_get_micro_step_res()`.
- **Enable** the stepper driver using `stepper_enable()`.
- **Disable** the stepper driver using `stepper_disable()`.
- Register an **event callback** using `stepper_set_event_cb()`.

Stepper Motion Controller API

The stepper motion controller API provides a common interface for stepper motion controllers.

- Configure **reference position** in microsteps using `stepper_ctrl_set_reference_position()` and `stepper_ctrl_get_actual_position()`.
- Set **step interval** in nanoseconds between steps using `stepper_ctrl_set_microstep_interval()`
- **Move by** +/- micro-steps also known as **relative movement** using `stepper_ctrl_move_by()`.
- **Move to** a specific position also known as **absolute movement** using `stepper_ctrl_move_to()`.
- Run continuously with a **constant step interval** in a specific direction until a stop is detected using `stepper_ctrl_run()`.
- **Stop** the stepper using `stepper_ctrl_stop()`.
- Check if the stepper is **moving** using `stepper_ctrl_is_moving()`.
- Register an **event callback** using `stepper_ctrl_set_event_cb()`.

Device Tree

In the context of stepper motion controllers, devicetree provides the initial hardware configuration for stepper drivers on a per device level. Each device must specify a device tree binding in Zephyr, and ideally, a set of hardware configuration options for things such as current settings, ramp parameters and furthermore. These can then be used in a boards devicetree to configure a stepper driver to its initial state.

Driver Composition Scenarios Below are two typical scenarios:

Integrated Stepper Motion Control and Driver A device composed of both motion controller and stepper driver blocks in a single IC is modeled as a multi-functional device in devicetree, and has two software drivers implementing Stepper Motion Controller and Stepper Hardware Driver APIs respectively. An example of such device is `adi,tmc50xx`.

```
/ {
    aliases {
        x_axis_stepper_ctrl = &tmc50xx_0_motion_controller;
        y_axis_stepper_ctrl =  &tmc50xx_1_motion_controller;
        x_axis_stepper_driver = &tmc50xx_0_stepper_driver;
        y_axis_stepper_driver = &tmc50xx_1_stepper_driver;
    };
};

&spi0 {
    /* SPI bus options here, not shown */

    /* Dual controller/driver for up to two 2-phase bipolar stepper motors */
    tmc50xx: tmc50xx@0 {
        compatible = "adi,tmc50xx";
        reg = <0>;
        spi-max-frequency = <DT_FREQ_M(8)>; /* Maximum SPI bus frequency */

        poscmp-enable; test-mode; lock-gconf; /* ADI TMC Global configuration␣
↪flags */
        clock-frequency = <DT_FREQ_M(16)>; /* Internal/External Clock frequency */

        tmc50xx_0_stepper_driver: stepper-driver-0 {
            idx = <0>;
             compatible = "adi,tmc50xx-stepper-driver";
             micro-step-res = <256>;
             /* ADI TMC stallguard settings specific to TMC50XX */
             stallguard2-threshold=<30>;
         };

        tmc50xx_0_motion_controller: motion-controller-0 {
            idx = <0>;
            compatible = "adi,tmc50xx-stepper-ctrl";
            ...
            vmax = <900000>;
            amax = <50000>;
            ...
            activate-stallguard2;
            ...
         };

        tmc50xx_1_stepper_driver: stepper-driver-1 {
            idx = <1>;
             compatible = "adi,tmc50xx-stepper-driver";
             micro-step-res = <256>;
             /* ADI TMC stallguard settings specific to TMC50XX */
             stallguard2-threshold=<30>;
         };

        tmc50xx_1_motion_controller: motion-controller-1 {
```

(continues on next page)

(continued from previous page)

```
            idx = <1>;
            compatible = "adi,tmc50xx-stepper-ctrl";
            ...
            vstart = <1000>;
            ...
            stallguard-threshold-velocity=<200000>;
        };
    };
};
```

Following the aforementioned configurations, the stepper driver subsystem can be used in the application code as follows:

```
static const struct device *x_stepper_ctrl =␣
↪DEVICE_DT_GET(DT_ALIAS(x_axis_stepper_ctrl));
static const struct device *x_stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(x_axis_stepper_driver));
static const struct device *y_stepper_ctrl =␣
↪DEVICE_DT_GET(DT_ALIAS(y_axis_stepper_ctrl));
static const struct device *y_stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(y_axis_stepper_driver));
...
stepper_ctrl_move_to(x_stepper_ctrl, 200);
stepper_ctrl_stop(x_stepper_ctrl);
stepper_disable(x_stepper_driver);
stepper_disable(y_stepper_driver);
```

Individual Stepper Motion Controller and Driver Following is an example of a device tree configuration for a stepper driver with a dedicated stepper motion controller:

```
/ {
    aliases {
        stepper_driver = &tmc2209
        stepper_ctrl = &step_dir_motion_control;
    };

    tmc2209: tmc2209 {
        compatible = "adi,tmc2209";
        enable-gpios = <&gpioa 6 GPIO_ACTIVE_HIGH>;
        m0-gpios = <&gpiob 0 GPIO_ACTIVE_HIGH>;
        m1-gpios = <&gpioa 7 GPIO_ACTIVE_HIGH>;
    };

    step_dir_motion_control: step-dir-motion-control {
        compatible = "zephyr,gpio-step-dir-stepper-ctrl";
        step-gpios = <&gpioa 9 GPIO_ACTIVE_HIGH>;
        dir-gpios = <&gpioc 7 GPIO_ACTIVE_HIGH>;
        invert-direction;
        stepper-driver = <&tmc2209>;
    };
};
```

Following the aforementioned configurations, the stepper driver subsystem can be used in the application code as follows:

```
static const struct device *stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(stepper_driver));
static const struct device *stepper_ctrl = DEVICE_DT_GET(DT_ALIAS(stepper_ctrl));
...
stepper_ctrl_move_to(stepper_ctrl, 200);
stepper_ctrl_stop(stepper_ctrl);
stepper_disable(stepper_driver);
```

Stepper Motion Controller API Test Suite

The stepper motion controller API test suite provides a set of tests that can be used to verify the functionality of stepper motion controllers.

```
# From the root of the zephyr repository
west build -b <board> --extra-dtc-overlay <path/to/board.overlay>␣
↪tests/drivers/stepper/stepper_ctrl
west flash
```

Sample Output Below is a snippet of the test output for the h-bridge-stepper-ctrl.

```

7.6.53 System Management Bus (SMBus)

- *Overview*
- *SMBus Controller API*
- *Configuration Options*
- *API Reference*

Overview

System Management Bus (SMBus) is derived from I2C for communication with devices on the motherboard. A system may use SMBus to communicate with the peripherals on the motherboard without using dedicated control lines. SMBus peripherals can provide various manufacturer information, report errors, accept control parameters, etc.

Devices on the bus can operate in three roles: as a Controller that initiates transactions and controls the clock, a Peripheral that responds to transaction commands, or a Host, which is a specialized Controller, that provides the main interface to the system's CPU. Zephyr has API for the Controller role.

SMBus peripheral devices can initiate communication with Controller with two methods:

- **Host Notify protocol**: Peripheral device that supports the Host Notify protocol behaves as a Controller to perform the notification. It writes a three-bytes message to a special address "SMBus Host (0x08)" with own address and two bytes of relevant data.
- **SMBALERT# signal**: Peripheral device uses special signal SMBALERT# to request attention from the Controller. The Controller needs to read one byte from the special "SMBus Alert Response Address (ARA) (0x0c)". The peripheral device responds with a data byte containing its own address.

Currently, the API is based on SMBus Specification version 2.0

Note

See *Rule A.2: Inclusive Language* for information about the terminology used in this API.

SMBus Controller API

Zephyr's SMBus controller API is used when an SMBus device controls the bus, particularly the start and stop conditions and the clock. This is the most common mode used to interact with SMBus peripherals.

7.6.54 Universal Asynchronous Receiver-Transmitter (UART)

Overview

Zephyr provides three different ways to access the UART peripheral. Depending on the method, different API functions are used according to below sections:

1. *Polling API*
2. *Interrupt-driven API*
3. *Asynchronous API* using *Direct Memory Access (DMA)*

Polling is the most basic method to access the UART peripheral. The reading function, `uart_poll_in()`, is a non-blocking function and returns a character or `-1` when no valid data is available. The writing function, `uart_poll_out()`, is a blocking function and the thread waits until the given character is sent.

With the Interrupt-driven API, possibly slow communication can happen in the background while the thread continues with other tasks. The Kernel's *Data Passing* features can be used to communicate between the thread and the UART driver.

The Asynchronous API allows to read and write data in the background using DMA without interrupting the MCU at all. However, the setup is more complex than the other methods.

Warning

Interrupt-driven API and the Asynchronous API should NOT be used at the same time for the same hardware peripheral, since both APIs require hardware interrupts to function properly. Using the callbacks for both APIs would result in interference between each other. `CONFIG_UART_EXCLUSIVE_API_CALLBACKS` is enabled by default so that only the callbacks associated with one API is active at a time.

Configuration Options

Most importantly, the Kconfig options define whether the polling API (default), the interrupt-driven API or the asynchronous API can be used. Only enable the features you need in order to minimize memory footprint.

Related configuration options:

7.6.56 USB Type-C Port Controller (TCPC)

Overview

TCPC (USB Type-C Port Controller) The TCPC is a device used to simplify the implementation of a USB-C system by providing the following three function:

- VBUS and VCONN control USB Type-C: The TCPC may provide a Source device, the mechanism to control VBUS sourcing, and a Sink device, the mechanism to control VBUS sinking. A similar mechanism is provided for the control of VCONN.
- CC control and sensing: The TCPC implements logic for controlling the CC pin pull-up and pull-down resistors. It also provides a way to sense and report what resistors are present on the CC pin.
- Power Delivery message reception and transmission USB Power Delivery: The TCPC sends and receives messages constructed in the TCPM and places them on the CC lines.

TCPC API The TCPC device driver functions as the liaison between the TCPC device and the application software; this is accomplished by the Zephyr's API provided by the device driver that's used to communicate with and control the TCPC device.

7.6.58 Video

The video driver API offers a generic interface to video devices.

Basic Operation

Video Device A video device is the abstraction of a hardware or software video function, which can produce, process, consume or transform video data. The video API is designed to offer flexible way to create, handle and combine various video devices.

Endpoint Each video device can have one or more endpoints. Output endpoints configure video output function and generate data. Input endpoints configure video input function and consume data.

Video Buffer A video buffer provides the transport mechanism for the data. There is no particular requirement on the content. The requirement for the content is defined by the endpoint format. A video buffer can be queued to a device endpoint for filling (input ep) or consuming (output ep) operation, once the operation is achieved, buffer can be dequeued for post-processing, release or reuse.

Controls A video control is accessed and identified by a CID (control identifier). It represents a video control property. Different devices will have different controls available which can be generic, related to a device class or vendor specific. The set/get control functions provide a generic scalable interface to handle and create controls.

7.6.60 Wakeup Controller (WUC)

Overview

The Wakeup Controller (WUC) API provides a common interface for enabling and managing wakeup sources that can bring the system out of low-power states. WUC devices are typically described in Devicetree and referenced by clients using `wuc_dt_spec`.

Devicetree Configuration

Wakeup controllers are referenced from client nodes with the `wakeup-ctrls` property. The property encodes a phandle to the WUC device and an identifier for the wakeup source.

Example Devicetree fragment:

```
wuc0: wakeup-controller@40000000 {
    compatible = "nxp,mcx-wuc";
    reg = <0x40000000 0x1000>;
    #wakeup-ctrl-cells = <1>;
};

button0: button@0 {
    wakeup-ctrls = <&wuc0 10>;
};
```

Basic Operation

Applications typically obtain a `wuc_dt_spec` using `WUC_DT_SPEC_GET` and then enable or disable the wakeup source as needed.

Listing 3: Enable a wakeup source from Devicetree

```
#define BUTTON0_NODE DT_NODELABEL(button0)

static const struct wuc_dt_spec button_wuc =
    WUC_DT_SPEC_GET(BUTTON0_NODE);

if (!device_is_ready(button_wuc.dev)) {
    return -ENODEV;
}

return wuc_enable_wakeup_source_dt(&button_wuc);
```

If a driver supports it, applications can check and clear a wakeup source's triggered state. When not implemented, the APIs return `-ENOSYS`.

Listing 4: Check and clear a wakeup source

```
int ret;

ret = wuc_check_wakeup_source_triggered_dt(&button_wuc);
if (ret > 0) {
```

(continues on next page)

(continued from previous page)

```
    (void)wuc_clear_wakeup_source_triggered_dt(&button_wuc);
}
```

7.7 Pin Control

This is a high-level guide to pin control. See *Pin Control API* for API reference material.

7.7.1 Introduction

The hardware blocks that control pin multiplexing and pin configuration parameters such as pin direction, pull-up/down resistors, etc. are named **pin controllers**. The pin controller's main users are SoC hardware peripherals, since the controller enables exposing peripheral signals, like for example, map `I2C0 SDA` signal to pin `PX0`. Not only that, but it usually allows configuring certain pin settings that are necessary for the correct functioning of a peripheral, for example, the slew-rate depending on the operating frequency. The available configuration options are vendor/SoC dependent and can range from simple pull-up/down options to more advanced settings such as debouncing, low-power modes, etc.

The way pin control is implemented in hardware is vendor/SoC specific. It is common to find a *centralized* approach, that is, all pin configuration parameters are controlled by a single hardware block (typically named pinmux), including signal mapping. The figure below illustrates this approach. `PX0` can be mapped to `UART0_TX`, `I2C0_SCK` or `SPI0_MOSI` depending on the `AF` control bits. Other configuration parameters such as pull-up/down are controlled in the same block via `CONFIG` bits. This model is used by several SoC families, such as many from NXP and STM32.

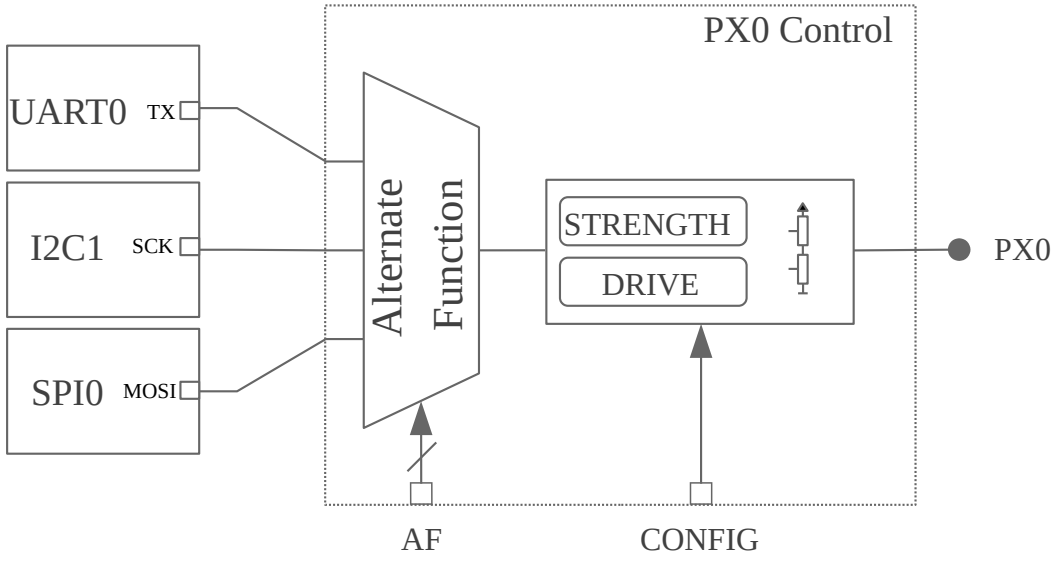

Fig. 3: Example of pin control centralized into a single per-pin block

Other vendors/SoCs use a *distributed* approach. In such case, the pin mapping and configuration are controlled by multiple hardware blocks. The figure below illustrates a distributed approach where pin mapping is controlled by peripherals, such as in Nordic nRF SoCs.

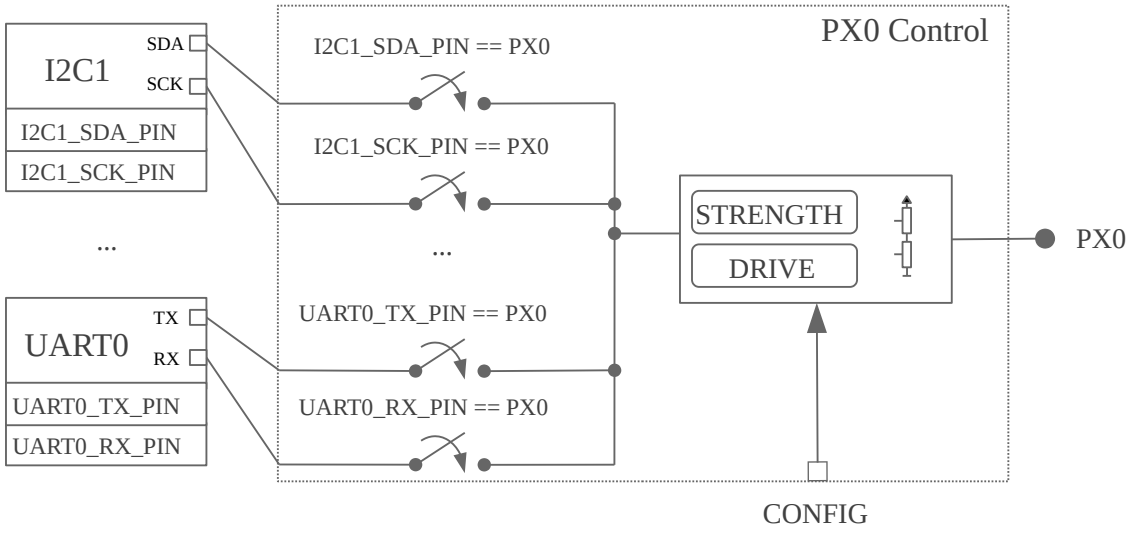

Fig. 4: Example pin control distributed between peripheral registers and per-pin block

From a user perspective, there is no difference in pin controller usage regardless of the hardware implementation: a user will always apply a state. The only difference lies in the driver implementation. In general, implementing a pin controller driver for a hardware that uses a distributed approach requires more effort, since the driver needs to gather knowledge of peripheral dependent registers.

Pin control vs. GPIO

Some functionality covered by a pin controller driver overlaps with GPIO drivers. For example, pull-up/down resistors can usually be enabled by both the pin control driver and the GPIO driver. In Zephyr context, the pin control driver purpose is to perform peripheral signal multiplexing and configuration of other pin parameters required for the correct operation of that peripheral. Therefore, the main users of the pin control driver are SoC peripherals. In contrast, GPIO drivers are for general purpose control of a pin, that is, when its logic level is read or controlled manually.

7.7.2 State model

For a device driver to operate correctly, a certain pin configuration needs to be applied. Some device drivers require a static configuration, usually set up at initialization time. Others need to change the configuration at runtime depending on the operating conditions, for example, to enable a low-power mode when suspending the device. Such requirements are modeled using **states**, a concept that has been adapted from the one in the Linux kernel. Each device driver owns a set of states. Each state has a unique name and contains a full pin configuration set (see the figure below). This effectively means that states are independent of each other, so they do not need to be applied in any specific order. Another advantage of the state model is that it isolates device drivers from pin configuration.

Table 3: Example pin configuration encoded using the states model

UART0 peripheral			
default state		sleep state	
TX	• Pin: PA0 • Pull: NONE • Low Power: NO	TX	• Pin: PA0 • Pull: NONE • Low Power: YES
RX	• Pin: PA1 • Pull: UP • Low Power: NO	RX	• Pin: PA1 • Pull: NONE • Low Power: YES

Standard states

The name assigned to pin control states or the number of them is up to the device driver requirements. In many cases a single state applied at initialization time will be sufficient, but in some other cases more will be required. In order to make things consistent, a naming convention has been established for the most common use cases. The figure below details the standardized states and its purpose.

Table 4: Standardized state names

State	Identifier	Purpose
default	PINCTRL_STATE_DEFAULT	State of the pins when the device is in operational state
sleep	PINCTRL_STATE_SLEEP	State of the pins when the device is in low power or sleep modes

Note that other standard states could be introduced in the future.

Custom states

Some device drivers may require using custom states beyond the standard ones. To achieve that, the device driver needs to have in its scope definitions for the custom state identifiers named as PINCTRL_STATE_{STATE_NAME}, where {STATE_NAME} is the capitalized state name. For example, if mystate has to be supported, a definition named PINCTRL_STATE_MYSTATE needs to be in the driver's scope.

Note

It is important that custom state identifiers start from PINCTRL_STATE_PRIV_START

If custom states need to be accessed from outside the driver, for example to perform dynamic pin control, custom identifiers should be placed in a header that is publicly accessible.

Skipping states

In most situations, the states defined in Devicetree will be the ones used in the compiled firmware. However, there are some cases where certain states will be conditionally used depending on a compilation flag. A typical case is the sleep state. This state is only used in practice if CONFIG_PM or CONFIG_PM_DEVICE is enabled. If a firmware variant without these power management configurations is needed, one should in theory remove the sleep state from Devicetree to not waste ROM space storing such unused state.

States can be skipped by the pinctrl Devicetree macros if a definition named PINCTRL_SKIP_{STATE_NAME} expanding to 1 is present when pin control configuration is defined.

In case of the sleep state, the pinctrl API already provides such definition conditional to the availability of device power management:

```
#if !defined(CONFIG_PM) && !defined(CONFIG_PM_DEVICE)
/** Out of power management configurations, ignore "sleep" state. */
#define PINCTRL_SKIP_SLEEP 1
#endif
```

7.7.3 Dynamic pin control

Dynamic pin control refers to the capability of changing pin configuration at runtime. This feature can be useful in situations where the same firmware needs to run onto slightly different boards, each having a peripheral routed at a different set of pins. This feature can be enabled by setting CONFIG_PINCTRL_DYNAMIC.

Note

Dynamic pin control should only be used on devices that have not been initialized. Changing pin configurations while a device is operating may lead to unexpected behavior. Since Zephyr does not support device de-initialization yet, this functionality should only be used during early boot stages.

One of the effects of enabling dynamic pin control is that pinctrl_dev_config will be stored in RAM instead of ROM (not states or pin configurations, though). The user can then use pinctrl_update_states() to update the states stored in pinctrl_dev_config with a new set. This effectively means that the device driver will apply the pin configurations stored in the updated states when it applies a state.

7.7.4 Devicetree representation

Because Devicetree is meant to describe hardware, it is the natural choice when it comes to storing pin control configuration. In the following sections you will find an overview on how states and pin configurations are represented in Devicetree.

States

Given a device, each of its pin control state is represented in Devicetree by pinctrl-N properties, being N the state index starting from zero. The pinctrl-names property is then used to assign a unique identifier for each state property by index, for example, pinctrl-names list entry 0 is the name for pinctrl-0.

```
periph0: periph@0 {
    ...
    /* state 0 ("default") */
    pinctrl-0 = <...>;
    ...
    /* state N ("mystate") */
    pinctrl-N = <...>;
    /* names for state 0 up to state N */
    pinctrl-names = "default", ..., "mystate";
    ...
};
```

Pin configuration

There are multiple ways to represent the pin configurations in Devicetree. However, all end up encoding the same information: the pin multiplexing and the pin configuration parameters. For example, `UART_RX` is mapped to `PX0` and pull-up is enabled. The representation choice largely depends on each vendor/SoC, so the Devicetree binding files for the pin control drivers are the best place to look for details.

A popular and versatile option is shown in the example below. One of the advantages of this choice is the grouping capability based on shared pin configuration. This allows to reduce the verbosity of the pin control definitions. Another advantage is that the pin configuration parameters for a particular state are enclosed in a single Devicetree node.

```
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_default>;
    pinctrl-names = "default";
};
```

```
/* vnd-soc-pkgxx.h
 * File with valid mappings for a specific package (may be autogenerated).
 * This file is optional, but recommended.
 */
...
#define PERIPH0_SIGA_PX0 VNDSOC_PIN(X, 0, MUX0)
#define PERIPH0_SIGB_PY7 VNDSOC_PIN(Y, 7, MUX4)
#define PERIPH0_SIGC_PZ1 VNDSOC_PIN(Z, 1, MUX2)
...
```

```
/* board-pinctrl.dtsi */
#include <vnd-soc-pkgxx.h>

&pinctrl {
    /* Node with pin configuration for default state */
    periph0_default: periph0_default {
        group1 {
            /* Mappings: PERIPH0_SIGA -> PX0, PERIPH0_SIGC -> PZ1 */
            pinmux = <PERIPH0_SIGA_PX0>, <PERIPH0_SIGC_PZ1>;
            /* Pins PX0 and PZ1 have pull-up enabled */
            bias-pull-up;
        };
        ...
        groupN {
            /* Mappings: PERIPH0_SIGB -> PY7 */
            pinmux = <PERIPH0_SIGB_PY7>;
        };
    };
};
```

Another popular model is based on having a node for each pin configuration and state. While this model may lead to shorter board pin control files, it also requires to have one node for each pin mapping and state, since in general, nodes can not be reused for multiple states. This method is discouraged if autogeneration is not an option.

Note

Because all Devicetree information is parsed into a C header, it is important to make sure its size is kept to a minimum. For this reason it is important to prefix pre-generated nodes with `/omit-if-no-ref/`. This prefix makes sure that the node is discarded when not used.

```
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_siga_px0_default &periph0_sigb_py7_default
                 &periph0_sigc_pz1_default>;
    pinctrl-names = "default";
};
```

```
/* vnd-soc-pkgxx.dtsi
 * File with valid nodes for a specific package (may be autogenerated).
 * This file is optional, but recommended.
 */

&pinctrl {
    /* Mapping for PERIPH0_SIGA -> PX0, to be used for default state */
    /omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
        pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    };

    /* Mapping for PERIPH0_SIGB -> PY7, to be used for default state */
    /omit-if-no-ref/ periph0_sigb_py7_default: periph0_sigb_py7_default {
        pinmux = <VNDSOC_PIN(Y, 7, MUX4)>;
    };

    /* Mapping for PERIPH0_SIGC -> PZ1, to be used for default state */
    /omit-if-no-ref/ periph0_sigc_pz1_default: periph0_sigc_pz1_default {
        pinmux = <VNDSOC_PIN(Z, 1, MUX2)>;
    };
};
```

```
/* board-pinctrl.dts */
#include <vnd-soc-pkgxx.dtsi>

/* Enable pull-up for PX0 (default state) */
&periph0_siga_px0_default {
    bias-pull-up;
};

/* Enable pull-up for PZ1 (default state) */
&periph0_sigc_pz1_default {
    bias-pull-up;
};
```

Note

It is discouraged to add pin configuration defaults in pre-defined nodes. In general, pin configurations depend on the board design or on the peripheral working conditions, so the decision should be made by the board. For example, enabling a pull-up by default may not always be

desired because the board already has one or because its value depends on the operating bus speed. Another downside of defaults is that user may not be aware of them, for example:

```
/* not evident that "periph0_siga_px0_default" also implies "bias-pull-up" */
/omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
    pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    bias-pull-up;
};
```

7.7.5 Implementation guidelines

Pin control drivers

Pin control drivers need to implement a single function: `pinctrl_configure_pins()`. This function receives an array of pin configurations that need to be applied. Furthermore, if `CONFIG_PINCTRL_STORE_REG` is set, it also receives the associated device register address for the given pins. This information may be required by some drivers to perform device specific actions.

The pin configuration is stored in an opaque type that is vendor/SoC dependent: `pinctrl_soc_pin_t`. This type needs to be defined in a header named `pinctrl_soc.h` file that is in the Zephyr's include path. It can range from a simple integer value to a struct with multiple fields. `pinctrl_soc.h` also needs to define a macro named `Z_PINCTRL_STATE_PINS_INIT` that accepts two arguments: a node identifier and a property name (`pinctrl-N`). With this information the macro needs to define an initializer for all pin configurations contained within the `pinctrl-N` property of the given node.

Regarding Devicetree pin configuration representation, vendors can decide which option is better for their devices. However, the following guidelines should be followed:

- Use `pinctrl-N` (N=0, 1, ...) and `pinctrl-names` properties to define pin control states. These properties are defined in `dts/bindings/pinctrl/pinctrl-device.yaml`.
- Use standard pin configuration properties as defined in `dts/bindings/pinctrl/pincfg-node.yaml`.

Representations not following these guidelines may be accepted if they are already used by the same vendor in other operating systems, e.g. Linux.

Device drivers

In this section you will find some tips on how a device driver should use the `pinctrl` API to successfully configure the pins it needs.

The device compatible needs to be modified in the corresponding binding so that the `pinctrl-device.yaml` is included. For example:

```
include: [base.yaml, pinctrl-device.yaml]
```

This file is needed to add `pinctrl-N` and `pinctrl-names` properties to the device.

From a device driver perspective there are two steps that need to be performed to be able to use the `pinctrl` API. First, the pin control configuration needs to be defined. This includes all states and pins. `PINCTRL_DT_DEFINE` or `PINCTRL_DT_INST_DEFINE` macros should be used for this purpose. Second, a reference to the device instance `pinctrl_dev_config` needs to be stored, since it is required to later use the API. This can be achieved using the `PINCTRL_DT_DEV_CONFIG_GET` and `PINCTRL_DT_INST_DEV_CONFIG_GET` macros.

It is worth to note that the only relationship between a device and its associated pin control configuration is based on variable naming conventions. The way an instance of `pinctrl_dev_config` is named for a corresponding device instance allows to later obtain a reference to it given the device's Devicetree node identifier. This allows to minimize ROM usage, since only devices requiring pin control will own a reference to a pin control configuration.

Once the driver has defined the pin control configuration and kept a reference to it, it is ready to use the API. The most common way to apply a state is by using `pinctrl_apply_state()`. It is also possible to use the lower level function `pinctrl_apply_state_direct()` to skip state lookup if it is cached in advance (e.g. at init time). Since state lookup time is expected to be fast, it is recommended to use `pinctrl_apply_state()`.

The example below contains a complete example of a device driver that uses the `pinctrl` API.

```
/* A driver for the "mydev" compatible device */
#define DT_DRV_COMPAT mydev

...
#include <zephyr/drivers/pinctrl.h>
...

struct mydev_config {
    ...
    /* Reference to mydev pinctrl configuration */
    const struct pinctrl_dev_config *pcfg;
    ...
};

...

static int mydev_init(const struct device *dev)
{
    const struct mydev_config *config = dev->config;
    int ret;
    ...
    /* Select "default" state at initialization time */
    ret = pinctrl_apply_state(config->pcfg, PINCTRL_STATE_DEFAULT);
    if (ret < 0) {
        return ret;
    }
    ...
}

#define MYDEV_DEFINE(i)                                                    \
    /* Define all pinctrl configuration for instance "i" */               \
    PINCTRL_DT_INST_DEFINE(i);                                             \
    ...                                                                    \
    static const struct mydev_config mydev_config_##i = {                 \
        ...                                                                \
        /* Keep a ref. to the pinctrl configuration for instance "i" */    \
        .pcfg = PINCTRL_DT_INST_DEV_CONFIG_GET(i),                         \
        ...                                                                \
    };                                                                     \
    ...                                                                    \
                                                                           \
    DEVICE_DT_INST_DEFINE(i, mydev_init, NULL, &mydev_data##i,             \
                          &mydev_config##i, ...);

DT_INST_FOREACH_STATUS_OKAY(MYDEV_DEFINE)

7.8 Porting

These pages document how to port Zephyr to new hardware.

7.8.1 Architecture Porting Guide

An architecture port is needed to enable Zephyr to run on an ISA (instruction set architecture) or an ABI (Application Binary Interface) that is not currently supported.

The following are examples of ISAs and ABIs that Zephyr supports:

- x86_32 ISA with System V ABI
- ARMv7-M ISA with Thumb2 instruction set and ARM Embedded ABI (aeabi)
- ARCv2 ISA

For information on Kconfig configuration, see *Setting Kconfig configuration values*. Architectures use a Kconfig configuration scheme similar to boards.

An architecture port can be divided in several parts; most are required and some are optional:

- **The early boot sequence**: each architecture has different steps it must take when the CPU comes out of reset (required).
- **Interrupt and exception handling**: each architecture handles asynchronous and unrequested events in a specific manner (required).
- **Thread context switching**: the Zephyr context switch is dependent on the ABI and each ISA has a different set of registers to save (required).
- **Thread creation and termination**: A thread's initial stack frame is ABI and architecture-dependent, and thread abortion possibly as well (required).
- **Device drivers**: most often, the system clock timer and the interrupt controller are tied to the architecture (some required, some optional).
- **Utility libraries**: some common kernel APIs rely on a architecture-specific implementation for performance reasons (required).
- **CPU idling/power management**: most architectures implement instructions for putting the CPU to sleep (partly optional, most likely very desired).
- **Fault management**: for implementing architecture-specific debug help and handling of fatal error in threads (partly optional).
- **Linker scripts and toolchains**: architecture-specific details will most likely be needed in the build system and when linking the image (required).
- **Memory Management and Memory Mapping**: for architecture-specific details on supporting memory management and memory mapping.

- **Stack Objects**: for architecture-specific details on memory protection hardware regarding stack objects.
- **User Mode Threads**: for supporting threads in user mode.
- **GDB Stub**: for supporting GDB stub to enable remote debugging.

Early Boot Sequence

The goal of the early boot sequence is to take the system from the state it is after reset to a state where is can run C code and thus the common kernel initialization sequence. Most of the time, very few steps are needed, while some architectures require a bit more work to be performed.

Common steps for all architectures:

- Setup an initial stack.
- If running an XIP (eXecute-In-Place) kernel, copy initialized data from ROM to RAM.
- If not using an ELF loader, zero the BSS section.
- Jump to `z_cstart()`, the early kernel initialization
  - `z_cstart()` is responsible for context switching out of the fake context running at startup into the main thread.

Some examples of architecture-specific steps that have to be taken:

- If given control in real mode on x86_32, switch to 32-bit protected mode.
- Setup the segment registers on x86_32 to handle boot loaders that leave them in an unknown or broken state.
- Initialize a board-specific watchdog on Cortex-M3/4.
- Switch stacks from MSP to PSP on Cortex-M.
- Use a different approach than calling into z_swap() on Cortex-M to prevent race conditions.
- Setup FIRQ and regular IRQ handling on ARCv2.

Early Boot Sequence Hooks Zephyr exposes several hooks (described in include/zephyr/platform/hooks.h) that allow execution of SoC- or board-specific code at precise moments of the boot process.

The kernel takes care of calling most of the hooks from architecture-agnostic code. However, some hooks must be called during the early boot sequence; since the sequence is implemented in architecture-specific code, the call to the hooks must also be done there. The following gives a rough overview of the early boot sequence and when hooks should be called by architecture-specific code:

1. Execution begins in an architecture-specific entry point whose name matches `CONFIG_KERNEL_ENTRY`.
2. Architecture-specific state is re-initialized immediately (if `CONFIG_INIT_ARCH_HW_AT_BOOT` is enabled).
3. `soc_early_reset_hook()` is called.

> **Note**
>
> It is not necessary to set up a valid stack before calling this hook. However, the hook is allowed to overwrite the stack pointer before returning. The architecture-specific code must not expect the stack pointer register value to be preserved across the call to `soc_early_reset_hook()`.

On architectures with multiple stack pointers, there is usually a *"primary"* stack pointer accessible directly and *"secondary"* stack pointer register(s). `soc_early_reset_hook()` implementations may overwrite the *"primary"* stack pointer must **not** read or modify the value of any *"secondary"* stack pointer. (This allows the architecture-specific code to set up any *"secondary"* stack pointer it desires before calling `soc_early_reset_hook()`)

For example, the ARM Cortex-A architecture defines several execution modes, each of which has its own stack pointer register `sp_mode`. When the processor is executing in mode `X`, operations involving the `sp` general-purpose register operate on `sp_X`. On this architecture, assuming that the processor is executing in mode `M` when `soc_early_reset_hook()` is called, the hook is allowed to overwrite `sp_M` (accessible through `sp`) but **must not** read or overwrite any other `sp_mode` (where `mode != M`).

`soc_early_reset_hook()` implementations are allowed to not return execution to the architecture-specific code, in which case they "take over" the system. Such hooks are not subject to the aforementioned rules and may read or overwrite any stack pointer. However, when such an implementation is provided, the rest of the early boot sequence obviously does not execute.

4. An initial stack is set up for next steps of the early boot sequence.
5. Architecture-specific "*resume from suspend-to-RAM*" logic is executed

Note

Refer to `CONFIG_PM_S2RAM` and the architecture-specific implementation for more details, but note that the rest of the early boot sequence is not executed if this logic determines that an exit from suspend-to-RAM is ongoing.

6. `soc_reset_hook()` is called.
7. *Architecture-specific operations (in assembly) are performed here...*
8. `z_prep_c()` is called. This architecture-specific function is implemented in C.
9. `z_prep_c()` immediately calls `soc_prep_hook()`.
10. *Architecture-specific operations (in C) are performed here...*
11. `z_cstart()` is called. Architecture-agnostic code begins executing.

Interrupt and Exception Handling

Each architecture defines interrupt and exception handling differently.

When a device wants to signal the processor that there is some work to be done on its behalf, it raises an interrupt. When a thread does an operation that is not handled by the serial flow of the software itself, it raises an exception. Both, interrupts and exceptions, pass control to a handler. The handler is known as an ISR (Interrupt Service Routine) in the case of interrupts. The handler performs the work required by the exception or the interrupt. For interrupts, that work is device-specific. For exceptions, it depends on the exception, but most often the core kernel itself is responsible for providing the handler.

The kernel has to perform some work in addition to the work the handler itself performs. For example:

- Prior to handing control to the handler:
  - Save the currently executing context.
  - Possibly getting out of power saving mode, which includes waking up devices.
  - Updating the kernel uptime if getting out of tickless idle mode.

- After getting control back from the handler:
  - Decide whether to perform a context switch.
  - When performing a context switch, restore the context being context switched in.

This work is conceptually the same across architectures, but the details are completely different:

- The registers to save and restore.
- The processor instructions to perform the work.
- The numbering of the exceptions.
- etc.

It thus needs an architecture-specific implementation, called the interrupt/exception stub.

Another issue is that the kernel defines the signature of ISRs as:

```
void (*isr)(void *parameter)
```

Architectures do not have a consistent or native way of handling parameters to an ISR. As such there are two commonly used methods for handling the parameter.

- Using some architecture defined mechanism, the parameter value is forced in the stub. This is commonly found in X86-based architectures.
- The parameters to the ISR are inserted and tracked via a separate table requiring the architecture to discover at runtime which interrupt is executing. A common interrupt handler demuxer is installed for all entries of the real interrupt vector table, which then fetches the device's ISR and parameter from the separate table. This approach is commonly used in the ARC and ARM architectures via the `CONFIG_GEN_ISR_TABLES` implementation. You can find examples of the stubs by looking at `_interrupt_enter()` in x86, `_isr_wrapper()` in ARM, or the full implementation description for ARC in arch/arc/core/isr_wrapper.S.

Each architecture also has to implement primitives for interrupt control:

- locking interrupts: `irq_lock()`, `irq_unlock()`.
- registering interrupts: `IRQ_CONNECT()`.
- programming the priority if possible `irq_priority_set()`.
- enabling/disabling interrupts: `irq_enable()`, `irq_disable()`.

Note

`IRQ_CONNECT` is a macro that uses assembler and/or linker script tricks to connect interrupts at build time, saving boot time and text size.

The vector table should contain a handler for each interrupt and exception that can possibly occur. The handler can be as simple as a spinning loop. However, we strongly suggest that handlers at least print some debug information. The information helps figuring out what went wrong when hitting an exception that is a fault, like divide-by-zero or invalid memory access, or an interrupt that is not expected (*spurious interrupt*). See the ARM implementation in arch/arm/core/cortex_m/fault.c for an example.

Thread Context Switching

Multi-threading is the basic purpose to have a kernel at all. Zephyr supports two types of threads: preemptible and cooperative. The rules for determining the next thread to schedule are handled by the kernel. However, it is up to the architecture port to implement the method of the context switch itself.

Zephyr provides two mutually exclusive interfaces for context switching. The preferred interface to use is `arch_switch` which is selected when `CONFIG_USE_SWITCH` is enabled. The alternative interface is `arch_swap`–selected when `CONFIG_USE_SWITCH` is disabled. When porting to a new architecture, only one of these needs to implemented; however, for SMP platforms it must be `arch_switch`.

A context switch can happen in several circumstances:

- When a thread executes a blocking operation, such as taking a semaphore that is currently unavailable.
- When a preemptible thread unblocks a thread of higher priority by releasing the object on which it was blocked.
- When an interrupt unblocks a thread of higher priority than the one currently executing, if the currently executing thread is preemptible.
- When a thread runs to completion.
- When a thread causes a fatal exception and is removed from the running threads. For example, referencing invalid memory,

Therefore, the context switching must thus be able to handle all these cases.

There are two types of context switches: *cooperative* and *preemptive*.

- A *cooperative* context switch happens when a thread willfully gives the control to another thread. There are two cases where this happens
  - When a thread explicitly yields.
  - When a thread tries to take an object that is currently unavailable and is willing to wait until the object becomes available.
- A *preemptive* context switch happens either because an ISR or a thread causes an operation that schedules a thread of higher priority than the one currently running, if the currently running thread is preemptible. An example of such an operation is releasing an object on which the thread of higher priority was waiting.

Note

Control is never taken from cooperative thread when one of them is the running thread.

A cooperative context switch is always done by having a thread call the internal kernel routine `z_swap` (or one of its variants). This in turn will call either `arch_switch` or `arch_swap` as appropriate. When these are called, no checks are done to determine if the context switch is to happen–the context switch must happen.

Note

On x86 and Nios2, `arch_swap` is generic enough and the architecture flexible enough that it can be called when exiting an interrupt to provoke the context switch. This should not be taken as a rule, since neither the ARM Cortex-M nor ARCv2 port do this.

Since `z_swap` is cooperative, the caller-saved registers from the ABI are already on the stack. There is no need to save them in the k_thread structure.

A context switch can also be performed preemptively. This happens upon exiting an ISR, in the kernel interrupt exit stub:

- `_interrupt_enter` on x86 after the handler is called.
- `z_arm_exc_exit` and `z_arm_int_exit` on ARM.

- `_firq_exit` and `_rirq_exit` on ARCv2.

The decision logic to invoke the context switch is simple and is only performed when exiting a non-nested interrupt:

When `CONFIG_USE_SWITCH` is enabled ...

- The interrupt exit code shall call `z_get_next_switch_handle()`, and return to the thread context identified by the returned switch handle

When `CONFIG_USE_SWITCH` is not enabled ...

- The interrupt exit code shall fetch the cached thread from the ready queue, and:
  - If the cached thread is not the current thread, invoke the context switch.
  - Otherwise do not invoke it.

This is simple, but crucial: if this is not implemented correctly, the kernel will not function as intended and will experience bizarre crashes, mostly due to stack corruption.

Thread Creation and Termination

To start a new thread, a stack frame must be constructed so that the context switch can pop it the same way it would pop one from a thread that had been context switched out. This is to be implemented in an architecture-specific `_new_thread` internal routine.

The thread entry point is also not to be called directly, i.e. it should not be set as the PC (program counter) for the new thread. Rather it must be wrapped in `_thread_entry`. This means that the PC in the stack frame shall be set to `_thread_entry`, and the thread entry point shall be passed as the first parameter to `_thread_entry`. The specifics of this depend on the ABI.

The need for an architecture-specific thread termination implementation depends on the architecture. There is a generic implementation, but it might not work for a given architecture.

One reason that has been encountered for having an architecture-specific implementation of thread termination is that aborting a thread might be different if aborting because of a graceful exit or because of an exception. This is the case for ARM Cortex-M, where the CPU has to be taken out of handler mode if the thread triggered a fatal exception, but not if the thread gracefully exits its entry point function.

This means implementing an architecture-specific version of `k_thread_abort()`, and setting the Kconfig option `CONFIG_ARCH_HAS_THREAD_ABORT` as needed for the architecture (e.g. see arch/arm/core/cortex_m/Kconfig).

Thread Local Storage

To enable thread local storage on a new architecture:

1. Implement `arch_tls_stack_setup()` to setup the TLS storage area in stack. Refer to the toolchain documentation on how the storage area needs to be structured. Some helper functions can be used:
   - Function `z_tls_data_size()` returns the size needed for thread local variables (excluding any extra data required by toolchain and architecture).
   - Function `z_tls_copy()` prepares the TLS storage area for thread local variables. This only copies the variable themselves and does not do architecture and/or toolchain specific data.
2. In the context switching, grab the `tls` field inside the new thread's `struct k_thread` and put it into an appropriate register (or some other variable) for access to the TLS storage area. Refer to toolchain and architecture documentation on which registers to use.
3. In kconfig, add `select CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` to kconfig related to the new architecture.

4. Run the `tests/kernel/threads/tls` to make sure the new code works.

Device Drivers

The kernel requires very few hardware devices to function. In theory, the only required device is the interrupt controller, since the kernel can run without a system clock. In practice, to get access to most, if not all, of the sanity check test suite, a system clock is needed as well. Since these two are usually tied to the architecture, they are part of the architecture port.

Interrupt Controllers There can be significant differences between the interrupt controllers and the interrupt concepts across architectures.

For example, x86 has the concept of an IDT and different interrupt controllers. The position of an interrupt in the IDT determines its priority.

On the other hand, the ARM Cortex-M has the NVIC (Nested Vectored Interrupt Controller) as part of the architecture definition. There is no need for an IDT-like table that is separate from the NVIC vector table. The position in the table has nothing to do with priority of an IRQ: priorities are programmable per-entry.

The ARCv2 has its interrupt unit as part of the architecture definition, which is somewhat similar to the NVIC. However, where ARC defines interrupts as having a one-to-one mapping between exception and interrupt numbers (i.e. exception 1 is IRQ1, and device IRQs start at 16), ARM has IRQ0 being equivalent to exception 16 (and weirdly enough, exception 1 can be seen as IRQ-15).

All these differences mean that very little, if anything, can be shared between architectures with regards to interrupt controllers.

System Clock x86 has APIC timers and the HPET as part of its architecture definition. ARM Cortex-M has the SYSTICK exception. Finally, ARCv2 has the timer0/1 device.

Kernel timeouts are handled in the context of the system clock timer driver's interrupt handler.

Console Over Serial Line There is one other device that is almost a requirement for an architecture port, since it is so useful for debugging. It is a simple polling, output-only, serial port driver on which to send the console (`printk`, `printf`) output.

It is not required, and a RAM console (`CONFIG_RAM_CONSOLE`) can be used to send all output to a circular buffer that can be read by a debugger instead.

Utility Libraries

The kernel depends on a few functions that can be implemented with very few instructions or in a lock-less manner in modern processors. Those are thus expected to be implemented as part of an architecture port.

- Atomic operators.
  - If instructions do exist for a given architecture, the implementation is configured using the `CONFIG_ATOMIC_OPERATIONS_ARCH` Kconfig option.
  - If instructions do not exist for a given architecture, a generic version that wraps `irq_lock()` or `irq_unlock()` around non-atomic operations exists. It is configured using the `CONFIG_ATOMIC_OPERATIONS_C` Kconfig option.
- Find-least-significant-bit-set and find-most-significant-bit-set.
  - If instructions do not exist for a given architecture, it is always possible to implement these functions as generic C functions.

It is possible to use compiler built-ins to implement these, but be careful they use the required compiler barriers.

CPU Idling/Power Management

The kernel provides support for CPU power management with two functions: `arch_cpu_idle()` and `arch_cpu_atomic_idle()`.

`arch_cpu_idle()` can be as simple as calling the power saving instruction for the architecture with interrupts unlocked, for example `hlt` on x86, `wfi` or `wfe` on ARM, `sleep` on ARC. This function can be called in a loop within a context that does not care if it get interrupted or not by an interrupt before going to sleep. There are basically two scenarios when it is correct to use this function:

- In a single-threaded system, in the only thread when the thread is not used for doing real work after initialization, i.e. it is sitting in a loop doing nothing for the duration of the application.
- In the idle thread.

`arch_cpu_atomic_idle()`, on the other hand, must be able to atomically re-enable interrupts and invoke the power saving instruction. It can thus be used in real application code, again in single-threaded systems.

Normally, idling the CPU should be left to the idle thread, but in some very special scenarios, these APIs can be used by applications.

Both functions must exist for a given architecture. However, the implementation can be simply the following steps, if desired:

1. unlock interrupts
2. NOP

However, a real implementation is strongly recommended.

Fault Management

In the event of an unhandled CPU exception, the architecture code must call into `z_fatal_error()`. This function dumps out architecture-agnostic information and makes a policy decision on what to do next by invoking `k_sys_fatal_error()`. This function can be overridden to implement application-specific policies that could include locking interrupts and spinning forever (the default implementation) or even powering off the system (if supported).

Toolchain and Linking

Toolchain support has to be added to the build system.

Some architecture-specific definitions are needed in include/zephyr/toolchain/gcc.h. See what exists in that file for currently supported architectures.

Each architecture also needs its own linker script, even if most sections can be derived from the linker scripts of other architectures. Some sections might be specific to the new architecture, for example the SCB section on ARM and the IDT section on x86.

Memory Management and Memory Mapping

If the target platform enables paging and requires drivers to memory-map their I/O regions, `CONFIG_MMU` needs to be enabled and the following API implemented:

- `arch_mem_map()`
- `arch_mem_unmap()`
- `arch_page_phys_get()`

Stack Objects

The presence of memory protection hardware affects how stack objects are created. All architecture ports must specify the required alignment of the stack pointer, which is some combination of CPU and ABI requirements. This is defined in architecture headers with ARCH_STACK_PTR_ALIGN and is typically something small like 4, 8, or 16 bytes.

Two types of thread stacks exist:

- "kernel" stacks defined with K_KERNEL_STACK_DEFINE() and related APIs, which can host kernel threads running in supervisor mode or used as the stack for interrupt/exception handling. These have significantly relaxed alignment requirements and use less reserved data. No memory is reserved for privilege elevation stacks.
- "thread" stacks which typically use more memory, but are capable of hosting thread running in user mode, as well as any use-cases for kernel stacks.

If CONFIG_USERSPACE is not enabled, "thread" and "kernel" stacks are equivalent.

Additional macros may be defined in the architecture layer to specify the alignment of the base of stack objects, any reserved data inside the stack object not used for the thread's stack buffer, and how to round up stack sizes to support user mode threads. In the absence of definitions some defaults are assumed:

- ARCH_KERNEL_STACK_RESERVED: default no reserved space
- ARCH_THREAD_STACK_RESERVED: default no reserved space
- ARCH_KERNEL_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_SIZE_ALIGN: default round up to ARCH_STACK_PTR_ALIGN

All stack creation macros are defined in terms of these.

Stack objects all have the following layout, with some regions potentially zero-sized depending on configuration. There are always two main parts: reserved memory at the beginning, and then the stack buffer itself. The bounds of some areas can only be determined at runtime in the context of its associated thread object. Other areas are entirely computable at build time.

Some architectures may need to carve-out reserved memory at runtime from the stack buffer, instead of unconditionally reserving it at build time, or to supplement an existing reserved area (as is the case with the ARM FPU). Such carve-outs will always be tracked in `thread.stack_info.start`. The region specified by `thread.stack_info.start` and `thread.stack_info.size` is always fully accessible by a user mode thread. `thread.stack_info.delta` denotes an offset which can be used to compute the initial stack pointer from the very end of the stack object, taking into account storage for TLS and ASLR random offsets.

```
+---------------------+ <- thread.stack_obj
| Reserved Memory     | } K_(THREAD|KERNEL)_STACK_RESERVED
+---------------------+
| Carved-out memory   |
|.....................| <- thread.stack_info.start
| Unused stack buffer |
|                     |
|.....................| <- thread's current stack pointer
| Used stack buffer   |
|                     |
|.....................| <- Initial stack pointer. Computable
| ASLR Random offset  |      with thread.stack_info.delta
+---------------------| <- thread.userspace_local_data
| Thread-local data   |
+---------------------+ <- thread.stack_info.start + thread.stack_info.size
```

At present, Zephyr does not support stacks that grow upward.

No Memory Protection If no memory protection is in use, then the defaults are sufficient.

HW-based stack overflow detection This option uses hardware features to generate a fatal error if a thread in supervisor mode overflows its stack. This is useful for debugging, although for a couple reasons, you can't reliably make any assertions about the state of the system after this happens:

- The kernel could have been inside a critical section when the overflow occurs, leaving important global data structures in a corrupted state.
- For systems that implement stack protection using a guard memory region, it's possible to overshoot the guard and corrupt adjacent data structures before the hardware detects this situation.

To enable the `CONFIG_HW_STACK_PROTECTION` feature, the system must provide some kind of hardware-based stack overflow protection, and enable the `CONFIG_ARCH_HAS_STACK_PROTECTION` option.

Two forms of HW-based stack overflow detection are supported: dedicated CPU features for this purpose, or special read-only guard regions immediately preceding stack buffers.

`CONFIG_HW_STACK_PROTECTION` only catches stack overflows for supervisor threads. This is not required to catch stack overflow from user threads; `CONFIG_USERSPACE` is orthogonal.

This feature only detects supervisor mode stack overflows, including stack overflows when handling system calls. It doesn't guarantee that the kernel has not been corrupted. Any stack overflow in supervisor mode should be treated as a fatal error, with no assertions about the integrity of the overall system possible.

Stack overflows in user mode are recoverable (from the kernel's perspective) and require no special configuration; `CONFIG_HW_STACK_PROTECTION` only applies to catching overflows when the CPU is in supervisor mode.

CPU-based stack overflow detection If we are detecting stack overflows in supervisor mode via special CPU registers (like ARM's SPLIM), then the defaults are sufficient.

Guard-based stack overflow detection We are detecting supervisor mode stack overflows via special memory protection region located immediately before the stack buffer that generates an exception on write. Reserved memory will be used for the guard region.

`ARCH_KERNEL_STACK_RESERVED` should be defined to the minimum size of a memory protection region. On most ARM CPUs this is 32 bytes. `ARCH_KERNEL_STACK_OBJ_ALIGN` should also be set to the required alignment for this region.

MMU-based systems should not reserve RAM for the guard region and instead simply leave an non-present virtual page below every stack when it is mapped into the address space. The stack object will still need to be properly aligned and sized to page granularity.

```
+---------------------------+ <- thread.stack_obj
| Guard reserved memory     | } K_KERNEL_STACK_RESERVED
+---------------------------+
| Guard carve-out           |
|...........................| <- thread.stack_info.start
| Stack buffer              |
.                           .
```

Guard carve-outs for kernel stacks are uncommon and should be avoided if possible. They tend to be needed for two situations:

- The same stack may be re-purposed to host a user thread, in which case the guard is unnecessary and shouldn't be unconditionally reserved. This is the case when privilege elevation stacks are not inside the stack object.
- The required guard size is variable and depends on context. For example, some ARM CPUs have lazy floating point stacking during exceptions and may decrement the stack pointer by a large value without writing anything, completely overshooting a minimally-sized guard and corrupting adjacent memory. Rather than unconditionally reserving a larger guard, the extra memory is carved out if the thread uses floating point.

User mode enabled Enabling user mode activates two new requirements:

- A separate fixed-sized privilege mode stack, specified by `CONFIG_PRIVILEGED_STACK_SIZE`, must be allocated that the user thread cannot access. It is used as the stack by the kernel when handling system calls. If stack guards are implemented, a stack guard region must be able to be placed before it, with support for carve-outs if necessary.
- The memory protection hardware must be able to program a region that exactly covers the thread's stack buffer, tracked in `thread.stack_info`. This implies that `ARCH_THREAD_STACK_SIZE_ADJUST()` will need to round up the requested stack size so that a region may cover it, and that `ARCH_THREAD_STACK_OBJ_ALIGN()` is also specified per the granularity of the memory protection hardware.

This becomes more complicated if the memory protection hardware requires that all memory regions be sized to a power of two, and aligned to their own size. This is common on older MPUs and is known with `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT`.

`thread.stack_info` always tracks the user-accessible part of the stack object, it must always be correct to program a memory protection region with user access using the range stored within.

Non power-of-two memory region requirements On systems without power-of-two region requirements, the reserved memory area for threads stacks defined by `K_THREAD_STACK_RESERVED` may be used to contain the privilege mode stack. The layout could be something like:

```
+-----------------------------+ <- thread.stack_obj
| Other platform data         |
+-----------------------------+
| Guard region (if enabled)   |
+-----------------------------+
| Guard carve-out (if needed) |
|.............................|
| Privilege elevation stack   |
+-----------------------------| <- thread.stack_obj +
| Stack buffer                |      K_THREAD_STACK_RESERVED =
.                             .      thread.stack_info.start
```

The guard region, and any carve-out (if needed) would be configured as a read-only region when the thread is created.

- If the thread is a supervisor thread, the privilege elevation region is just extra stack memory. An overflow will eventually crash into the guard region.
- If the thread is running in user mode, a memory protection region will be configured to allow user threads access to the stack buffer, but nothing before or after it. An overflow in user mode will crash into the privilege elevation stack, which the user thread has no access to. An overflow when handling a system call will crash into the guard region.

On an MMU system there should be no physical guards; the privilege mode stack will be mapped into kernel memory, and the stack buffer in the user part of memory, each with non-present virtual guard pages below them to catch runtime stack overflows.

Other platform data may be stored before the guard region, but this is highly discouraged if such data could be stored in `thread.arch` somewhere.

`ARCH_THREAD_STACK_RESERVED` will need to be defined to capture the size of the reserved region containing platform data, privilege elevation stacks, and guards. It must be appropriately sized such that an MPU region to grant user mode access to the stack buffer can be placed immediately after it.

Power-of-two memory region requirements Thread stack objects must be sized and aligned to the same power of two, without any reserved memory to allow efficient packing in memory. Thus, any guards in the thread stack must be completely carved out, and the privilege elevation stack must be allocated elsewhere.

`ARCH_THREAD_STACK_SIZE_ADJUST()` and `ARCH_THREAD_STACK_OBJ_ALIGN()` should both be defined to `Z_POW2_CEIL()`. `K_THREAD_STACK_RESERVED` must be 0.

For the privilege stacks, the `CONFIG_GEN_PRIV_STACKS` must be, enabled. For every thread stack found in the system, a corresponding fixed-size kernel stack used for handling system calls is generated. The address of the privilege stacks can be looked up quickly at runtime based on the thread stack address using `z_priv_stack_find()`. These stacks are laid out the same way as other kernel-only stacks.

```
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj)
| Reserved memory             | } K_KERNEL_STACK_RESERVED
+-----------------------------+
| Guard carve-out (if needed) |
|.............................|
| Privilege elevation stack   |
|                             |
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj) +
                                     K_KERNEL_STACK_RESERVED +
                                     CONFIG_PRIVILEGED_STACK_SIZE

+-----------------------------+ <- thread.stack_obj
| MPU guard carve-out         |
| (supervisor mode only)      |
|.............................| <- thread.stack_info.start
| Stack buffer                |
.                             .
```

The guard carve-out in the thread stack object is only used if the thread is running in supervisor mode. If the thread drops to user mode, there is no guard and the entire object is used as the stack buffer, with full access to the associated user mode thread and `thread.stack_info` updated appropriately.

User Mode Threads

To support user mode threads, several kernel-to-arch APIs need to be implemented, and the system must enable the `CONFIG_ARCH_HAS_USERSPACE` option. Please see the documentation for each of these functions for more details:

- `arch_buffer_validate()` to test whether the current thread has access permissions to a particular memory region
- `arch_user_mode_enter()` which will irreversibly drop a supervisor thread to user mode privileges. The stack must be wiped.
- `arch_syscall_oops()` which generates a kernel oops when system call parameters can't be validated, in such a way that the oops appears to be generated from where the system call was invoked in the user thread

- arch_syscall_invoke0() through arch_syscall_invoke6() invoke a system call with the appropriate number of arguments which must all be passed in during the privilege elevation via registers.
- arch_is_user_context() return nonzero if the CPU is currently running in user mode
- arch_mem_domain_max_partitions_get() which indicates the max number of regions for a memory domain. MMU systems have an unlimited amount, MPU systems have constraints on this.

Some architectures may need to update software memory management structures or modify hardware registers on another CPU when memory domain APIs are invoked. If so, CONFIG_ARCH_MEM_DOMAIN_SYNCHRONOUS_API must be selected by the architecture and some additional APIs must be implemented. This is common on MMU systems and uncommon on MPU systems:

- arch_mem_domain_thread_add()
- arch_mem_domain_thread_remove()
- arch_mem_domain_partition_add()
- arch_mem_domain_partition_remove()

Please see the doxygen documentation of these APIs for details.

In addition to implementing these APIs, there are some other tasks as well:

- _new_thread() needs to spawn threads with K_USER in user mode
- On context switch, the outgoing thread's stack memory should be marked inaccessible to user mode by making the appropriate configuration changes in the memory management hardware.. The incoming thread's stack memory should likewise be marked as accessible. This ensures that threads can't mess with other thread stacks.
- On context switch, the system needs to switch between memory domains for the incoming and outgoing threads.
- Thread stack areas must include a kernel stack region. This should be inaccessible to user threads at all times. This stack will be used when system calls are made. This should be fixed size for all threads, and must be large enough to handle any system call.
- A software interrupt or some kind of privilege elevation mechanism needs to be established. This is closely tied to how the _arch_syscall_invoke macros are implemented. On system call, the appropriate handler function needs to be looked up in _k_syscall_table. Bad system call IDs should jump to the K_SYSCALL_BAD handler. Upon completion of the system call, care must be taken not to leak any register state back to user mode.

GDB Stub

To enable GDB stub for remote debugging on a new architecture:

1. Create a new gdbstub.h header file under appropriate architecture include directory (include/zephyr/arch/<arch>/gdbstub.h).
   - Create a new struct struct gdb_ctx as the GDB context.
     - Must define a member named exception of type unsigned int to store the GDB exception reason. This value needs to be set before entering z_gdb_main_loop().
     - Architecture can define as many members as needed for GDB stub to function.
     - Pointer to this struct needs to be passed to z_gdb_main_loop(), where this pointer will be passed to other GDB stub functions.
2. Functions for entering and exiting GDB stub main loop.

- If the architecture relies on interrupts to service breakpoints, interrupt service routines (ISR) need to be implemented, which will serve as the entry point to GDB stub main loop.
- These functions need to save and restore context so code execution can continue as if no breakpoints have been encountered.
- These functions need to call `z_gdb_main_loop()` after saving execution context to go into the GDB stub main loop to receive commands from GDB.
- Before calling `z_gdb_main_loop()`, `gdb_ctx.exception` must be set to specify the exception reason.

3. Implement necessary functions to support GDB stub functionality:
   - `arch_gdb_init()`
     - This needs to initialize necessary bits to support GDB stub functionality, for example, setting up the GDB context and connecting debug interrupts.
     - This must stop code execution via architecture specific method (e.g. raising debug interrupts). This allows GDB to connect during boot.
   - `arch_gdb_continue()`
     - This function is called when GDB sends a `c` or `continue` command to continue code execution.
   - `arch_gdb_step()`
     - This function is called when GDB sends a `si` or `stepi` command to execute one machine instruction, before returning to GDB prompt.
   - Hardware register read/write functions:
     - Since the GDB stub is running on the target, manipulation of hardware registers need to cached to avoid affecting the execution of GDB stub. Think of it as context switching, where the execution context is changed to the GDB stub. So that the register values of the running thread before context switch need to be stored. Manipulation of register values must only be done to this cached copy. The updated values will then be written to hardware registers before switching back to the previous running thread.
     - `arch_gdb_reg_readall()`
       - This collects all hardware register values that would appear in a `g`/`G` packets which will be sent back to GDB. The format of the G-packet is architecture specific. Consult GDB on what is expected.
       - Note that, for most architectures, a valid G-packet must be returned and sent to GDB. If a packet without incorrect length is sent to GDB, GDB will abort the debugging session.
     - `arch_gdb_reg_writeall()`
       - This takes a G-packet sent by GDB and populates the hardware registers with values from the G-packet.
     - `arch_gdb_reg_readone()`
       - This reads the value of one hardware register and sends the result to GDB.
     - `arch_gdb_reg_writeone()`
       - This writes the value of one hardware register received from GDB.
   - Breakpoints:
     - `arch_gdb_add_breakpoint()` and `arch_gdb_remove_breakpoint()`

  - GDB may decide to use software breakpoints which modifies the memory at the breakpoint locations to replace the instruction with software breakpoint or trap instructions. GDB will then restore the memory content once execution reaches the breakpoints. GDB supports this by default and there is usually no need to handle software breakpoints in the architecture code (where breakpoint type is `0`).
  - Hardware breakpoints (type `1`) are required if the code is in ROM or flash that cannot be modified at runtime. Consult the architecture datasheet on how to enable hardware breakpoints.
  - If hardware breakpoints are not supported by the architecture, there is no need to implement these in architecture code. GDB will then rely on software breakpoints.

4. For architecture where certain memory regions are not accessible, an array named `gdb_mem_region_array` of type `gdb_mem_region` needs to be defined to specify regions that are accessible. For each array item:
   - `gdb_mem_region.start` specifies the start of a memory region.
   - `gdb_mem_region.end` specifies the end of a memory region.
   - `gdb_mem_region.attributes` specifies the permission of a memory region.
     - `GDB_MEM_REGION_RO`: region is read-only.
     - `GDB_MEM_REGION_RW`: region is read-write.
   - `gdb_mem_region.alignment` specifies read/write alignment of a memory region. Use `0` if there is no alignment requirement and read/write can be done byte-by-byte.

7.8.2 SoC Porting Guide

This page describes how to add support for a new *SoC* in Zephyr, be it in the upstream Zephyr project or locally in your own repository.

SoC Definitions

It is expected that you are familiar with the board concept in Zephyr. A high level overview of the hardware support hierarchy and terms used in the Zephyr documentation can be seen in *Hardware support hierarchy*.

For SoC porting, the most important terms are:

- SoC: the exact system on a chip the board's CPU is part of.
- SoC series: a group of tightly related SoCs.
- SoC family: a wider group of SoCs with similar characteristics.
- CPU cluster: a cluster of one or more CPU cores.
- CPU core: a particular CPU instance of a given architecture.
- Architecture: an instruction set architecture.

Architecture See *Architecture Porting Guide*.

Create your SoC directory

Each SoC must have a unique name. Use the official name given by the SoC vendor and check that it's not already in use. In some cases someone else may have contributed a SoC with identical name. If the SoC name is already in use, then you should probably improve the existing SoC instead of creating a new one. The script `list_hardware` can be used to retrieve a list of all SoCs known in Zephyr, for example `./scripts/list_hardware.py --soc-root=. --socs` from the Zephyr base directory for a list of names that are already in use.

Start by creating the directory `zephyr/soc/<VENDOR>/soc1`, where `<VENDOR>` is your vendor sub-directory.

Note

A `<VENDOR>` subdirectory is mandatory if contributing your SoC to Zephyr, but if your SoC is placed in a local repo, then any folder structure under `<your-repo>/soc` is permitted. The `<VENDOR>` subdirectory must match a vendor defined in the list in dts/bindings/vendor-prefixes.txt. If the SoC vendor does not have a prefix in that list, then one must be created.

Note

The SoC directory name does not need to match the name of the SoC. Multiple SoCs can even be defined in one directory. In Zephyr, SoCs are often organized in sub-folders in a common SoC Family or SoC Series tree.

Your SoC directory should look like this:

```
soc/<VENDOR>/<soc-name>
├── soc.yml
├── soc.h
├── CMakeLists.txt
├── Kconfig
├── Kconfig.soc
└── Kconfig.defconfig
```

Replace `<soc-name>` with your SoC's name.

The mandatory files are:

1. `soc.yml`: a YAML file describing the high-level meta data of the SoC such as:
   - SoC name: the name of the SoC
   - CPU clusters: CPU clusters if the SoC contains one or more clusters
   - SoC series: the SoC series to which the SoC belong
   - SoC family: the SoC family to which the series belong
2. `soc.h`: a header file which can be used to describe or provide configuration macros for the SoC. The `soc.h` will often be included in drivers, sub-systems, boards, and other source code found in Zephyr.
3. `Kconfig.soc`: the base SoC configuration which defines a Kconfig SoC symbol in the form of `config SOC_<soc-name>` and provides the SoC name to the Kconfig `SOC` setting. If the `soc.yml` describes a SoC family and series, then those must also be defined in this file. Kconfig settings outside of the SoC tree must not be selected. To select general Zephyr Kconfig settings the `Kconfig` file must be used.
4. `CMakeLists.txt`: CMake file loaded by the Zephyr build system. This CMake file can define additional include paths and/or source files to be used when a build targets the SoC. Also the base line linker script to use must be defined.

The optional files are:

- `Kconfig`, `Kconfig.defconfig` software configuration in *Configuration System (Kconfig)* format. These select the architecture and peripherals available.

Write your SoC YAML

The SoC YAML file describes the SoC family, SoC series, and SoC at a high level.

Detailed configurations, such as hardware description and configuration are done in devicetree and Kconfig.

The skeleton of a simple SoC YAML file containing just one SoC is:

```yaml
socs:
  - name: <soc1>
```

It is possible to have multiple SoC located in the SoC folder. For example if they belong to a common family or series it is recommended to locate such SoC in a common tree. Multiple SoCs and SoC series in a common folder can be described in the `soc.yml` file as:

```yaml
family:
  - name: <family-name>
    series:
      - name: <series-1-name>
        socs:
          - name: <soc1>
            cpuclusters:
```

(continues on next page)

(continued from previous page)

```
              - name: <coreA>
              - name: <coreB>
                ...
          - name: <soc2>
      - name: <series-2-name>
        ...
```

Write your SoC devicetree

SoC devicetree include files are located in the `<zephyr-repo>/dts` folder under a corresponding `<ARCH>/<VENDOR>`.

The SoC `dts/<ARCH>/<VENDOR>/<soc>.dtsi` describes your SoC hardware in the Devicetree Source (DTS) format and must be included by any boards which use the SoC.

If a highlevel `<arch>.dtsi` file exists, then a good starting point is to include this file in your `<soc>.dtsi`.

In general, `<soc>.dtsi` should look like this:

```
#include <arch>/<arch>.dtsi

/ {
        chosen {
                /* common chosen settings for your SoC */
        };

        cpus {
                #address-cells = <m>;
                #size-cells = <n>;

                cpu@0 {
                device_type = "cpu";
                compatible = "<compatibles>";
                /* ... your CPU definitions ... */
        };

        soc {
                /* Your SoC definitions and peripherals */
                /* such as ram, clock, buses, peripherals. */
        };
};
```

Hint

It is possible to structure multiple `<VENDOR>/<soc>.dtsi` files in sub-directories for a cleaner file system structure. For example organized pre SoC series, like this: `<VENDOR>/<SERIES>/<soc>.dtsi`.

Multiple CPU clusters Devicetree reflects the hardware. The memory space and peripherals available to one CPU cluster can be very different from another CPU cluster, therefore each CPU cluster will often have its own `.dtsi` file.

CPU cluster `.dtsi` files should follow the naming scheme `<soc>_<cluster>.dtsi`. A `<soc>_<cluster>.dtsi` file will look similar to a SoC `.dtsi` without CPU clusters.

Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your SoC needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in *Setting Kconfig configuration values*.

There is one mandatory Kconfig file in the SoC directory, and two optional files for a SoC:

```
soc/<vendor>/<your soc>
├── Kconfig.soc
├── Kconfig
└── Kconfig.defconfig
```

`Kconfig.soc`
: A shared Kconfig file which can be sourced both in Zephyr Kconfig and sysbuild Kconfig trees.

  This file selects the SoC family and series in the Kconfig tree and potential other SoC related Kconfig settings. In some cases a SOC_PART_NUMBER. This file must not select anything outside the reusable Kconfig SoC tree.

  A `Kconfig.soc` may look like this:

```
config SOC_FAMILY_<SOC_FAMILY_NAME>
        bool

config SOC_SERIES_<SOC_SERIES_NAME>
        bool
        select SOC_FAMILY_<SOC_FAMILY_NAME>

config SOC_<SOC_NAME>
        bool
        select SOC_SERIES_<SOC_SERIES_NAME>

config SOC_FAMILY
        default "<soc_family_name>" if SOC_FAMILY_<SOC_FAMILY_NAME>

config SOC_SERIES
        default "<soc_series_name>" if SOC_SERIES_<SOC_SERIES_NAME>

config SOC
        default "<soc_name>" if SOC_<SOC_NAME>
```

  Notice that `SOC_NAME` is a pure uppercase version of the SoC name, `SOC_SERIES_NAME` is a pure uppercase version of SoC series name and `SOC_FAMILY_NAME` is a pure uppercase version of the SoC family name. If these fields do not appear in the `soc.yml` file then they should not be present in the `Kconfig.soc` file.

  The Kconfigs `SOC`, `SOC_SERIES` and `SOC_FAMILY` settings are globally defined as strings and therefore the `Kconfig.soc` file shall only define the default string values and not the types. Notice that the string values must match the values used in the `soc.yml` file.

Note

The build system supports any variation of case for `soc_name`, `soc_series_name` and `soc_family_mame`, but when submitting boards for inclusion in Zephyr itself, these must be purely lowercase versions of the Kconfig names

`Kconfig`
: Included by soc/Kconfig.

  This file can add Kconfig settings which are specific to the current SoC.

  The `Kconfig` will often indicate given hardware support using a setting of the form `HAS_<support>`.

```
config SOC_<SOC_NAME>
        select ARM
        select CPU_HAS_FPU
```

  If the setting name is identical to an existing Kconfig setting in Zephyr and only modifies the default value of said setting, then `Kconfig.defconfig` should be used instead.

`Kconfig.defconfig`
: SoC specific default values for Kconfig options.

  Not all SoCs have a `Kconfig.defconfig` file.

  The entire file should be inside a pair of `if SOC_<SOC_NAME>` / `endif` or `if SOC_SERIES_<SERIES_NAME>` / `endif`, like this:

```
if SOC_<SOC_NAME>

config NUM_IRQS
        default 32

endif # SOC_<SOC_NAME>
```

Multiple CPU clusters CPU clusters must provide additional Kconfig settings in the `Kconfig.soc` file. This will usually be in the form of `SOC_<SOC_NAME>_<CLUSTER>` so for a given `soc1` with two clusters `clusterA` and `clusterB`, then this will look like:

SoC's When a SoC defines CPU cluster

```
config SOC_SOC1_CLUSTERA
        bool
        select SOC_SOC1

config SOC_SOC1_CLUSTERB
        bool
        select SOC_SOC1
```

7.8.3 Board Porting Guide

To add Zephyr support for a new *board*, you at least need a *board directory* with various files in it. Files in the board directory inherit support for at least one SoC and all of its features. Therefore, Zephyr must support your *SoC* as well.

Transition to the current hardware model

Shortly after Zephyr 3.6.0 was released, a new hardware model was introduced to Zephyr. This new model overhauls the way both SoCs and boards are named and defined, and adds support for features that had been identified as important over the years. Among them:

- Support for multi-core, multi-arch AMP (Asymmetrical Multi Processing) SoCs
- Support for multi-SoC boards
- Support for reusing the SoC and board Kconfig trees outside of the Zephyr build system

- Support for advanced use cases with *Sysbuild (System build)*
- Removal of all existing arbitrary and inconsistent uses of Kconfig and folder names

All the documentation in this page refers to the current hardware model. Please refer to the documentation in Zephyr v3.6.0 (or earlier) for information on the previous, now obsolete, hardware model.

More information about the rationale, development and concepts behind the new model can be found in the original issue, the original Pull Request and, for a complete set of changes introduced, the hardware model v2 commit.

Some non-critical features, enhancements and improvements of the new hardware model are still in development. Check the hardware model v2 enhancements issue for a complete list.

The transition from the previous hardware model to the current one (commonly referred to as "hardware model v2") requires modifications to all existing board and SoC definitions. A decision was made not to provide direct backwards compatibility for the previous model, which leaves users transitioning from a previous version of Zephyr to one including the new model (v3.7.0 and onwards) with two options if they have an out-of-tree board (or SoC):

1. Convert the out-of-tree board to the current hardware model (recommended)
2. Take the SoC definition from Zephyr v3.6.0 and copy it to your downstream repository (ensuring that the build system can find it via a *zephyr module* or `SOC_ROOT`). This will allow your board, defined in the previous hardware model, to continue to work

When converting your board from the previous to the current hardware model, we recommend first reading through this page to understand the model in detail. You can then use the example-application conversion Pull Request as an example on how to port a simple board. Additionally, a conversion script is available and works reliably in many cases (though multi-core SoCs may not be handled entirely). Finally, the hardware model v2 commit contains the full conversion of all existing boards from the old to the current model, so you can use it as a complete conversion reference.

Hardware support hierarchy

Zephyr's hardware support is based on a series of hierarchical abstractions. Primarily, each *board* has one or more *SoC*. Each SoC can be optionally classed into an *SoC series*, which in turn may optionally belong to an *SoC family*. Each SoC has one or more *CPU cluster*, each containing one or more *CPU core* of a particular *architecture*.

You can visualize the hierarchy in the diagram below:

Below are some examples of the hierarchy described in this section, in the form of a *board* per row with its corresponding hierarchy entries. Notice how the *SoC series* and *SoC family* levels are not always used.

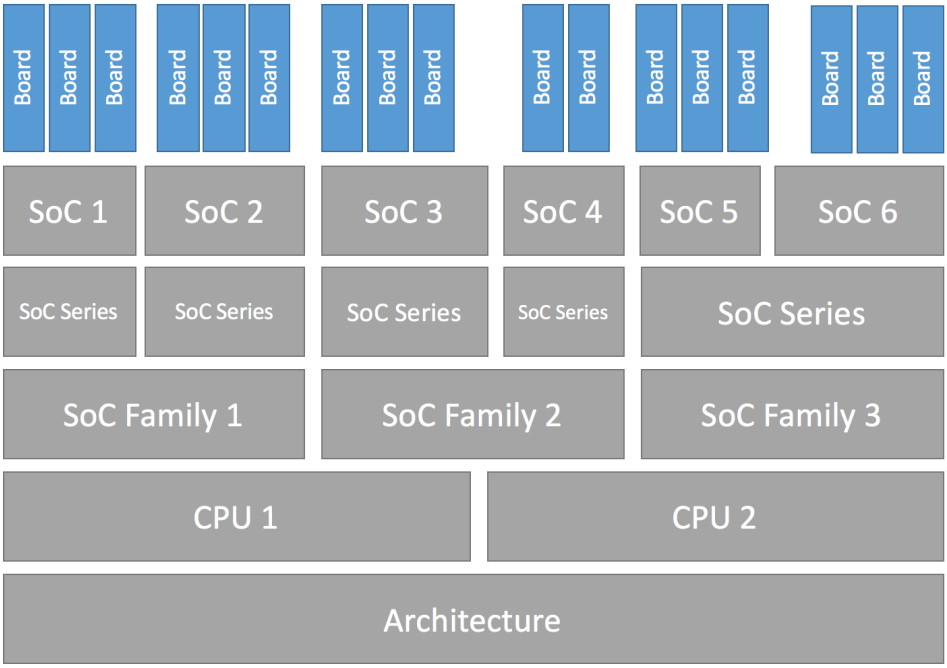

Fig. 5: Hardware support Hierarchy

board name	*board qualifiers*	*SoC*	*SoC Series*	*SoC family*	CPU core	*architecture*
nrf52dk	nrf52832	nRF52832	nRF52	Nordic nRF	Arm Cortex-M4	ARMv7-M
frdm_k64f	mk64f12	MK64F12	Kinetis K6x	NXP Kinetis	Arm Cortex-M4	ARMv7-M
rv32m1_vega	openisa_rv32m1/r	RV32M1	(Not used)	(Not used)	RI5CY	RISC-V RV32
nrf5340dk	nrf5340/cpuapp	nRF5340	nRF53	Nordic nRF	Arm Cortex-M33	ARMv8-M
	nrf5340/cpunet	nRF5340	nRF53	Nordic nRF	Arm Cortex-M33	ARMv8-M
mimx8mp_e	mimx8ml8/a53	i.MX8M Plus	i.MX8M	NXP i.MX	Arm Cortex-A53	ARMv8-A
	mimx8ml8/m7	i.MX8M Plus	i.MX8M	NXP i.MX	Arm Cortex-M7	ARMv7-M
	mimx8ml8/adsp	i.MX8M Plus	i.MX8M	NXP i.MX	Cadence HIFI4	Xtensa LX6

Additional details about terminology can be found in the next section.

Board terminology

The previous section introduced the hierarchical manner in which Zephyr classifies and implements hardware support. This section focuses on the terminology used around hardware support, and in particular when defining and working with boards and SoCs.

The overall set of terms used around the concept of board in Zephyr is depicted in the image below, which uses the bl5340_dvk board as reference.

The diagram shows the different terms that are used to describe boards:

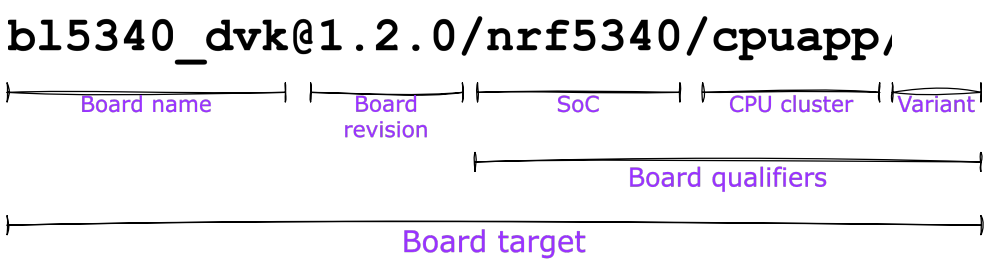

Fig. 6: Board terminology diagram

- The *board name*: `bl5340_dvk`
- The optional *board revision*: `1.2.0`
- The *board qualifiers*, that optionally describe the *SoC*, *CPU cluster* and *variant*: `nrf5340/cpuapp/ns`
- The *board target*, which uniquely identifies a combination of the above and can be used to specify the hardware to build for when using the tooling provided by Zephyr: `bl5340_dvk@1.2.0/nrf5340/cpuapp/ns`

Formally this can also be seen as *board name*`[@`*revision*`][/`*board qualifiers*`]`, which can be extended to *board name*`[@`*revision*`][/`*SoC*`[/`*CPU cluster*`][/`*variant*`]]`.

If a board contains only one single-core SoC, then the SoC can be omitted from the board target. This implies that if the board does not define any board qualifiers, the board name can be used as a board target. Conversely, if board qualifiers are part of the board definition, then the SoC can be omitted by leaving it out but including the corresponding forward-slashes: `//`.

Continuing with the example above, The board bl5340_dvk is a single SoC board where the SoC defines two CPU clusters: `cpuapp` and `cpunet`. One of the CPU clusters, `cpuapp`, additionally defines a non-secure board variant, `ns`.

The board qualifiers `nrf5340/cpuapp/ns` can be read as:

- `nrf5340`: The SoC, which is a Nordic nRF5340 dual-core SoC
- `cpuapp`: The CPU cluster `cpuapp`, which consists of a single Cortex-M33 CPU core. The number of cores in a CPU cluster cannot be determined from the board qualifiers.
- `ns`: a variant, in this case `ns` is a common variant name in Zephyr denoting a non-secure build for boards supporting *Trusted Firmware-M (TF-M)*.

Not all SoCs define CPU clusters or variants. For example a simple board like the thingy52 contains a single SoC with no CPU clusters and no variants. For `thingy52` the board target `thingy52/nrf52832` can be read as:

- `thingy52`: board name.
- `nrf52832`: The board qualifiers, in this case identical to the SoC, which is a Nordic nRF52832.

Make sure your SoC is supported

Start by making sure your SoC is supported by Zephyr. If it is, it's time to *Create your board directory*. If you don't know, try:

- checking boards for names that look relevant, and reading individual board documentation to find out for sure.
- asking your SoC vendor

If you need to add a SoC, CPU cluster, or even architecture support, this is the wrong page, but here is some general advice.

Architecture See *Architecture Porting Guide*.

CPU Core CPU core support files go in `core` subdirectories under arch, e.g. arch/x86/core.

See *Install a Toolchain* for information about toolchains (compiler, linker, etc.) supported by Zephyr. If you need to support a new toolchain, *Build and Configuration Systems* is a good place to start learning about the build system. Please reach out to the community if you are looking for advice or want to collaborate on toolchain support.

SoC Zephyr SoC support files are in architecture-specific subdirectories of soc. They are generally grouped by SoC family.

When adding a new SoC family or series for a vendor that already has SoC support within Zephyr, please try to extract common functionality into shared files to avoid duplication. If there is no support for your vendor yet, you can add it in a new directory `zephyr/soc/<VENDOR>/<YOUR-SOC>`; please use self-explanatory directory names.

Create your board directory

Once you've found an existing board that uses your SoC, you can usually start by copy/pasting its board directory and changing its contents for your hardware.

You need to give your board a unique name. Run `west boards` for a list of names that are already taken, and pick something new. Let's say your board is called `plank` (please don't actually use that name).

Start by creating the board directory `zephyr/boards/<VENDOR>/plank`, where `<VENDOR>` is your vendor subdirectory. (You don't have to put your board directory in the zephyr repository, but it's the easiest way to get started. See *Custom Board, Devicetree and SOC Definitions* for documentation on moving your board directory to a separate repository once it's working.)

Note

A `<VENDOR>` subdirectory is mandatory if contributing your board to Zephyr, but if your board is placed in a local repo, then any folder structure under `<your-repo>/boards` is permitted. If the vendor is defined in the list in dts/bindings/vendor-prefixes.txt then you must use that vendor prefix as `<VENDOR>`. `others` may be used as vendor prefix if the vendor is not defined.

Note

The board directory name does not need to match the name of the board. Multiple boards can even be defined in one directory.

Your board directory should look like this:

```
boards/<VENDOR>/plank
├── board.yml
├── board.cmake
├── CMakeLists.txt
├── doc
│   ├── plank.webp
│   └── index.rst
├── Kconfig.plank
├── Kconfig.defconfig
├── plank_<qualifiers>_defconfig
```

(continues on next page)

(continued from previous page)

```
├── plank_<qualifiers>.dts
└── plank_<qualifiers>.yaml
```

Replace `plank` with your board's name, of course.

The mandatory files are:

1. `board.yml`: a YAML file describing the high-level meta data of the boards such as the boards names, their SoCs, and variants. CPU clusters for multi-core SoCs are not described in this file as they are inherited from the SoC's YAML description.
2. `plank_<qualifiers>.dts`: a hardware description in *devicetree* format. This declares your SoC, connectors, and any other hardware components such as LEDs, buttons, sensors, or communication peripherals (USB, Bluetooth controller, etc).
3. `Kconfig.plank`: the base software configuration for selecting SoC and other board and SoC related settings. Kconfig settings outside of the board and SoC tree must not be selected. To select general Zephyr Kconfig settings the `Kconfig` file must be used.

The optional files are:

- `Kconfig`, `Kconfig.defconfig` software configuration in *Configuration System (Kconfig)* formats. This provides default settings for software features and peripheral drivers.
- `plank_defconfig` and `plank_<qualifiers>_defconfig`: software configuration in Kconfig `.conf` format.
- `board.cmake`: used for *Flash and debug support*
- `CMakeLists.txt`: if you need to add additional source files to your build.
- `doc/index.rst`, `doc/plank.webp`: documentation for and a picture of your board. You only need this if you're *Contributing your board* to Zephyr.
- `plank_<qualifiers>.yaml`: a YAML file with miscellaneous metadata used by the *Test Runner (Twister)*.

Board qualifiers of the form `<soc>/<cpucluster>/<variant>` are normalized so that `/` is replaced with `_` when used for filenames, for example: `soc1/foo` becomes `soc1_foo` when used in filenames.

Write your board YAML

The board YAML file describes the board at a high level. This includes the SoC, board variants, and board revisions.

Detailed configurations, such as hardware description and configuration are done in devicetree and Kconfig.

The skeleton of the board YAML file is:

```
board:
  name: <board-name>
  vendor: <board-vendor>
  revision:
    format: <major.minor.patch|letter|number|custom>
    default: <default-revision-value>
    exact: <true|false>
    revisions:
    - name: <revA>
    - name: <revB>
      ...
  socs:
```

(continues on next page)

(continued from previous page)

```
  - name: <soc-1>
    variants:
    - name: <variant-1>
    - name: <variant-2>
      variants:
      - name: <sub-variant-2-1>
        ...
  - name: <soc-2>
    ...
```

It is possible to have multiple boards located in the board folder. If multiple boards are placed in the same board folder, then the file `board.yml` must describe those in a list as:

```
boards:
- name: <board-name-1>
  vendor: <board-vendor>
  ...
- name: <board-name-2>
  vendor: <board-vendor>
  ...
...
```

Write your devicetree

The devicetree file `boards/<vendor>/plank/plank_<qualifiers>.dts` describes your board hardware in the Devicetree Source (DTS) format (as usual, change `plank` to your board's name). If you're new to devicetree, see *Introduction to devicetree*.

In general, `plank_<qualifiers>.dts` should look like this:

```
/dts-v1/;
#include <your_soc_vendor/your_soc.dtsi>

/ {
        model = "A human readable name";
        compatible = "yourcompany,plank";

        chosen {
                zephyr,console = &your_uart_console;
                zephyr,sram = &your_memory_node;
                /* other chosen settings  for your hardware */
        };

        /*
         * Your board-specific hardware: buttons, LEDs, sensors, etc.
         */

        leds {
                compatible = "gpio-leds";
                led0: led_0 {
                        gpios = < /* GPIO your LED is hooked up to */ >;
                        label = "LED 0";
                };
                /* ... other LEDs ... */
        };
```

(continues on next page)

(continued from previous page)

```
        buttons {
                compatible = "gpio-keys";
                /* ... your button definitions ... */
        };

        /* These aliases are provided for compatibility with samples */
        aliases {
                led0 = &led0; /* now you support the blinky sample! */
                /* other aliases go here */
        };
};

&some_peripheral_you_want_to_enable { /* like a GPIO or SPI controller */
        status = "okay";
};

&another_peripheral_you_want {
        status = "okay";
};
```

In the case a board has only a single SoC, without any board variants then the dts file can be named `<plank>.dts` instead, however this is not recommended due to the file silently be unused if a variant or other SoC is added to the board.

If you're in a hurry, simple hardware can usually be supported by copy/paste followed by trial and error. If you want to understand details, you will need to read the rest of the devicetree documentation and the devicetree specification.

Example: FRDM-K64F and Hexiwear K64 This section contains concrete examples related to writing your board's devicetree.

The FRDM-K64F and Hexiwear K64 board devicetrees are defined in frdm_k64fs.dts and hexiwear_k64.dts respectively. Both boards have NXP SoCs from the same Kinetis SoC family, the K6X.

Common devicetree definitions for K6X are stored in nxp_k6x.dtsi, which is included by both board `.dts` files. nxp_k6x.dtsi in turn includes armv7-m.dtsi, which has common definitions for Arm v7-M cores.

Since nxp_k6x.dtsi is meant to be generic across K6X-based boards, it leaves many devices disabled by default using `status` properties. For example, there is a CAN controller defined as follows (with unimportant parts skipped):

```
can0: can@40024000 {
     ...
     status = "disabled";
     ...
};
```

It is up to the board `.dts` or application overlay files to enable these devices as desired, by setting `status = "okay"`. The board `.dts` files are also responsible for any board-specific configuration of the device, such as adding nodes for on-board sensors, LEDs, buttons, etc.

For example, FRDM-K64 (but not Hexiwear K64) `.dts` enables the CAN controller and sets the bus speed:

```
&can0 {
     status = "okay";
};
```

The `&can0 { ... };` syntax adds/overrides properties on the node with label `can0`, i.e. the `can@4002400` node defined in the `.dtsi` file.

Other examples of board-specific customization is pointing properties in `aliases` and `chosen` to the right nodes (see *Aliases and chosen nodes*), and making GPIO/pinmux assignments.

Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your board needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in *Setting Kconfig configuration values*.

There is one mandatory Kconfig file in the board directory, and several optional files for a board named `plank`:

```
boards/<vendor>/plank
├── Kconfig
├── Kconfig.plank
├── Kconfig.defconfig
└── plank_<qualifiers>_defconfig
```

`Kconfig.plank`
: A shared Kconfig file which can be sourced both in Zephyr Kconfig and sysbuild Kconfig trees.

  This file selects the SoC in the Kconfig tree and potential other SoC related Kconfig settings. This file must not select anything outside the reusable Kconfig board and SoC trees.

  A `Kconfig.plank` may look like this:

  ```
  config BOARD_PLANK
          select SOC_SOC1
  ```

  The Kconfig symbols `BOARD_`*`board`* and `BOARD_`*`normalized_board_target`* are constructed by the build system, therefore no type shall be defined in above code snippet.

`Kconfig`
: Included by boards/Kconfig.

  This file can add Kconfig settings which are specific to the current board.

  Not all boards have a `Kconfig` file.

  A board specific setting should be defining a custom setting and usually with a prompt, like this:

  ```
  config BOARD_FEATURE
          bool "Board specific feature"
  ```

  If the setting name is identical to an existing Kconfig setting in Zephyr and only modifies the default value of said setting, then `Kconfig.defconfig` should be used instead.

`Kconfig.defconfig`
: Board-specific default values for Kconfig options.

  Not all boards have a `Kconfig.defconfig` file.

  The entire file should be inside an `if BOARD_PLANK` / `endif` pair of lines, like this:

  ```
  if BOARD_PLANK

  config FOO
  ```

(continues on next page)

(continued from previous page)

```
        default y

if NETWORKING

config SOC_ETHERNET_DRIVER
        default y

endif # NETWORKING

endif # BOARD_PLANK
```

plank_<qualifiers>_defconfig (or plank_defconfig in limited circumstances)
A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board.

`plank_defconfig` can only be used with boards that have no qualifiers, no variants and a single SoC present, though this style of naming is not recommended due to samples/tests or downstream usage breaking suddenly without warning if a new SoC or board variant/qualifier is added to an board in upstream Zephyr.

Note

Multiple files are not merged and there is no fallback mechanism for files, this means if there is a board with 2 different SoCs and each one has 2 board variants, a `plank_defconfig` file would be wholly unused, for the first qualifier and variant `plank_<soc1>_<variant1>_defconfig` will be used, it will not include other file.

The `_defconfig` should contain mandatory settings for your UART, console, etc. The results are architecture-specific, but typically look something like this:

```
CONFIG_GPIO=y
CONFIG_CONSOLE=y
CONFIG_UART_CONSOLE=y
CONFIG_SERIAL=y
```

plank_x_y_z_defconfig / plank_<qualifiers>_x_y_z_defconfig
A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board revision `x.y.z`.

Build, test, and fix

Now it's time to build and test the application(s) you want to run on your board until you're satisfied.

For example:

```
west build -b plank samples/hello_world
west flash
```

For `west flash` to work, see *Flash and debug support* below. You can also just flash `build/zephyr/zephyr.elf`, `zephyr.hex`, or `zephyr.bin` with any other tools you prefer.

General recommendations

For consistency and to make it easier for users to build applications which remain board agnostic, please follow these guidelines when porting a board you intend to contribute to Zephyr:

Enable valuable components in Devicetree
: Devicetree nodes for valuable onboard components (LEDs, buttons, sensors, onboard USB/Ethernet/BLE/Wi-Fi, etc.) must be **enabled by default** and have correct pin control and driver configuration so that they work out of the box.

Keep subsystems disabled by default (Kconfig)
: Do not enable subsystems in the board defconfig unless they are strictly required for basic board operation, or are explicitly listed as exceptions in these recommendations.

Configure system clock and tick source
: Set up a functioning system clock and tick source.

Provide a default console
: Use the `zephyr,console` chosen node to point to the UART controller used for console output.

  Boards with built-in debug or a USB-to-UART adapter should set the console to the UART controller connected to that adapter.

  USB-only boards without any debug adapter must include the common USB CDC-ACM Kconfig and DTS fragments to enable CDC-ACM UART as a default backend for logging and shell.

Add *shield interface* definitions
: For boards exposing standard expansion headers, add connector nodes and pin-muxing. Enable only the peripherals needed for the expected/standard connector functionality.

Configure pins and peripheral instances
: Map peripherals to the correct pins (e.g., SPI on Arduino SPI pins) and provide default pinmux entries supporting the board's features.

Enable networking interfaces
: If networking hardware is present, configure default interfaces for each supported technology so that networking samples work out of the box.

Enable GPIO controllers
: All GPIO ports connected to onboard components or expansion headers should be enabled.

Enable MPU and stack protection
: It is recommended to enable the MPU when available (unless memory resources are too limited). When the MPU is enabled, it is recommended to also enable hardware stack protection (`CONFIG_HW_STACK_PROTECTION`) to ease debugging by allowing the kernel to detect stack overflows.

Flash and debug support

Zephyr supports *Building, Flashing and Debugging* via west extension commands.

To add `west flash` and `west debug` support for your board, you need to create a `board.cmake` file in your board directory. This file's job is to configure a "runner" for your board. (There's nothing special you need to do to get `west build` support for your board.)

"Runners" are Zephyr-specific Python classes that wrap *flash and debug host tools* and integrate with west and the zephyr build system to support `west flash` and related commands. Each runner supports flashing, debugging, or both. You need to configure the arguments to these Python scripts in your `board.cmake` to support those commands like this example `board.cmake`:

```
board_runner_args(jlink "--device=nrf52" "--speed=4000")
board_runner_args(pyocd "--target=nrf52" "--frequency=4000000")

include(${ZEPHYR_BASE}/boards/common/nrfutil.board.cmake)
include(${ZEPHYR_BASE}/boards/common/nrfjprog.board.cmake)
include(${ZEPHYR_BASE}/boards/common/jlink.board.cmake)
include(${ZEPHYR_BASE}/boards/common/pyocd.board.cmake)
```

This example configures the nrfutil, nrfjprog, jlink, and pyocd runners.

Warning

Runners usually have names which match the tools they wrap, so the jlink runner wraps Segger's J-Link tools, and so on. But the runner command line options like --speed etc. are specific to the Python scripts.

Note

Runners and board configuration should be created without being targeted to a single operating system if the tool supports multiple operating systems, nor should it rely upon special system setup/configuration. For example; do not assume that a user will have prior knowledge/configuration or (if using Linux) special udev rules installed, do not assume one specific /dev/X device for all platforms as this will not be compatible with Windows or macOS, and allow for overriding of the selected device so that multiple boards can be connected to a single system and flashed/debugged at the choice of the user.

For more details:

- Run west flash --context to see a list of available runners which support flashing, and west flash --context -r <RUNNER> to view the specific options available for an individual runner.
- Run west debug --context and west debug --context <RUNNER> to get the same output for runners which support debugging.
- Run west flash --help and west debug --help for top-level options for flashing and debugging.
- See *Configuration Options* for Python APIs.
- Look for board.cmake files for other boards similar to your own for more examples.

To see what a west flash or west debug command is doing exactly, run it in verbose mode:

```
west --verbose flash
west --verbose debug
```

Verbose mode prints any host tool commands the runner uses.

The order of the include() calls in your board.cmake matters. The first include sets the default runner if it's not already set. For example, including nrfjprog.board.cmake first means that nrfjprog is the default flash runner for this board. Since nrfjprog does not support debugging, jlink is the default debug runner.

Multiple board revisions

See *Building for a board revision* for basics on this feature from the user perspective.

Board revisions are described in the revision entry of the board.yml.

```
board:
  revision:
    format: <major.minor.patch|letter|number|custom>
    default: <default-revision-value>
    exact: <true|false>
    revisions:
```

(continues on next page)

(continued from previous page)

```
  - name: <revA>
  - name: <revB>
```

Zephyr natively supports the following revision formats:

- `major.minor.patch`: match a three digit revision, such as `1.2.3`.
- `number`: matches integer revisions
- `letter`: matches single letter revisions from `A` to `Z` only

Fuzzy revision matching Fuzzy revision matching is enabled per default.

If the user selects a revision between those available, the closest revision number that is not larger than the user's choice is used. For example, if the board `plank` defines revisions `0.5.0`, and `1.5.0` and the user builds for `plank@0.7.0`, the build system will target revision `0.5.0`.

The build system will print this at CMake configuration time:

```
-- Board: plank, Revision: 0.7.0 (Active: 0.5.0)
```

This allows you to only create revision configuration files for board revision numbers that introduce incompatible changes.

Similarly for `letter` revision format, if revisions `A`, `D`, and `F` are defined and the user builds for `plank@E`, the build system will target revision `D`.

Exact revision matching Exact revision matching is enabled when `exact: true` is specified in the revision section in `board.yml`.

When exact is defined then building for `plank@0.7.0` in the above example will result in the following error message:

```
Board revision `0.7.0` not found.  Please specify a valid board revision.
```

Board revision configuration adjustment When the user builds for board `plank@<revision>` it is possible to make adjustments to the board's normal configuration.

As described in the *Write your devicetree* and *Write Kconfig files* sections the board default configuration is created from the files `<board>.dts` / `<board>_<qualifiers>.dts` and `<board>_defconfig` / `<board>_<qualifiers>_defconfig`. When building for a specific board revision, the above files are used as a starting point and the following board files will be used in addition:

- `<board>_<qualifiers>_<revision>_defconfig`: a specific revision defconfig which is only used for the board and SOC / variants identified by `<board>_<qualifiers>`.
- `<board>_<revision>_defconfig`: a specific revision defconfig which is used for the board regardless of the SOC / variants.
- `<board>_<qualifiers>_<revision>.overlay`: a specific revision dts overlay which is only used for the board and SOC / variants identified by `<board>_<qualifiers>`.
- `<board>_<revision>.overlay`: a specific revision dts overlay which is used for the board regardless of the SOC / variants.

This split allows boards with multiple SoCs, multi-core SoCs, or variants to place common revision adjustments which apply to all SoCs and variants in a single file, while still providing the ability to place SoC or variant specific adjustments in a dedicated revision file.

Using the `plank` board from previous sections, then we could have the following revision adjustments:

```
boards/zephyr/plank
├── plank_0_5_0_defconfig          # Kconfig adjustment for all plank board␣
↪qualifiers on revision 0.5.0
├── plank_0_5_0.overlay            # DTS overlay for all plank board qualifiers on␣
↪revision 0.5.0
└── plank_soc1_foo_1_5_0_defconfig # Kconfig adjustment for plank board when␣
↪building for soc1 variant foo on revision 1.5.0
```

Custom revision.cmake files

Some boards may not use board revisions supported natively by Zephyr. For example string revisions.

One reason why Zephyr doesn't support string revisions is that strings can take many forms and it's not always clear if the given strings are just strings, such as `blue`, `green`, `red`, etc. or if they provide an order which can be matched against higher or lower revisions, such as `alpha`, `beta`', `gamma`.

Due to the sheer number of possibilities with strings, including the possibility of doing regex matches internally, then string revisions must be done using `custom` revision type.

To indicate to the build system that `custom` revisions are used, the format field in the `revision` section of the `board.yml` must be written as:

```
board:
  revision:
    format: custom
```

When using custom revisions then a `revision.cmake` must be created in the board directory.

The `revision.cmake` will be included by the build system when building for the board and it is the responsibility of the file to validate the revision specified by the user.

The `BOARD_REVISION` variable holds the revision value specified by the user.

To signal to the build system that it should use a different revision than the one specified by the user, `revision.cmake` can set the variable `ACTIVE_BOARD_REVISION` to the revision to use instead. The corresponding Kconfig files and devicetree overlays must be named `<board>_<ACTIVE_BOARD_REVISION>_defconfig` and `<board>_<ACTIVE_BOARD_REVISION>.overlay`.

Contributing your board

If you want to contribute your board to Zephyr, first – thanks!

There are some extra things you'll need to do:

1. Make sure you've followed all the *General recommendations*. They are requirements for boards included with Zephyr.
2. Add documentation for your board using the template file doc/templates/board.tmpl. See *Documentation Generation* for information on how to build your documentation before submitting your pull request.
3. Prepare a pull request adding your board which follows the *Contribution Guidelines*.

Board extensions

The board hardware model in Zephyr allows you to extend an existing board with new board variants. Such board extensions can be done in your custom repository and thus outside of the Zephyr repository.

Extending an existing board with an extra variant allows you to adjust an existing board and thereby during build to select building for the existing, unmodified board, or the new variant.

To extend an existing board, first create a `board.yml` in your extended board. Make sure to use the directory structure described in *Create your board directory*.

The skeleton of the board YAML file for extending a board is:

```
board:
  extend: <existing-board-name>
  variants:
    - name: <new-variant>
      qualifier: <existing-qualifier>
```

When extending a board, your board directory should look like:

```
boards/<VENDOR>/plank
├── board.yml
├── plank_<new-qualifiers>_defconfig
└── plank_<new-qualifiers>.dts
```

Replace `plank` with the real name of the board you extend.

In some cases you might want to also adjust additional settings, like the `Kconfig.defconfig` or `Kconfig.board`. Therefore it is also possible to provide the following in addition when extending a board.

```
boards/<VENDOR>/plank
├── board.cmake
├── Kconfig
├── Kconfig.plank
├── Kconfig.defconfig
└── plank_<new-qualifiers>.yaml
```

7.8.4 Shields

Shields, also known as “add-on” or “daughter boards”, attach to a board to extend its features and services for easier and modularized prototyping. In Zephyr, the shield feature provides Zephyr-formatted shield descriptions for easier compatibility with applications.

Shield activation

Activate support for one or more shields by adding the matching `--shield` arguments to the west command:

```
west build -b your_board --shield x_nucleo_idb05a1 --shield␣
↪x_nucleo_iks01a1 your_app
```

Alternatively, it could be set by default in a project’s CMakeLists.txt:

```
set(SHIELD x_nucleo_iks01a1)
```

Shield interfaces

A shield is defined by two key characteristics:

1. **Physical connectors** - the mechanical interface
2. **Electrical signals** - what each pin actually does

The connection between a shield and a board happens through Devicetree files:

- Board side: The board's devicetree file uses a *GPIO nexus node* to map connector pins to the microcontroller's actual GPIO pins. It also defines labels for buses exposed through the connector (like `arduino_i2c`, `arduino_spi`, `arduino_uart`).
- Shield side: The shield's .overlay file references these same labels to describe how its components connect to the board.

At build time, the board's devicetree and the shield's overlay are combined to create a complete picture of the hardware setup.

For example, let's say you have a board with an Arduino connector but no built-in accelerometer. You can add one using an Arduino shield:

1. The board's Devicetree defines an `arduino_i2c` label: it is the I2C bus made available on the Arduino connector
2. The accelerometer shield's overlay file also references `arduino_i2c` to indicate it uses that same I2C bus. If it needs to use GPIO pins from the connector, it references the GPIO nexus node defined by the board's Devicetree (e.g. `arduino_header`).

When you then build for this board with this shield, Zephyr automatically "wires them" together.

Note

Some boards and shields may only support a limited set of features of a shield hardware interface. Refer to their documentation for more details.

Arduino MKR This is the form factor of the Arduino MKR boards.

Fig. 7: Arduino MKR Zero, an example of a board with the Arduino MKR shield interface

Relevant devicetree node labels:

- `arduino_mkr_header` See `arduino-mkr-header` for details on GPIO pin definitions and includes for use in devicetree files.
- `arduino_mkr_i2c`

- arduino_mkr_spi
- arduino_mkr_serial

Arduino Nano This is the form factor of the Arduino Nano boards.

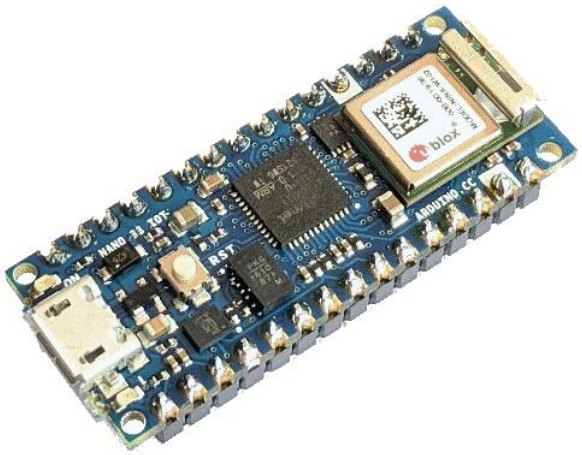

Fig. 8: Arduino Nano 33 IOT, an example of a board with the Arduino Nano shield interface

Relevant devicetree node labels:

- arduino_nano_header See arduino-nano-header for details on GPIO pin definitions and includes for use in devicetree files.
- arduino_nano_i2c
- arduino_nano_spi
- arduino_nano_serial

Arduino Uno R3 This is the form factor of the Arduino Uno R3 board.

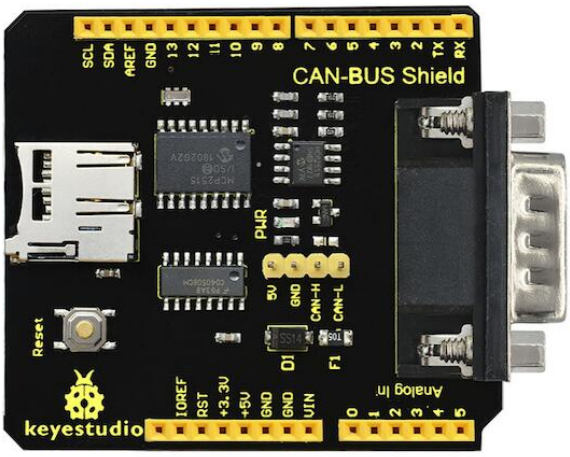

Fig. 9: Keyestudio CAN-BUS, an example of an Arduino shield (Credit: Keyestudio)

Relevant devicetree node labels:

- arduino_header See arduino-header-r3 for details on GPIO pin definitions and includes for use in devicetree files.
- arduino_adc See arduino,uno-adc

- `arduino_pwm` See `arduino-header-pwm`
- `arduino_serial`
- `arduino_i2c`
- `arduino_spi`

For technical details, see Arduino Uno R3 pinout.

Camera and display connectors These describe connections to cameras and displays (strictly speaking not shields).

- `arducam,dvp-20pin-connector`
- `nxp,cam-44pins-connector`
- `nxp,parallel-lcd-connector`
- `raspberrypi,csi-connector`
- `weact,dcmi-camera-connector`

Feather This is the form factor of the Adafruit Feather series of boards. Shields intended for Feather boards are called Featherwings.

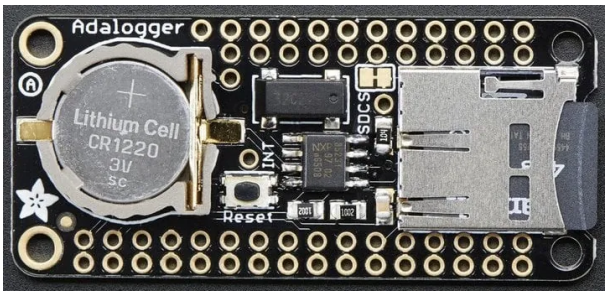

Fig. 10: Adafruit Adalogger, an example of a Featherwing (Credit: Adafruit)

Relevant devicetree node labels:

- `feather_header` See `adafruit-feather-header` for GPIO pin definitions.
- `feather_adc`
- `feather_i2c`
- `feather_serial`
- `feather_spi`

Microbit This is for the edge connector of the Microbit boards.

See `microbit,edge-connector` for GPIO pin definitions and links to technical requirements.

mikroBUS™ This is an interface standard for add-on boards, developed by Mikroe.

Relevant devicetree node labels:

- `mikrobus_header` See `mikro-bus` for GPIO pin definitions and links to technical specifications.
- `mikrobus_adc`
- `mikrobus_i2c`
- `mikrobus_spi`

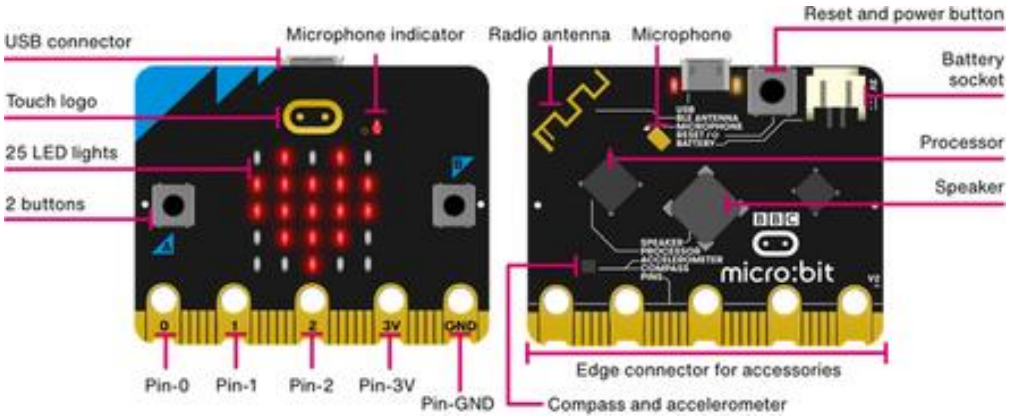

Fig. 11: Microbit V2 board uses the Microbit shield interface

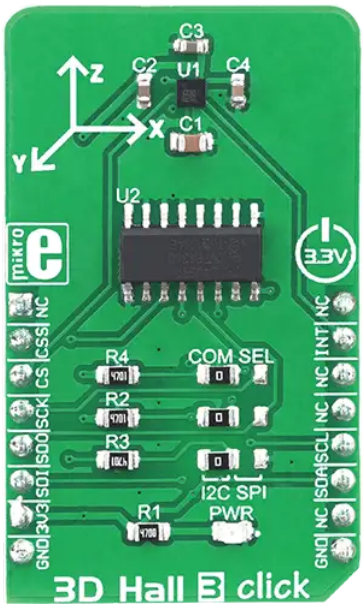

Fig. 12: 3D Hall 3 Click, an example of a mikroBUS™ shield

- `mikrobus_serial`

Note that boards with several mikroBUS™ connectors might define for example `mikrobus_2_spi`.

Pico This is the form factor of the Raspberry Pi Pico boards.

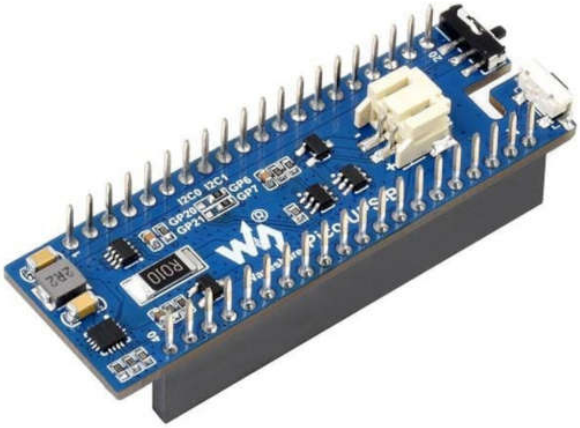

Fig. 13: Waveshare Pico UPS-B, an example of a Pico shield

Relevant devicetree node labels:

- `pico_header` See `raspberrypi,pico-header` for GPIO pin definitions.
- `pico_i2c` A node label that refers to the same node as either the node label `pico_i2c0` or `pico_i2c1`. It references the node that should be used with priority or as default.
- `pico_i2c0`
- `pico_i2c1`
- `pico_serial`
- `pico_spi`

ST Morpho Development boards from ST Microelectronics often uses the ST Morpho shield interface.

Fig. 14: X-NUCLEO-GFX01M2, an example of an ST Morpho shield

Relevant devicetree node labels:

- `st_morpho_header` See `st-morpho-header` for details on GPIO pin definitions and includes for use in devicetree files.

- st_morpho_lcd_spi
- st_morpho_flash_spi

Xiao This is the form factor of the Seeeduino XIAO boards.

Fig. 15: Seeed Studio XIAO Expansion Board, an example of a Xiao shield (Credit: Seeed Studio)

Relevant devicetree node labels:

- xiao_d See seeed,xiao-gpio for GPIO pin definitions.
- xiao_spi
- xiao_i2c
- xiao_serial
- xiao_adc
- xiao_dac

zephyr_i2c / Stemma QT / Quiic These are four-pin I2C connectors. SparkFun calls these connectors “Qwiic”, and Adafruit calls them “Stemma QT”. The I2C connectors have four pins; GND, +3.3 Volt, I2C data and I2C clock. The most common physical connector is the 1.0 mm pitch JST-SH.

Due to the different brand names, the interface is labeled “zephyr_i2c”.

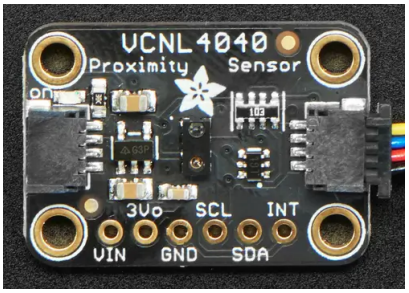

Fig. 16: Adafruit VCNL4040, an example of a zephyr_i2c shield (Credit: Adafruit)

See stemma-qt-connector and grove-header for descriptions and links to further details.

Relevant devicetree node labels:

- zephyr_i2c

Shield porting and configuration

Shield configuration files are available in the board directory under boards/shields:

```
boards/shields/<shield>
├── shield.yml
├── <shield>.overlay
├── Kconfig.shield
├── Kconfig.defconfig
└── pre_dt_shield.cmake
```

These files provides shield configuration as follows:

- **shield.yml**: This file provides metadata about the shield in YAML format. It must contain the following fields:
  - `name`: Name of the shield used in Kconfig and build system (required)
  - `full_name`: Full commercial name of the shield (required)
  - `vendor`: Manufacturer/vendor of the shield (required)
  - `supported_features`: List of hardware features the shield supports (optional). In order to help users identify the features a shield supports without having to dig into its overlay file, the `supported_features` field can be used to list the types of features the shield supports. The values should be the same as the ones defined in the dts/bindings/binding-types.txt file.

  Example:

  ```
  name: foo_shield
  full_name: Foo Shield for Arduino
  vendor: acme
  supported_features:
    - display
    - input
  ```

- **<shield>.overlay**: This file provides a shield description in devicetree format that is merged with the board's *devicetree* before compilation.
- **Kconfig.shield**: This file defines shield Kconfig symbols that will be used for default shield configuration. To ease use with applications, the default shield configuration here should be consistent with those in the *Write your devicetree*.
- **Kconfig.defconfig**: This file defines the default shield configuration. It is made to be consistent with the *Write your devicetree*. Hence, shield configuration should be done by keeping in mind that features activation is application responsibility.
- **pre_dt_shield.cmake**: This optional file can be used to pass additional arguments to the devicetree compiler `dtc`.

Besides, in order to avoid name conflicts with devices that may be defined at board level, it is advised, specifically for shields devicetree descriptions, to provide a device nodelabel is the form <device>_<shield>, for instance:

```
sdhc_myshield: sdhc@1 {
        reg = <1>;
        ...
};
```

Adding Source Code

It is possible to add source code to shields, as a way to meet configuration requirements that are specific to the shield (e.g: initialization routines, timing constraints, etc), in order to enable it for

proper operation with the different Zephyr components.

> **Note**
>
> Source code in shields shall not be used for purposes other than the one described above. Generic functionalities that could be reused among shields (and/or targets) shall not be captured here.

To effectively incorporate source code: add a `CMakeLists.txt` file, as well as the corresponding source files (referenced in CMake similar to other areas of Zephyr, e.g: boards).

Board compatibility

Hardware shield-to-board compatibility depends on the use of well-known connectors used on popular boards (such as Arduino and 96boards). For software compatibility, boards must also provide a configuration matching their supported connectors.

This should be done at two different level:

- Pinmux: Connector pins should be correctly configured to match shield pins
- Devicetree: A board *devicetree* file, `BOARD.dts` should define an alternate nodelabel for each connector interface. For example, for Arduino I2C:

```
arduino_i2c: &i2c1 {};
```

Board specific shield configuration If modifications are needed to fit a shield to a particular board or board revision, you can override a shield description for a specific board by adding board or board revision overriding files to a shield, as follows:

```
boards/shields/<shield>
└── boards
    ├── <board>_<revision>.overlay
    ├── <board>.overlay
    ├── <board>.defconfig
    ├── <board>_<revision>.conf
    └── <board>.conf
```

Shield variants

Some shields may support several variants or revisions. In that case, it is possible to provide multiple version of the shields description:

```
boards/shields/<shield>
├── <shield_v1>.overlay
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
└── <shield_v2>.defconfig
```

In this case, a shield-particular revision name can be used:

```
west build -b None --shield shield_v2 your_app
```

You can also provide a board-specific configuration to a specific shield revision:

```
boards/shields/<shield>
├── <shield_v1>.overlay
```

(continues on next page)

(continued from previous page)

```
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
├── <shield_v2>.defconfig
└── boards
    └── <shield_v2>
        ├── <board>.overlay
        └── <board>.defconfig
```

GPIO nexus nodes

GPIOs accessed by the shield peripherals must be identified using the shield GPIO abstraction, for example from the `arduino-header-r3` compatible. Boards that provide the header must map the header pins to SOC-specific pins. This is accomplished by including a nexus node that looks like the following into the board devicetree file:

```
arduino_header: connector {
        compatible = "arduino-header-r3";
        #gpio-cells = <2>;
        gpio-map-mask = <0xffffffff 0xffffffc0>;
        gpio-map-pass-thru = <0 0x3f>;
        gpio-map = <0 0 &gpioa 0 0>,    /* A0 */
                   <1 0 &gpioa 1 0>,    /* A1 */
                   <2 0 &gpioa 4 0>,    /* A2 */
                   <3 0 &gpiob 0 0>,    /* A3 */
                   <4 0 &gpioc 1 0>,    /* A4 */
                   <5 0 &gpioc 0 0>,    /* A5 */
                   <6 0 &gpioa 3 0>,    /* D0 */
                   <7 0 &gpioa 2 0>,    /* D1 */
                   <8 0 &gpioa 10 0>,   /* D2 */
                   <9 0 &gpiob 3 0>,    /* D3 */
                   <10 0 &gpiob 5 0>,   /* D4 */
                   <11 0 &gpiob 4 0>,   /* D5 */
                   <12 0 &gpiob 10 0>,  /* D6 */
                   <13 0 &gpioa 8 0>,   /* D7 */
                   <14 0 &gpioa 9 0>,   /* D8 */
                   <15 0 &gpioc 7 0>,   /* D9 */
                   <16 0 &gpiob 6 0>,   /* D10 */
                   <17 0 &gpioa 7 0>,   /* D11 */
                   <18 0 &gpioa 6 0>,   /* D12 */
                   <19 0 &gpioa 5 0>,   /* D13 */
                   <20 0 &gpiob 9 0>,   /* D14 */
                   <21 0 &gpiob 8 0>;   /* D15 */
};
```

This specifies how Arduino pin references like `<&arduino_header 11 0>` are converted to SOC gpio pin references like `<&gpiob 4 0>`.

In Zephyr GPIO specifiers generally have two parameters (indicated by `#gpio-cells = <2>`): the pin number and a set of flags. The low 6 bits of the flags correspond to features that can be configured in devicetree. In some cases it's necessary to use a non-zero flag value to tell the driver how a particular pin behaves, as with:

```
drdy-gpios = <&arduino_header 11 GPIO_ACTIVE_LOW>;
```

After preprocessing this becomes `<&arduino_header 11 1>`. Normally the presence of such a flag would cause the map lookup to fail, because there is no map entry with a non-zero flags value. The `gpio-map-mask` property specifies that, for lookup, all bits of the pin and all but the low 6 bits

of the flags are used to identify the specifier. Then the `gpio-map-pass-thru` specifies that the low 6 bits of the flags are copied over, so the SOC GPIO reference becomes `<&gpiob 4 1>` as intended.

See nexus node for more information about this capability.

7.9 Virtualization

These pages document Zephyr virtualization facilities.

7.9.1 Virtual I/O (VIRTIO)

Overview

Virtual I/O (VIRTIO) is a protocol used for communication with various devices, typically used in virtualized environments. Its main goal is to provide an efficient and standardized mechanism for interfacing with virtual devices from within a virtual machine. The communication relies on virtqueues and standard transfer methods like PCI or MMIO.

Concepts

Virtio defines various components used during communication and initialization. It specifies both the host (named "device" in the specification) and guest (named "driver" in the specification) sides. Currently Zephyr can only work as a guest. On top of the facilities exposed by the Virtio driver, a driver for a specific device (e.g. network card) can be implemented.

A high-level overview of a system with a Virtio device is shown below.

Configuration space Each device provides configuration space, used for initialization and configuration. It allows selection of device and driver features, enabling specific virtqueues and setting their addresses. Once the device is configured, most of its configuration cannot be changed without resetting the device. The exact layout of the configuration space depends on the transfer method.

Driver and device features The configuration space provides a way to negotiate feature bits, determining some non-mandatory capabilities of the devices. The exact available feature bits depend on the device and platform.

Device-specific configuration Some of the devices offer device-specific configuration space, providing additional configuration options.

Virtqueues The main mechanism used for transferring data between host and guest is a virtqueue. Specific devices have different numbers of virtqueues, for example devices supporting bidirectional transfer usually have one or more tx/rx virtqueue pairs. Virtio specifies two types of virtqueues: split virtqueues and packed virtqueues. Zephyr currently supports only split virtqueues.

Split virtqueues A split virtqueue consists of three parts: descriptor table, available ring and used ring.

The descriptor table holds descriptors of buffers, that is their physical addresses, lengths and flags. Each descriptor is either device writeable or driver writeable. The descriptors can be chained, creating descriptor chains. Typically a chain begins with descriptors containing the data for the device to read and ends with the device writeable part, where the device places its response.

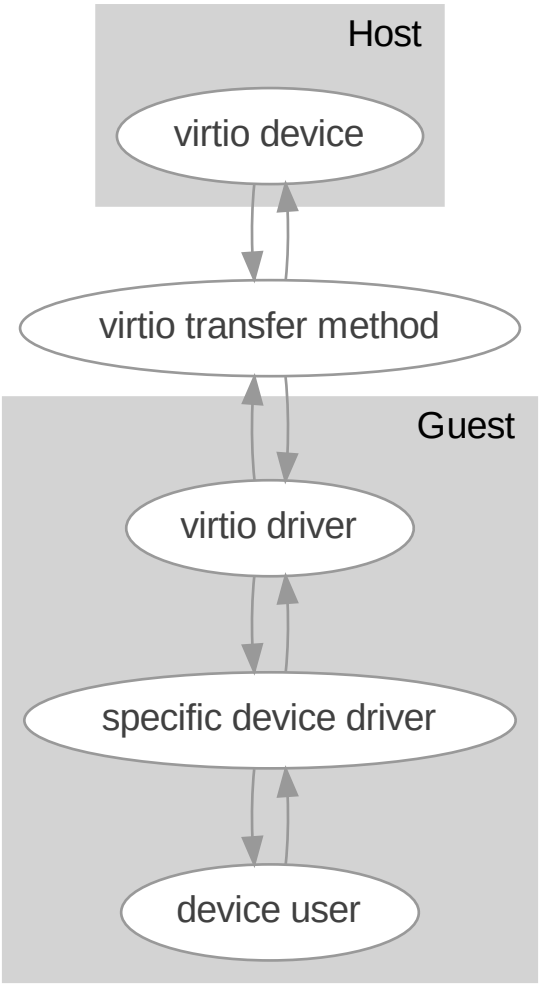

Fig. 17: Virtual I/O overview

The main part of the available ring is a circular buffer of references (in the form of indexes) to the descriptors in the descriptor table. Once the guest decides to send the data to the host, it adds the index of the head of the descriptor chain to the top of the available ring.

The used ring is similar to the available ring, but it's used by the host to return descriptors to the guest. In addition to storing descriptor indexes, it also provides information about the amount of data written to them.

Common Virtio libraries

Zephyr provides an API for interfacing with Virtio devices and virtqueues, which allows performing necessary operations over the lifetime of the Virtio device.

Device initialization Once the Virtio driver finishes performing low-level initialization common to the all devices using a given transfer method, like finding device on the bus and mapping Virtio structures, the device specific driver steps in and performs the next stages of initialization with the help of the Virtio API.

The first thing the device-specific driver does is feature bits negotiation. It uses `virtio_read_device_feature_bit()` to determine which features the device offers, and then selects the ones it needs using `virtio_write_driver_feature_bit()`. After all required features have been selected, the device-specific driver calls `virtio_commit_feature_bits()`. Then, virtqueues are initialized with `virtio_init_virtqueues()`. This function enumerates the virtqueues, invoking the provided callback `virtio_enumerate_queues` to determine the required size of each virtqueue. Initialization process is finalized by calling `virtio_finalize_init()`. From this point, if none of the functions returned errors, the virtqueues are operational. If the specific device provides one, the device-specific config can be obtained by calling `virtio_get_device_specific_config()`.

Virtqueue operation Once the virtqueues are operational, they can be used to send and receive data. To do so, the pointer to the nth virtqueue has to be acquired using `virtio_get_virtqueue()`. To send data consisting of a descriptor chain, `virtq_add_buffer_chain()` has to be used. Along the descriptor chain, it takes pointer to the callback that will be invoked once the device returns the given descriptor chain. After that, the virtqueue has to be notified using `virtio_notify_virtqueue()` from the Virtio API.

Guest-side Virtio drivers

Currently Zephyr provides drivers for Virtio over PCI and Virtio over MMIO and drivers for two devices using virtio - virtiofs, used to access the filesystem of the host and virtio-entropy, used as an entropy source.

Virtiofs This driver provides support for virtiofs - a filesystem allowing a virtual machine guest to access a directory on the host. It uses FUSE messages to communicate between the host and the guest in order to perform filesystem operations such as opening and reading files. Every time the guest wants to perform some filesystem operation it places in the virtqueue a descriptor chain starting with the device readable part, containing the FUSE input header and input data, and ending it with the device writeable part, with place for the FUSE output header and output data.

Virtio-entropy This driver allows using virtio-entropy as an entropy source in Zephyr. The operation of this device is simple - the driver places a buffer in the virtqueue and receives it back, filled with random data.

Virtio samples

A sample showcasing the use of a driver relying on Virtio is provided in virtiofs. If you wish to check code interfacing directly with the Virtio driver, you can check the virtiofs driver, especially

`virtiofs_init()` for initialization and `virtiofs_send_receive()` with the `virtiofs_recv_cb()` for data transfer to/from the Virtio device.

VIRTIO

Virtqueue Interface

Chapter 8

Contributing to Zephyr

Contributions from the community are the backbone of the project. Whether it is by submitting code, improving documentation, or proposing new features, your efforts are highly appreciated. This page lists useful resources and guidelines to help you in your contribution journey.

8.1 General Guidelines

8.1.1 Contribution Guidelines

As an open-source project, we welcome and encourage the community to submit patches directly to the project. In our collaborative open source environment, standards and methods for submitting changes help reduce the chaos that can result from an active development community.

This document explains how to participate in project conversations, log bugs and enhancement requests, and submit patches to the project so your patch will be accepted quickly in the codebase.

Prerequisites

As a contributor, you'll want to be familiar with the Zephyr project, how to configure, install, and use it as explained in the Zephyr Project website and how to set up your development environment as introduced in the Zephyr *Getting Started Guide*.

You should be familiar with common developer tools such as Git and CMake, and platforms such as GitHub.

If you haven't already done so, you'll need to create a (free) GitHub account on https://github.com and have Git tools available on your development system.

Note

The Zephyr development workflow supports all 3 major operating systems (Linux, macOS, and Windows) but some of the tools used in the sections below are only available on Linux and macOS. On Windows, instead of running these tools yourself, you will need to rely on the Continuous Integration (CI) service using Github Actions, which runs automatically on GitHub when you submit your Pull Request (PR). You can see any failure results in the workflow details link near the end of the PR conversation list. See *Continuous Integration* for more information

Licensing

Licensing is very important to open source projects. It helps ensure the software continues to be available under the terms that the author desired.

Zephyr uses the Apache 2.0 license (as found in the LICENSE file in the project's GitHub repo) to strike a balance between open contribution and allowing you to use the software however you would like to. The Apache 2.0 license is a permissive open source license that allows you to freely use, modify, distribute and sell your own products that include Apache 2.0 licensed software. (For more information about this, check out articles such as Why choose Apache 2.0 licensing and Top 10 Apache License Questions Answered).

A license tells you what rights you have as a developer, as provided by the copyright holder. It is important that the contributor fully understands the licensing rights and agrees to them. Sometimes the copyright holder isn't the contributor, such as when the contributor is doing work on behalf of a company.

Components using other Licenses There are some imported or reused components of the Zephyr project that use other licensing, as described in *Licensing of Zephyr Project components*.

Importing code into the Zephyr OS from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board.

By carefully reviewing potential contributions and also enforcing a *Developer Certification of Origin (DCO)* for contributed code, we can ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

See *Contributing External Components* for more information about this contributing and review process for imported components.

Licensing of Zephyr Project components The Zephyr kernel tree imports or reuses packages, scripts and other files that are not covered by the Apache 2.0 License. In some places there is no LICENSE file or way to put a LICENSE file there, so we describe the licensing in this document.

Continuous Integration Scripts

- *Origin:* Linux Kernel
- *Licensing:* GPLv2 License
- *Impact:* These files are used in Continuous Integration (CI) and never linked into the firmware.
- *Files:*
  - scripts/checkpatch.pl
  - scripts/checkstack.pl
  - scripts/spelling.txt

Coccinelle Scripts

- *Origin:* Coccinelle
- *Licensing:* GPLv2 License
- *Impact:* These files are used by Coccinelle, a tool for transforming C-code, and never linked into the firmware.
- *Files:*
  - scripts/coccicheck
  - scripts/coccinelle/array_size.cocci

  - scripts/coccinelle/deref_null.cocci
  - scripts/coccinelle/deref_null.cocci
  - scripts/coccinelle/deref_null.cocci
  - scripts/coccinelle/mini_lock.cocci
  - scripts/coccinelle/mini_lock.cocci
  - scripts/coccinelle/mini_lock.cocci
  - scripts/coccinelle/noderef.cocci
  - scripts/coccinelle/noderef.cocci
  - scripts/coccinelle/returnvar.cocci
  - scripts/coccinelle/semicolon.cocci

GCOV Coverage Header File

- *Origin:* GCC, the GNU Compiler Collection
- *Licensing:* GPLv2 License with Runtime Library Exception
- *Impact:* This file is only linked into the firmware if `CONFIG_COVERAGE_GCOV` is enabled.
- *Files:*
  - subsys/testsuite/coverage/coverage.h

ENE KB1200_EVB Board OpenOCD Configuration

- *Licensing:* GPLv2 License
- *Impact:* This file is used by OpenOCD when programming and debugging the kb1200_evb board. It is never linked into the firmware.
- *Files:*
  - boards/ene/kb1200_evb/support/openocd.cfg

Thread-Metric RTOS Test Suite Source Files

- *Origin:* ThreadX
- *Licensing:* MIT License
- *Impact:* These files are only linked into the Thread-Metric RTOS Test Suite test firmware.
- *Files:*
  - tests/benchmarks/thread_metric/thread_metric_readme.txt
  - tests/benchmarks/thread_metric/src/tm_api.h
  - tests/benchmarks/thread_metric/src/tm_basic_processing_test.c
  - tests/benchmarks/thread_metric/src/tm_cooperative_scheduling_test.c
  - tests/benchmarks/thread_metric/src/tm_interrupt_preemption_processing_test.c
  - tests/benchmarks/thread_metric/src/tm_interrupt_processing_test.c
  - tests/benchmarks/thread_metric/src/tm_memory_allocation_test.c
  - tests/benchmarks/thread_metric/src/tm_message_processing_test.c
  - tests/benchmarks/thread_metric/src/tm_porting_layer.h
  - tests/benchmarks/thread_metric/src/tm_porting_layer_zephyr.c

  - tests/benchmarks/thread_metric/src/tm_preemptive_scheduling_test.c
  - tests/benchmarks/thread_metric/src/tm_synchronization_processing_test.c

OpenThread Spinel HDLC RCP Host Interface Files

- *Origin:* OpenThread
- *Licensing:* BSD-3-clause
- *Impact:* These files are only linked into the firmware if `CONFIG_HDLC_RCP_IF` is enabled.
- *Files*:
  - modules/openthread/platform/hdlc_interface.hpp
  - modules/openthread/platform/radio_spinel.cpp
  - modules/openthread/platform/hdlc_interface.cpp

Python Devicetree library test files

- *Licensing:* BSD-3-clause
- *Impact:* These are only used for testing and never linked with the firmware.
- *Files*:
  - Various yaml files under `scripts/dts/python-devicetree/tests`

FUSE Interface Definition Header File

- *Licensing:* BSD-2-clause
- *Impact:* This header is used in Zephyr build only if `CONFIG_FUSE_CLIENT` is enabled.
- *Files*:
  - subsys/fs/fuse_client/fuse_abi.h

Copyright and License Notices Zephyr follows SPDX/REUSE-style file headers. Add a machine-readable copyright notice and a license identifier at the top of each file so tooling can detect them (for example *west spdx*, which uses the REUSE tool).

The Zephyr Project follows the Community Best Practice for copyright notices from the Linux Foundation, therefore we recommend using the following copyright notice:

```
SPDX-FileCopyrightText: Copyright The Zephyr Project Contributors
```

Include the license identifier alongside it:

```
SPDX-License-Identifier: Apache-2.0
```

Practical guidance:

- Place both lines at the very top of the file using the file's native comment syntax.
- If you authored substantial, original content, you *may* add an additional line for yourself or your organization.

Developer Certification of Origin (DCO)

To make a good faith effort to ensure licensing criteria are met, the Zephyr project requires the Developer Certificate of Origin (DCO) process to be followed.

The DCO is an attestation attached to every contribution made by every developer. In the commit message of the contribution, (described more fully later in this document), the developer simply adds a `Signed-off-by` statement and thereby agrees to the DCO.

When a developer submits a patch, it is a commitment that the contributor has the right to submit the patch per the license. The DCO agreement is shown below and at https://developercertificate.org/.

```
Developer's Certificate of Origin 1.1

By making a contribution to this project, I certify that:

(a) The contribution was created in whole or in part by me and I
    have the right to submit it under the open source license
    indicated in the file; or

(b) The contribution is based upon previous work that, to the
    best of my knowledge, is covered under an appropriate open
    source license and I have the right under that license to
    submit that work with modifications, whether created in whole
    or in part by me, under the same open source license (unless
    I am permitted to submit under a different license), as
    Indicated in the file; or

(c) The contribution was provided directly to me by some other
    person who certified (a), (b) or (c) and I have not modified
    it.

(d) I understand and agree that this project and the contribution
    are public and that a record of the contribution (including
    all personal information I submit with it, including my
    sign-off) is maintained indefinitely and may be redistributed
    consistent with this project or the open source license(s)
    involved.
```

DCO Sign-Off The "sign-off" in the DCO is a "Signed-off-by:" line in each commit's log message. The Signed-off-by: line must be in the following format:

```
Signed-off-by: Your Name <your.email@example.com>
```

For your commits, replace:

- `Your Name` with your legal name (pseudonyms, hacker handles, and the names of groups are not allowed)
- `your.email@example.com` with the real email address you are using to author the commit. Pseudo or anonymized emails such as `you-id+your-username@users.noreply.github.com` are not allowed. The email must match the one you use to author the commit (CI will fail if there is no match).

You can automatically add the Signed-off-by: line to your commit body using `git commit -s`. Use other commits in the zephyr git history as examples. See *Git Setup* for instructions on configuring user and email settings in Git.

Additional requirements:

- If you are altering an existing commit created by someone else, you must add your Signed-off-by: line without removing the existing one.

AI Coding Assistants

This section provides guidance for contributors using AI tools and assistants when contributing to the Zephyr project.

Licensing and Legal Requirements All contributions must comply with the licensing requirements of the project and be compatible with Zephyr's licensing (e.g. Apache-2.0, see *Licensing* for more details).

Signed-off-by and Developer Certificate of Origin AI agents **must not** add `Signed-off-by` tags. Only humans can legally certify the *Developer Certification of Origin (DCO)*. The human submitter is responsible for:

- Reviewing all AI-generated code.
- Ensuring compliance with licensing requirements.
- Adding their own Signed-off-by tag to certify the DCO.
- Taking full responsibility for the contribution.

Usage disclosure and attribution When AI tools are being used to help write a contribution, proper attribution helps track the evolving role of AI in the development process. Contributions should include an `Assisted-by:` tag in the following format:

```
Assisted-by: [Agent Name]:[Model Version] [Tool1] [Tool2]
```

Where:

- `[Agent Name]` is the name of the AI tool or framework.
- `[Model Version]` is the specific model version used.
- `[Tool1] [Tool2]` are optional specialized analysis tools used.

Basic development tools (git, gcc, make, editors) should not be listed.

Example:

```
Assisted-by: Claude:claude-opus-4.6 coccinelle
```

Source Tree Structure

To clone the main Zephyr Project repository use the instructions in *Get Zephyr and install Python dependencies*.

This section describes the main repository's source tree. In addition to the Zephyr kernel itself, you'll also find the sources for technical documentation, sample code, supported board configurations, and a collection of subsystem tests. All of these are available for developers to contribute to and enhance.

Understanding the Zephyr source tree can help locate the code associated with a particular Zephyr feature.

At the top of the tree, several files are of importance:

`CMakeLists.txt`
: The top-level file for the CMake build system, containing a lot of the logic required to build Zephyr.

`Kconfig`
: The top-level Kconfig file, which refers to the file `Kconfig.zephyr` also found in the top-level directory.

  See *the Kconfig section of the manual* for detailed Kconfig documentation.

`west.yml`
: The *West (Zephyr's meta-tool)* manifest, listing the external repositories managed by the west command-line tool.

The Zephyr source tree also contains the following top-level directories, each of which may have one or more additional levels of subdirectories not described here.

`arch`
: Architecture-specific kernel and system-on-chip (SoC) code. Each supported architecture (for example, x86 and ARM) has its own subdirectory, which contains additional subdirectories for the following areas:

  - architecture-specific kernel source files
  - architecture-specific kernel include files for private APIs

`soc`
: SoC related code and configuration files.

`boards`
: Board related code and configuration files.

`doc`
: Zephyr technical documentation source files and tools used to generate the https://docs.zephyrproject.org web content.

`drivers`
: Device driver code.

`dts`
: *devicetree* source files used to describe non-discoverable board-specific hardware details.

`include`
: Include files for all public APIs, except those defined under `lib`.

`kernel`
: Architecture-independent kernel code.

`lib`
: Library code, including the minimal standard C library.

`misc`
: Miscellaneous code that doesn't belong to any of the other top-level directories.

`samples`
: Sample applications that demonstrate the use of Zephyr features.

`scripts`
: Various programs and other files used to build and test Zephyr applications.

`cmake`
: Additional build scripts needed to build Zephyr.

`subsys`
: Subsystems of Zephyr, including:

  - USB device stack code
  - Networking code, including the Bluetooth stack and networking stacks
  - File system code
  - Bluetooth host and controller

`tests`
: Test code and benchmarks for Zephyr features.

`share`
: Additional architecture independent data. It currently contains Zephyr's CMake package.

Pull Requests and Issues

Before starting on a patch, first check in our issues Zephyr Project Issues system to see what's been reported on the issue you'd like to address. Have a conversation on the Zephyr devel mailing list (or the Zephyr Discord Server) to see what others think of your issue (and proposed solution). You may find others that have encountered the issue you're finding, or that have similar ideas for changes or additions. Send a message to the Zephyr devel mailing list to introduce and discuss your idea with the development community.

It's always a good practice to search for existing or related issues before submitting your own. When you submit an issue (bug or feature request), the triage team will review and comment on the submission, typically within a few business days.

You can find all open pull requests on GitHub and open Zephyr Project Issues in Github issues.

Git Setup

We need to know who you are, and how to contact you. To add this information to your Git installation, set the Git configuration variables `user.name` to your full name, and `user.email` to your email address.

For example, if your name is `Zephyr Developer` and your email address is `z.developer@example.com`:

```
git config --global user.name "Zephyr Developer"
git config --global user.email "z.developer@example.com"
```

Note

`user.name` must be your full name (first and last at minimum), not a pseudonym or hacker handle. The email address that you use in your Git configuration must match the email address you use to sign your commits. If they don't match, the CI system will fail your pull request.

If you intend to edit commits using the Github.com UI, ensure that your github profile `email address` and profile `name` also match those used in your git configuration (`user.name` & `user.email`).

Pull Request Guidelines

When opening a new Pull Request, adhere to the following guidelines to ensure compliance with Zephyr standards and facilitate the review process.

If in doubt, it's advisable to explore existing Pull Requests within the Zephyr repository. Use the search filters and labels to locate PRs related to changes similar to the ones you are proposing.

Note

GitHub's default code UI uses 4-character tabs. However, Zephyr follows the Linux kernel coding style, which uses 8-character tabs.

To ensure your view of the code is consistent with other developers, please go to your user preferences on GitHub and change the tab width to 8 spaces.

Commit Message Guidelines Changes are submitted as Git commits. Each commit has a *commit message* describing the change. Acceptable commit messages look like this:

```
[area]: [summary of change]

[Commit message body (must be non-empty)]

Signed-off-by: [Your Full Name] <[your.email@address]>
```

You need to change text in square brackets (`[like this]`) above to fit your commit.

Here is an example of a good commit message.

```
drivers: sensor: abcd1234: fix bus I/O error handling

The abcd1234 sensor driver is failing to check the flags field in
the response packet from the device which signals that an error
occurred. This can lead to reading invalid data from the response
buffer. Fix it by checking the flag and adding an error path.

Signed-off-by: Zephyr Developer <z.developer@example.com>
```

[area]: [summary of change] This line is called the commit's *title*. Titles must be:

- one line
- less than 72 characters long
- followed by a completely blank line

[area]
: The `[area]` prefix usually identifies the area of code being changed. It can also identify the change's wider context if multiple areas are affected.

  Here are some examples:

  - `doc: ...` for documentation changes
  - `drivers: foo:` for `foo` driver changes
  - `Bluetooth: Shell:` for changes to the Bluetooth shell
  - `net: ethernet:` for Ethernet-related networking changes
  - `dts:` for treewide devicetree changes
  - `style:` for code style changes

  If you're not sure what to use, try running `git log FILE`, where `FILE` is a file you are changing, and using previous commits that changed the same file as inspiration.

[summary of change]
: The `[summary of change]` part should be a quick description of what you've done. Here are some examples:

  - `doc: update wiki references to new site`
  - `drivers: sensor: sensor_shell: fix channel name collision`

Warning

An empty commit message body is not permitted. Even for trivial changes, please include a descriptive commit message body. Your pull request will fail CI checks if you do not.

Commit Message Body This part of the commit should explain what your change does, and why it's needed. Be specific. A body that says `"Fixes stuff"` will be rejected. Be sure to include the following as relevant:

- **what** the change does,
- **why** you chose that approach,
- **what** assumptions were made, and
- **how** you know it works – for example, which tests you ran.

Each line in your commit message should usually be 75 characters or less. Use newlines to wrap longer lines. Exceptions include lines with long URLs, email addresses, etc.

For examples of accepted commit messages, you can refer to the Zephyr GitHub changelog.

Tip

You should have set your *Git Setup* already. Create your commit with `git commit -s` to add the Signed-off-by: line automatically using this information.

Signed-off-by: ... For open source licensing reasons, your commit must include a Signed-off-by: line that looks like this:

```
Signed-off-by: [Your Full Name] <[your.email@address]>
```

For example, if your full name is `Zephyr Developer` and your email address is `z.developer@example.com`:

```
Signed-off-by: Zephyr Developer <z.developer@example.com>
```

This means that you have personally made sure your change complies with the *Developer Certification of Origin (DCO)*. For this reason, you must use your legal name. Pseudonyms or "hacker aliases" are not permitted.

Your name and the email address you use must match the name and email in the Git commit's `Author:` field.

See the *Contributor Expectations* for a more complete discussion of contributor and reviewer expectations.

Adding Links If your change addresses a specific GitHub issue, include a reference in the pull request description using the following format:

```
Fixes zephyrproject-rtos/zephyr#[issue number]
```

For pull requests to the Zephyr project only, the short form can also be used, for example:

```
Fixes #[issue number]
```

Replace [issue number] with the relevant GitHub issue number. For example:

```
Fixes zephyrproject-rtos/zephyr#1234
```

This syntax ensures that the issue is automatically closed when the pull request is merged. Always specify the full repository path (zephyrproject-rtos/zephyr) to avoid ambiguity, especially when working across multiple repositories.

The same format can also be used in commit messages.

For linking to additional external resources—such as related issues, datasheets, or technical reference manuals—use the `Link:` tag:

```
Link: https://github.com/zephyrproject-rtos/zephyr/issues/<issue number>
```

Continuous Integration (CI) The Zephyr Project operates a Continuous Integration (CI) system that runs on every Pull Request (PR) in order to verify several aspects of the PR:

- Git commit formatting
- Coding Style
- Twister builds for multiple architectures and boards
- Documentation build to verify any doc changes

CI is run on Github Actions and it uses the same tools described in the *CI Tests* section. The CI results must be green indicating "All checks have passed" before the Pull Request can be merged. CI is run when the PR is created, and again every time the PR is modified with a commit.

The current status of the CI run can always be found at the bottom of the GitHub PR page, below the review status. Depending on the success or failure of the run you will see:

- "All checks have passed"
- "All checks have failed"

In case of failure you can click on the "Details" link presented below the failure message in order to navigate to `Github Actions` and inspect the results. Once you click on the link you will be taken to the `Github actions` summary results page where a table with all the different builds will be shown. To see what build or test failed click on the row that contains the failed (i.e. non-green) build.

Running CI Tests Locally

check_compliance.py The scripts/ci/check_compliance.py script serves as a valuable tool for assessing code compliance with Zephyr's established guidelines and best practices. The script acts as wrapper for a suite of tools that performs various checks, including linters and formatters.

Developers are encouraged to run the script locally to validate their changes before opening a new Pull Request:

```
./scripts/ci/check_compliance.py -c <commit range>
```

> **Note**
>
> On Windows if the .pl extension has not yet been associated with an application, then the first time a .pl file is run without specifying an interpreter, Windows will ask what application will open Perl files. Set the default app to Strawberry Perl. By default the executable is installed at `C:\Strawberry\perl\bin\perl.exe`.

KeepSorted Check The KeepSorted check ensures that specified blocks of code, configuration, or documentation remain in sorted order.

To use the KeepSorted check, wrap your sorted content between dedicated lines containing start and stop markers, typically using comments:

```
// zephyr-keep-sorted-start
option_a
option_b
option_c
// zephyr-keep-sorted-stop
```

KeepSorted Marker Options The sorting behavior of each block can be customized in several ways. To do this, one or more of the following parameters can be added on the same line as the start marker itself:

re(regex_pattern)
Enables regex mode where only lines matching the specified regular expression are checked for sorting. Other lines are ignored.

Example checking sorted properties in a yaml file:

```
# zephyr-keep-sorted-start re(^\s+\- name:)
projects:
  - name: application
    revision: main
  - name: library1
    revision: feature-branch
  - name: library2
    revision: main
# zephyr-keep-sorted-stop
```

strip(characters)
Strips the specified characters from lines before performing the sort comparison. This is useful when lines have optional prefixes or suffixes that should be ignored during sorting.

Example stripping quotes from yaml dictionary keys:

```
# zephyr-keep-sorted-start strip(":)
ACPI:
  status: odd fixes
"West project: acpica":
  status: odd fixes
# zephyr-keep-sorted-stop
```

nofold
Disables line folding. By default, indented lines following a main line are concatenated (folded) together for sorting comparison. The `nofold` option disables this behavior and ignores indented lines.

ignorecase
Enables case-insensitive sorting using Python's str.casefold. This allows mixing uppercase and lowercase items in sorted blocks without causing sort order violations. Defaults to Python's string ordering if omitted.

Multiple options can be combined on the same marker line:

```
.. zephyr-keep-sorted-start re(^\* \w) ignorecase
* Shell
  Some important message about the shell.

* STM32
  Updates for this vendor.
.. zephyr-keep-sorted-stop
```

> **Note**
>
> twister is only fully supported on Linux; on Windows and MacOS the execution of tests is not supported on all target devices.

twister If you think your change may break some test, you can submit your PR as a draft and let the project CI automatically run the *Test Runner (Twister)* for you.

If a test fails, you can check from the CI run logs how to rerun it locally, for example:

```
west twister -p native_sim -s␣
↪tests/drivers/build_all/sensor/drivers.sensor.generic_test
```

Static Code Analysis

Coverity Scan is a free service for static code analysis of Open Source projects. It is based on Coverity's commercial product and is able to analyze C, C++ and Java code.

Coverity's static code analysis doesn't run the code. Instead of that it uses abstract interpretation to gain information about the code's control flow and data flow. It's able to follow all possible code paths that a program may take. For example the analyzer understands that malloc() returns a memory that must be freed with free() later. It follows all branches and function calls to see if all possible combinations free the memory. The analyzer is able to detect all sorts of issues like resource leaks (memory, file descriptors), NULL dereferencing, use after free, unchecked return values, dead code, buffer overflows, integer overflows, uninitialized variables, and many more.

The results are available on the Coverity Scan website. In order to access the results you have to create an account yourself. From the Zephyr project page, you may select "Add me to project" to be added to the project. New members must be approved by an admin.

Static analysis of the Zephyr codebase is conducted on a bi-weekly basis. GitHub issues are automatically created for any issues detected by static analysis tools. These issues will have the same (or equivalent) priority initially defined by the tool.

To ensure accountability and efficient issue resolution, they are assigned to the respective maintainer who is responsible for the affected code.

A dedicated team comprising members with expertise in static analysis, code quality, and software security ensures the effectiveness of the static analysis process and verifies that identified issues are properly triaged and resolved in a timely manner.

Workflow If after analyzing the Coverity report it is concluded that it is a false positive please set the classification to either "False positive" or "Intentional", the action to "Ignore", owner to your own account and add a comment why the issue is considered false positive or intentional.

Update the related Github issue in the zephyr project with the details, and only close it after completing the steps above on scan service website. Any issues closed without a fix or without ignoring the entry in the scan service will be automatically reopened if the issue continues to be present in the code.

Contribution Workflow

One general practice we encourage, is to make small, controlled changes. This practice simplifies review, makes merging and rebasing easier, and keeps the change history clear and clean.

When contributing to the Zephyr Project, it is also important you provide as much information as you can about your change, update appropriate documentation, and test your changes thoroughly before submitting.

The general GitHub workflow used by Zephyr developers uses a combination of command line Git commands and browser interaction with GitHub. As it is with Git, there are multiple ways of getting a task done. We'll describe a typical workflow here:

1. Create a Fork of Zephyr to your personal account on GitHub. (Click on the fork button in the top right corner of the Zephyr project repo page in GitHub.)
2. On your development computer, change into the `zephyr` folder that was created when you *obtained the code*:

   ```
   cd zephyrproject/zephyr
   ```

   Rename the default remote pointing to the upstream repository from `origin` to `upstream`:

   ```
   git remote rename origin upstream
   ```

   Let Git know about the fork you just created, naming it `origin`:

   ```
   git remote add origin https://github.com/<your github id>/zephyr
   ```

   and verify the remote repos:

   ```
   git remote -v
   ```

   The output should look similar to:

   ```
   origin   https://github.com/<your github id>/zephyr (fetch)
   origin   https://github.com/<your github id>/zephyr (push)
   upstream https://github.com/zephyrproject-rtos/zephyr (fetch)
   upstream https://github.com/zephyrproject-rtos/zephyr (push)
   ```

3. Create a topic branch (off of `main`) for your work (if you're addressing an issue, we suggest including the issue number in the branch name):

   ```
   git checkout main
   git checkout -b fix_comment_typo
   ```

   Some Zephyr subsystems do development work on a separate branch from `main` so you may need to indicate this in your checkout:

   ```
   git checkout -b fix_out_of_date_patch origin/net
   ```

4. Make changes, test locally, change, test, test again, ... (Check out the prior chapter on *twister* as well).
5. When things look good, start the pull request process by adding your changed files:

   ```
   git add [file(s) that changed, add -p if you want to be more specific]
   ```

   You can see files that are not yet staged using:

   ```
   git status
   ```

6. Verify changes to be committed look as you expected:

   ```
   git diff --cached
   ```

7. Commit your changes to your local repo:

   ```
   git commit -s
   ```

The `-s` option automatically adds your `Signed-off-by:` to your commit message. Your commit will be rejected without this line that indicates your agreement with the *Developer Certification of Origin (DCO)*. See the *Commit Message Guidelines* section for specific guidelines for writing your commit messages.

8. Push your topic branch with your changes to your fork in your personal GitHub account:

```
git push origin fix_comment_typo
```

9. In your web browser, go to your forked repo and click on the `Compare & pull request` button for the branch you just worked on and you want to open a pull request with.

10. Review the pull request changes, and verify that you are opening a pull request for the `main` branch. The title and message from your commit message should appear as well.

11. A bot will assign one or more suggested reviewers (based on the MAINTAINERS file in the repo). If you are a project member, you can select additional reviewers now too.

12. Click on the submit button and your pull request is sent and awaits review. Email will be sent as review comments are made, or you can check on your pull request at https://github.com/zephyrproject-rtos/zephyr/pulls.

13. While you're waiting for your pull request to be accepted and merged, you can create another branch to work on another issue. (Be sure to make your new branch off of `main` and not the previous branch.):

```
git checkout main
git checkout -b fix_another_issue
```

and use the same process described above to work on this new topic branch.

14. If reviewers do request changes to your patch, you can interactively rebase commit(s) to fix review issues. In your development repo:

```
git rebase -i <offending-commit-id>^
```

In the interactive rebase editor, replace `pick` with `edit` to select a specific commit (if there's more than one in your pull request), or remove the line to delete a commit entirely. Then edit files to fix the issues in the review.

As before, inspect and test your changes. When ready, continue the patch submission:

```
git add [file(s)]
git rebase --continue
```

Update commit comment if needed, and continue:

```
git push --force origin fix_comment_typo
```

By force pushing your update, your original pull request will be updated with your changes so you won't need to resubmit the pull request.

15. After pushing the requested change, check on the PR page if there is a merge conflict. If so, rebase your local branch:

```
git fetch --all
git rebase --ignore-whitespace upstream/main
```

The `--ignore-whitespace` option stops `git apply` (called by rebase) from changing any whitespace. Resolve the conflicts and push again:

```
git push --force origin fix_comment_typo
```

> **Note**
>
> While amending commits and force pushing is a common review model outside GitHub, and the one recommended by Zephyr, it's not the main model supported by GitHub. Forced pushes can cause unexpected behavior, such as not being able to use "View Changes" buttons except for the last one - GitHub complains it can't find older commits. You're also not always able to compare the latest reviewed version with the latest submitted version. When rewriting history GitHub only guarantees access to the latest version.

16. If the CI run fails, you will need to make changes to your code in order to fix the issues and amend your commits by rebasing as described above. Additional information about the CI system can be found in *Continuous Integration*.

Contribution Tips The following is a list of tips to improve and accelerate the review process of Pull Requests. If you follow them, chances are your pull request will get the attention needed and it will be ready for merge sooner than later:

1. When pushing follow-up changes, use the `--keep-base` option of git-rebase
2. On the PR page, check if the change can still be merged with no merge conflicts
3. Make sure title of PR explains what is being fixed or added
4. Make sure your PR has a body with more details about the content of your submission
5. Make sure you reference the issue you are fixing in the body of the PR
6. Watch early CI results immediately after submissions and fix issues as they are discovered
7. Revisit PR after 1-2 hours to see the status of all CI checks, make sure all is green
8. If you get request for changes and submit a change to address them, make sure you click the "Re-request review" button on the GitHub UI to notify those who asked for the changes

Identifying Contribution Origin When adding a new file to the tree, it is important to detail the source of origin on the file, provide attributions, and detail the intended usage. In cases where the file is an original to Zephyr, the commit message should include the following ("Original" is the assumption if no Origin tag is present):

```
Origin: Original
```

In cases where the file is *imported from an external project*, the commit message shall contain details regarding the original project, the location of the project, the SHA-id of the origin commit for the file and the intended purpose.

For example, a copy of a locally maintained import:

```
Origin: Contiki OS
License: BSD 3-Clause
URL: https://www.contiki-os.org/
commit: 853207acfdc6549b10eb3e44504b1a75ae1ad63a
Purpose: Introduction of networking stack.
```

For example, a copy of an externally maintained import in a module repository:

```
Origin: Tiny Crypt
License: BSD 3-Clause
URL: https://github.com/01org/tinycrypt
commit: 08ded7f21529c39e5133688ffb93a9d0c94e5c6e
Purpose: Introduction of TinyCrypt
```

Contributions to External Modules

Follow the guidelines in the *Modules (External projects)* section for contributing *new modules* and submitting changes to *existing modules*.

Treewide Changes

This section describes contributions that are treewide changes and some additional associated requirements that apply to them. These requirements exist to try to give such changes increased review and user visibility due to their large impact.

Definition and Decision Making A *treewide change* is defined as any change to Zephyr APIs, coding practices, or other development requirements that either implies required changes throughout the zephyr source code repository or can reasonably be expected to do so for a wide class of external Zephyr-based source code.

This definition is informal by necessity. This is because the decision on whether any particular change is treewide can be subjective and may depend on additional context.

Project maintainers should use good judgement and prioritize the Zephyr developer experience when deciding when a proposed change is treewide. Protracted disagreements can be resolved by the Zephyr Project's Technical Steering Committee (TSC), but please avoid premature escalation to the TSC.

Requirements for Treewide Changes

- The zephyr repository must apply the 'treewide' GitHub label to any issues or pull requests that are treewide changes
- The person proposing a treewide change must create an RFC issue describing the change, its rationale and impact, etc. before any pull requests related to the change can be merged
- The project's Architecture Working Group (WG) must include the issue on the agenda and discuss whether the project will accept or reject the change before any pull requests related to the change can be merged (with escalation to the TSC if consensus is not reached at the WG)
- The Architecture WG must specify the procedure for merging any PRs associated with each individual treewide change, including any required approvals for pull requests affecting specific subsystems or extra review time requirements
- The person proposing a treewide change must email devel@lists.zephyrproject.org about the RFC if it is accepted by the Architecture WG before any pull requests related to the change can be merged

Examples Some example past treewide changes are:

- the deprecation of version 1 of the *Logging API* in favor of version 2 (see commit 262cc55609)
- the removal of support for a legacy *Devicetree bindings* syntax (6bf761fc0a)

Note that adding a new version of a widely used API while maintaining support for the old one is not a treewide change. Deprecation and removal of such APIs, however, are treewide changes.

Specialized driver requirements

Drivers for standalone devices should use the Zephyr bus APIs (SPI, I2C...) whenever possible so that the device can be used with any SoC from any vendor implementing a compatible bus.

If it is not technically possible to achieve full performance using the Zephyr APIs due to specialized accelerators in a particular SoC family, one could extend the support for an external

device by providing a specialized path for that SoC family. However, the driver must still provide a regular path (via Zephyr APIs) for all other SoCs. Every exception must be approved by the Architecture WG in order to be validated and potentially to be learned/improved from.

8.1.2 Contributor Expectations

The Zephyr project encourages *contributors* to submit changes as smaller pull requests. Smaller pull requests (PRs) have the following benefits:

- Reviewed more quickly and reviewed more thoroughly. It's easier for reviewers to set aside a few minutes to review smaller changes several times than it is to allocate large blocks of time to review a large PR.
- Less wasted work if reviewers or maintainers reject the direction of the change.
- Easier to rebase and merge. Smaller PRs are less likely to conflict with other changes in the tree.
- Easier to revert if the PR breaks functionality.

> **Note**
>
> This page does not apply to draft PRs which can have any size, any number of commits and any combination of smaller PRs for testing and preview purposes. Draft PRs have no review expectation and PRs created as drafts from the start do not notify anyone by default.

Defining Smaller PRs

- Smaller PRs should encompass one self-contained logical change.
- When adding a new large feature or API, the PR should address only one part of the feature. In this case create an *RFC proposal* to describe the additional parts of the feature for reviewers.
- PRs should include tests or samples under the following conditions:
  - Adding new features or functionality.
  - Modifying a feature, especially for API behavior contract changes.
  - Fixing a hardware agnostic bug. The test should fail without the bug fixed and pass with the fix applied.
- PRs must update any documentation affected by a functional code change.
- If introducing a new API, the PR must include an example usage of the API. This provides context to the reviewer and prevents submitting PRs with unused APIs.

Multiple Commits on a Single PR

Contributors are further encouraged to break up PRs into multiple commits. Keep in mind each commit in the PR must still build cleanly and pass all the CI tests.

For example, when introducing an extension to an API, contributors can break up the PR into multiple commits targeting these specific changes:

1. Introduce the new APIs, including shared devicetree bindings
2. Update driver implementation X, with driver specific devicetree bindings
3. Update driver implementation Y
4. Add tests for the new API
5. Add a sample using the API

6. Update the documentation

Large Changes

Large changes to the Zephyr project must submit an *RFC proposal* describing the full scope of change and future work. The RFC proposal provides the required context to reviewers, but allows for smaller, incremental, PRs to get reviewed and merged into the project. The RFC should also define the minimum viable implementation.

Changes which require an RFC proposal include:

- Submitting a new feature.
- Submitting a new API.
- *Treewide Changes*.
- Other large changes that can benefit from the RFC proposal process.

Maintainers have the discretion to request that contributors create an RFC for PRs that are too large or complicated.

PR Requirements

Important

Pull requests that do not meet the quality expectations outlined below are less likely to receive reviewer engagement, and reviewers may request changes on such pull requests without detailed feedback.

Contributors are expected to self-review their changes and ensure all requirements are met before requesting a review.

- Each commit in the PR must provide a commit message following the *Commit Message Guidelines*.
- No fixup or merge commits are allowed, see *Contribution Workflow* for more information.
- The PR description must include a summary of the changes and their rationales.
- All files in the PR must comply with *Licensing Requirements*.
- The code must follow the Zephyr *Coding Style Guidelines* and *Coding Guidelines*.
- The PR must pass all CI checks, as described in *Merge Criteria*. Contributors may mark a PR as draft and explicitly request reviewers to provide early feedback, even with failing CI checks.
- Commits in a pull request should represent clear, logical units of change that are easy to review and maintain bisectability. The following guidelines expand on this principle:

  1. Distinct, Logical Units of Change

     Each commit should correspond to a self-contained, meaningful change. For example, adding a feature, fixing a bug, or refactoring existing code should be separate commits. Avoid mixing different types of changes (e.g., feature implementation and unrelated refactoring) in the same commit.

  2. Retain Bisectability

     Every commit in the pull request must build successfully and pass all relevant tests. This ensures that git bisect can be used effectively to identify the specific commit that introduced a bug or issue.

3. Squash Intermediary or Non-Final Development History

   During development, commits may include intermediary changes (e.g., partial implementations, temporary files, or debugging code). These should be squashed or rewritten before submitting the pull request. Remove non-final artifacts, such as:

   – Temporary renaming of files that are later renamed again.

   – Code that was rewritten or significantly changed in later commits.

4. Ensure Clean History Before Submission

   Use interactive rebasing (git rebase -i) to clean up the commit history before submitting the pull request. This helps in:

   – Squashing small, incomplete commits into a single cohesive commit.

   – Ensuring that each commit remains bisectable.

   – Maintaining proper attribution of authorship while improving clarity.

5. Renaming and Code Rewrites

   If files or code are renamed or rewritten in later commits during development, squash or rewrite earlier commits to reflect the final structure. This ensures that:

   – The history remains clean and easy to follow.

   – Bisectability is preserved by eliminating redundant renaming or partial rewrites.

6. Attribution of Authorship

   While cleaning up the commit history, ensure that authorship attribution remains accurate.

7. Readable and Reviewable History

   The final commit history should be easy to understand for future maintainers. Logical units of change should be grouped into commits that tell a clear, coherent story of the work done.

- When major new functionality is added, tests for the new functionality shall be added to the automated test suite. All API functions should have test cases and there should be tests for the behavior contracts of the API. Maintainers and reviewers have the discretion to determine if the provided tests are sufficient. The examples below demonstrate best practices on how to test APIs effectively.

  – Kernel timer tests provide around 85% test coverage for the kernel timer, measured by lines of code.

  – Emulators for off-chip peripherals are an effective way to test driver APIs. The fuel gauge tests use the smart battery emulator, providing test coverage for the fuel gauge API and the smart battery driver.

  – Code coverage reports for the Zephyr project are available on Codecov.

- Incompatible changes to APIs must also update the release notes for the next release detailing the change. APIs marked as experimental are excluded from this requirement.
- Changes to APIs must increment the API version number according to the API version rules.
- Documentation must be added and/or updated to reflect the changes in the code introduced by the PR. The documentation changes must use the proper terminology as present in the existing pages, and must be written in American English. If you include images as part of the documentation, those must follow the rules in *Images*. Please refer to *Documentation Guidelines* for additional information.
- PRs must also satisfy all *Merge Criteria* before a member of the release engineering team merges the PR into the zephyr tree.

Maintainers may request that contributors break up a PR into smaller PRs and may request that they create an *RFC proposal*.

Workflow Suggestions That Help Reviewers

- Unless they applied the reviewer's recommendation exactly, authors must not resolve and hide comments, they must let the initial reviewer do it. The Zephyr project does not require all comments to be resolved before merge. Leaving some completed discussions open can sometimes be useful to understand the greater picture.
- Respond to comments using the "Start Review" and "Add Review" green buttons in the "Files changed" view. This allows responding to multiple comments and publishing the responses in bulk. This reduces the number of emails sent to reviewers.
- As GitHub does not implement `git range-diff`, try to minimize rebases in the middle of a review. If a rebase is required, push this as a separate update with no other changes since the last push of the PR. When pushing a rebase only, add a comment to the PR indicating which commit is the rebase.

Getting PRs Reviewed The Zephyr community is a diverse group of individuals, with different levels of commitment and priorities. As such, reviewers and maintainers may not get to a PR right away.

- After 1 week of inactivity, ping the Assignee or reviewers on the PR by adding a comment to the PR.
- After 2 weeks of inactivity, post a message on the #pr-help channel on Discord linking to the PR.

PR Technical Escalation In cases where a contributor objects to change requests from reviewers, Zephyr defines the following escalation process for resolving technical disagreements.

Before escalation of technical disagreements, follow the steps below:

- Resolve in the PR among assignee, maintainers and reviewer.
  - Assignee to act as moderator if applicable.
- If no progress is made, the assignee (maintainer) has the right to dismiss stale, unrelated or irrelevant change requests by reviewers giving the reviewers a minimum of 1 business day to respond and revisit their initial change requests or start the escalation process.

  The assignee has the responsibility to document the reasoning for dismissing any reviews in the PR and should notify the reviewer about their review being dismissed.

  To give the reviewers time to respond and escalate, the assignee is expected to block the PR from being merged either by not approving the PR or by setting the *DNM* label.

Escalation can be triggered by any party participating in the review process (assignee, reviewers or the original author of the change) following the steps below:

- Escalate to the Architecture Working Group by adding the *Architecture Review* label on the PR. Beside the weekly meeting where such escalations are processed, the Architecture Working Group shall facilitate an offline review of the escalation if requested, especially if any of the parties can't attend the meeting.
- If all avenues of resolution and escalation have failed, assignees can escalate to the TSC and get a binding resolution in the TSC by adding the *TSC* label on the PR.
- The Assignee is expected to ensure the resolution of the escalation and the outcome is documented in the related pull request or issues on Github.

8.1.3 Reviewer Expectations

- Be respectful when commenting on PRs. Refer to the Zephyr Code of Conduct for more details.
- The Zephyr Project recognizes that reviewers and maintainers have limited bandwidth. As a reviewer, prioritize review requests in the following order:
  1. PRs related to items in the Zephyr Release Plan or those targeting the next release during the stabilization period (after RC1).
  2. PRs where the reviewer has requested blocking changes.
  3. PRs assigned to the reviewer as the area maintainer.
  4. All other PRs.
- Reviewers shall strive to advance the PR to a mergeable state with their feedback and engagement with the PR author.
- Try to provide feedback on the entire PR in one shot. This provides the contributor an opportunity to address all comments in the next PR update.
- Partial reviews are permitted, but the reviewer must add a comment indicating what portion of the PR they reviewed. Examples of useful partial reviews include:
  - Domain specific reviews (e.g. Devicetree).
  - Code style changes that impact the readability of the PR.
  - Reviewing commits separately when the requested changes cascade into the later commits.
- Avoid increasing scope of the PR by requesting new features, especially when there is a corresponding *RFC* associated with the PR. Instead, reviewers should add suggestions as a comment to the *RFC*. This also encourages more collaboration as it is easier for multiple contributors to work on a feature once the minimum implementation has merged.
- When using the "Request Changes" option, mark trivial, non-functional, requests as "Non-blocking" in the comment. Reviewers should approve PRs once only non-blocking changes remain. The PR author has discretion as to whether they address all non-blocking comments. PR authors should acknowledge every review comment in some way, even if it's just with an emoticon.
- Style changes that the reviewer disagrees with but that are not documented as part of the project can be pointed out as non-blocking, but cannot constitute a reason for a request for changes. The reviewer can optionally correct any potential inconsistencies in the tree, document the new guidelines or rules, and then enforce them as part of the review.
- Whenever requesting style related changes, reviewers should be able to point out the corresponding guideline, rule or rationale in the project's documentation. This does not apply to certain types of requests for changes, notably those specific to the changes being submitted (e.g. the use of a particular data structure or the choice of locking primitives).
- Reviewers shall be *clear* about what changes they are requesting when the "Request Changes" option is used. Requested changes shall be in the scope of the PR in question and following the contribution and style guidelines of the project. Furthermore, reviewers must be able to point back to the exact issues in the PR that triggered a request for changes.
- Reviewers should not request changes for issues which are automatically caught by CI, as this causes the pull request to remain blocked even after CI failures have been addressed and may unnecessarily delay it from being merged.
- Reviewers shall not close a PR due to technical or structural disagreement. If requested changes cannot be resolved within the review process, the *PR Technical Escalation* path shall be used for any potential resolution path, which may include closing the PR.
- When using AI tools to assist in reviewing code or drafting responses:

- Reviewers are responsible for following up on comments generated by the AI tools they may be using (e.g. GitHub Copilot).
- Reviewers must never paste raw, unverified LLM output as a PR comment.
- In general: all AI-generated feedback must be vetted, verified, and contextualized by a human reviewer who assumes full accountability for the accuracy and tone of the comment or review.

8.1.4 Coding Guidelines

Main rules

The coding guideline rules are based on MISRA-C 2012 and are a **subset** of MISRA-C. The subset is listed in the table below with a summary of the rules, its MISRA-C severity and the equivalent rules from other standards for reference.

The severity and other references in the table below are for informational purposes only. The listed rules are all required for Zephyr and all new code should comply with the rules listed below.

Note

For existing Zephyr maintainers and collaborators, if you are unable to obtain a copy through your employer, a limited number of copies will be made available through the project. If you need a copy of MISRA-C 2012, please send email to safety@lists.zephyrproject.org and provide details on reason why you can't obtain one through other options and expected contributions once you have one. The safety committee will review all requests.

Table 1: Main rules

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
1	Any implementation-defined behaviour on which the output of the program depends shall be documented and understood	Dir 1.1	FLP30-C MSC09-C EXP11-C
2	All source files shall compile without any compilation errors	Dir 2.1	N/A
3	All code shall be traceable to documented requirements	Dir 3.1	N/A
4	Run-time failures shall be minimized	Dir 4.1	N/A
5	All usage of assembly language should be documented	Dir 4.2	N/A
6	Sections of code should not be "commented out"	Dir 4.4	MSC04-C
7	Identifiers in the same name space with overlapping visibility should be typographically unambiguous	Dir 4.5	DCL02-C
8	typedefs that indicate size and signedness should be used in place of the basic numerical types	Dir 4.6	N/A
9	If a function returns error information, then that error information shall be tested	Dir 4.7	N/A

continues on next page

Table 1 – continued from previous page

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
10	If a pointer to a structure or union is never dereferenced within a translation unit, then the implementation of the object should be hidden	Dir 4.8 example 1 Dir 4.8 example 2	DCL12-C
11	A function should be used in preference to a function-like macro where they are interchangeable	Dir 4.9	PRE00-C

127	The library functions bsearch and qsort of <stdlib.h> shall not be used	Rule 21.9	N/A
128	The standard header file <tgmath.h> shall not be used	Rule 21.11	N/A
129	The exception handling features of <fenv.h> should not be used	Rule 21.12	N/A
130	Any value passed to a function in <ctype.h> shall be representable as an unsigned char or be the value EOF	Rule 21.13	N/A
131	The Standard Library function memcmp shall not be used to compare null terminated strings	Rule 21.14	N/A
132	The pointer arguments to the Standard Library functions memcpy, memmove and memcmp shall be pointers to qualified or unqualified versions of compatible types	Rule 21.15	N/A
133	The pointer arguments to the Standard Library function memcmp shall point to either a pointer type, an essentially signed type, an essentially unsigned type, an essentially Boolean type or an essentially enum type	Rule 21.16	N/A
134	Use of the string handling functions from <string.h> shall not result in accesses beyond the bounds of the objects referenced by their pointer parameters	Rule 21.17	N/A
135	The size_t argument passed to any function in <string.h> shall have an appropriate value	Rule 21.18	N/A
136	The pointers returned by the Standard Library functions localeconv, getenv, setlocale or, strerror shall only be used as if they have pointer to const-qualified type	Rule 21.19	N/A
137	The pointer returned by the Standard Library functions asctime, ctime, gmtime, localtime, localeconv, getenv, setlocale or strerror shall not be used following a subsequent call to the same function	Rule 21.20	N/A
138	All resources obtained dynamically by means of Standard Library functions shall be explicitly released	Rule 22.1	N/A
139	A block of memory shall only be freed if it was allocated by means of a Standard Library function	Rule 22.2	N/A
140	The same file shall not be open for read and write access at the same time on different streams	Rule 22.3	N/A
141	There shall be no attempt to write to a stream which has been opened as read-only	Rule 22.4	N/A
142	A pointer to a FILE object shall not be dereferenced	Rule 22.5	N/A
143	The value of a pointer to a FILE shall not be used after the associated stream has been closed	Rule 22.6	N/A

continues on next page

Table 1 – continued from previous page

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
144	The macro EOF shall only be compared with the unmodified return value from any Standard Library function capable of returning EOF	Rule 22.7	N/A
145	The value of errno shall be set to zero prior to a call to an errno-setting-function	Rule 22.8	N/A
146	The value of errno shall be tested against zero after calling an errno-setting-function	Rule 22.9	N/A
147	The value of errno shall only be tested when the last function to be called was an errno-setting-function	Rule 22.10	N/A

Additional rules

Rule A.1: Conditional Compilation

Severity
Required

Description
Do not conditionally compile function declarations in header files. Do not conditionally compile structure declarations in header files. You may conditionally exclude fields within structure definitions to avoid wasting memory when the feature they support is not enabled.

Rationale
Excluding declarations from the header based on compile-time options may prevent their documentation from being generated. Their absence also prevents use of `if (IS_ENABLED(CONFIG_FOO)) {}` as an alternative to preprocessor conditionals when the code path should change based on the selected options.

Rule A.2: Inclusive Language

Severity
Required

Description
Do not introduce new usage of offensive terms listed below. This rule applies but is not limited to source code, comments, documentation, and branch names. Replacement terms may vary by area or subsystem, but should aim to follow updated industry standards when possible.

Exceptions are allowed for maintaining existing implementations or adding new implementations of industry standard specifications governed externally to the Zephyr Project.

Existing usage is recommended to change as soon as updated industry standard specifications become available or new terms are publicly announced by the governing body, or immediately if no specifications apply.

Offensive Terms	Recommended Replacements
{master,leader} / slave	• {primary,main} / {secondary,replica} • {initiator,requester} / {target,responder} • {controller,host} / {device,worker,proxy, target} • director / performer • central / peripheral
blacklist / whitelist	• denylist / allowlist • blocklist / allowlist • rejectlist / acceptlist
grandfather policy	• legacy
sanity	• coherence • confidence

Rationale

Offensive terms do not create an inclusive community environment and therefore violate the Zephyr Project Code of Conduct. This coding rule was inspired by a similar rule in Linux.

Status

Related GitHub Issues and Pull Requests are tagged with the Inclusive Language Label.

Area	Selected Replacements	Status
Bluetooth	See Bluetooth Appropriate Language Mapping Tables	
CAN	This CAN in Automation Inclusive Language news post has a list of general recommendations. See CAN in Automation Inclusive Language for terms to be used in specification document updates.	
eSPI	• `master / slave => controller / target`	Refer to eSPI Specification for new terminology
gPTP	• `master / slave => TBD`	
Inter-Integrated Circuit (I2C) Bus	• `master / slave => TBD`	NXP publishes the I2C Specification and has selected `controller / target` as replacement terms, but the timing to publish an announcement or new specification is TBD. Zephyr will update I2C when replacement terminology is confirmed by a public announcement or updated specification. See Zephyr issue 27033.
Inter-IC Sound (I2S) Bus	• `master / slave => TBD`	
SMP/AI	• `master / slave => TBD`	
Serial Peripheral Interface (SPI) Bus	• `master / slave => controller / peripheral` • `MOSI / MISO / SS => SDO / SDI / CS`	The Open Source Hardware Association has selected these replacement terms. See OSHWA Resolution to Redefine SPI Signal Names
Test Runner (Twiste	• `platform_whitelist => platform_allow` • `sanitycheck => twister`	

Rule A.3: Macro name collisions

Severity

Required

Description

Macros with commonly used names such as `MIN`, `MAX`, `ARRAY_SIZE`, must not be modified or protected to avoid name collisions with other implementations. In particular, they must not be prefixed to place them in a Zephyr-specific namespace, re-defined using `#undef`, or conditionally excluded from compilation using `#ifndef`. Instead, if a conflict arises with an existing definition originating from a *module*, the module's code itself needs to be modified (ideally upstream, alternatively via a change in Zephyr's own fork).

This rule applies to Zephyr as a project in general, regardless of the time of introduction of the macro or its current name in the tree. If a macro name is commonly used in several other well-known open source projects then the implementation in Zephyr should use that

name. While there is a subjective and non-measurable component to what "commonly used" means, the ultimate goal is to offer users familiar macros.

Finally, this rule applies to inter-module name collisions as well: in that case both modules, prior to their inclusion, should be modified to use module-specific versions of the macro name that collides.

Rationale

Zephyr is an RTOS that comes with additional functionality and dependencies in the form of modules. Those modules are typically independent projects that may use macro names that can conflict with other modules or with Zephyr itself. Since, in the context of this documentation, Zephyr is considered the central or main project, it should implement the non-namespaced versions of the macros. Given that Zephyr uses a fork of the corresponding upstream for each module, it is always possible to patch the macro implementation in each module to avoid collisions.

Rule A.4: C Standard Library Usage Restrictions in Zephyr Kernel

Severity

Required

Description

The use of the C standard library functions and macros in the Zephyr kernel shall be limited to the following functions and macros from the ISO/IEC 9899:2011 standard, also known as C11, and their extensions:

Table 2: List of allowed libc functions and macros in the Zephyr kernel

Function	Source
abort()	ISO/IEC 9899:2011
abs()	ISO/IEC 9899:2011
aligned_alloc()	ISO/IEC 9899:2011

strtoull()	ISO/IEC 9899:2011
time()	ISO/IEC 9899:2011
tolower()	ISO/IEC 9899:2011
toupper()	ISO/IEC 9899:2011
vfprintf()	ISO/IEC 9899:2011
vprintf()	ISO/IEC 9899:2011
vsnprintf()	ISO/IEC 9899:2011
vsprintf()	ISO/IEC 9899:2011

All of the functions listed above must be implemented by the *minimal libc* to ensure that the Zephyr kernel can build with the minimal libc.

In addition, any functions from the above list that are not part of the ISO/IEC 9899:2011 standard must be implemented by the *common libc* to ensure their availability across multiple C standard libraries.

Introducing new C standard library functions to the Zephyr kernel is allowed with justification given that the above requirements are satisfied.

Note that the use of the functions listed above are subject to secure and safe coding practices and it should not be assumed that their use in the Zephyr kernel is unconditionally permitted by being listed in this rule.

The “Zephyr kernel” in this context consists of the following components:

- Kernel (`kernel`)

- OS Library (`lib/os`)
- Architecture Port (`arch`)
- Logging Subsystem (`subsys/logging`)

Rationale

Zephyr kernel must be able to build with the *minimal libc*, a limited C standard library implementation that is part of the Zephyr RTOS and maintained by the Zephyr Project, to allow self-contained testing and verification of the kernel and core OS services.

In order to ensure that the Zephyr kernel can build with the minimal libc, it is necessary to restrict the use of the C standard library functions and macros in the Zephyr kernel to the functions and macros that are available as part of the minimal libc.

Rule A.5: C Standard Library Usage Restrictions in Zephyr Codebase

Severity

Required

Description

The use of the C standard library functions and macros in the Zephyr codebase shall be limited to the functions, excluding the Annex K "Bounds-checking interfaces", from the ISO/IEC 9899:2011 standard, also known as C11, unless exempted by this rule.

The "Zephyr codebase" in this context refers to all embedded source code files committed to the main Zephyr repository, except the Zephyr kernel as defined by the *Rule A.3: Macro name collisions*. With embedded source code we refer to code which is meant to be executed in embedded targets, and therefore excludes host tooling, and code specific for the native test targets.

The following non-ISO 9899:2011, hereinafter referred to as non-standard, functions and macros are exempt from this rule and allowed to be used in the Zephyr codebase:

Table 3: List of allowed non-standard libc functions

Function	Source
gmtime_r()	POSIX.1-2001
strnlen()	POSIX.1-2008
strtok_r()	POSIX.1-2001

All non-standard functions and macros listed above must be implemented by the *common libc* in order to make sure that these functions can be made available when using a C standard library that does not implement these functions.

Adding a new non-standard function from common C standard libraries to the above list is allowed with justification, given that the above requirement is satisfied. However, when there exists a standard function that is functionally equivalent, the standard function shall be used.

Rationale

Some C standard libraries, such as Newlib and Picolibc, include additional functions and macros that are defined by the standards and de-facto standards that extend the ISO C standard (e.g. POSIX, Linux).

The ISO/IEC 9899:2011 standard does not require C compiler toolchains to include the support for these non-standard functions, and therefore using these functions can lead to compatibility issues with the third-party toolchains that come with their own C standard libraries.

8.1.5 Coding Style Guidelines

Naming conventions

This section describes the naming conventions adopted by the Zephyr Project, for each individual programming language or tool used in it.

C Code naming conventions The naming conventions in this section apply to C source and header files, as stated in each individual sub-section.

Public symbol prefixes All *public APIs* introduced to Zephyr must be prefixed according to the area or subsystem they belong to. Examples of area or subsystem prefixes are provided below for reference.

- `k_` for the kernel
- `sys_` for system-wide code and features
- `net_` for the networking subsystem
- `bt_` for the Bluetooth subsystem
- `i2c_` for the I2C controller subsystem

C Code and General Style Guidelines

Coding style is enforced on any new or modified code, but contributors are not expected to correct the style on existing code that they are not modifying.

For style aspects where the guidelines don't offer explicit guidance or permit multiple valid ways to express something, contributors should follow the style of existing code in the tree, with higher importance given to "nearby" code (first look at the function, then the same file, then subsystem, etc).

In general, follow the Linux kernel coding style, with the following exceptions and clarifications:

- Tabs are 8 characters.
- Use snake case for code and variables.
- The line length is 100 columns or fewer. In the documentation, longer lines for URL references are an allowed exception.
- Add braces to every `if`, `else`, `do`, `while`, `for` and `switch` body, even for single-line code blocks.
- Use spaces instead of tabs to align comments after declarations, as needed.
- Use C89-style single line comments, `/* */`. The C99-style single line comment, `//`, is not allowed.
- Use `/** */` for doxygen comments that need to appear in the documentation.
- Avoid using binary literals (constants starting with `0b`).
- Avoid using non-ASCII symbols in code, unless it significantly improves clarity, avoid emojis in any case.
- Use proper capitalization of nouns in code comments (e.g. `UART` and not `uart`, `CMake` and not `cmake`).

Doxygen Style Guidelines

The Zephyr Project uses Doxygen to generate API documentation from source code comments. This guide defines the conventions for documenting Zephyr public APIs consistently.

All the Doxygen commands are available for use even if they don't explicitly appear in this document.

To build and preview Zephyr's Doxygen documentation locally, refer to *Documentation Generation*.

General Rules All *public header files and their public API symbols* (functions, structs, enums, unions, typedefs, macros, and global variables):

- Must be fully documented (see *Hiding internal details* for exceptions)
- Must belong to at least one Doxygen group (see *Groups*)

You must use the following syntax when documenting public APIs:

- Use `/**` to start a block comment and `*/` to end it.
- Use `/**<` for trailing comments on the same line as a symbol.
- Use `@` (not `\`) for Doxygen commands (e.g., `@param` not `\param`).
- The `@brief` command is optional. If not used, the first sentence (ending with a period) is treated as the brief description.

Constructs meant only for internal use must be hidden from the public documentation, as described in *Hiding internal details*.

What to document For any API element that accepts, returns, or stores a value (function parameters, return values, struct/union members, enum values, typedefs, and macros), their documentation must describe the following items when applicable:

Semantics
: What this element represents and how callers/users should interpret it. Don't restate the identifier or the C type.

  Example:

  - Avoid: `@param timeout Timeout value in ms.`
  - Prefer: `@param timeout Maximum time to wait before returning, in milliseconds.`

Valid values
: What values are accepted, and how they are interpreted. Specify one or more of the following:

  - Range: minimum/maximum values (for example, the type is `uint8_t` but only 0–100 are valid).
  - Discrete set: permitted values, when only a subset is allowed.
  - Enum: whether the value must be a valid member of a given enum (and whether all enumerators are allowed or only a subset).
  - Flags/bitmasks: which bits are valid and whether combinations are allowed.
  - Nullability: whether `NULL` is allowed for pointer values, and what it means.

Units
: When the value represents a quantity, specify the unit and reference (for example, milliseconds vs ticks, Hertz, bytes). Use SI unit symbols when applicable, and write a space between the number and the unit symbol (for example, `10 ms`).

Representation
: Any non-obvious encoding or scaling (for example, fixed-point scale, Q format, split integer and fractional fields, endianness requirements).

Ownership and lifetime
: For pointers/buffers, state who allocates/frees and how long the memory must remain valid. Note required size/alignment when relevant.

Writing style Brief descriptions should use the imperative mood (a verb phrase) rather than third-person prose. This keeps API summaries consistent and scannable.

- Avoid: “Transmits data through a pipe.”, “This function gets the device state.”.
- Prefer: “Transmit data through a pipe.”, “Get the device state.”, “Initialize the subsystem.”.

Parameter and member descriptions may be sentence fragments, but they should remain descriptive and avoid repeating the parameter/member name.

Groups Groups organize related symbols into a hierarchy that helps users navigate the API.

- Define each group once with `@defgroup`.
  - The provided title should be a short, descriptive name for the group. As groups inherently collapse various interfaces/API together, do *not* use “API” or “Interface” (or any other variant of these) terms in the title, as this would be redundant.
  - The brief description of the group should not paraphrase its title.
- Group names use snake_case.
- Use `@ingroup` to specify the parent group(s) a group belongs to.

Example:

```
/**
 * @defgroup mqtt_socket MQTT Client library
 * @ingroup networking
 * @since 1.14
 * @version 0.8.0
 * @{
 */

 /* documented contents of the MQTT header file */

 /** @} */
```

Note

A group may belong to multiple parent groups, so you may have multiple `@ingroup` commands. For example, device driver emulators typically appear both in “Emulator Interfaces” and “Device drivers” groups. See I2C Emulation Interface for an example.

API Versioning Use `@since` and `@version` on group definitions (`@defgroup`) to document API history and maturity:

- `@since` indicates the Zephyr release when the API was introduced (e.g., `@since 3.7`)
- `@version` indicates the current API version, following semantic versioning

The version number reflects the API’s maturity as defined in *API Overview*.

Example:

Listing 1: Example for an API introduced in Zephyr 1.14, with current version 0.8.0 (unstable).

```
/**
 * @defgroup mqtt_socket MQTT Client library
 * @ingroup networking
 * @since 1.14
 * @version 0.8.0
 * @{
 */

 /* documented contents of the MQTT header file */

 /** @} */
```

Files Each public header file must have an `@file` block at the top, appearing after the SPDX license and copyright notice.

The `@file` block must also belong to a Doxygen group, typically the one defined in the same header file. This allows users browsing by file to easily navigate to the associated group.

```
/**
 * @file
 * @brief Public API for the GPIO driver.
 * @ingroup gpio_interface
 */
```

Type Definitions Document `struct`, `enum`, `union`, and `typedef` definitions with a brief description.

Document each member (struct field, enum value, etc.) as well. It is recommended to use `/**<` trailing comments style when only a brief description is provided and it can fit on a single line.

Listing 2: Examples of fully documented enum, struct, and typedef.

```
/** @brief Parity modes */
enum uart_config_parity {
     UART_CFG_PARITY_NONE,   /**< No parity */
     UART_CFG_PARITY_ODD,    /**< Odd parity */
     UART_CFG_PARITY_EVEN,   /**< Even parity */
     UART_CFG_PARITY_MARK,   /**< Mark parity */
     UART_CFG_PARITY_SPACE,  /**< Space parity */
};

/**
 * GPIO pin configuration.
 *
 * Specifies direction, pull resistor, and interrupt settings.
 */
struct gpio_config {
    uint32_t flags;    /**< Pin configuration flags. */
    gpio_pin_t pin;    /**< Pin number within the port. */
};

/**
 * @brief Identifies a set of pins associated with a port.
```

(continues on next page)

(continued from previous page)

```
 *
 * The pin with index n is present in the set if and only if the bit
 * identified by (1U << n) is set.
 */
typedef uint32_t gpio_port_pins_t;
```

Functions

Parameters

- Document parameters with `@param` in declaration order
- Use `@param[out]` for pointers the function writes to.
- Use `@param[in,out]` for pointers the function both reads and writes.
- You may omit direction specifiers for const pointers and scalars (implicitly input-only).

Return Values

- Use `@return <description>` for general descriptions (e.g., boolean or computed values).
- Use `@retval <value> <description>` for specific, discrete return values (typically error codes), starting with the success case (when applicable). The `<value>` must be provided as the first word, followed by the description (e.g., `@retval -EINVAL Invalid arguments`, not `@retval -EINVAL if invalid arguments`).

> **Note**
>
> Since there might be multiple reasons for the same discrete value to be returned, it is allowed to use the same value in multiple `@retval` statements.

Example:

Listing 3: Examples of fully documented functions.

```
/**
 * @brief Transmit data through a pipe
 *
 * @param[in] pipe Pipe to transmit through
 * @param buf Data to transmit
 * @param size Number of bytes to transmit
 *
 * @return Number of bytes placed in @p pipe
 * @retval -EPERM Pipe is closed
 * @retval -errno Negative error code on error
 */
int modem_pipe_transmit(struct modem_pipe *pipe, const uint8_t *buf, size_t size);

/**
 * @brief Helper function for converting struct sensor_value to float.
 *
 * @param val A pointer to a sensor_value struct.
 * @return The converted value.
 */
static inline float sensor_value_to_float(const struct sensor_value *val)
{
```

(continues on next page)

(continued from previous page)

```
    return (float)val->val1 + (float)val->val2 / 1000000;
}
```

Macros For function-like macros, document parameters like you would for functions.

Listing 4: Example of a fully documented function-like macro.

```
/**
 * @brief Get a node's (only) register block size
 *
 * Equivalent to DT_REG_SIZE_BY_IDX(node_id, 0).
 *
 * @param node_id node identifier
 * @return node's only register block's size
 */
#define DT_REG_SIZE(node_id) DT_REG_SIZE_BY_IDX(node_id, 0)
```

Hiding internal details Use `@cond INTERNAL_HIDDEN` / `@endcond` to hide internal details from generated documentation.

You may still optionally document these internal symbols to provide a useful reference to internal users.

```
/** Timer structure.
 *
 * Opaque type for a timer object. All the fields in this structure are internal␣
↪and should not
 * be accessed outside of kernel code.
 */
struct k_timer {
    /** @cond INTERNAL_HIDDEN */

    /* ... internal members ... */

    /** @endcond */
};
```

Conditional code To ensure conditionally-compiled code appears in documentation, use either of the following approaches:

1. Add the Kconfig macro (`CONFIG_...`) that is gating the code to the `PREDEFINED` list in doc/zephyr.doxyfile.in. This makes the code visible to Doxygen during documentation generation.
2. Alternatively, you can rely on the `__DOXYGEN__` macro being set to make the conditional code visible to Doxygen, as this macro is automatically defined by Doxygen.

```
struct coap_packet {
    uint8_t *data;  /**< User allocated buffer. */
#if defined(CONFIG_COAP_KEEP_USER_DATA) || defined(__DOXYGEN__)
    /**
     * Application-specific user data.
     * @kconfig_dep{CONFIG_COAP_KEEP_USER_DATA}
     */
    void *user_data;
```

(continues on next page)

(continued from previous page)

```
#endif
};
```

Kconfig Dependencies The `@kconfig_dep` command can be used to document the Kconfig option(s) that are required in order for an API symbol to be available to the user. The command can be used with one, two or three Kconfig options.

For example, adding `@kconfig_dep{CONFIG_PM,CONFIG_SMP}` to the Doxygen documentation of an API symbol will cause the generated documentation to include a note reading: "Available only when the following Kconfig options are enabled: `CONFIG_PM`, `CONFIG_SMP`.".

You can see an example of `@kconfig_dep` usage in the documentation of `coap_packet`.

CMake Style Guidelines

General Formatting

- **Indentation**: Use **2 spaces** for indentation. Avoid tabs to ensure consistency across different environments.
- **Line Length**: Limit line length to **100 characters** where possible.
- **Empty Lines**: Use empty lines to separate logically distinct sections within a CMake file.
- **No Space Before Opening Brackets**: Do not add a space between a command and the opening parenthesis. Use `if(...)` instead of `if (...)`.

```
# Good:
if(ENABLE_TESTS)
  add_subdirectory(tests)
endif()

# Bad:
if (ENABLE_TESTS)
  add_subdirectory(tests)
endif()
```

Commands and Syntax

- **Lowercase Commands**: Always use **lowercase** CMake commands (e.g., `add_executable`, `find_package`). This improves readability and consistency.

```
# Good:
add_library(my_lib STATIC src/my_lib.cpp)

# Bad:
ADD_LIBRARY(my_lib STATIC src/my_lib.cpp)
```

- **One File Argument per Line**: Break the file arguments across multiple lines to make it easier to scan and identify each source file or item.

```
# Good:
target_sources(my_target PRIVATE
  src/file1.cpp
  src/file2.cpp
)

 # Bad:
target_sources(my_target PRIVATE src/file1.cpp src/file2.cpp)
```

Variable Naming

- **Use Uppercase for Cache Variables or variables shared across CMake files**: When defining cache variables using `option` or `set(... CACHE ...)`, use **UPPERCASE names**.

```
option(ENABLE_TESTS "Enable test suite" ON)
set(CMAKE_CXX_STANDARD 17 CACHE STRING "C++ standard version")
```

- **Use Lowercase for Local Variables**: For local variables within CMake files, use **lowercase** or **snake_case**.

```
set(output_dir "${CMAKE_BINARY_DIR}/output")
```

- **Consistent Prefixing**: Use consistent prefixes for variables to avoid name conflicts, especially in large projects.

```
set(MYPROJECT_SRC_DIR "${CMAKE_SOURCE_DIR}/src")
```

Quoting

- **Quote Strings and Variables**: Always quote string literals and variables to prevent unintended behavior, especially when dealing with paths or arguments that may contain spaces.

```
# Good:
set(my_path "${CMAKE_SOURCE_DIR}/include")

# Bad:
set(my_path ${CMAKE_SOURCE_DIR}/include)
```

- **Do Not Quote Boolean Values**: For boolean values (`ON`, `OFF`, `TRUE`, `FALSE`), avoid quoting them.

```
option(BUILD_SHARED_LIBS "Build shared libraries" OFF)
```

Avoid Hardcoding Paths

- Use CMake variables (`CMAKE_SOURCE_DIR`, `CMAKE_BINARY_DIR`, `CMAKE_CURRENT_SOURCE_DIR`) instead of hardcoding paths.

```
set(output_dir "${CMAKE_BINARY_DIR}/bin")
```

Conditional Logic

- Use `if`, `elseif`, and `else` with proper indentation, and close with `endif()`.

```
if(ENABLE_TESTS)
  add_subdirectory(tests)
endif()
```

Documentation

- Use comments to document complex logic in the CMake files.

```
# Find LlvmLld components required for building with llvm
find_package(LlvmLld 14.0.0 REQUIRED)
```

Devicetree Style Guidelines

- Indent with tabs.
- Tab size is 8 characters.
- Follow the Devicetree specification conventions and rules.
- If the Linux kernel rules in Devicetree Sources (DTS) Coding Style make a recommendation, it's the preferred style in Zephyr too.
- You can split related groups of properties into "paragraphs" by separating them with one empty line (two newline characters) if it aids readability.
- Use dashes (-) as word separators for node and property names.
- Use underscores (_) as word separators in node labels.
- Leave a single space on each side of the equal sign (=) in property definitions.
- Don't insert empty lines before a dedenting `};`.
- Insert a single empty line to separate nodes at the same hierarchy level.
- When splitting long property values across multiple lines, specify the first value on the same line as the opening bracket (`<` or `[`). Place the closing bracket and semicolon (`>;` or `];`) on the same line after the final value of the property.

Examples:

```
/dts-v1/;

/ {
        /* Node labels use the "_" separator, but node names use "-". */
        psa_rng: psa-rng {
                compatible = "zephyr,psa-crypto-rng";
                status = "okay";
        };

        ramdisk0 {
                compatible = "zephyr,ram-disk";
                /* Property names use the "-" separator. */
                disk-name = "RAM";
                sector-size = <512>;
                sector-count = <128>;
        };

        periph0 {
                /* Wrap array values to conform with line lengths. Indent
                 * continuation so that values align.
                 */
                pinctrl-0 = <&periph0_siga_px0_default &periph0_sigb_py7_default
                             &periph0_sigc_pz1_default>;
                pinctrl-names = "default";
        };

        mipi-dbi {
                compatible = "zephyr,mipi-dbi-spi";

                lcd0: lcd@0 {
                        compatible = "sitronix,st7735r";
                        /* Split array values across multiple lines to help␣
↪readability. */
```

(continues on next page)

(continued from previous page)

```
                        gamctrp1 = [10 0e 02 03
                                    0e 07 02 07
                                    0a 12 27 37
                                    00 0d 0e 10];
                        gamctrn1 = [10 0e 03 03
                                    0f 06 02 08
                                    0a 13 26 36
                                    00 0d 0e 10];
                };
        };
};
```

Kconfig Style Guidelines

This document provides style guidelines for writing Kconfig files in the Zephyr project. Following these guidelines ensures consistency and readability across the codebase, making it easier for developers to understand and maintain configuration options.

The following sections provide guidelines with examples to illustrate proper Kconfig formatting and naming conventions.

Basic Formatting Rules When writing Kconfig files, follow these basic formatting rules:

- **Line length**: Keep lines to 100 columns or fewer.
- **Indentation**: Use tabs for indentation, except for `help` entry text which should be placed at one tab plus two extra spaces.
- **Spacing**: Leave a single empty line between option declarations.
- **Comments**: Format comments as `# Comment` rather than `#Comment`.
- **Conditional blocks**: Insert an empty line before/after each top-level `if` and `endif` statement.

For guidance on using statements like `select`, see *Kconfig - Tips and Best Practices* for more information.

Symbol Naming and Structure The following examples demonstrate proper Kconfig symbol naming and structure:

```
# Symbol to enable/disable the feature ("enabling symbol")
config ADC_AD405X
        bool "AD405X ADC driver"
        depends on DT_HAS_ADI_AD4052_ADC_ENABLED || DT_HAS_ADI_AD4050_ADC_ENABLED
        select SPI
        default y
        help
          Enable ADC driver for AD405X.
```

```
# Symbol to enable/disable the feature ("enabling symbol")
menuconfig ADC_AD4114
        bool "AD4114 ADC driver"
        depends on DT_HAS_ADI_AD4114_ADC_ENABLED
        select SPI
        default y
        help
          Enable the AD4114 ADC driver.
```

(continues on next page)

(continued from previous page)

```
if ADC_AD4114

# Symbol to configure the behavior of the feature ("config symbol")
config ADC_AD4114_ACQUISITION_THREAD_STACK_SIZE
        int "Stack size for the data acquisition thread"
        default 512
        help
          Size of the stack used for the internal data acquisition
          thread.

# Symbol to configure the behavior of the feature ("config symbol")
config ADC_AD4114_ACQUISITION_THREAD_PRIO
        int "Priority for the data acquisition thread"
        default 0
        help
          Priority level for the internal ADC data acquisition thread.

endif # ADC_AD4114
```

Naming Conventions

- As a general rule, symbols concerning the same component should be distinct from other symbols. This can usually be accomplished by using a common prefix. This prefix can be a simple keyword or, as in the case for drivers, several keywords for more precision.
- A common prefix usually indicates the subsystem or component the symbol belongs to.
- An enabling symbol name should consist of keywords to provide the context of the symbol in a scope from most general to most specific (e.g. *Driver Type -> Driver Name*).
- The prompt for an enabling symbol should use the same logic as the symbol name itself but use the keywords in reversed order.
  - Adhering to this style makes searching for symbols easier in the UI because one can filter by a scope keyword.
- When the enabling symbol is dependent on a devicetree node, consider depending on the *automatically created* `DT_HAS_<node>_ENABLED` symbol.
- When building complex expressions based on devicetree node compatibles, use the *automatically defined* `DT_COMPAT_VND_DEVICE` instead of defining a variable equal to *vnd*, *device* manually.

The specific formats by subtree:

- **Drivers (/drivers)**: Use the format `{Driver Type}_{Driver Name}` for symbols and `{Driver Name} {Driver Type} driver` for prompts.
- **Sensors (/drivers/sensors)**: Use the format `SENSOR_{Sensor Name}` for symbols and `{Sensor Name} {Sensor Type} sensor driver` for prompts.
- **Architecture (/arch)**: Many symbols are shared across architectures. Before creating new symbols, check if similar ones already exist in other architectures.
- **Samples (/samples)**: Use `SAMPLE_` for symbols, this is to prevent conflicts with external modules.
- **Tests (/tests)**: Use `TEST_` for symbols, this is to prevent conflicts with external modules.
- **Boards (/boards)**: Use `BOARD_` for symbols.

- **SoCs (/soc)**: Use the most appropriate base for symbols: `SOC_FAMILY_{SoC family}_` if it relates to a whole SoC family, `SOC_SERIES_{SoC series}_` if it relates to a whole SoC series, or `SOC_{SoC}_` if it relates to a specific SoC - see *SoC Porting Guide* for details on these terms and where they must originate from. This is to prevent conflicts with other vendors and external modules.

> **Note**
>
> The following examples only show the symbol and prompt lines for brevity.

Examples **Driver Examples:**

```
config ADC_AD405X
        bool "AD405X ADC driver"

config CAN_MAX32
        bool "MAX32 CAN driver"

config I2C_EMUL
        bool "I2C emulator driver"
```

Sensor Examples:

```
config SENSOR_BMP581
        bool "BMP581 barometric pressure sensor driver"

config SENSOR_TMP007
        bool "TMP007 infrared thermopile sensor driver"

config SENSOR_LM75
        bool "LM75 temperature sensor driver"
```

Sample examples:

```
config SAMPLE_LOCK
        bool "Locking feature"

config SAMPLE_TEMPERATURE_READINGS
        bool "Fetch readings from temperature sensor"
```

Test examples:

```
config TEST_ITERATIONS
        int "Number of times test should run"
        default 3
```

SoC examples:

```
# This assumes the following soc.yml file:
# family:
#   - name: alpha
#     series:
#       - name: foxtrot
#         socs:
#           - name: charlie

config SOC_FAMILY_ALPHA_JTAG_LOCK
```

(continues on next page)

(continued from previous page)

```
        bool "Lock JTAG access"

config SOC_SERIES_FOXTROT_EMULATE_POWER_OFF
        bool "Emulate power off mode"

config SOC_CHARLIE_IMAGE_HEADER
        bool "Include image header"
```

Configuration Symbol Organization When a feature uses config symbols to configure its behavior:

- Use `menuconfig` instead of `config` to define the enabling feature (even when the config symbol has no prompt).
- Encapsulate the config symbols in an `if` statement to declare their dependency on the enabling symbol (this automatically groups these symbols under the enabling symbol in the UI).
- Prefix the config symbol with the enabling symbol's name for scope and context.
- In the prompt of the config symbol, describe what the symbol configures without repeating the scope keywords, because the grouping in the UI provides this context.

File Organization When organizing Kconfig files:

- Keep the Kconfig file close to the source files it configures.
- When dealing with large Kconfig files (e.g. with many config symbols), consider grouping (some of) them into a separate file and import it using the `source` directive to improve readability.

Python Style Guidelines

Python should be formatted in a PEP 8 compliant manner. Zephyr uses the ruff formatter to achieve this. This opinionated formatter aims for consistency, generality, readability and reducing git diffs.

To apply the formatter, run:

```
ruff check --select I --fix <file> # Sort imports
ruff format <file>
```

Ruff configuration A small set of options is applied on top of the defaults:

- Line length of 100 columns or fewer.
- Both single `'` and double `"` quote styles are allowed.
- Line endings will be converted to `\n`. The default line ending on Unix.

Excluded files The formatter is enforced in CI, but only for newly added Python files, because the project already had a large Python codebase when this was introduced. The .ruff-excludes.toml file has a `[format]` section where all the files that are currently excluded are listed. It is encouraged for contributors, when changing an excluded file, to remove it from the list and format it in a separate commit.

Style Tools

Checkpatch The Linux kernel GPL-licensed tool `checkpatch` is used to check coding style conformity.

> **Note**
>
> checkpatch does not currently run on Windows.

Checkpatch is available in the scripts directory. To invoke it when committing code, make the file *$ZEPHYR_BASE/.git/hooks/pre-commit* executable and edit it to contain:

```
#!/bin/sh
set -e exec
exec git diff --cached | ${ZEPHYR_BASE}/scripts/checkpatch.pl -
```

Instead of running checkpatch at each commit, you may prefer to run it only before pushing on zephyr repo. To do this, make the file *$ZEPHYR_BASE/.git/hooks/pre-push* executable and edit it to contain:

```
#!/bin/sh
remote="$1"
url="$2"

z40=0000000000000000000000000000000000000000

echo "Run push hook"

while read local_ref local_sha remote_ref remote_sha
do
    args="$remote $url $local_ref $local_sha $remote_ref $remote_sha"
    exec ${ZEPHYR_BASE}/scripts/series-push-hook.sh $args
done

exit 0
```

If you want to override checkpatch verdict and push you branch despite reported issues, you can add option –no-verify to the git push command.

A different way for running `checkpatch` is by using *check_compliance.py* script, which does additional style and compliance related checks.

clang-format The clang-format tool can be helpful to quickly reformat large amounts of new source code to our *Coding Style Guidelines* standards together with the `.clang-format` configuration file provided in the repository. `clang-format` is well integrated into most editors, but you can also run it manually like this:

```
clang-format -i my_source_file.c
```

`clang-format` is part of LLVM, which can be downloaded from the project releases page. Note that if you are a Linux user, `clang-format` will likely be available as a package in your distribution repositories.

When there are differences between the *Coding Style Guidelines* guidelines and the formatting generated by code formatting tools, the *Coding Style Guidelines* guidelines take precedence. If there is ambiguity between formatting tools and the guidelines, maintainers may decide which style should be adopted.

dts-linter The dts-linter can be helpful to quickly reformat large amounts of devicetree files to our *Coding Style Guidelines* standards. You can also run it manually like this:

For individual files

```
npx --prefix ./scripts/ci dts-linter --format --file board.dts --file␣
↪board_pinctrl.dtsi --patchFile diff.patch
git apply diff.patch
```

You can omit `--file` and this will format all files under the directory where the command has been called. Alternatively `--cwd` can also be passed set the base dir where the tool should look for files. This option is also used to make the paths relative in the patch file.

You can also fix in place with

```
npx --prefix ./scripts/ci dts-linter --formatFixAll
```

Editor Integration

- For VS Code: Install the extension from the VS Code Marketplace or Open VSIX
- For other editors with LSP Client support: Use the devicetree-language-server devicetree-language-server

Make sure you follow Devicetree Style Guidelines requirements to configure the editor correctly.

8.1.6 Proposals and RFCs

Many changes, including bug fixes and documentation improvements can be implemented and reviewed via the normal GitHub pull request workflow.

Many changes however are "substantial" and need to go through a design process and produce a consensus among the project stakeholders.

The "RFC" (request for comments) process is intended to provide a consistent and controlled path for new features to enter the project.

Contributors and project stakeholders should consider using this process if they intend to make "substantial" changes to Zephyr or its documentation. Some examples that would benefit from an RFC are:

- A new feature that creates new API surface area, and would require a feature flag if introduced.
- The modification of an existing stable API.
- The removal of features that already shipped as part of Zephyr.
- The introduction of new idiomatic usage or conventions, even if they do not include code changes to Zephyr itself.

The RFC process is a great opportunity to get more eyeballs on proposals coming from contributors before it becomes a part of Zephyr. Quite often, even proposals that seem "obvious" can be significantly improved once a wider group of interested people have a chance to weigh in.

The RFC process can also be helpful to encourage discussions about a proposed feature as it is being designed, and incorporate important constraints into the design while it's easier to change, before the design has been fully implemented.

For a Major Feature, first open an issue and outline your proposal so that it can be discussed. This will also allow us to better coordinate our efforts, prevent duplication of work, and help you to craft the change so that it is successfully accepted into the project. Providing the following information will increase the chances of your issue being dealt with quickly:

- Overview of the Proposal

- Motivation for or Use Case
- Design Details
- Alternatives
- Test Strategy

Some changes or contributions do not require an RFC, the rationale and details of the changes should however be part of the pull-request:

- Small enhancements and modifications to existing and established subsystems.
- Rephrasing, reorganizing or refactoring
- Addition or removal of warnings
- Addition of new boards, SoCs or drivers to existing subsystems
- ...

The process in itself consists in creating a GitHub issue with the *RFC label* that documents the proposal thoroughly. You are encouraged to use the RFC form to make sure the proposal follows a template which project participants are already familiar with.

As with Pull Requests, RFCs might require discussion in the context of one of the Zephyr meetings in order to move it forward in cases where there is either disagreement or not enough voiced opinions in order to proceed. Make sure to either label it appropriately or include it in the corresponding GitHub project in order for it to be examined during the next meeting.

8.1.7 Modifying Contributions made by other developers

Scenarios

Zephyr contributors and collaborators are encouraged to assist as reviewers in pull requests, so that patches may be approved and merged to Zephyr's main branch as part of the original pull requests. The authors of the pull requests are responsible for amending their original commits following the review process.

There are occasions, however, when a contributor might need to modify patches included in pull requests that are submitted by other Zephyr contributors. For instance, this is the case when:

- a developer cherry-picks commits submitted by other contributors into their own pull requests in order to:
  - integrate useful content which is part of a stale pull request, or
  - get content merged to the project's main branch as part of a larger patch
- a developer pushes to a branch or pull request opened by another contributor in order to:
  - assist in updating pull requests in order to get the patches merged to the project's main branch
  - drive stale pull requests to completion so they can be merged

Accepted policies

A developer who intends to cherry-pick and potentially modify patches sent by another contributor shall:

- clarify in their pull request the reason for cherry-picking the patches, instead of assisting in getting the patches merged in their original pull request, and
- invite the original author of the patches to their pull request review.

A developer who intends to force-push to a branch or pull request of another Zephyr contributor shall clarify in the pull request the reason for pushing and for modifying the existing patches (e.g. stating that it is done to drive the pull request review to completion, when the pull request author is not able to do so).

Note

Developers should try to limit the above practice to pull requests identified as *stale*. Read about how to identify pull requests as stale in *development processes and tools*

If the original patches are substantially modified, the developer can either:

- (preferably) reach out to the original author and request them to acknowledge that the modified patches may be merged while having the original sign-off line and author identity, or
- submit the modified patches as their *own* work (i.e. with their *own* sign-off line and author identity). In this case, the developer shall identify in the commit message(s) the original source the submitted work is based on (mentioning, for example, the original PR number).

Note

Contributors should uncheck the box *"Allow Edits By Maintainers"* to indicate that they do not wish their patches to be amended, inside their original branch or pull request, by other Zephyr developers.

Contribution Guidelines
: Learn about the overall process and guidelines for contributing to the Zephyr project.

  This page is a mandatory read for first-time contributors as it contains important information on how to ensure your contribution can be considered for inclusion in the project and potentially merged.

Contributor Expectations
: This document is another mandatory read that describes the expected behavior of *all* contributors to the project.

Reviewer Expectations
: This document is another mandatory read that describes the expected behavior when reviewing contributions to the project.

Coding Guidelines
: Code contributions are expected to follow a set of coding guidelines to ensure consistency and readability across the code base.

Coding Style Guidelines
: Code contributions are expected to follow a set of style guidelines to ensure consistency and readability across the code base.

Proposals and RFCs
: Learn when and how to submit RFCs (Request for Comments) for new features and changes to the project.

Modifying Contributions made by other developers
: Guidelines for modifying contributions made by other developers and how to deal with stale pull requests.

8.2 Documentation

The Zephyr project thrives on good documentation. Whether it is as part of a code contribution or as a standalone effort, contributing documentation is particularly valuable to the project.

8.2.1 Documentation Guidelines

> **Note**
>
> For instructions on building the documentation, see *Documentation Generation*.

Zephyr Project content is written using the reStructuredText[2] markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted standalone website. Developers can view this content either in its raw form as .rst markup files, or (with Sphinx installed) they can *build the documentation* locally to generate the documentation in HTML or PDF format. The HTML content can then be viewed using a web browser. This same .rst content is served by the Zephyr documentation[4] website.

You can read details about reStructuredText[2] and about Sphinx extensions[1] from their respective websites.

This document provides a quick reference for commonly used reST and Sphinx-defined directives and roles used to create the documentation you're reading.

For instructions regarding writing good C API documentation, see *Doxygen Style Guidelines*.

Content Structure

Tabs, spaces, and indenting Indenting is significant in reST file content, and using spaces is preferred. Extra indenting can (unintentionally) change the way content is rendered too. For lists and directives, indent the content text to the first non-white space in the preceding line. For example:

```
* List item that spans multiple lines of text
  showing where to indent the continuation line.

1. And for numbered list items, the continuation
   line should align with the text of the line above.

.. code-block::

   The text within a directive block should align with the
   first character of the directive name.
```

Refer to the Zephyr *Coding Style Guidelines* for additional requirements.

Headings While reST allows use of both an overline and matching underline to indicate a heading, we only use an underline indicator for headings.

- Document title (h1) use # for the underline character
- First section heading level (h2) use *
- Second section heading level (h3) use =
- Third section heading level (h4) use -

[2] https://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html
[4] https://docs.zephyrproject.org
[1] https://www.sphinx-doc.org/en/stable/contents.html

The heading underline must be the same length as the heading text.

For example:

```
This is a title heading
#######################

some content goes here

First section heading
*********************
```

Lists For bullet lists, place an asterisk (*) or hyphen (-) at the start of a paragraph and indent continuation lines with two spaces.

The first item in a list (or sublist) must have a blank line before it and should be indented at the same level as the preceding paragraph (and not indented itself).

For numbered lists start with a 1. or a. for example, and continue with autonumbering by using a # sign. Indent continuation lines with three spaces:

```
* This is a bulleted list.
* It has two items, the second
  item and has more than one line of reST text.  Additional lines
  are indented to the first character of the
  text of the bullet list.

1. This is a new numbered list. If the wasn't a blank line before it,
   it would be a continuation of the previous list (or paragraph).
#. It has two items too.

a. This is a numbered list using alphabetic list headings
#. It has three items (and uses autonumbering for the rest of the list)
#. Here's the third item

#. This is an autonumbered list (default is to use numbers starting
   with 1).

   #. This is a second-level list under the first item (also
      autonumbered).  Notice the indenting.
   #. And a second item in the nested list.
#. And a second item back in the containing list.  No blank line
   needed, but it wouldn't hurt for readability.
```

Definition lists (with a term and its definition) are a convenient way to document a word or phrase with an explanation. For example this reST content:

```
The Makefile has targets that include:

html
   Build the HTML output for the project

clean
   Remove all generated output, restoring the folders to a
   clean state.
```

Would be rendered as:

The Makefile has targets that include:

html
Build the HTML output for the project

clean
Remove all generated output, restoring the folders to a clean state.

Multi-column lists If you have a long bullet list of items, where each item is short, you can indicate the list items should be rendered in multiple columns with a special `.. rst-class:: rst-columns` directive. The directive will apply to the next non-comment element (e.g., paragraph), or to content indented under the directive. For example, this unordered list:

```
.. rst-class:: rst-columns

* A list of
* short items
* that should be
* displayed
* horizontally
* so it doesn't
* use up so much
* space on
* the page
```

would be rendered as:

- A list of
- short items
- that should be
- displayed
- horizontally
- so it doesn't
- use up so much
- space on
- the page

A maximum of three columns will be displayed, and change based on the available width of the display window, reducing to one column on narrow (phone) screens if necessary. We've deprecated use of the `hlist` directive because it misbehaves on smaller screens.

Tables There are a few ways to create tables, each with their limitations or quirks. Grid tables offer the most capability for defining merged rows and columns, but are hard to maintain:

```
+------------------------+------------+----------+----------+
| Header row, column 1   | Header 2   | Header 3 | Header 4 |
| (header rows optional) |            |          |          |
+========================+============+==========+==========+
| body row 1, column 1   | column 2   | column 3 | column 4 |
+------------------------+------------+----------+----------+
| body row 2             | ...        | ...      | you can  |
+------------------------+------------+----------+ easily   +
| body row 3 with a two column span   | ...      | span     |
+------------------------+------------+----------+ rows     +
| body row 4             | ...        | ...      | too      |
+------------------------+------------+----------+----------+
```

This example would render as:

Header row, column 1 (header rows optional)	Header 2	Header 3	Header 4
body row 1, column 1	column 2	column 3	column 4
body row 2	...	...	you can easily span rows too
body row 3 with a two column span		...	
body row 4	...	...	

List tables are much easier to maintain, but don't support row or column spans:

```
.. list-table:: Table title
   :widths: 15 20 40
   :header-rows: 1

   * - Heading 1
     - Heading 2
     - Heading 3
   * - body row 1, column 1
     - body row 1, column 2
     - body row 1, column 3
   * - body row 2, column 1
     - body row 2, column 2
     - body row 2, column 3
```

This example would render as:

Table 4: Table title

Heading 1	Heading 2	Heading 3
body row 1, column 1	body row 1, column 2	body row 1, column 3
body row 2, column 1	body row 2, column 2	body row 2, column 3

The `:widths:` parameter lets you define relative column widths. The default is equal column widths. If you have a three-column table and you want the first column to be half as wide as the other two equal-width columns, you can specify `:widths: 1 2 2`. If you'd like the browser to set the column widths automatically based on the column contents, you can use `:widths: auto`.

Tabbed Content As introduced in the *Getting Started Guide*, you can provide alternative content to the reader via a tabbed interface. When the reader clicks on a tab, the content for that tab is displayed, for example:

```
.. tabs::

   .. tab:: Apples

      Apples are green, or sometimes red.

   .. tab:: Pears

      Pears are green.
```

(continues on next page)

(continued from previous page)

```
   .. tab:: Oranges

      Oranges are orange.
```

will display as:

Apples

Apples are green, or sometimes red.

Pears

Pears are green.

Oranges

Oranges are orange.

Tabs can also be grouped, so that changing the current tab in one area changes all tabs with the same name throughout the page. For example:

Linux

Linux Line 1

macOS

macOS Line 1

Windows

Windows Line 1

Linux

Linux Line 2

macOS

macOS Line 2

Windows

Windows Line 2

In this latter case, we're using `.. group-tab::` instead of simply `.. tab::`. Under the hood, we're using the sphinx-tabs extension that's included in the Zephyr setup. Within a tab, you can have most any content *other than a heading* (code-blocks, ordered and unordered lists, pictures, paragraphs, and such). You can read more about sphinx-tabs from the link above.

Text Formatting

ReSTructuredText supports a variety of text formatting options. This section provides a quick reference for some of the most commonly used text formatting options in Zephyr documentation. For an exhaustive list, refer to the reStructuredText Quick Reference[5], reStructuredText Interpreted Text Roles[6] as well as the additional roles provided by Sphinx[7].

Content Highlighting Some common reST inline markup samples:

- one asterisk: `*text*` for emphasis (*italics*),
- two asterisks: `**text**` for strong emphasis (**boldface**), and
- two backquotes: ``` ``text`` ``` for `inline code` samples.

[5] https://docutils.sourceforge.io/docs/user/rst/quickref.html
[6] https://docutils.sourceforge.io/docs/ref/rst/roles.html
[7] https://www.sphinx-doc.org/en/master/usage/restructuredtext/roles.html

If asterisks or backquotes appear in running text and could be confused with inline markup delimiters, you can eliminate the confusion by adding a backslash (\) before it.

File Names and Commands Sphinx extends reST by supporting additional inline markup elements (called "roles") used to tag text with special meanings and allow style output formatting. (You can refer to the Sphinx Inline Markup[3] documentation for the full list).

While double quotes can be used for rendering text as "code", you are encouraged to use the following roles for marking up file names, command names, and other "special" text.

- `file` for file names, e.g., `:file:\`CMakeLists.txt\`` will render as `CMakeLists.txt`

> **Note**
>
> In case you want to indicate a "variable" file path, you may use curly braces to enclose the variable part of the path, e.g., `:file:\`{boardname}_defconfig\`` will render as *boardname*`_defconfig`.

- `command` for command names, e.g., `:command:\`make\`` will render as **make**
- `envvar` for environment variables, e.g., `:envvar:\`ZEPHYR_BASE\`` will render as *ZEPHYR_BASE*

For creating references to files that are hosted in the Zephyr organization on GitHub, refer to *Cross-referencing files in the Zephyr tree* section below.

User Interaction When documenting user interactions, such as key combinations or GUI interactions, use the following roles to highlight the commands in a meaningful way:

- `kbd` for keyboard input, e.g., `:kbd:\`Ctrl-C\`` will render as `Ctrl-C`
- `menuselection` for menu selections, e.g., `:menuselection:\`File --> Open\`` will render as *File ▸ Open*
- `guilabel` for GUI labels, e.g., `:guilabel:\`Cancel\`` will render as *Cancel*

Mathematical Formulas You can include mathematical formulas using either the `math` role or `math` directive. The directive provides more flexibility in case you have a more complex formula.

The input language for mathematics is LaTeX markup. Example:

```
The answer to life, the universe, and everything is :math:`30 + 2^2 + \sqrt{64} =␣
↪42`.
```

This would render as:

> The answer to life, the universe, and everything is $30 + 2^2 + \sqrt{64} = 42$.

Non-ASCII Characters Prefer plain ASCII unless a specific symbol is required for correctness or conventional typography (for example units like µ, or well-known marks like ™).

Avoid adding non-ASCII characters purely for aesthetic purposes.

The file doc/substitutions.txt contains some basic HTML substitution definitions for special formatting needs (e.g. to force line breaks), but Unicode characters can and should be used directly in the documentation source files.

[3] https://sphinx-doc.org/markup/inline.html#inline-markup

Code Blocks and Command Examples Use the reST `code-block` directive to create a highlighted block of fixed-width text, typically used for showing formatted code or console commands and output. Smart syntax highlighting is also supported (using the Pygments package). You can also directly specify the highlighting language. For example:

```
.. code-block:: c

   struct k_object {
      char *name;
      uint8_t perms[CONFIG_MAX_THREAD_BYTES];
      uint8_t type;
      uint8_t flags;
      uint32_t data;
   } __packed;
```

Note the blank line between the `code-block` directive and the first line of the code-block body, and the body content is indented three spaces (to the first non-white space of the directive name).

This would be rendered as:

```c
struct k_object {
   char *name;
   uint8_t perms[CONFIG_MAX_THREAD_BYTES];
   uint8_t type;
   uint8_t flags;
   uint32_t data;
} __packed;
```

Other languages are of course supported (see languages supported by Pygments[8]), and in particular, you are encouraged to make use of the following when appropriate:

- `c` for C code
- `cpp` for C++ code
- `python` for Python code
- `console` for console output, i.e. interactive shell sessions where commands are prefixed by a prompt (ex. `$` for Linux, or `uart:~$` for Zephyr's shell), and where the output is also shown. The commands will be highlighted, and the output will not. What's more, copying code block using the "copy" button will automatically copy just the commands, excluding the prompt and the outputs of the commands.
- `shell` or `bash` for shell commands. Both languages get highlighted the same but you may use `bash` for conveying that the commands are bash-specific, and `shell` for generic shell commands.

> **Note**
>
> Do not use `bash` or `shell` if your code block includes a prompt, use `console` instead.
>
> Reciprocally, do not use `console` if your code block does not include a prompt and is not showcasing an interactive session with command(s) and their output.

[8] https://pygments.org/languages/

Table 5: When to use bash/shell vs. console

Use case	code-block snippet	Expected output

One or several commands, no output	`.. code-block:: shell`
	
	`echo "Hello World!"`
		`echo "Hello World!"`

An interactive shell session with command(s) and their output	`.. code-block:: console`
	
	`$ echo "Hello World!"`
	`Hello World!`
		`$ echo "Hello World!"`
		`Hello World!`

An interactive Zephyr shell session, with commands and their outputs	`.. code-block:: console`
	
	`uart:~$ version`
	`Zephyr version 3.5.99`
	`uart:~$ kernel uptime`
	`Uptime: 20970 ms`
		`uart:~$ version`
		`Zephyr version 3.5.99`
		`uart:~$ kernel uptime`
		`Uptime: 20970 ms`

- `bat` for Windows batch files
- `cfg` for config files with "KEY=value" entries (ex. Kconfig `.conf` files)
- `cmake` for CMake
- `devicetree` for Devicetree
- `kconfig` for Kconfig
- `yaml` for YAML
- `rst` for reStructuredText

When no language is specified, the language is set to `none` and the code block is not highlighted. You may also use `none` explicitly to achieve the same result; for example:

```
.. code-block:: none

   This would be a block of text styled with a background
   and box, but with no syntax highlighting.
```

Would display as:

```
This would be a block of text styled with a background
and box, but with no syntax highlighting.
```

There's a shorthand for writing code blocks too: end the introductory paragraph with a double colon (`::`) and indent the code block content that follows it by three spaces. On output, only one colon will be shown. The code block will have no highlighting (i.e. `none`). You may however use the `highlight` directive to customize the default language used in your document (see for example how this is done at the beginning of this very document).

Links and Cross-References

Cross-referencing internal content Traditional ReST links are only supported within the current file using the notation:

```
Refer to the `internal-linking`_ page
```

which renders as,

> Refer to the *internal-linking* page

Note the use of a trailing underscore to indicate an outbound link. In this example, the label was added immediately before a heading, so the text that's displayed is the heading text itself. You can change the text that's displayed as the link writing this as:

```
Refer to the `show this text instead <internal-linking_>`_ page
```

which renders as,

> Refer to the *show this text instead* page

Cross-referencing external content With Sphinx's help, we can create link-references to any tagged text within the Zephyr Project documentation.

Target locations in a document are defined with a label directive:

```
.. _my label name:

Heading
=======
```

Note the leading underscore indicating an inbound link. The content immediately following this label must be a heading, and is the target for a `:ref:`my label name`` reference from anywhere within the Zephyr documentation. The heading text is shown when referencing this label. You can also change the text that's displayed for this link, such as:

```
:ref:`some other text <my label name>`
```

To enable easy cross-page linking within the site, each file should have a reference label before its title so it can be referenced from another file. These reference labels must be unique across the whole site, so generic names such as "samples" should be avoided. For example the top of this document's .rst file is:

```
.. _doc_guidelines:

Documentation Guidelines for the Zephyr Project
###############################################
```

Other .rst documents can link to this document using the `:ref:`doc_guidelines`` tag and it will show up as *Documentation Guidelines*. This type of internal cross reference works across multiple files, and the link text is obtained from the document source so if the title changes, the link text will update as well.

You can also define links to any URL and then reference it in your document. For example, with this label definition in the document:

```
.. _Zephyr Wikipedia Page:
   https://en.wikipedia.org/wiki/Zephyr_(operating_system)
```

you can reference it with:

```
Read the `Zephyr Wikipedia Page`_ for more information about the
project.
```

Tip

When a document contains many external links, it can be useful to list them in a single "References" section at the end of the document. This can be done using the `target-notes` directive. Example:

```
References
==========

.. target-notes::

.. _external_link1: https://example.com
.. _external_link2: https://example.org
```

Cross-referencing C documentation

:c:member:

:c:data:

:c:var:

:c:func:

:c:macro:

:c:struct:

:c:union:

:c:enum:

:c:enumerator:

:c:type:

You may use these roles to cross-reference the Doxygen documentation of C functions, macros, types, etc.

They are rendered in the HTML output as links to the corresponding Doxygen documentation for the item. For example:

```
Check out :c:function:`gpio_pin_configure` for more information.
```

Will render as:

> Check out `gpio_pin_configure()` for more information.

You may provide a custom link text, similar to the built-in `ref` role.

Visual Elements

Images Images are included in the documentation by using an `image` directive:

```
.. image:: ../../../../images/doc-gen-flow.png
   :align: center
   :alt: alt text for the image
```

or if you'd like to add an image caption, use:

```
.. figure:: ../../../../images/doc-gen-flow.png
   :alt: image description

   Caption for the figure
```

The file name specified is relative to the document source file, and we recommend putting images into an `images` folder where the document source is found.

The usual image formats handled by a web browser are supported: WebP, PNG, GIF, JPEG, and SVG.

Keep the image size only as large as needed, generally at least 500 px wide but no more than 1000 px, and no more than 100 KB unless a particularly large image is needed for clarity.

Recommended image formats based on content

- **Screenshots**: WebP or PNG.
- **Diagrams**: Consider using Graphviz for simple diagrams (see dedicated section below. If using an external tool, SVG is preferred.
- **Photos** (ex. boards): WebP. Use transparency if possible/available.

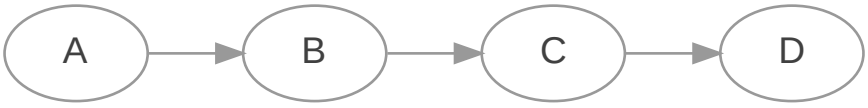
Graphviz Graphviz[9] is a tool for creating diagrams specified in a simple text language. As it's important to allow for diagrams used in the documentation to be easily maintained, we encourage the use of Graphviz for creating diagrams. Graphviz is particularly well suited for creating state diagrams, flow charts, and other types of diagrams that can be expressed as a graph.

To include a Graphviz diagram in a document, use the `graphviz` directive. For example:

```
.. graphviz::

   digraph G {
      rankdir=LR;
      A -> B;
      B -> C;
      C -> D;
   }
```

Would render as:



Please refer to the Graphviz documentation[10] for more information on how to create diagrams using Graphviz's DOT language.

Custom Sphinx Roles and Directives

The Zephyr documentation uses custom Sphinx roles and directives to provide additional functionality and to make it easier to write and maintain consistent documentation.

Application build commands

`.. zephyr-app-commands::`

Generate consistent documentation of the shell commands needed to manage (build, flash, etc.) an application

For example, to generate commands to build `samples/hello_world` for `qemu_x86` use:

[9] https://graphviz.org
[10] https://graphviz.org/documentation

```
.. zephyr-app-commands::
   :zephyr-app: samples/hello_world
   :board: qemu_x86
   :goals: build
```

This will render as:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
```

Options

`:tool: (string)`
: Which tool to use. Valid options are currently `cmake`, `west` and `all`. The default is `west`.

`:app: (string)`
: Path to the application to build.

`:zephyr-app: (string)`
: Path to the application to build, this is an app present in the upstream zephyr repository. Mutually exclusive with `:app:`.

`:cd-into: (no value)`
: If set, build instructions are given from within the `:app:` folder, instead of outside of it.

`:generator: (string)`
: Which build system to generate.

  Valid options are currently `ninja` and `make`. The default is `ninja`. This option is not case sensitive.

`:host-os:`
: Which host OS the instructions are for.

  Valid options are `unix`, `win` and `all`. The default is `all`.

`:board: (string)`
: If set, build commands will target the given board.

`:shield: (string)`
: If set, build commands will target the given shield.

  Multiple shields can be provided in a comma separated list.

`:conf:`
: If set, build commands will use the given configuration file(s).

  If multiple configuration files are provided, enclose the space-separated list of files with double quotes, e.g., *"a.conf b.conf"*.

`:gen-args: (string)`
: If set, indicates additional arguments to the CMake invocation.

`:build-args: (string)`
: If set, indicates additional arguments to the build invocation.

`:west-args: (string)`
: If set, additional arguments to the west invocation (ignored for `:tool: cmake`).

`:flash-args: (string)`
: If set, additional arguments to the flash invocation.

`:debug-args: (string)`
: If set, additional arguments to the debug invocation.

`:debugserver-args: (string)`
: If set, additional arguments to the debugserver invocation.

`:attach-args: (string)`
: If set, additional arguments to the attach invocation.

`:snippets: (string)`
: If set, indicates the application should be compiled with the listed snippets.

  Multiple snippets can be provided in a comma separated list.

`:build-dir: (string)`
: If set, the application build directory will *APPEND* this relative, Unix-separated, path to the standard build directory. This is mostly useful for distinguishing builds for one application within a single page.

`:build-dir-fmt: (string)`
: If set, assume that *west config build.dir-fmt‘* has been set to this path.

  Exclusive with `:build-dir:` and depends on `:tool: west`.

`:goals: (string)`
: A whitespace-separated list of what to do with the app (any of `build`, `flash`, `debug`, `debugserver`, `run`).

  Commands to accomplish these tasks will be generated in the right order.

`:maybe-skip-config: (no value)`
: If set, this indicates the reader may have already created a build directory and changed there, and will tweak the text to note that doing so again is not necessary.

`:compact: (no value)`
: If set, the generated output is a single code block with no additional comment lines.

Cross-referencing files in the Zephyr tree Special roles are available to reference files in the Zephyr tree. For example, referencing this very file can be done using the *`zephyr_file`* role.

`:zephyr_file:`
: This role is used to reference a file in the Zephyr tree. For example:

```
Check out :zephyr_file:`doc/contribute/documentation/guidelines.rst` for more␣
↪information.
```

  Will render as:

  Check out doc/contribute/documentation/guidelines.rst for more information.

  You can reference specific lines or line ranges in a file by appending `#L`*`line_number`* or `#L`*`start_line`*`-L`*`end_line`* to the file path:

```
See :zephyr_file:`doc/contribute/documentation/guidelines.rst#L3` for the␣
↪main heading of
this document.
```

  Will render as:

  See doc/contribute/documentation/guidelines.rst#L3 for the main heading of this document.

  The role automatically verifies that the referenced file exists in the Zephyr tree and will generate a warning during documentation build if the file is not found.

> **Note**
>
> Use the line references sparingly as keeping them accurate over time can be challenging as the content of the linked file is subject to change.

You may use the *zephyr_raw* role instead if you want to reference the "raw" content.

:zephyr_raw:

This role is used to reference the raw content of a file in the Zephyr tree. For example:

```
Check out :zephyr_raw:`doc/contribute/documentation/guidelines.rst` for more␣
↪information.
```

Will render as:

> Check out doc/contribute/documentation/guidelines.rst for more information.

:module_file:

This role is used to reference a module in the Zephyr tree. For example:

```
Check out :module_file:`hal_stm32:CMakeLists.txt` for more information.
```

Will render as:

> Check out hal_stm32:CMakeLists.txt for more information.

Similar to *zephyr_file*, you can reference specific lines or line ranges in a file.

Cross-referencing GitHub issues and pull requests

:github:

This role is used to reference a GitHub issue or pull request.

For example, to reference issue #1234:

```
Check out :github:`1234` for more background about this known issue.
```

This will render as:

> Check out GitHub #1234 for more background about this known issue.

Doxygen API documentation

.. doxygengroup:: name

This directive is used to output a short description of a Doxygen group and a link to the corresponding Doxygen-generated documentation.

All the code samples (declared using the *zephyr:code-sample* directive) indicating the group as relevant will automatically be list and referenced in the rendered output.

For example:

```
.. doxygengroup:: can_interface
```

Will render as:

> CAN

Options

:project: (project name (optional))

Associated Doxygen project. This can be useful when multiple Doxygen projects are configured.

`:c:group:`
: This role is used to reference a Doxygen group in the Zephyr tree. In the HTML documentation, they are rendered as links to the corresponding Doxygen-generated documentation for the group. For example:

```
Check out :c:group:`gpio_interface` for more information.
```

Will render as:

> Check out GPIO for more information.

You may provide a custom link text, similar to the built-in `ref` role.

Kconfig options If you want to reference a Kconfig option from a document, you can use the *`kconfig:option`* role and provide the name of the option you want to reference. The role will automatically generate a link to the documentation of the Kconfig option when building HTML output.

Make sure to use the full name of the Kconfig option, including the `CONFIG_` prefix.

`:kconfig:option:`
: This role is used to reference a Kconfig option in the Zephyr tree. For example:

```
Check out :kconfig:option:`CONFIG_GPIO` for more information.
```

Will render as:

> Check out `CONFIG_GPIO` for more information.

`:kconfig:option-regex:`
: This role is used to create links to regex searches for Kconfig options. It generates a link to the Kconfig search page with the provided regex pattern automatically filled in as the search query. It is useful for referencing multiple Kconfig options that share a common prefix, or belong to a common category. For example:

```
Check out␣
↪:kconfig:option-regex:`CONFIG_SECURE_STORAGE_ITS_(STORE|TRANSFORM)_.*_CUSTOM`␣
↪for
the various customization possibilities.
```

Will render as:

> Check out `CONFIG_SECURE_STORAGE_ITS_(STORE|TRANSFORM)_.*_CUSTOM` for the various customization possibilities.

It is encouraged to provide a custom link text to make the reference more readable. For example:

```
Check out the :kconfig:option-regex:`ITS Kconfig options
↪<CONFIG_SECURE_STORAGE_ITS_.*>`
for more information.
```

Will render as:

> Check out the ITS Kconfig options for more information.

Devicetree bindings If you want to reference a Devicetree binding from a document, you can use the *`dtcompatible`* role and provide the compatible string of the binding you want to reference. The role will automatically generate a link to the documentation of the binding when building HTML output.

`:dtcompatible:`

This role can be used inline to make a reference to the generated documentation for the Devicetree compatible given as argument.

There may be more than one page for a single compatible. For example, that happens if a binding behaves differently depending on the bus the node is on. If that occurs, the reference points at a "disambiguation" page which links out to all the possibilities, similarly to how Wikipedia disambiguation pages work. Example:

```
Check out :dtcompatible:`zephyr,input-longpress` for more information.
```

Will render as:

> Check out `zephyr,input-longpress` for more information.

Code samples

`.. zephyr:code-sample:: id`

This directive is used to describe a code sample, including which noteworthy APIs it may be exercising.

For example:

```
.. zephyr:code-sample:: blinky
   :name: Blinky
   :relevant-api: gpio_interface

   Blink an LED forever using the GPIO API.
```

The content of the directive is used as the description of the code sample.

Options

`:name: (text)`

Indicates the human-readable short name of the sample.

`:relevant-api: (text)`

Optional space-separated list of Doxygen group names that correspond to the APIs exercised by the code sample.

`:zephyr:code-sample:`

This role is used to reference a code sample described using *`zephyr:code-sample`*.

For example:

```
Check out :zephyr:code-sample:`blinky` for more information.
```

Will render as:

> Check out blinky for more information.

This can be used exactly like the built-in `ref` role, i.e. you may provide a custom link text. For example:

```
Check out :zephyr:code-sample:`blinky code sample <blinky>` for more␣
↪information.
```

Will render as:

> Check out blinky code sample for more information.

`.. zephyr:code-sample-category:: id`

This directive is used to define a category for grouping code samples.

For example:

```
.. zephyr:code-sample-category:: gpio
   :name: GPIO
   :show-listing:

   Samples related to the GPIO subsystem.
```

The contents of the directive is used as the description of the category. It can contain any valid reStructuredText content.

Options

`:name: (text)`

Indicates the human-readable name of the category.

`:show-listing: (flag)`

If set, a listing of code samples in the category will be shown. The listing is automatically generated based on all code samples found in the subdirectories of the current document.

`:glob: (text)`

A glob pattern to match the files to include in the listing. The default is */* but it can be overridden e.g. when samples may be found in directories not sitting directly under the category directory.

`:zephyr:code-sample-category:`

This role is used to reference a code sample category described using *zephyr:code-sample-category*.

For example:

```
Check out :zephyr:code-sample-category:`cloud` samples for more information.
```

Will render as:

Check out cloud samples for more information.

`.. zephyr:code-sample-listing::`

This directive is used to show a listing of all code samples found in one or more categories.

For example:

```
.. zephyr:code-sample-listing::
   :categories: cloud
```

Will render as:

- AWS IoT Core MQTTConnect to AWS IoT Core and publish messages using MQTT.
- Microsoft Azure IoT Hub MQTTConnect to Azure IoT Hub and publish messages using MQTT.
- TagoIO HTTP PostSend random temperature values to TagoIO IoT Cloud Platform using HTTP.

Options

`:categories: (text)`

A space-separated list of category IDs for which to show the listing.

`:live-search: (flag)`

A flag to include a search box right above the listing. The search box allows users to filter the listing by code sample name/description, which can be useful for categories with a large number of samples. This option is only available in the HTML builder.

Boards

`.. zephyr:board:: name`

This directive is used at the beginning of a document to indicate it is the main documentation page for a board whose name is given as the directive argument.

For example:

```
.. zephyr:board:: wio_terminal
```

The metadata for the board is read from various config files and used to automatically populate some sections of the board documentation. A board documentation page that uses this directive can be linked to using the *zephyr:board* role.

`:zephyr:board:`

This role is used to reference a board documented using *zephyr:board*.

For example:

```
Check out :zephyr:board:`wio_terminal` for more information.
```

Will render as:

Check out wio_terminal for more information.

`.. zephyr:board-catalog::`

This directive is used to generate a catalog of Zephyr-supported boards that can be used to quickly browse the list of all supported boards and filter them according to various criteria.

`:zephyr:board-catalog:`

This role is used to reference the board catalog page, optionally with filter parameters. For example:

```
Check out :zephyr:board-catalog:`` for more information.
```

Will render as:

Check out :zephyr:board-catalog:“ for more information.

This role can be used exactly like the built-in `ref` role, i.e. you may provide a custom link text. For example:

```
Check out the :zephyr:board-catalog:`boards using this compatible <
↪#compatibles=ti,hdc2080>`
for more information.
```

Will render as:

Check out the boards using this compatible for more information.

`.. zephyr:board-supported-hw::`

This directive is used to show supported hardware features for all the targets of the board documented in the current page. The tables are automatically generated based on the board's Devicetree.

The directive must be used in a document that also contains a *zephyr:board* directive, as it relies on the board information to generate the table.

> **Note**
>
> This directive requires that the documentation is built with hardware features generation enabled (`zephyr_generate_hw_features` config option set to `True`). If disabled, a warning message will be shown instead of the hardware features tables.
>
> It is possible to limit the hardware features generation to boards from a specific list of vendors to speed up documentation builds without completely disabling the hardware features table. Set the config option `zephyr_hw_features_vendor_filter` to the list of vendors to generate features for. If the option is empty, hardware features are generated for all boards from all vendors.

`.. zephyr:board-supported-runners::`

This directive is used to show the supported runners for the board documented in the current page, including which runner is the default for flashing and debugging.

The directive must be used in a document that also contains a *zephyr:board* directive, as it relies on the board information to generate the table.

> **Note**
>
> Similar to *zephyr:board-supported-hw*, this directive requires hardware features generation to be enabled (`zephyr_generate_hw_features` config option set to `True`) to produce a complete table. If disabled, a warning message will be shown instead of the runners tables.

Accessibility Guidelines

Accessibility is an important aspect of documentation, ensuring that all users, including those with disabilities, can access and understand the content.

When writing and maintaining Zephyr Project documentation, please follow these guidelines to improve accessibility for everyone.

Images and Figures All images and figures must include appropriate alternative text (alt text) to convey the meaning of the visual content to users who rely on screen readers or cannot view images.

- Use the `:alt:` attribute when including images using the `image` directive. Example:

```
.. image:: ../../../../contribute/documentation/image/doc-gen-flow.png
   :alt: Documentation generation process overview
```

- If the image contains text, ensure that the alt text includes this text verbatim.
- When using the `figure` directive, which allows for a caption, the `:alt:` text is still important. The alt text should describe the image itself, while the caption provides additional context or interpretation. Example:

```
.. figure:: ../../../../images/arch-diagram.png
   :alt: High-level overview of Zephyr OS architecture showing layers and␣
↪components.

   High-level overview of Zephyr OS architecture.
```

- Avoid using images as the sole method of conveying information that can be explained clearly with text.

Best Practices for writing alt text

- **Be Accurate and Equivalent**: Present the same essential information as the image.
- **Be Succinct**: Convey the core message of the image concisely.
- **Avoid Redundancy**: Do not use phrases like "Image of..." or "Picture of..." as screen readers typically announce the element as an image.
- **Describe, Don't Interpret**: Stick to describing what is visually present on the image.
- **Complex Images**: For charts, diagrams, or other complex visuals, provide a summary in the alt text. If a full understanding requires more detail, consider providing a more detailed description in the surrounding text or as part of the figure caption. Using text-based diagram tools like *Graphviz* can also improve accessibility.

Headings and Structure Use *headings* to structure your document logically. This allows users of assistive technologies to understand the document's organization and navigate it efficiently.

Tables Tables should be used only for tabular data and must be accessible to screen readers.

- Always define headers for rows and columns.
- Use the `list-table` directive when possible for better responsiveness and accessibility.
- Include a caption for tables where context is not immediately obvious. Example:

```
.. list-table:: GPIO Pin Configuration Options
   :widths: 15 30
   :header-rows: 1

   * - Field
     - Description
   * - GPIO_INPUT
     - Configures pin as input
   * - GPIO_OUTPUT
     - Configures pin as output
```

Additional Resources For more general guidance on web accessibility you may refer to W3C's Web Content Accessibility Guidelines (WCAG)[11]

References

8.2.2 Documentation Generation

These instructions will walk you through generating the Zephyr Project's documentation on your local system using the same documentation sources as we use to create the online documentation found at https://docs.zephyrproject.org

Documentation overview

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted stand-alone website. Developers can view this content either in its raw form as .rst markup files, or you

[11] https://www.w3.org/WAI/standards-guidelines/wcag/

can generate the HTML content and view it with a web browser directly on your workstation. This same .rst content is also fed into the Zephyr Project's public website documentation area (with a different theme applied).

You can read details about reStructuredText, and Sphinx from their respective websites.

The project's documentation contains the following items:

- ReStructuredText source files used to generate documentation found at the https://docs.zephyrproject.org website. Most of the reStructuredText sources are found in the `/doc` directory, but others are stored within the code source tree near their specific component (such as `/samples` and `/boards`)
- Doxygen-generated material used to create all API-specific documents also found at https://docs.zephyrproject.org
- Script-generated material for kernel configuration options based on Kconfig files found in the source code tree

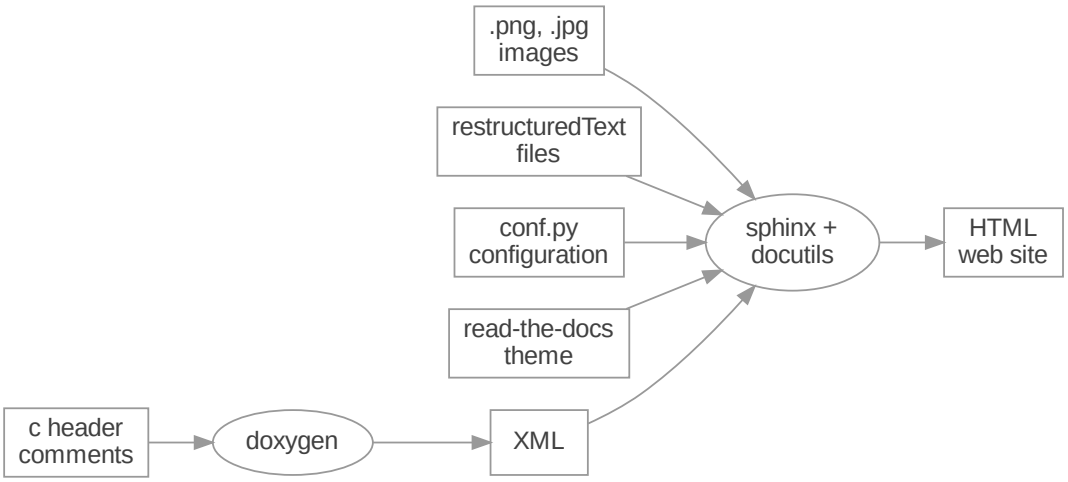


Fig. 1: Schematic of the documentation build process

The reStructuredText files are processed by the Sphinx documentation system, and make use of the doxygen-generated API material. Additional tools are required to generate the documentation locally, as described in the following sections.

Installing the documentation processors

Our documentation processing has been tested to run with:

- Doxygen version 1.15.0
- Graphviz 2.43
- Latexmk version 4.83
- All Python dependencies listed in the repository file `doc/requirements.txt`

In order to install the documentation tools, first install Zephyr as described in *Getting Started Guide*. Then install additional tools that are only required to generate the documentation, as described below:

Linux

Common to all Linux installations, install the Python dependencies required to build the documentation:

```
pip install -U -r ~/zephyrproject/zephyr/doc/requirements.txt
```

On Ubuntu Linux:

```
sudo apt-get install --no-install-recommends doxygen graphviz librsvg2-bin \
texlive-latex-base texlive-latex-extra latexmk texlive-fonts-recommended␣
↪imagemagick
```

On Fedora Linux:

```
sudo dnf install doxygen graphviz texlive-latex latexmk \
texlive-collection-fontsrecommended librsvg2-tools ImageMagick
```

On Clear Linux:

```
sudo swupd bundle-add texlive graphviz ImageMagick
```

On Arch Linux:

```
sudo pacman -S graphviz doxygen librsvg texlive-core texlive-bin \
texlive-latexextra texlive-fontsextra imagemagick
```

macOS

Install the Python dependencies required to build the documentation:

```
pip install -U -r ~/zephyrproject/zephyr/doc/requirements.txt
```

Use `brew` and `tlmgr` to install the tools:

```
brew install doxygen graphviz mactex librsvg imagemagick
tlmgr install latexmk
tlmgr install collection-fontsrecommended
```

Windows

Install the Python dependencies required to build the documentation:

```
pip install -U -r %HOMEPATH$\zephyrproject\zephyr\doc\requirements.txt
```

Open a `cmd.exe` window as **Administrator** and run the following command:

```
choco install doxygen.install graphviz strawberryperl miktex rsvg-convert␣
↪imagemagick
```

Note

On Windows, the Sphinx executable `sphinx-build.exe` is placed in the `Scripts` folder of your Python installation path. Depending on how you have installed Python, you might need to add this folder to your `PATH` environment variable. Follow the instructions in Windows Python Path to add those if needed.

Documentation presentation theme

Sphinx supports easy customization of the generated documentation appearance through the use of themes. Replace the theme files and do another `make html` and the output layout and style is changed. The `read-the-docs` theme is installed as part of the *Get Zephyr and install Python dependencies* step you took in the getting started guide.

Running the documentation processors

The /doc directory in your cloned copy of the Zephyr project git repo has all the .rst source files, extra tools, and Makefile for generating a local copy of the Zephyr project's technical documentation. Assuming the local Zephyr project copy is in a folder zephyr in your home folder, here are the commands to generate the html content locally:

```
# On Linux/macOS
cd ~/zephyrproject/zephyr/doc
# On Windows
cd %userprofile%\zephyrproject\zephyr\doc

# Use cmake to configure a Ninja-based build system:
cmake -GNinja -B_build .

# Enter the build directory
cd _build

# To generate HTML output, run ninja on the generated build system:
ninja html
# If you modify or add .rst files, run ninja again:
ninja html

# To generate PDF output, run ninja on the generated build system:
ninja pdf
```

Warning

The documentation build system creates copies in the build directory of every .rst file used to generate the documentation, along with dependencies referenced by those .rst files.

This means that Sphinx warnings and errors refer to the **copies**, and **not the version-controlled original files in Zephyr**. Be careful to make sure you don't accidentally edit the copy of the file in an error message, as these changes will not be saved.

Depending on your development system, it will take up to 15 minutes to collect and generate the HTML content. When done, you can view the HTML output with your browser started at doc/_build/html/index.html and if generated, the PDF file is available at doc/_build/latex/zephyr.pdf.

If you want to build the documentation from scratch just delete the contents of the build folder and run cmake and then ninja again.

Note

If you add or remove a file from the documentation, you need to re-run CMake.

On Unix platforms a convenience doc/Makefile can be used to build the documentation directly from there:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output
make html

# To generate PDF output
make pdf
```

Developer-mode Document Building

When making and testing major changes to the documentation, we provide an option to temporarily stub-out the auto-generated Devicetree bindings documentation so the doc build process runs faster.

To enable this mode, set the following option when invoking cmake:

```
-DDT_TURBO_MODE=1
```

Another step that typically takes a long time is the generation of the list of supported features for each board. This can be disabled by setting the following option when invoking cmake:

```
-DHW_FEATURES_TURBO_MODE=1
```

Invoking **make** with the following target will build the documentation without either of the aforementioned features:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output without detailed Devicetree bindings documentation
# and supported features index
make html-fast
```

When working with documentation for boards from a specific vendor, it is also possible to limit generation of the list of supported features to subset of board vendors. This can be done by setting the following option when invoking cmake:

```
-DHW_FEATURES_VENDOR_FILTER=vendor1,vendor2
```

This option can also be used with the **make** wrapper:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output with supported features limited to a subset of vendors
make html HW_FEATURES_VENDOR_FILTER=vendor1,vendor2
```

Viewing generated documentation locally

The generated HTML documentation can be hosted locally with python for viewing with a web browser:

```
$ python3 -m http.server -d _build/html
```

Note

WSL2 users may need to explicitly bind the address to `127.0.0.1` in order to be accessible from the host machine:

```
$ python3 -m http.server -d _build/html --bind 127.0.0.1
```

Alternatively, the documentation can be built with the `make html-live` (or `make html-live-fast`) command, which will build the documentation, host it locally, and watch the documentation directory for changes. When changes are observed, it will automatically rebuild the documentation and refresh the hosted files.

Linking external Doxygen projects against Zephyr

External projects that build upon Zephyr functionality and wish to refer to Zephyr documentation in Doxygen (through the use of @ref), can utilize the tag file exported at zephyr.tag

Once downloaded, the tag file can be used in a custom `doxyfile.in` as follows:

```
TAGFILES = "/
↪path/to/zephyr.tag=https://docs.zephyrproject.org/latest/doxygen/html/"
```

For additional information refer to Doxygen External Documentation.

Documentation Guidelines
: This page provides some simple guidelines for writing documentation using the reSTructuredText (reST) markup language and Sphinx documentation generator.

Documentation Generation
: As you write documentation, it can be helpful to see how it will look when rendered.

  This page describes how to build the Zephyr documentation locally.

8.3 Dealing with external components

8.3.1 Contributing External Components

In some cases it is desirable to leverage existing, external source code in order to avoid re-implementing basic functionality or features that are readily available in other open source projects.

This section describes the circumstances under which external source code can be imported into Zephyr, and the process that governs the inclusion.

There are three main factors that will be considered during the inclusion process in order to determine whether it will be accepted. These will be described in the following sections.

Note that most of this page deals with external components that end up being compiled and linked into the final image, and programmed into the target hardware. For external tooling that is only used during compilation, code analysis, testing or simulation please refer to the *Contributing External Tooling* section at the end of the page.

Software License

> **Note**
>
> External source code licensed under the Apache-2.0 license is not subject to this section.

Integrating code into the Zephyr Project from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board, as described in the Zephyr project charter. The board will automatically reject licenses that have not been approved by the Open Source Initiative (OSI). See the *Submission and review process* section for more details.

By carefully reviewing potential contributions and also enforcing a *Developer Certification of Origin (DCO)* for contributed code, we ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

Merit

Just like with any other regular contribution, one that contains external code needs to be evaluated for merit. However, in the particular case of code that comes from an existing project,

there are additional questions that must be answered in order to accept the contribution. More specifically, the following will be considered by the Technical Steering Committee and evaluated carefully before the external source code is accepted into the project:

- Is this the most optimal way to introduce the functionality to the project? Both the cost of implementing this internally and the one incurred in maintaining an externally developed codebase need to be evaluated.
- Is the external project being actively maintained? This is particularly important for source code that deals with security or cryptography.
- Have alternatives to the particular implementation proposed been considered? Are there other open source project that implement the same functionality?

Mode of integration

There are two ways of integrating external source code into the Zephyr Project, and careful consideration must be taken to choose the appropriate one for each particular case.

Integration in the main tree The first way to integrate external source code into the project is to simply import the source code files into the main `zephyr` repository. This automatically implies that the imported source code becomes part of the "mainline" codebase, which in turn requires that:

- The code is formatted according to the Zephyr *Coding Style Guidelines*
- The code adheres to the project's *Coding Guidelines*
- The code is subject to the same checks and verification requirements as the rest of the code in the main tree, including static analysis
- All files contain an SPDX tag if not already present
- If the source is not Apache 2.0 licensed, an entry is added to the *licensing page*.

This mode of integration can be applicable to both small and large external codebases, but it is typically used more commonly with the former.

Integration as a module The second way of integrating external source code into the project is to import the whole or parts of the third-party open source project into a separate repository, and then include it under the form of a *module*. With this approach the code is considered as being developed externally, and thus it is not automatically subject to the requirements of the previous section.

Integration in main manifest file (west.yaml) Integrating external code into the main `west.yml` manifest file is limited to code that is used by a Zephyr subsystem (libraries), by a platform, drivers (HAL) or tooling needed to test or build Zephyr components.

The integration of modules in this group is validated by the Zephyr project CI, and verified to be working with each Zephyr release.

Integrated modules will not be removed from the tree without a detailed migration plan.

Integration as optional modules Standalone or loose integration of modules/projects without any incoming dependencies shall be made optional and shall be kept standalone. Optional projects that provide value to users directly and through a Zephyr subsystem or platform shall be added to an optional manifest file that is filtered by default. (`submanifests/optional.yml`).

Such optional projects might include samples and tests in their own repositories.

There shall not be any direct dependency added in the Zephyr code tree (Git repository) and all sample or test code shall be maintained as part of the module.

> **Note**
>
> This is valid for all new optional modules. Existing optional modules with samples and test code in the Zephyr Git repository will be transitioned out over time.

Integration as external modules Similar to optional modules, but added to the Zephyr project as an entry in the documentation using a pre-defined template. This type of modules exists outside the Zephyr project manifest with documentation instructing users and developers how to integrate the functionality.

Ongoing maintenance

Regardless of the mode of integration, external source code that is integrated in Zephyr requires regular ongoing maintenance. The submitter of the proposal to integrate external source code must therefore commit to maintain the integration of such code for the foreseeable future. This may require adding an entry in the `MAINTAINERS.yml` as part of the process.

Submission and review process

Before external source code can be included in the project, it must be reviewed and accepted by the Technical Steering Committee (TSC) and, in some cases, by the Zephyr governing board.

A request for external source code integration must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the source code and how it integrates into the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the *Contributing External Components* section in detail, so that you are informed of the criteria used by the TSC and board in order to approve or reject a request
2. Use the New External Source Code Issue to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Optionally you can also create a Pull Request that demonstrates the integration of the external source code and link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the conclusion is that integrating external source code is the best solution, and the external source code is licensed under the Apache-2.0 license, the submission process is complete and the external source code can be integrated.

If, however, the external source code uses a license other than Apache-2.0, then these additional steps must be followed:

1. The TSC chair will forward the link to the GitHub issue created during the early submission process to the Zephyr governing board for further review
2. The Zephyr governing board has two weeks to review and ask questions:
   - If there are no objections, the matter is closed. Approval can be accelerated by unanimous approval of the board before the two weeks are up
   - If a governing board member raises an objection that cannot be resolved via email, the board will meet to discuss whether to override the TSC approval or identify other approaches that can resolve the objections
3. On approval of the Zephyr TSC and governing board the submission process is complete

The flowchart below shows an overview of the process:

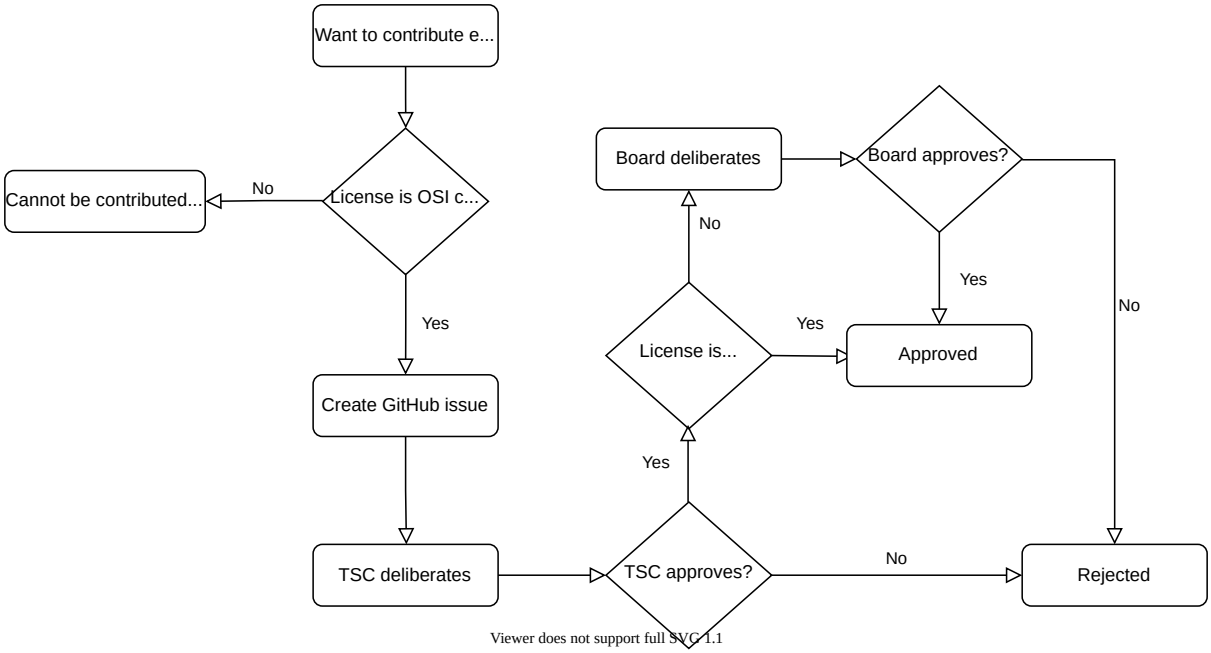

Fig. 2: Submission process

Contributing External Tooling

This section deals exclusively with the inclusion of external tooling in the Zephyr project, where tooling is defined as software that assists the compilation, testing or simulation processes but in no case ends up being part of the code compiled and linked into the final image. "Inclusion" in this context means becoming part of the Zephyr default distribution either in the main tree directly under the `scripts/` folder or indirectly as a west project in the main `west.yml` manifest. Therefore, this section does not apply to 3rd-party tooling such as toolchains, simulators or others, which may still be referenced by the Zephyr build system or docs without being included in Zephyr.

Tooling components must be released under a license approved by the Open Source Initiative (OSI).

Just like with regular external components, tooling that is imported from another project can be integrated either in the main tree or as a *west project*. Note that in this case the corresponding west project will not be a *module*, because tooling does not make use of the Zephyr build system and does not need to be processed by it. Please see *Modules vs west projects* for additional information on the differences.

If the tool is integrated in the main tree it should be placed under the `scripts/` folder. If the tool is integrated as a west project, then the project repository can be hosted outside the zephyrproject-rtos GitHub organization, provided that the project is made optional via the `group-filter:` field in the main `west.yml` manifest. More info on optional projects can be found in *this section*.

The TSC must approve every Pull Request that introduces a new external tooling component. This will be done on a case-by-case, individual analysis of the proposed addition by the TSC representatives.

Additional considerations about the main manifest

In general, any additions or removals whatsoever to the `projects:` section of the main manifest file requires TSC approval. This includes, but is not limited to:

- Adding and removing groups and group filters
- Adding and removing projects

- Adding and removing `import` statements

8.3.2 Binary Blobs

In the context of an operating system that supports multiple architectures and many different IC families, some functionality may be unavailable without the help of executable code distributed in binary form. Binary blobs (or blobs for short) are files containing proprietary machine code or data in a binary format, e.g. without corresponding source code released under an OSI approved license.

Zephyr supports downloading and using third-party binary blobs via its built-in mechanisms, with some important caveats, described in the following sections. It is important to note that all the information in this section applies only to upstream (vanilla) Zephyr.

There are no limitations whatsoever (except perhaps license compatibility) in the support for binary blobs in forks or third-party distributions of Zephyr. In fact, Zephyr's build system supports arbitrary use cases related to blobs. This includes linking against libraries, flashing images to targets, etc. Users are therefore free to create Zephyr-based downstream software which uses binary blobs if they cannot meet the requirements described in this page.

Software license

Most binary blobs are distributed under proprietary licenses which vary significantly in nature and conditions. It is up to the vendor to specify the license as part of the blob submission process. Blob vendors may impose a click-through or other EULA-like workflow when users fetch and install blobs.

Hosting

Blobs must be hosted on the Internet and managed by third-party infrastructure. Two potential examples are Git repositories and web servers managed by individual hardware vendors.

The Zephyr Project does not host binary blobs in its Git repositories or anywhere else.

Fetching blobs

Blobs are fetched from official third-party sources by the *west blobs* command.

The blobs themselves must be specified in the *module.yml* files included in separate Zephyr *module repositories* maintained by their respective vendors. This means that in order to include a reference to a binary blob to the upstream Zephyr distribution, a module repository must exist first or be created as part of the submission process.

Each blob which may be fetched must be individually identified in the corresponding `module.yml` file. A specification for a blob must contain:

- An abstract description of the blob itself
- Version information
- A reference to vendor-provided documentation
- The blob's *type*, which must be one of the allowed types
- A checksum for the blob, which `west blobs` checks after downloading. This is required for reproducibility and to allow bisecting issues as blobs change using Git and west
- License text applicable to the blob or a reference to such text, in SPDX format

See the *corresponding section* for a more formal definition of the fields.

The *west blobs* command can be used to list metadata of available blobs and to fetch blobs from user-selected modules.

The `west blobs` command only fetches and stores the binary blobs themselves. Any accompanying code, including interface header files for the blobs, must be present in the corresponding module repository.

Tainting

Inclusion of binary blobs will taint the Zephyr build. The definition of tainting originates in the Linux kernel and, in the context of Zephyr, a tainted image will be one that includes binary blobs in it.

Tainting will be communicated to the user in the following manners:

- One or more Kconfig options `TAINT_BLOBS_*` will be set to `y`
- The Zephyr build system, during its configuration phase, will issue a warning. It will be possible to disable the warning using Kconfig
- The `west spdx` command will include the tainted status in its output
- The kernel's default fatal error handler will also explicitly print out the kernel's tainted status
- The boot banner prints the kernel's tainted status

Allowed types

The following binary blob types are acceptable in Zephyr:

- Precompiled libraries: Hardware enablement libraries, distributed in precompiled binary form, typically for SoC peripherals. An example could be an enablement library for a wireless peripheral
- Firmware images: An image containing the executable code for a secondary processor or CPU. This can be full or partial (typically delta or patch data) and is generally copied into RAM or flash memory by the main CPU. An example could be the firmware for the core running a Bluetooth LE Controller
- Miscellaneous binary data files. An example could be pre-trained neural network model data

Hardware agnostic features provided via a proprietary library are not acceptable. For example, a proprietary and hardware agnostic TCP/IP stack distributed as a static archive would be rejected.

Note that just because a blob has an acceptable type does not imply that it will be unconditionally accepted by the project; any blob may be rejected for other reasons on a case by case basis (see library-specific requirements below). In case of disagreement, the TSC is the arbiter of whether a particular blob fits in one of the above types.

Precompiled library-specific requirements

This section contains additional requirements specific to precompiled library blobs.

Any person who wishes to submit a precompiled library must represent that it meets these requirements. The project may remove a blob from the upstream distribution if it is discovered that the blob fails to meet these requirements later on.

Interface header files The precompiled library must be accompanied by one or more header files, distributed under a non-copyleft OSI approved license, that define the interface to the library.

Allowed dependencies This section defines requirements related to external symbols that a library blob requires the build system to provide.

- The blob must not depend on Zephyr APIs directly. In other words, it must have been possible to build the binary without any Zephyr source code present at all. This is required for loose coupling and maintainability, since Zephyr APIs may change and such blobs cannot be modified by all project maintainers
- Instead, if the code in the precompiled library requires functionality provided by Zephyr (or an RTOS in general), an implementation of an OS abstraction layer (aka porting layer) can be provided alongside the library. The implementation of this OS abstraction layer must be in source code form, released under an OSI approved license and documented using Doxygen.

Toolchain requirements Precompiled library blobs must be in a data format which is compatible with and can be linked by a toolchain supported by the Zephyr Project. This is required for maintainability and usability. Use of such libraries may require special compiler and/or linker flags, however. For example, a porting layer may require special flags, or a static archive may require use of specific linker flags.

Limited scope Allowing arbitrary library blobs carries a risk of degrading the degree to which the upstream Zephyr software distribution is open source. As an extreme example, a target with a zephyr kernel clock driver that is just a porting layer around a library blob would not be bootable with open source software.

To mitigate this risk, the scope of upstream library blobs is limited. The project maintainers define an open source test suite that an upstream target must be able to pass using only open source software included in the mainline distribution and its modules. The open source test suite currently consists of:

- `samples/philosophers`
- `tests/kernel`

The scope of this test suite may grow over time. The goal is to specify tests for a minimal feature set which must be supported via open source software for any target with upstream Zephyr support.

At the discretion of the release team, the project may remove support for a hardware target if it cannot pass this test suite.

Support and maintenance

The Zephyr Project is not expected to be responsible for the maintenance and support of contributed binary blobs. As a consequence, at the discretion of the Zephyr Project release team, and on a case-by-case basis:

- GitHub issues reported on the zephyr repository tracker that require use of blobs to reproduce may not be treated as bugs
- Such issues may be closed as out of scope of the Zephyr project

This does not imply that issues which require blobs to reproduce will be closed without investigation. For example, the issue may be exposing a bug in a Zephyr code path that is difficult or impossible to trigger without a blob. Project maintainers may accept and attempt to resolve such issues.

However, some flexibility is required because project maintainers may not be able to determine if a given issue is due to a bug in Zephyr or the blob itself, may be unable to reproduce the bug due to lack of hardware, etc.

Blobs must have designated maintainers that must be responsive to issue reports from users and provide updates to the blobs to address issues. At the discretion of the Zephyr Project release

team, module revisions referencing blobs may be removed from `zephyr/west.yml` at any time due to lack of responsiveness or support from their maintainers. This is required to maintain project control over bit-rot, security issues, etc.

The submitter of the proposal to integrate a binary blob must commit to maintain the integration of such blob for the foreseeable future.

Regarding Continuous Integration, binary blobs will **not** be fetched in the project's CI infrastructure that builds and optionally executes tests and samples to prevent regressions and issues from entering the codebase. This includes both CI ran when a new GitHub Pull Request is opened as well as any other regularly scheduled execution of the CI infrastructure.

Submission and review process

For references to binary blobs to be included in the project, they shall be submitted through the standard pull request (PR) workflow and do not require Technical Steering Committee (TSC) approval. Maintainers and reviewers are responsible for ensuring that all blob-related submissions conform to the documented criteria as defined in *Binary Blobs*.

The PR for initial integration with binary blobs shall include details about the blobs and the functionality they provide. The PR shall have the following information to support the review:

- Binary blob origin.
- Type of blob (precompiled library, firmware image).
- Zephyr module that the blob(s) will be referenced from.
- Brief description of what the blob(s) do.
- What other components do the blob(s) depend on, if any?
- License the blob(s) are distributed under.

If the initial integration PR receives the appropriate approvals the binary blob(s) can be integrated. The standard *PR escalation procedures* shall apply for any technical disagreements.

Subsequent updates to binary blobs follow the *module update procedure*.

Contributing External Components
: Basic functionality or features that would make useful addition to Zephyr might be readily available in other open source projects, and it is recommended and encouraged to reuse such code. This page describes in more details when and how to import external source code into Zephyr.

Contributing External Tooling
: Similarly, external tooling used during compilation, code analysis, testing or simulation, can be beneficial and is covered in this section.

Binary Blobs
: As some functionality might only be made available with the help of executable code distributed in binary form, this page describes the process and guidelines for *contributing binary blobs* to the project.

8.4 Need help along the way?

If you have questions related to the contribution process, the Zephyr community is here to help. You may join our Discord channel or use the Developer Mailing List.

Chapter 9

Project and Governance

9.1 Technical Steering Committee (TSC)

9.1.1 TSC Member Role

The TSC role and its responsibilities is defined in the Zephyr project charter.

Membership

A TSC member plays a pivotal role in shaping the technical direction of the Zephyr Project. TSC members work collaboratively with other TSC members, contributors, and stakeholders to ensure the project's success and sustainability.

By fulfilling the rights and responsibilities below, TSC members contribute to the overall success and growth of the Zephyr Project, ensuring that it remains a vibrant and thriving open-source community for years to come.

Rights

Decision Making
: Participate in key decisions related to the project's technical direction, including architectural changes, feature additions, and release planning.

Voting
: Exercise voting rights on important matters discussed within the TSC, including feature proposals, code contributions, and community initiatives.

Access
: Gain access to relevant project repositories, documentation, and communication channels to stay informed and contribute effectively.

Leadership
: Take on leadership roles within working groups or subcommittees dedicated to specific technical areas or initiatives.

Representation
: Act as a representative of the broader Zephyr community, advocating for the interests of contributors, users, and stakeholders.

Responsibilities TSC members are expected to fulfill the following responsibilities, though it is not mandatory to fulfill all:

Technical Oversight
: Provide guidance and oversight on technical matters, ensuring alignment with project

goals, standards, and best practices through active participation as core members in working groups and committees.

Code Review
Participate in code reviews to maintain code quality, consistency, and compatibility with project standards.

Community Engagement
Engage with the community through forums, mailing lists, conferences, and other channels to foster collaboration, address concerns, and gather feedback.

Documentation
Contribute to the development and maintenance of project documentation, including technical guides, API references, and best practices.

Release Management
Collaborate with the release manager and other stakeholders to plan and coordinate project releases, ensuring timely delivery and quality assurance.

Contributor Support
Support and mentor new contributors, helping them navigate the project's codebase, processes, and community norms.

Issue Triage
Assist in triaging and prioritizing issues reported by users and contributors, facilitating timely resolution and communication.

Compliance and Licensing
Ensure compliance with project licensing requirements and open-source best practices, addressing any licensing-related issues that may arise.

Conflict Resolution
Facilitate constructive discussions and resolution of technical disagreements or conflicts within the community, promoting a healthy and inclusive environment.

Continuous Improvement
Continuously seek opportunities to improve project governance, processes, and infrastructure, driving innovation and sustainability.

Appointed TSC Members

See Zephyr project charter for more details.

- Appointed TSC members have no term limits besides the term of their employment at the organization they represent or their organization's membership in the Zephyr Project.
- Appointed TSC members can select an Alternate from the same organization.

Elected TSC Members

Per the Zephyr project charter, TSC members can nominate representatives from the technical community at the rate of no more than one per quarter.

- Majority vote is required to confirm a candidate.
- Once elected, a TSC member serves for 2 years.
- Elected TSC members do not have the right to appoint an Alternate.
- To ensure continuity of the TSC, at the end of the 2 year term, the TSC is required to reconfirm the membership of elected members. If the elected member declines a new term or if the TSC fails to reconfirm the term, the seat will be open for new nominations.
- If an elected TSC member resigns before the end of the 2 year term, their spot will be open for new members outside of the quarterly nomination limit. The elected member will serve a 2 year term.

- The TSC has the right to terminate elected members who become inactive and are not fulfilling the responsibilities of TSC members as described in this document.
- The number of elected members shall not exceed 20% of the total of appointed members.
- Existing TSC members who were elected before May 2024 shall be re-confirmed after completing the 2 year term since they were first elected.

Suspensions

As noted under Section 8b of the Project Charter, voting rights for a representative who misses three consecutive meetings are subject to suspension and suspended representatives do not count towards the quorum requirement.

A representative's suspension will end and voting rights be restored at the start of the next attended meeting. The TSC enforces the suspension policy for voting members who miss three consecutive TSC weekly meetings.

Multi-day meetings (F2F events) are counted as "one" meeting. The TSC voted on February 16, 2022 to discontinue default enforcement of the suspension policy. The TSC voted on January 18, 2023 to re-enact default enforcement of the suspension policy.

Notice of suspension will be sent to representatives who miss three consecutive meetings, noting that rights will be restored upon next attendance of a TSC meeting.

Note

As per Section 4b of the Project Charter, Platinum and Silver Members may choose to opt out of a voting seat on the TSC.

Members who opt out and then wish to reclaim their seat later will have their voting rights restored at the start of the second consecutive meeting attended following notification to the TSC Chair.

Voting

Voting in the Zephyr Project is defined under Section 8 of the Project Charter.

Additional points of clarity / TSC interpretation have been added below. The Governing Board may opt to update the Charter to include the below refinements. Until then, additional clarifications (if/where needed) will be discussed in the Process Working Group, and approved in the TSC.

- TSC In-Meeting Voting For items requesting an in-meeting vote of the Zephyr Technical Steering Committee (TSC), assuming quorum requirements have been met, the default voting mechanism will be a verbal motion to determine if there is general consensus.
- If there are no objections to a motion being brought forward, general consensus is assumed and the motion passes.
- Should there be any objections raised, the vote will move to email, and be executed using the Voting Guidelines outlined in Section 8 of the Project Charter.
- Should a motion be deemed urgent by the TSC Chair, and assuming quorum requirements have been met, the Chair may call for a roll call vote in-meeting.

Voting Options

- Voting Options are:
  - "Yes",
  - "No" or

– “Abstain”

Abstention Abstentions do not count in tallying the vote negatively or positively; when members abstain, they are in effect attending only to contribute to a quorum.

Abstentions do not impact the number of votes needed to decide a vote.

Quorum Quorum for TSC meetings shall require 60% of the voting representatives… (ref 8b of the Charter)

Decisions Decisions by vote shall be based on a majority vote, provided that at least sixty percent (60%) of the **TSC** representatives must be either present or participating electronically or by written action in order to conduct a valid vote. (ref 8c of the Charter)

Example A:

> 40 eligible TSC voters. 3 abstain from a vote on a motion. 12 vote Yes. 11 vote No.
>
> Quorum reached: 26 votes cast (quorum = 60% of 40 = 24) Majority vote: 12 Yes vs. 11 No. Yes wins. Motion adopted.

Example B:

> 40 eligible TSC voters. 5 abstain from a vote on a motion. 12 vote Yes. 6 vote No. Quorum reached? 23 votes cast (quorum = 60% of 40 = 24)
>
> Vote is not valid. Quorum not reached.

Example C:

> 40 eligible TSC voters. 21 abstain from a vote on a motion. 2 vote Yes. 1 votes No. Quorum reached? 24 votes cast (quorum = 60% of 40 = 24)
>
> Majority vote: 2 Yes vs. 1 No. Yes wins.

Immutable Votes

Votes are considered immutable once cast. A voter may not change their vote, once cast, between the time a Motion is brought forth and the time at which results are announced.

9.2 TSC Project Roles

9.2.1 Project Roles

TSC projects generally will involve *Maintainers*, *Collaborators*, and *Contributors*:

Maintainer: lead Collaborators on an area identified by the TSC (e.g. Architecture, code subsystems, etc.). Maintainers shall also serve as the area’s representative on the TSC as needed. Maintainers may become voting members of the TSC under the guidelines stated in the project Charter.

Collaborator: A highly involved Contributor in one or more areas. May become a Maintainer with approval of existing TSC voting members.

Contributor: anyone in the community that contributes code or documentation to the project. Contributors may become Collaborators by approval of the existing Collaborators and Maintainers of the particular code base areas or subsystems.

Contributor

A *Contributor* is a developer who wishes to contribute to the project, at any level.

Contributors are granted the following rights and responsibilities:

- Right to contribute code, documentation, translations, artwork, etc.
- Right to report defects (bugs) and suggestions for enhancement.
- Right to participate in the process of reviewing contributions by others.
- Right to initiate and participate in discussions in any communication methods.
- Right to approach any member of the community with matters they believe to be important.
- Right to participate in the feature development process.
- Responsibility to abide by decisions, once made. They are welcome to provide new, relevant information to reopen decisions.
- Responsibility for issues and bugs introduced by one's own contributions.
- Responsibility to respect the rules of the community.
- Responsibility to provide constructive advice whenever participating in discussions and in the review of contributions.
- Responsibility to follow the project's code of conduct (https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md)

Contributors are initially only given Read access to the Zephyr GitHub repository. Specifically, at the Read access level, Contributors are not allowed to assign reviewers to their own pull requests. An automated process will assign reviewers. You may also share the pull request on the Zephyr devel mailing list or on the Zephyr Discord Server.

Contributors who show dedication and skill are granted the Triage permission level to the Zephyr GitHub repository.

You may nominate yourself, or another GitHub user, for promotion to the Triage permission level by creating a GitHub issue, using the nomination template.

Contributors granted the Triage permission level are permitted to add reviewers to a pull request and can be added as a reviewer by other GitHub users. Contributor change requests or approval on pull requests are not counted with respect to accepting and merging a pull request. However, Contributors comments and requested changes should still be considered by the pull request author.

Zephyr Contributor Badge

When your first contribution to the Zephyr project gets merged, you'll become eligible to claim your Zephyr Contributor Badge. This digital badge can be displayed on your website, blog, social media profile, etc. It will allow you to showcase your involvement in the Zephyr project and help raise its awareness.

You may apply for your Contributor Badge by filling out the Zephyr Contributor Badge form.

Collaborator

A *Collaborator* is a Contributor who is also responsible for the maintenance of Zephyr source code. Their opinions weigh more when decisions are made, in a fully meritocratic fashion.

Collaborators have the following rights and responsibilities, in addition to those listed for Contributors:

- Right to set goals for the short and medium terms for the project being maintained, alongside the Maintainer.

- Responsibility to participate in the feature development process.
- Responsibility to review relevant code changes within reasonable time.
- Responsibility to ensure the quality of the code to expected levels.
- Responsibility to participate in community discussions.
- Responsibility to mentor new contributors when appropriate
- Responsibility to participate in the quality verification and release process, when those happen.

Contributors are promoted to the Collaborator role by adding the GitHub user name to one or more `collaborators` sections of the *MAINTAINERS File* in the Zephyr repository.

Collaborator change requests on pull requests should be addressed by the original submitter. In cases where the changes requested do not follow the *expectations* and the guidelines of the project or in cases of disagreement, it is the responsibility of the assignee to advance the review process and resolve any disagreements.

Collaborator approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

Maintainer

A *Maintainer* is a Collaborator who is also responsible for knowing, directing and anticipating the needs of a given zephyr source code area.

Maintainers have the following rights and responsibilities, in addition to those listed for Contributors and Collaborators:

- Right to set the overall architecture of the relevant subsystems or areas of involvement.
- Right to make decisions in the relevant subsystems or areas of involvement, in conjunction with the collaborators and submitters. See *PR Technical Escalation*.
- Responsibility to convey the direction of the relevant subsystem or areas to the TSC
- Responsibility to ensure all contributions of the project have been reviewed within reasonable time.
- Responsibility to enforce the Code of Conduct. As leaders in the community, maintainers are expected to be role models in upholding the project's code of conduct and creating a welcoming and inclusive environment for everyone.
- Responsibility to triage static analysis issues in their code area. See *Static Code Analysis*.

Contributors or Collaborators are promoted to the Maintainer role by adding the GitHub user name to one or more `maintainers` sections of the *MAINTAINERS File* in the Zephyr repository. Candidates who are neither Contributors nor Collaborators must be approved by the TSC before they can assume the role of Maintainer.

Maintainer approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

9.2.2 Role Retirement

- Individuals elected to the following Project roles, including, Maintainer, Release Engineering Team member, Release Manager, but are no longer engaged in the project as described by the rights and responsibilities of that role, may be requested by the TSC to retire from the role they are elected.
- Such a request needs to be raised as a motion in the TSC and be approved by the TSC voting members. By approval of the TSC the individual is considered to be retired from the role they have been elected.

- The above applies to elected TSC Project roles that may be defined in addition.

9.2.3 Teams and Supporting Activities

Assignee

An *Assignee* is one of the maintainers of a subsystem or code being changed. Assignees are set either automatically based on the code being changed or set by the other Maintainers, the Release Engineering team can set an assignee when the latter is not possible.

- Responsibility to drive the pull request to a mergeable state
- Right to dismiss stale and unrelated reviews or reviews not following *expectations* from reviewers and seek reviews from additional maintainers, developers and contributors
- Right to block pull requests from being merged until issues or changes requested are addressed
- Responsibility to re-assign a pull request if they are the original submitter of the code
- Solicit approvals from maintainers of the subsystems affected
- Responsibility to drive the *PR Technical Escalation* process

Static Analysis Audit Team

The Static Analysis Audit team works closely with the release engineering team to ensure that static analysis defects opened during a release cycle are properly addressed. The team has the following rights and responsibilities:

- Right to revert any triage in a static analysis tool (e.g: Coverity) that does not follow the project expectations.
- Responsibility to inform code owners about improper classifications.
- Responsibility to alert TSC if any issues are not adequately addressed by the responsible code owners.

Joining the Static Analysis Audit team

- Contributors highly involved in the project with some expertise in static analysis.

Release Engineering Team

A team of active Maintainers involved in multiple areas.

- The members of the Release Engineering team are expected to fill the Release Manager role based on a defined cadence and selection process.
- The cadence and selection process are defined by the Release Engineering team and are approved by the TSC.
- The team reports directly into the TSC.

Release Engineering team has the following rights and responsibilities:

- Right to merge code changes to the zephyr tree following the project rules.
- Right to revert any changes that have broken the code base
- Right to close any stale changes after <N> months of no activity
- Responsibility to take directions from the TSC and follow them.
- Responsibility to coordinate code merges with maintainers.
- Responsibility to merge all contributions regardless of their origin and area if they have been approved by the respective maintainers and follow the merge criteria of a change.

- Responsibility to keep the Zephyr code base in a working and passing state (as per CI)

Joining the Release Engineering team

- Maintainers highly involved in the project may be nominated by a TSC voting member to join the Release Engineering team. Nominees may become members of the team by approval of the existing TSC voting members.
- To ensure a functional Release Engineering team the TSC shall periodically review the team's followed processes, the appropriate size, and the membership composition (ensure, for example, that team members are geographically distributed across multiple locations and time-zones).

Release Manager

A *Maintainer* responsible for driving a specific release to completion following the milestones and the roadmap of the project for this specific release.

- TSC has to approve a release manager.

A Release Manager is a member of the Release Engineering team and has the rights and responsibilities of that team in addition to the following:

- Right to manage and coordinate all code merges after the code freeze milestone (M3, see program management overview.)
- Responsibility to drive and coordinate the triaging process for the release
- Responsibility to create the release notes of the release
- Responsibility to notify all stakeholders of the project, including the community at large about the status of the release in a timely manner.
- Responsibility to coordinate with QA and validation and verify changes either directly or through QA before major changes and major milestones.

Roles / Permissions

Table 1: Project Roles vs GitHub Permissions

		Admin	**Merge Rights**	Member	Owner	Collaborator
Main Roles	Contributor					x
	Collaborator			x		
	Maintainer			x		
Supportive Roles	QA/Validation			x		x

9.2.4 MAINTAINERS File

Generic guidelines for deciding and filling in the Maintainers' list

- We should keep the granularity of code maintainership at a manageable level
- We should be looking for maintainers for areas of code that are orphaned (i.e. without an explicit maintainer)
  - Un-maintained areas should be indicated clearly in the MAINTAINERS file
- All submitted pull requests should have an assignee

- We Introduce an area/subsystem hierarchy to address the above point
  - Parent-area maintainer should be acting as default substitute/fallback assignee for unmaintained sub-areas
  - Area maintainer gets precedence over parent-area maintainer
- Pull requests may be re-assigned if this is needed or more appropriate
  - Re-assigned by original assignee
- In general, updates to the MAINTAINERS file should be in a standalone commit alongside other changes introducing new files and directories to the tree.
- Major changes to the file, including the addition of new areas with new maintainers should come in as standalone pull requests and require TSC review.
- If additional review by the TSC is required, the maintainers of the file should send the requested changes to the TSC and give members of the TSC two (2) days to object to any of the changes to maintainership of areas or the addition of new maintainers or areas.
- Path, collaborator and name changes do not require a review by the TSC.
- Addition of new areas without a maintainer do not require review by the TSC.
- The MAINTAINERS file itself shall have a maintainer
- Architectures, core components, sub-systems, samples, tests
  - Each area shall have an explicit maintainer
- Boards (incl relevant samples, tests), SoCs (incl DTS) * May have a maintainer, shall have a higher-level platform maintainer
- Drivers
  - Shall have a driver-area (and API) maintainer
  - Could have individual driver implementation maintainers but preferably collaborator/contributors
  - In the above case, platform-specific PRs may be re-assigned to respective collaborator/contributor of driver implementation

9.3 TSC Working Groups

9.3.1 Overview

The TSC, at its discretion, may establish working groups or subcommittees to serve as focused teams dedicated to specific technical areas, initiatives, or tasks.

9.3.2 Membership

Working Group Membership Eligibility

- Each Working group (WG) shall determine its own membership eligibility, in consultation with the TSC.
- Each working group shall have a team of members who are actively involved in its activities and decision-making processes.
- It is expected that WG membership shall be **open to all** Zephyr project *Collaborators*; however, working groups may impose restrictions such as the number of participants from a single company.
- All TSC members are eligible to join a working group as members, part of the responsibilities being a TSC member.

- The minimal number of members may vary depending on the complexity of the tasks and the breadth of expertise required to address them effectively.
- A working group should aim to have at least five to seven members to ensure diversity of perspectives, collaboration, and continuity.
- The structure of each working group within the Zephyr Project should be designed to ensure effectiveness, productivity, and inclusivity. While the optimal size of a working group can vary depending on the specific context and scope of its activities.
- Participation in WG meetings and discussions is open to all project *contributors*.

Working Group Chair / Co-chair

Each working group may elect a Chair and optionally a Co-Chair who is responsible for leading meetings and representing the working group to the TSC.

Working Group Chair / Co-Chair Elections

- The Chair and Co-Chair shall be elected by the members of the working group
- Any member of the working group has the right to nominate themselves for the chair/co-chair positions.
- The term for the chair/co-chair is one year
- If a chair/co-chair resigns from the position before the end of the term, a vote is to be held to elect a new chair/co-chair.

Working Group Voter Eligibility

- Voting for a Chair or Co-Chair is open to the members of the working group.
- Only 1 working group member from each company may vote in the election.
- The Chair and Co-Chair shall be members of the working group.

Working Group Election Confirmation

- The elected Chair (and/or Co-Chair) is submitted to the TSC for confirmation.
- The TSC decides to accept the outcome or requests a new voting.

9.3.3 Advisory role

- Working Groups are advisory in nature. They provide advice to the projects and to the TSC.
- Working groups operate on a rough consensus basis. If the working group is unable to reach consensus on what advice to offer, the working group Chair shall raise the issue with the TSC or the relevant committee (Safety and Security), where a formal vote can be taken, or advise the project that the working group cannot reach consensus.
- Working groups shall keep track of discussions and record any votes, decisions, or recommendations made and share results with the community and the TSC.
- Working group meetings and offline discussions shall be captured in a standalone document with all supporting details such as attendance, quorum, actions to be taken, and next steps.
- Decisions made within a working group are non-binding and are only considered ratified after communicating decisions and outcomes to the TSC.
- Lacking any objections from the TSC within 1 week after the communication or report of any results, decisions of a working group are considered confirmed and ratified.

9.3.4 TSC Working Group Lifecycle

Creation of a TSC working group

In order to create a TSC working group, a TSC member shall make a proposal to the TSC (via TSC email list) that shall cover at least the following:

- TSC working group name.
- TSC working group purpose
- TSC working group expected deliverables
- TSC working group starting participants with at least one TSC member acting as a sponsor.
- Optionally TSC working group definition of done

Update of a TSC working group

The TSC can modify a TSC working group via a TSC decision. To request such a modification, a request is made to the TSC email list.

Conclusion of a TSC working group

The TSC decides the termination of the TSC working group in accordance with the TSC decision procedure. The submission of a request to terminate the TSC working group should cover:

- TSC working group name
- TSC working group deliveries
- Motivation for termination of the TSC working group

9.4 Release Process

The Zephyr project releases on a time-based cycle, rather than a feature-driven one. Zephyr releases represent an aggregation of the work of many contributors, companies, and individuals from the community.

A time-based release process enables the Zephyr project to provide users with a balance of the latest technologies and features and excellent overall quality. A roughly 6-month release cycle allows the project to coordinate development of the features that have actually been implemented, allowing the project to maintain the quality of the overall release without delays because of one or two features that are not ready yet.

Each release period will consist of a development phase followed by a stabilization phase. Release candidates will be created during the stabilization phase.

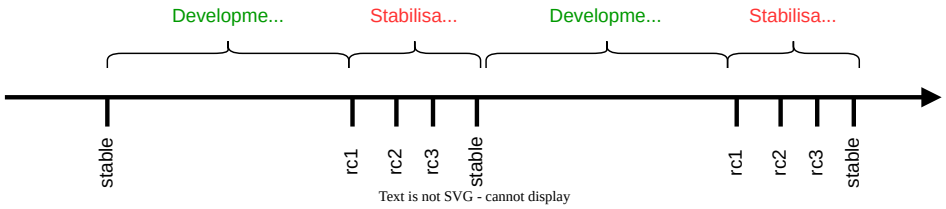

Fig. 1: Release Cycle

Note

The milestones for the current major version can be found on the Official GitHub Wiki. Information on previous releases can be found here.

9.4.1 Development Phase

A relatively straightforward discipline is followed with regard to the merging of patches for each release. At the beginning of each development cycle, the main branch is said to be open for development. At that time, code which is deemed to be sufficiently stable (and which is accepted by the maintainers and the wide community) is merged into the mainline tree. The bulk of changes for a new development cycle (and all of the major changes) will be merged during this time.

The development phase lasts for approximately five months. At the end of this time, the release owner will declare that the development phase is over and releases the first of the release candidates. For the codebase release which is destined to be 3.1.0, for example, the release which happens at the end of the development phase will be called 3.1.0-rc1. The -rc1 release is the signal that the time to merge new features has passed, and that the time to stabilize the next release of the code base has begun.

9.4.2 Stabilization Phase

Over the following weeks and depending on the release milestone, only stabilization, cosmetic updates, bug fixes, documentation improvements, and new tests for existing features are permitted. (See *table* below).

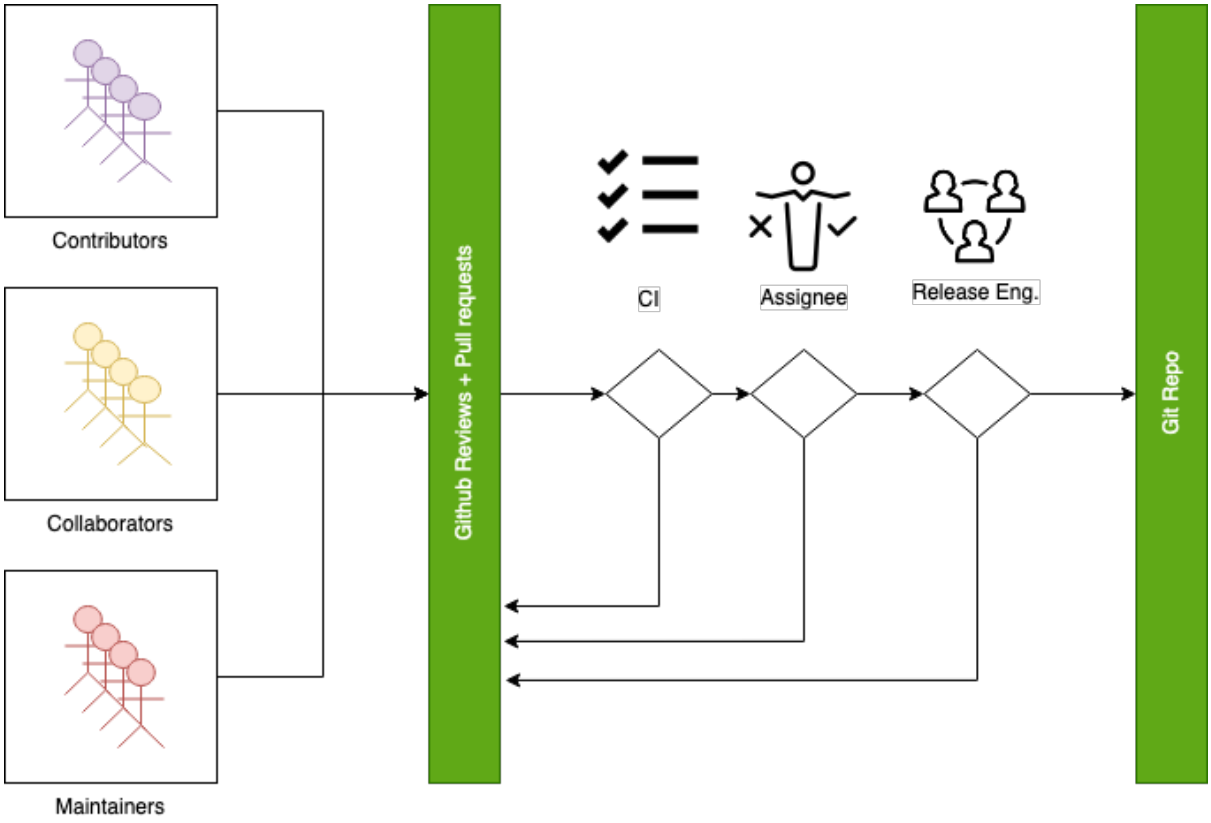
On occasion, more significant changes and new features will be allowed, but such occasions are rare and require a TSC approval and a justification. As a general rule, if you miss submitting your code during the development phase for a given feature, the best thing to do is to wait for the next development cycle. (An occasional exception is made for drivers for previously unsupported hardware; if they do not touch any other in-tree code, they cannot cause regressions and should be safe to add at any time).

As fixes make their way into the mainline, the patch rate will slow over time. The mainline release owner releases new -rc drops once or twice a week; a normal series will get up to somewhere between -rc4 and -rc6 before the code base is considered to be sufficiently stable and the release criteria have been achieved at which point the final 3.1.0 release is made.

At that point, the whole process starts over again.

9.4.3 Merge Criteria

- All *PR Requirements* must be met.
- Minimal of 2 approvals, including an approval by the designated assignee.
- Pull requests should be reviewed by at least a maintainer or collaborator of each affected area; Unless the changes to a given area are considered trivial enough, in which case approvals by other affected subsystems maintainers/collaborators would suffice.
- Four eye principle on the organisation level. We already require at least 2 approvals (basic four eye principle), however, such reviews and approvals might be unintentionally biased in the case where the submitter is from the same organisation as the approvers. To allow for project wide review and approvals, the merge criteria is extended with the guidelines below:
  - Changes or additions to common and shared code shall have approvals from different organisations (at least one approval from an organisation different than the submit-



ters'). Common and shared code is defined as anything that does not fall under `soc`, `boards` and `drivers/*/*`.

  - Changes or additions to hardware support (driver, SoC, boards) shall at least have the merger be from a different organisation. This applies only to implementation of an API supporting vendor specific hardware and not the APIs.
  - Release engineers may make exceptions for areas with contributions primarily coming from one organisation and where reviews from other organisations are not possible, however, merges shall be completed by a person from a different organisation. In such cases, the minimum review period of at least 2 days shall be strictly followed to allow for additional reviews.
  - Release engineers shall not merge code changes originating and reviewed only by their own organisation. To be able to merge such changes, at least one review shall be from a different organisation.

- A minimum review period of 2 business days, 4 hours for trivial changes (see *Give reviewers time to review before code merge*).
- Hotfixes can be merged at any time after CI has passed and are excluded from most of the conditions listed above.
- All required checks are passing:
  - Device Tree
  - Documentation
  - Code linters (Gitlint, Pylint, Ruff, Sphinx, etc.)
  - Identity/Emails
  - Kconfig
  - License checks

  - Checkpatch (Coding Style)
  - Integration Tests (Via twister) on emulation/simulation platforms
  - Simulated Bluetooth Tests

9.4.4 Release Criteria

The main motivation is to clearly have the criteria in place that must be met for a release. This will help define when a release is "done" in terms that most people can understand and in ways that help new people to understand the process and participate in creating successful releases:

- The release criteria documents all the requirements of our target audience for each Zephyr release
- The target audiences for each release can be different, and may overlap
- The criteria at any given time are not set in stone: there may be requirements that have been overlooked, or that are new, and in these cases, the criteria should be expanded to ensure all needs are covered.

Below is the high level criteria to be met for each release:

- No blocker bugs / blocking issues
- All relevant tests shall pass on `Tier 0` platforms
- All relevant tests shall pass on Tier 0 and 1 platforms (at least 1 per architecture/architecture variant/Hardware features)
- All applicable samples/tests shall build on Tiers 0, 1 and 2
- All high and critical static analysis and security issues addressed
- Release Notes are up-to-date.

Blocker Bugs

Blocker bug process kicks in during the release process and is in effect after the feature freeze milestone. An issue labeled as a blocker practically blocks a release from happening. All blocker bugs shall be resolved before a release is created.

A fix for a bug that is granted `blocker` status can be merged to 'main' and included in the release all the way until the final release date.

Bugs of moderate severity and higher that have impact on all users are typically the candidates to be promoted to blocker bugs

Contributors and member of the release engineering team shall follow these guidelines for release blocker bugs:

- Only mark bugs as blockers if the software (Zephyr) must not be released with the bug present.
- All collaborators can add or remove blocking labels.
- Evaluate bugs as potential blockers based on their severity and prevalence.
- Provide detailed rationale whenever adding or removing a blocking label.
- Ensure all blockers have the milestone tagged.
- Release managers have final say on blocking status; contact them with any questions.

9.4.5 Release Milestones

Table 2: Release Milestones

Timeline	Checkpoint	Description	Owner
T-5M	Planning	Finalize dates for release, Assign release owner and agree on project wide goals for this release.	TSC
T-7W	Review target milestones	Finalize target milestones for features in flight.	Release Engineering
T-5W	Release Announcement	Release owner announces feature freeze and timeline for release.	Release Manager
T-4W	Release Timeline reminder	Release owner sends a reminder of the feature freeze and timeline for release.	Release Manager
T-3W	Feature Freeze (RC1)	After RC1, no new features may be introduced. Only stabilization, cosmetic updates, bug fixes, documentation improvements, and new tests for existing features are permitted.	Release Engineering
T-2W	2nd Release Candidate	No new features after RC2, ONLY stabilization and cosmetic changes, bug and doc fixes are allowed.	Release Manager
T-1W	Hard Freeze (RC3)	Only blocker bug fixes after RC3, documentation improvements and changes to release notes are allowed. Release notes need to be complete by this checkpoint. Release Criteria is met.	Release Manager
T-0W	Release		Release Manager

9.4.6 Releases

Long Term Support (LTS)

Long-term support releases are designed to be supported and maintained for an extended period and are the recommended release for products and the auditable branch used for certification.

An LTS release is defined as:

- **Product focused**
- **Extended Stabilisation period**: Allow for more testing and bug fixing
- **Stable APIs**
- **Quality Driven Process**
- **Long Term**: Maintained for an extended period of time (at least 5 years).

Product Focused Zephyr LTS is the recommended release for product makers with an extended support and maintenance which includes general stability and bug fixes, security fixes.

An LTS includes both mature and new features. API and feature maturity is documented and tracked. The footprint and scope of mature and stable APIs expands as we move from one LTS to the next giving users access to bleeding edge features and new hardware while keeping a stable foundation that evolves over time.

Extended Stabilisation Period Zephyr LTS development cycle differs from regular releases and has an extended stabilization period. Feature freeze of regular releases happens 3-4 weeks before the scheduled release date. The stabilization period for LTS is extended by 3 weeks with

the feature freeze occurring 6-7 weeks before the anticipated release date. The time between code freeze and release date is extended in this case.

Stable APIs Zephyr LTS provides a stable and long-lived foundation for developing products. To guarantee stability of the APIs and the implementation of such APIs it is required that any release software that makes the core of the OS went through the Zephyr API lifecycle and stabilized over at least 2 releases. This guarantees that we release many of the highlighted and core features with mature and well-established implementations with stable APIs that are supported during the lifetime of the release LTS.

- API Freeze (LTS - 2)
  - All stable APIs need to be frozen 2 releases before an LTS. APIs can be extended with additional features, but the core implementation is not modified. This is valid for the following subsystems for example:
    - Device Drivers (i2c.h, spi.h)...
    - Kernel (k_*):
    - OS services (logging,debugging, ..)
    - DTS: API and bindings stability
    - Kconfig
  - New APIs for experimental features can be added at any time as long as they are standalone and documented as experimental or unstable features/APIs.
- Feature Freeze (LTS - 1) - No new features or overhaul/restructuring of code covering major LTS features.
  - Kernel + Base OS
  - Additional advertised LTS features
  - Auxiliary features on top of and/or extending the base OS and advertised LTS features can be added at any time and should be marked as experimental if applicable

Quality Driven Process The Zephyr project follows industry standards and processes with the goal of providing a quality oriented releases. This is achieved by providing the following products to track progress, integrity and quality of the software components provided by the project:

- Compliance with published coding guidelines, style guides and naming conventions and documentation of deviations.
- Static analysis reports
  - Regular static analysis on the complete tree using available commercial and open-source tools, and documentation of deviations and false positives.
- Documented components and APIS
- Requirements Catalog
- Verification Plans
- Verification Reports
- Coverage Reports
- Requirements Traceability Matrix (RTM)
- SPDX License Reports

Each release is created with the above products to document the quality and the state of the software when it was released.

Long Term Support and Maintenance LTS releases are published every 2.5 to 3 years and are branched and maintained independently from the main tree for approximately 5 years after they were released.

Support is provided in three main phases:

- **Phase 1 (first 2 years):** General bug fixes and security fixes, including platform and driver fixes.
- **Phase 2 (following 3+ years):** Security and OS stability fixes only.
- **Phase 3:** Extended support may be available through third parties (details to be determined).

Support for a given LTS release (LTS *N*) continues until the initial release of the LTS two versions ahead (LTS *N+2*). A final release of LTS *N* occurs shortly after the initial release of LTS *N+2*.

The list of currently supported LTS releases and their EOL dates can be found here.

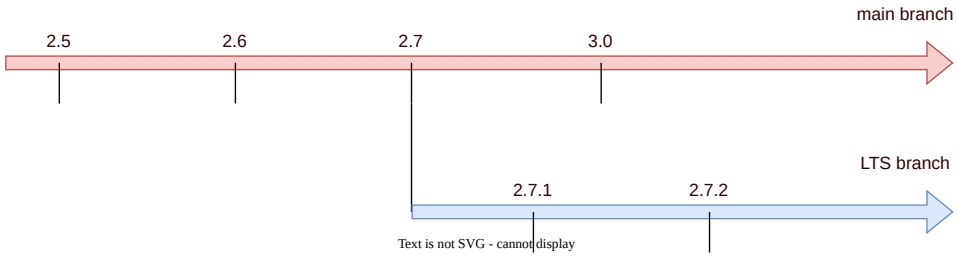


Fig. 2: Long Term Support Release

Changes and fixes flow in both directions. However, changes from main branch to an LTS branch will be limited to fixes that apply to both branches and for existing features only.

All fixes for an LTS branch that apply to the mainline tree shall be submitted to mainline tree as well.

Auditable Code Base

An auditable code base is to be established from a defined subset of Zephyr OS features and will be limited in scope. The LTS, development tree, and the auditable code bases shall be kept in sync after the audit branch is created, but with a more rigorous process in place for adding new features into the audit branch used for certification.

This process will be applied before new features move into the auditable code base.

The initial and subsequent certification targets will be decided by the Zephyr project governing board.

Processes to achieve selected certification will be determined by the Security and Safety Working Groups and coordinated with the TSC.

9.4.7 Host Tools Support Policy

9.4.8 Python Version Policy

Zephyr tracks the Python upstream release schedule when determining its minimum supported Python version.

The minimum supported version is selected to balance long-term support and practical availability in mainstream, actively supported Linux distributions (e.g. current Ubuntu LTS and Debian Stable releases).

A Python version is considered for removal when:

- It is approaching or has reached upstream end-of-life (EOL), and
- Newer Python versions are broadly available in current, actively supported major Linux distributions.

9.4.9 Hardware Support Tiers

Tier 0: Emulation Platforms

- Tests are both built and run in these platforms in CI, and therefore runtime failures can block Pull Requests.
- Supported by the Zephyr project itself, commitment to fix bugs in releases.
- One Tier 0 platform is required for each new architecture.
- Bugs reported against platforms of this tier are to be evaluated and treated as a general bug in Zephyr and should be dealt with the highest priority.

Tier 1: Supported Platforms

- Commitment from a specific team to run tests using twister device testing for the “Zephyr compatibility test suite” (details TBD) on a regular basis using open-source and publicly available drivers.
- Commitment to fix bugs in time for releases. Not supported by “Zephyr Project” itself.
- General availability for purchase
- Bugs reported against platforms of this tier are to be evaluated and treated as a general bug in Zephyr and should be dealt with medium to high priority.

Tier 2: Community Platforms

- Platform implementation is available in upstream, no commitment to testing, may not be generally available.
- Has a dedicated maintainer who commits to respond to issues / review patches.
- Bugs reported against platforms of this tier are NOT considered as a general bug in Zephyr.

Tier 3: Deprecated and unsupported Platforms

- Platform implementation is available, but no owner or unresponsive owner.
- No commitment to support is available.
- May be removed from upstream if no one works to bring it up to tier 2 or better.
- Bugs reported against platforms of this tier are NOT considered as a general bug in Zephyr.

9.4.10 Release Procedure

This section documents the Release manager responsibilities so that it serves as a knowledge repository for Release managers.

Release Checklist

Each release has a GitHub issue associated with it that contains the full checklist. After a release is complete, a checklist for the next release is created.

Tagging

The following syntax should be used for releases and tags in Git:

- Release [Major].[Minor].[Patch Level]
- Release Candidate [Major].[Minor].[Patch Level]-rc[RC Number]
- Tagging:
  - v[Major].[Minor].[Patch Level]-rc[RC Number]
  - v[Major].[Minor].[Patch Level]
  - v[Major].[Minor].99 - A tag applied to main branch to signify that work on v[Major].[Minor+1] has started. For example, v1.7.99 will be tagged at the start of v1.8 process. The tag corresponds to VERSION_MAJOR/VERSION_MINOR/PATCHLEVEL macros as defined for a work-in-progress main branch version. Presence of this tag allows generation of sensible output for "git describe" on main branch, as typically used for automated builds and CI tools.

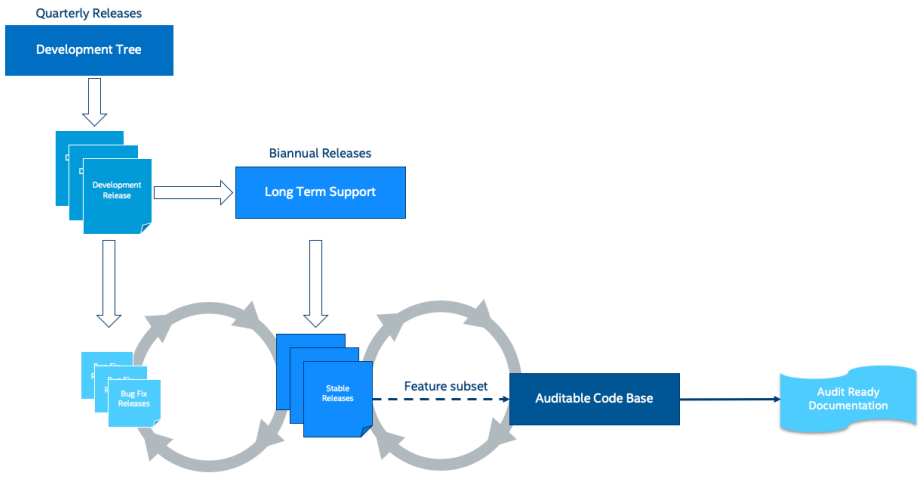

Fig. 3: Zephyr Code and Releases

The final release and each release candidate shall be tagged using the following steps:

> **Note**
>
> Tagging needs to be done via explicit git commands and not via GitHub's release interface. The GitHub release interface does not generate annotated tags (it generates 'lightweight' tags regardless of release or pre-release). You should also upload your gpg public key to your GitHub account, since the instructions below involve creating signed tags. However, if you do not have a gpg public key you can opt to remove the `-s` option from the commands below.

Release Candidate

> **Note**
>
> This section uses tagging 1.11.0-rc1 as an example, replace with the appropriate release candidate version.

1. Update the version variables in the VERSION file located in the root of the Git repository to match the version for this release candidate. The `EXTRAVERSION` variable is used to identify the rc[RC Number] value for this candidate:

```
EXTRAVERSION = rc1
```

2. Post a PR with the updated VERSION file using `release: Zephyr 1.11.0-rc1` as the commit subject. Merge the PR after successful CI.
3. Tag and push the version, using an annotated tag:

```
$ git pull
$ git tag -s -m "Zephyr 1.11.0-rc1" v1.11.0-rc1
```

4. Verify that the tag has been signed correctly, `git show` for the tag must contain a signature (look for the `BEGIN PGP SIGNATURE` or `BEGIN SSH SIGNATURE` marker in the output):

```
$ git show v1.11.0-rc1
```

5. Push the tag:

```
$ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0-rc1
```

6. Send an email to the mailing lists (`announce` and `devel`) with a link to the release

Final Release

Note

This section uses tagging 1.11.0 as an example, replace with the appropriate final release version.

When all final release criteria has been met and the final release notes have been approved and merged into the repository, the final release version will be set and repository tagged using the following procedure:

1. Update the version variables in the VERSION file located in the root of the Git repository. Set `EXTRAVERSION` variable to an empty string to indicate final release:

```
EXTRAVERSION =
```

2. Post a PR with the updated VERSION file using `release: Zephyr 1.11.0` as the commit subject. Merge the PR after successful CI.
3. Tag and push the version, using two annotated tags:

```
$ git pull
$ git tag -s -m "Zephyr 1.11.0" v1.11.0
```

4. Verify that the tag has been signed correctly, `git show` for the tag must contain a signature (look for the `BEGIN PGP SIGNATURE` or `BEGIN SSH SIGNATURE` marker in the output):

```
$ git show v1.11.0
```

5. Push the tag:

```
$ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0
```

6. Find the new `v1.11.0` tag at the top of the releases page and edit the release with the `Edit tag` button with the following:
   - Copy the overview of `docs/releases/release-notes-1.11.rst` into the release notes textbox and link to the full release notes file on docs.zephyrproject.org.
7. Send an email to the mailing lists (`announce` and `devel`) with a link to the release

9.5 Feature Tracking

For feature tracking we use Github labels to classify new features and enhancements. The following is the description of each category:

Enhancement
: Changes to existing features that are not considered a bug and would not block a release. This is an incremental enhancement to a feature that already exists in Zephyr.

Feature request
: A request for the implementation or inclusion of a new unit of functionality that is not part of any release plans yet, that has not been vetted, and needs further discussion and details.

Feature
: A committed and planned unit of functionality with a detailed design and implementation proposal and an owner. Features must go through an RFC process and must be vetted and discussed in the TSC before a target milestone is set.

Hardware Support
: A request or plan to port an existing feature or enhancement to a particular hardware platform. This ranges from porting Zephyr itself to a new architecture, SoC or board to adding an implementation of a peripheral driver API for an existing hardware platform.

Meta
: A label to group other GitHub issues that are part of a single feature or unit of work.

The following workflow should be used to process features:.

This is the formal way for asking for a new feature in Zephyr and indicating its importance to the project. Often, the requester may have a readiness and willingness to drive implementation of the feature in an upcoming release, and should assign the request to themselves. If not though, an owner will be assigned after evaluation by the TSC. A feature request can also have a companion RFC with more details on the feature and a proposed design or implementation.

- Label new features requests as `feature-request`
- The TSC discusses new `feature-request` items regularly and triages them. Items are examined for similarity with existing features, how they fit with the project goals and other timeline considerations. The priority is determined as follows:
  - High = Next milestone
  - Medium = As soon as possible
  - Low = Best effort
- After the initial discussion and triaging, the label is moved from `feature-request` to `feature` with the target milestone and an assignee.

All items marked as `feature-request` are non-binding and those without an assignee are open for grabs, meaning that they can be picked up and implemented by any project member or the community. You should contact an assigned owner if you'd like to discuss or contribute to that feature's implementation

9.5.1 Roadmap and Release Plans

Project roadmaps and release plans are both important tools for the project, but they have very different purposes and should not be confused. A project roadmap communicates the high-level overview of a project's strategy, while a release plan is a tactical document designed to capture and track the features planned for upcoming releases.

- The project roadmap communicates the why; a release plan details the what
- A release plan spans only a few months; a product roadmap might cover a year or more

Project Roadmap

The project roadmap should serve as a high-level, visual summary of the project's strategic objectives and expectations.

If built properly, the roadmap can be a valuable tool for several reasons. It can help the project present its plan in a compelling way to existing and new stakeholders, to help recruit new members and it can be a helpful resource the team and community can refer to throughout the project's development, to ensure they are still executing according to plan.

As such, the roadmap should contain only strategic-level details, major project themes, epics, and goals.

Release Plans

The release plan comes into play when the project roadmap's high-level strategy is translated into an actionable plan built on specific features, enhancements, and fixes that need to go into a specific release or milestone.

The release plan communicates those features and enhancements slated for your project' next release (or the next few releases). So it acts as more of a project plan, breaking the big ideas down into smaller projects the community and main stakeholders of the project can make progress on.

Items labeled as `features` are short or long term release items that shall have an assignee and a milestone set.

9.6 Code Flow and Branches

9.6.1 Introduction

The zephyr Git repository has three types of branches:

main
: Which contains the latest state of development

collab-*
: Collaboration branches that are used for shared development of new features to be introduced into the main branch when ready. Creating a new collaboration branch requires a justification and TSC approval. Collaboration branches shall be based off the main branch and any changes developed in the collab branch shall target the main development branch. For released versions of Zephyr, the introduction of fixes and new features, if approved by the TSC, shall be done using backport pull requests.

vx.y-branch
: Branches which track maintenance releases based on a major release

Development in collaboration branches before features go to mainline allows teams to work independently on a subsystem or a feature, improves efficiency and turnaround time, and encourages collaboration and streamlines communication between developers.

Changes submitted to a collaboration branch can evolve and improve incrementally in a branch, before they are submitted to the mainline tree for final integration.

By dedicating an isolated branch to complex features, it's possible to initiate in-depth discussions around new additions before integrating them into the official project.

Collaboration branches are ephemeral and shall be removed once the collaboration work has been completed. When a branch is requested, the proposal should include the following:

- Define exit criteria for merging the collaboration branch changes back into the main branch.
- Define a timeline for the expected life cycle of the branch. It is recommended to select a Zephyr release to set the timeline. Extensions to this timeline requires TSC approval.

9.6.2 Roles and Responsibilities

Collaboration branch owners have the following responsibilities:

- Use the infrastructure and tools provided by the project (GitHub, Git)
- All changes to collaboration branches shall come in form of github pull requests.
- Force pushing a collaboration branch is only allowed when rebasing against the main branch.
- Review changes coming from team members and request review from branch owners when submitting changes.
- Keep the branch in sync with upstream and update on a regular basis.
- Push changes frequently to upstream using the following methods:
  - GitHub pull requests: for example, when reviews have not been done in the local branch (one-man branch).
  - Merge requests: When a set of changes has been done in a local branch and has been reviewed and tested in a collaboration branch.

9.7 Development Environment and Tools

9.7.1 Code Review

GitHub is intended to provide a framework for reviewing every commit before it is accepted into the code base. Changes, in the form of Pull Requests (PR) are uploaded to GitHub but don't actually become a part of the project until they've been reviewed, passed a series of checks (CI), and are approved by maintainers. GitHub is used to support the standard open source practice of submitting patches, which are then reviewed by the project members before being applied to the code base.

Pull requests should be appropriately *labeled*, and linked to any relevant *bug or feature tracking issues* .

The Zephyr project uses GitHub for code reviews and Git tree management. When submitting a change or an enhancement to any Zephyr component, a developer should use GitHub. GitHub Actions automatically assigns a responsible reviewer on a component basis, as defined in the MAINTAINERS.yml file stored with the code tree in the Zephyr project repository. A limited set of release managers are allowed to merge a pull request into the main branch once reviews are complete.

Give reviewers time to review before code merge

The Zephyr project is a global project that is not tied to a certain geography or timezone. We have developers and contributors from across the globe. When changes are proposed using pull request, we need to allow for a minimal review time to give developers and contributors the opportunity to review and comment on changes. There are different categories of changes and we know that some changes do require reviews by subject matter experts and owners of the subsystem being changed. Many changes fall under the "trivial" category that can be addressed with general reviews and do not need to be queued for a maintainer or code-owner review. Additionally, some changes might require further discussions and a decision by the TSC or the Security working group. To summarize the above, the diagram below proposes minimal review times for each category:

Workflow

- An author of a change can suggest in his pull-request which category a change should belong to. A project maintainers or TSC member monitoring the inflow of changes can change

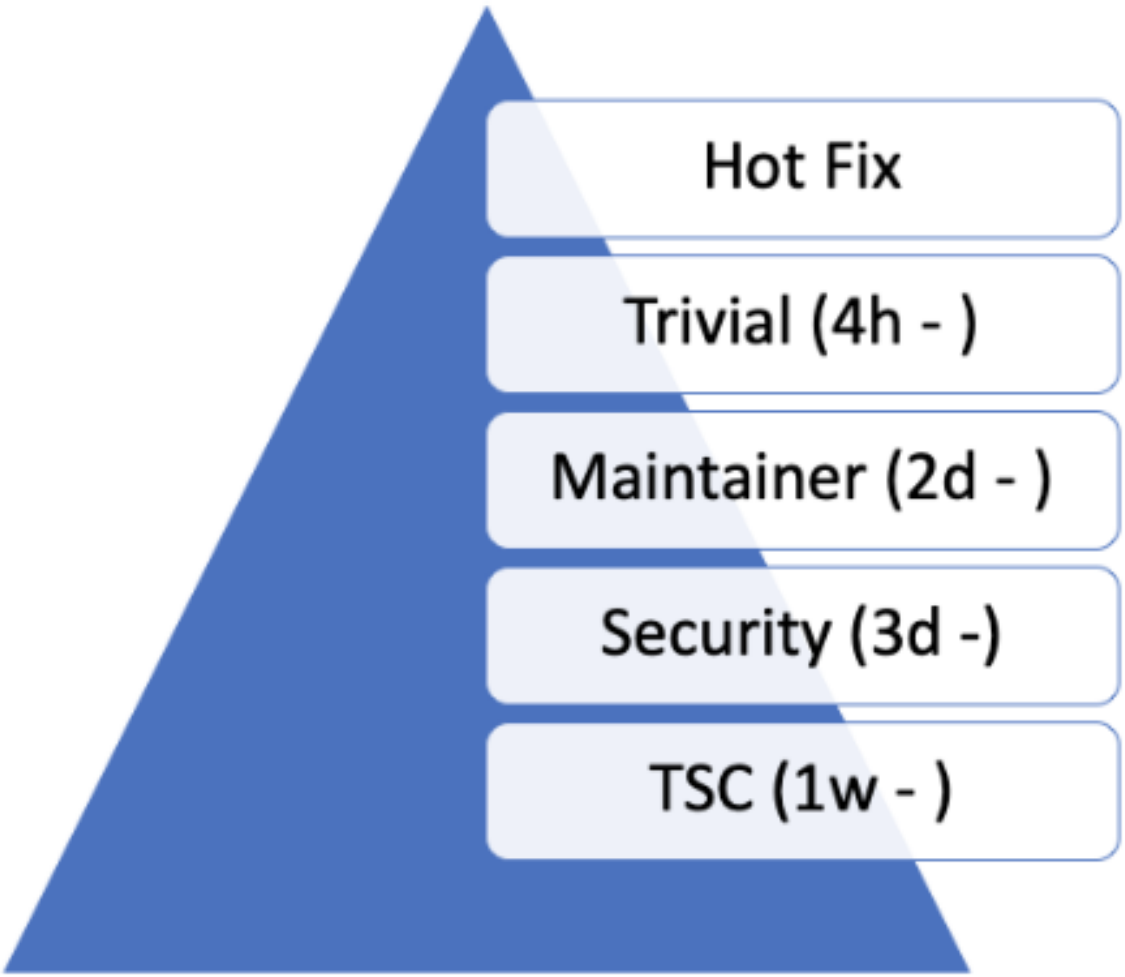

Fig. 4: Pull request classes

the label of a pull request by adding a comment justifying why a change should belong to another category.

- The project will use the label system to categorize the pull requests.
- Changes should not be merged before the minimal time has expired.

Categories/Labels

Hotfix
: Any change that is a fix to an issue that blocks developers from doing their daily work, for example CI breakage, Test breakage, Minor documentation fixes that impact the user experience.

  Such fixes can be merged at any time after they have passed CI checks. Depending on the fix, severity, and availability of someone to review them (other than the author) they can be merged with justification without review by one of the project owners.

Trivial
: Trivial changes are those that appear obvious enough and do not require maintainer or code-owner involvement. Such changes should not change the logic or the design of a subsystem or component. For example a trivial change can be:

  - Documentation changes
  - Configuration changes
  - Minor Build System tweaks
  - Minor optimization to code logic without changing the logic
  - Test changes and fixes
  - Sample modifications to support additional configuration or boards etc.

Maintainer
: Any changes that touch the logic or the original design of a subsystem or component will need to be reviewed by the code owner or the designated subsystem maintainer. If the code changes is initiated by a contributor or developer other than the owner the pull request needs to be assigned to the code owner who will have to drive the pull request to a mergeable state by giving feedback to the author and asking for more reviews from other developers.

Security
: Changes that appear to have an impact to the overall security of the system need to be reviewed by a security expert from the security working group.

TSC and Working Groups
: Changes that introduce new features or functionality or change the way the overall system works need to be reviewed by the TSC or the responsible Working Group. For example for *breaking API changes*, the proposal needs to be presented in the Architecture meeting so that the relevant stakeholders are made aware of the change.

A Pull-Request should have an Assignee

- An assignee to a pull request should not be the same as the author of the pull-request
- An assignee to a pull request is responsible for driving the pull request to a mergeable state
- An assignee is responsible for dismissing stale reviews and seeking reviews from additional developers and contributors
- Pull requests should not be merged without an approval by the assignee.

Pull Request should not be merged by author without review

All pull requests need to be reviewed and should not be merged by the author without a review. The following exceptions apply:

- Hot fixes: Fixing CI issues, reverts, and system breakage
- Release related changes: Changing version file, applying tags and release related activities without any code changes.

Developers and contributors should always seek review, however there are cases when reviewers are not available and there is a need to get a code change into the tree as soon as possible.

Reviewers shall not 'Request Changes' without comments or justification

Any change requests (-1) on a pull request have to be justified. A reviewer should avoid blocking a pull-request with no justification. If a reviewer feels that a change should not be merged without their review, then: Request change of the category: for example:

- Trivial -> Maintainer
- Assign Pull Request to yourself, this will mean that a pull request should not be merged without your approval.

Pull Requests should have at least 2 approvals before they are merged

A pull-request shall be merged only with two positive reviews (approval). Beside the person merging the pull-request (merging != approval), two additional approvals are required to be able to merge a pull request. The person merging the request can merge without approving or approve and merge to get to the 2 approvals required.

Reviewers should keep track of pull requests they have provided feedback to

If a reviewer has requested changes in a pull request, he or she should monitor the state of the pull request and/or respond to mention requests to see if his feedback has been addressed. Failing to do so, negative reviews shall be dismissed by the assignee or an owner of the repository. Reviews will be dismissed following the criteria below:

- The feedback or concerns were visibly addressed by the author
- The reviewer did not revisit the pull request after 2 week and multiple pings by the author
- The review is unrelated to the code change or asking for unjustified structural changes such as:
  - Split the PR
  - Can you fix this unrelated code that happens to appear in the diff
  - Can you fix unrelated issues
  - Etc.

Closing Stale Issues and Pull Requests

- The Pull requests and issues sections on Github are NOT discussion forums. They are items that we need to execute and drive to closure. Use the mailing lists for discussions.
- In case of both issues and pull-requests the original poster needs to respond to questions and provide clarifications regarding the issue or the change. After one week without a response to a request, a second attempt to elicit a response from the contributor will be made. After one more week without a response the item may be closed (draft and DNM tagged pull requests are excluded).

9.7.2 Continuous Integration

All changes submitted to GitHub are subject to tests that are run on emulated platforms and architectures to identify breakage and regressions that can be immediately identified. Testing using Twister additionally performs build tests of all boards and platforms. Documentation changes are also verified through review and build testing to verify doc generation will be successful.

Any failures found during the CI test run will result in a negative review assigned automatically by the CI system. Developers are expected to fix issues and rework their patches and submit again.

The CI infrastructure currently runs the following tests:

- Run `checkpatch` for code style issues (can vote -1 on errors; see note)
- Gitlint: Git commit style based on project requirements
- License Check: Check for conflicting licenses
- Run `twister` script
  - Run kernel tests in QEMU (can vote -1 on errors)
  - Build various samples for different boards (can vote -1 on errors)
- Verify documentation builds correctly.

Note

`checkpatch` is a Perl script that uses regular expressions to extract information that requires a C language parser to process accurately. As such it sometimes issues false positives. Known cases include constructs like:

```
static uint8_t __aligned(PAGE_SIZE) page_pool[PAGE_SIZE * POOL_PAGES];
IOPCTL_Type *base = config->base;
```

Both lines produce a diagnostic regarding spaces around the `*` operator: the first is misidentified as a pointer type declaration that would be correct as `PAGE_SIZE *POOL_PAGES` while the second is misidentified as a multiplication expression that would be correct as `IOPCTL_Type * base`.

Maintainers can override the -1 in cases where the CI infrastructure gets the wrong answer.

9.7.3 Labeling issues and pull requests in GitHub

The project uses GitHub issues and pull requests (PRs) to track and manage daily and long-term work and contributions to the Zephyr project. We use GitHub **labels** to classify and organize these issues and PRs by area, type, priority, and more, making it easier to find and report on relevant items.

All GitHub issues or pull requests must be appropriately labeled. Issues and PRs often have multiple labels assigned, to help classify them in the different available categories. When reviewing a PR, if it has missing or incorrect labels, maintainers shall fix it.

This saves us all time when searching, reduces the chances of the PR or issue being forgotten, speeds up reviewing, avoids duplicate issue reports, etc.

These are the labels we currently have, grouped by applicability:

Labels applicable to issues only

Label	Description
priority: {high|medium|low}	To classify the impact and importance of a bug or *feature*. Note: Issue priorities are generally set or changed during the bug-triage or TSC meetings.
Regression	Something, which was working, but does not anymore (bug subtype).
Enhancement	Changes/Updates/Additions to existing *features*.
Feature request	A request for a new *feature*.
Feature	A *planned feature* with a milestone.
Hardware Support	Covers porting an existing feature (including Zephyr itself) to new hardware.
Duplicate	This issue is a duplicate of another issue (please specify).
Good first issue	Good for a first time contributor to take.
Release Notes	Issues that need to be mentioned in release notes as known issues with additional information.

Any issue must be classified and labeled as either *Bug*, *Enhancement*, *RFC*, *Feature*, *Feature Request* or *Hardware Support*. More information on how feature requests are handled and become features can be found in *Feature Tracking*.

Labels applicable to pull requests only

The issue or PR describes a change to a stable API.

Label	Description
Hotfix	Fix for an issue blocking development.
Trivial	Simple changes that can have shorter review time and be reviewed by anyone, i.e. typos, straightforward one-liner bug fixes, etc.
Maintainer	Maintainer review required.
Security Review	To be reviewed by a security expert.
DNM	This PR should not be merged (Do Not Merge). For work in progress, GitHub “draft” PRs are preferred.
Needs review	The PR needs attention from the maintainers.
Backport	The PR is a backport or should be backported.
Licensing	The PR has licensing issues which require a licensing expert to review it.

Note

For all labels applicable to PRs: Please note that the label, together with PR complexity, affects how long a merge should be held to ensure proper review. See *review process* for details.

Labels applicable to both pull requests and issues

Label	Description
area: {area-name}	Indicates Zephyr subsystems (e.g, *area: Kernel*, *area: I2C*, *area: Memory Management*), project functions (e.g., *area: Debugging*, *area: Documentation*, *area: Process*), or other categories (e.g., *area: Coding Style*, *area: MISRA-C*) affected by the bug or the pull request. An area maintainer should be able to filter by an area label and find all issues and PRs which relate to that area.
platform: {platform name}	An issue or PR which affects only a particular platform.
dev-review	The issue is to be discussed in the following dev-review if time permits.
TSC	TSC stands for Technical Steering Committee. The issue is to be discussed in the following TSC meeting if time permits.
Breaking API Change	The issue or PR describes a breaking change to a stable API. See additional information in *Introducing breaking API changes*.
bug	The issue is a bug, or the PR is fixing a bug.
Coverity	A Coverity detected issue or its fix.
Waiting for response	The Zephyr developers are waiting for the submitter to respond to a question, or address an issue.
Blocked	Blocked by another PR or issue.
Stale	An issue or a PR which seems abandoned, and requires attention by the author.
In progress	For PRs: is work in progress and should not be merged yet. For issues: Is being worked on.
RFC	The author would like input from the community. For a PR it should be considered a draft.
LTS	Long term release branch related.
EXT	Related to an external component.

9.8 Bug Reporting

To maintain traceability and relation between proposals, changes, features, and issues, it is recommended to cross-reference source code commits with the relevant GitHub issues and vice versa. Any changes that originate from a tracked feature or issue should contain a reference to the feature by mentioning the corresponding issue or pull-request identifiers.

At any time it should be possible to establish the origin of a change and the reason behind it by following the references in the code.

9.8.1 Reporting a regression issue

It could happen that the issue being reported is identified as a regression, as the use case is known to be working on earlier commit or release. In this case, providing directly the guilty commit when submitting the bug gains a lot of time in the eventual bug fixing.

To identify the commit causing the regression, several methods could be used, but tree bisecting method is an efficient one that doesn't require deep code expertise and can be used by every one.

For this, git bisect is the recommended tool.

Recommendations on the process:

- Run `west update` on each bisection step.
- Once the bisection is over and a culprit identified, verify manually the result.

9.9 Communication and Collaboration

The Zephyr Discord Server is the primary chat forum used by Zephyr developers, contributors, and users.

The Zephyr project mailing lists are used as an additional communication tool by project members, contributors, and the community. There are specialized mailing lists for specific interests. Several lists are public and open. Mailing lists are always available for use in situations where Discord is unavailable or an unsuitable forum.

In general, bug reports and other issues should be reported as GitHub Issues and not broadcasted to the mailing list. The same applies to code reviews.

9.10 Code Documentation

9.10.1 API Documentation

Well documented APIs enhance the experience for developers and are an essential requirement for defining an API's success. Doxygen is a general purpose documentation tool that the zephyr project uses for documenting APIs. It generates either an on-line documentation browser (in HTML) and/or provides input for other tools that is used to generate a reference manual from documented source files. In particular, doxygen's XML output is used as an input when producing the Zephyr project's online documentation.

9.10.2 Reference to Requirements

APIs for the most part document the implementation of requirements or advertised features and can be traced back to features. We use the API documentation as the main interface to trace implementation back to documented features. This is done using custom _doxygen_ tags that reference requirements maintained somewhere else in a requirement catalogue.

9.10.3 Test Documentation

To help understand what each test does and which functionality it tests we also document all test code using the same tools and in the same context and generate documentation for all unit and integration tests maintained in the same environment. Tests are documented using references to the APIs or functionality they validate by creating a link back to the APIs and by adding a reference to the original requirements.

9.10.4 Documentation Guidelines

Test Code

The Zephyr project uses several test methodologies, the most common being the *Ztest framework*. Test documentation should only be done on the entry test functions (usually prefixed with test_) and those that are called directly by the Ztest framework. Those tests are going to appear in test

reports and using their name and identifier is the best way to identify them and trace back to them from requirements.

Test documentation should not interfere with the actual API documentation and needs to follow a new structure to avoid confusion. Using a consistent naming scheme and following a well-defined structure we will be able to group this documentation in its own module and identify it uniquely when parsing test data for traceability reports. Here are a few guidelines to be followed:

- All test code documentation should be grouped under the `all_tests` doxygen group
- All test documentation should be under doxygen groups that are prefixed with tests_

The custom doxygen `@verify` directive signifies that a test verifies a requirement:

```
/**
* @brief Tests for the Semaphore kernel object
* @defgroup kernel_semaphore_tests Semaphore
* @ingroup all_tests
* @{
*/

...
/**
* @brief A brief description of the tests
* Some details about the test
* more details
*
* @verify{@req{1111}}
*/
void test_sema_thread2thread(void)
{
...
}
...

/**
* @}
*/
```

To get coverage of how an implementation or a piece of code satisfies a requirements, we use the `satisfy` alias in doxygen:

```
/**
* @brief Give a semaphore.
*
* This routine gives @a sem, unless the semaphore is already at its maximum
* permitted count.
*
* @note Can be called by ISRs.
*
* @param sem Address of the semaphore.
*
* @satisfy{@req{015}}
*/
__syscall void k_sem_give(struct k_sem *sem);
```

To generate the matrix, you will first need to build the documentation, specifically you will need to build the doxygen XML output:

```
$ make doxygen
```

Parse the generated XML data from doxygen to generate the traceability matrix.

The Zephyr project defines a development process workflow using GitHub **Issues** to track feature, enhancement, and bug reports together with GitHub **Pull Requests** (PRs) for submitting and reviewing changes. Zephyr community members work together to review these Issues and PRs, managing feature enhancements and quality improvements of Zephyr through its regular releases, as outlined in the program management overview.

We can only manage the volume of Issues and PRs, by requiring timely reviews, feedback, and responses from the community and contributors, both for initial submissions and for followup questions and clarifications. Read about the project's *development processes and tools* and specifics about *review timelines* to learn about the project's goals and guidelines for our active developer community.

TSC Project Roles describes in detail the Zephyr project roles and associated permissions with respect to the development process workflow.

9.11 Terminology

- mainline: The main tree where the core functionality and core features are being developed.
- subsystem/feature branch: is a branch within the same repository. In our case, we will use the term branch also when referencing branches not in the same repository, which are a copy of a repository sharing the same history.
- upstream: A parent branch the source code is based on. This is the branch you pull from and push to, basically your upstream.
- LTS: Long Term Support

Chapter 10

Security

These documents describe the requirements, processes, and developer guidelines for ensuring security is addressed within the Zephyr project.

10.1 Zephyr Security Overview

10.1.1 Introduction

This document outlines the steps of the Zephyr Security Subcommittee towards a defined security process that helps developers build more secure software while addressing security compliance requirements. It presents the key ideas of the security process and outlines which documents need to be created. After the process is implemented and all supporting documents are created, this document is a top-level overview and entry point.

Overview and Scope

We begin with an overview of the Zephyr development process, which mainly focuses on security functionality.

In subsequent sections, the individual parts of the process are treated in detail. As depicted in Figure 1, these main steps are:

1. **Secure Development:** Defines the system architecture and development process that ensures adherence to relevant coding principles and quality assurance procedures.
2. **Secure Design:** Defines security procedures and implement measures to enforce them. A security architecture of the system and relevant sub-modules is created, threats are identified, and countermeasures designed. Their correct implementation and the validity of the threat models are checked by code reviews. Finally, a process shall be defined for reporting, classifying, and mitigating security issues.
3. **Security Certification:** Defines the certifiable part of the Zephyr RTOS. This includes an evaluation target, its assets, and how these assets are protected. Certification claims shall be determined and backed with appropriate evidence.

Intended Audience

This document is a guideline for the development of a security process by the Zephyr Security Subcommittee and the Zephyr Technical Steering Committee. It provides an overview of the Zephyr security process for (security) engineers and architects.

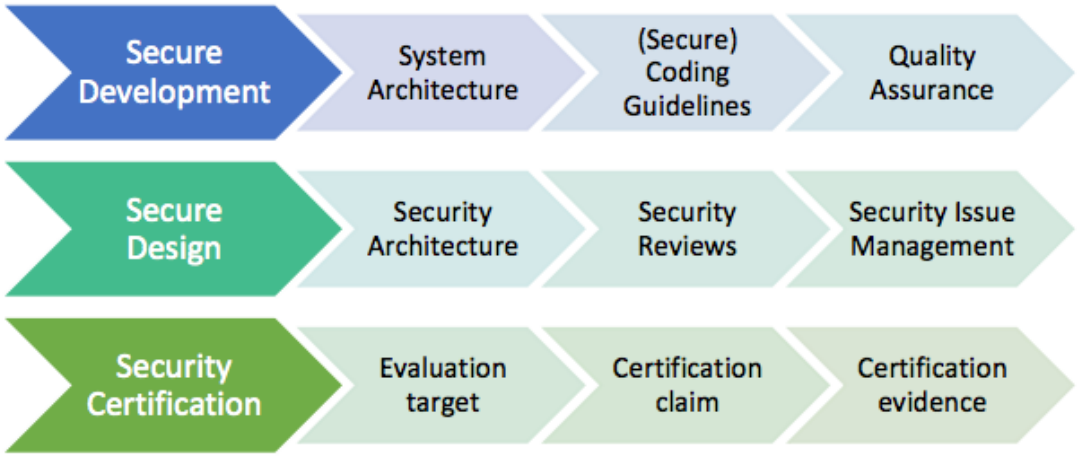

Fig. 1: Figure 1. Security Process Steps

Nomenclature

In this document, the keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in **[?]**.

These words are used to define absolute requirements (or prohibitions), highly recommended requirements, and truly optional requirements. As noted in RFC-2119, “These terms are frequently used to specify behavior with security implications. The effects on security of not implementing a MUST or SHOULD, or doing something the specification says MUST NOT or SHOULD NOT be done may be very subtle. Document authors should take the time to elaborate the security implications of not following recommendations or requirements as most implementers will not have had the benefit of the experience and discussion that produced the specification.”

Security Document Update

This document is a living document. As new requirements, features, and changes are identified, they will be added to this document through the following process:

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Security Subcommittee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

10.1.2 Current Security Definition

This section recapitulates the current status of secure development within the Zephyr RTOS. Currently, focus is put on functional security and code quality assurance, although additional security features are scoped.

The three major security measures currently implemented are:

- **Security Functionality** with a focus on cryptographic algorithms and protocols. Support for cryptographic hardware is scoped for future releases. The Zephyr runtime architecture is a monolithic binary and removes the need for dynamic loaders, thereby reducing the exposed attack surface.

- **Quality Assurance** is driven by using a development process that requires all code to be reviewed before being committed to the common repository. Furthermore, the reuse of proven building blocks such as network stacks increases the overall quality level and guarantees stable APIs. Static code analyses provide additional quality checks.
- **Execution Protection** including thread separation, stack and memory protection is currently available in the upstream Zephyr RTOS starting with version 1.9.0 (stack protection). Memory protection and thread separation were added in version 1.10.0 for X86 and in version 1.11.0 for ARM and ARC.

These topics are discussed in more detail in the following subsections.

Security Functionality

The security functionality in Zephyr hinges mainly on the inclusion of cryptographic algorithms, and on its monolithic system design.

The cryptographic features are provided through PSA Crypto, with mbedTLS as the underlying implementation. Applications leverage PSA Crypto APIs, ensuring a standardized and secure approach to cryptographic operations. mbedTLS, as the implementation of PSA Crypto, supports a wide range of cryptographic algorithms, making it suitable for various application requirements.

APIs for vendor specific cryptographic IPs in both hardware and software are planned, including secure key storage in the form of secure access modules (SAMs), Trusted Platform Modules (TPMs), and Trusted Execution Environments (TEEs).

The security architecture is based on a monolithic design where the Zephyr kernel and all applications are compiled into a single static binary. System calls are implemented as function calls without requiring context switches. Static linking eliminates the potential for dynamically loading malicious code.

Additional protection features are available in later releases. Stack protection mechanisms are provided to protect against stack overruns. In addition, applications can take advantage of thread separation features to split the system into privileged and unprivileged execution environments. Memory protection features provide the capability to partition system resources (memory, peripheral address space, etc.) and assign resources to individual threads or groups of threads. Stack, thread execution level, and memory protection constraints are enforced at the time of context switch.

Quality Assurance

The Zephyr project uses an automated quality assurance process. The goal is to have a process including mandatory code reviews, feature and issue management/tracking, and static code analyses.

Code reviews are documented and enforced using a voting system before getting checked into the repository by the responsible subsystem's maintainer. The main goals of the code review are:

- Verifying correct functionality of the implementation
- Increasing the readability and maintainability of the contributed source code
- Ensuring appropriate usage of string and memory functions
- Validation of the user input
- Reviewing the security relevant code for potential issues

The current coding principles focus mostly on coding styles and conventions. Functional correctness is ensured by the build system and the experience of the reviewer. Especially for security relevant code, concrete and detailed guidelines need to be developed and aligned with the developers (see: *Secure Coding*).

Static code analyses are run on the Zephyr code tree on a regular basis, see *Static Code Analysis*.

Bug and issue tracking and management is performed using Github. The term “survivability” was coined to cover pro-active security tasks such as security issue categorization and management. A problem identified as vulnerability is managed within Github security advisories.

Issues determined by static analyses should have more stringent reviews before they are closed as non-issues (at least another person educated in security processes need to agree on non-issue before closing).

A security subcommittee has been formed to develop a security process in more detail; this document is part of that process.

Execution Protection

Execution protection is supported and can be categorized into the following tasks:

- **Memory separation:** Memory will be partitioned into regions and assigned attributes based on the owner of that region of memory. Threads will only have access to regions they control.
- **Stack protection:** Stack guards would provide mechanisms for detecting and trapping stack overruns. Individual threads should only have access to their own stacks.
- **Thread separation:** Individual threads should only have access to their own memory resources. As threads are scheduled, only memory resources owned by that thread will be accessible. Topics such as program flow protection and other measures for tamper resistance are currently not in scope.

System Level Security (Ecosystem, ...)

System level security encompasses a wide variety of categories. Some examples of these would be:

- Secure/trusted boot
- Over the air (OTA) updates
- External Communication
- Device authentication
- Access control of onboard resources
  - Flash updating
  - Secure storage
  - Peripherals
- Root of trust
- Reduction of attack surface

Some of these categories are interconnected and rely on multiple pieces to be in place to produce a full solution for the application.

10.1.3 Secure Development Process

The development of secure code shall adhere to certain criteria. These include coding guidelines and development processes that can be roughly separated into two categories related to software quality and related to software security. Furthermore, a system architecture document shall be created and kept up-to-date with future development.

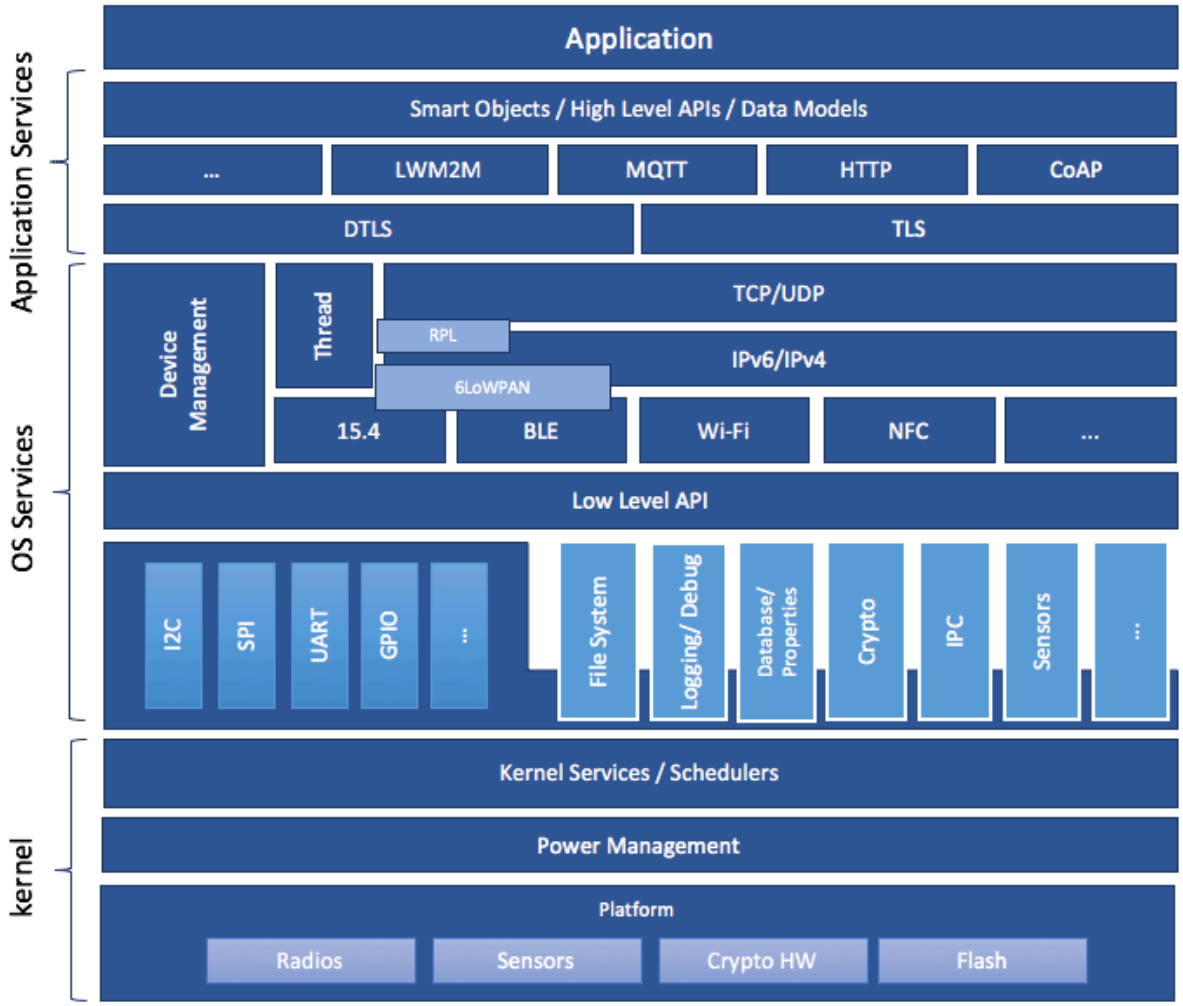

Fig. 2: Figure 2: Zephyr System Architecture

System Architecture

A high-level schematic of the Zephyr system architecture is given in Figure 2. It separates the architecture into an OS part (*kernel + OS Services*) and a user-specific part (*Application Services*). The OS part itself contains low-level, platform specific drivers and the generic implementation of I/O APIs, file systems, kernel-specific functions, and the cryptographic library.

A document describing the system architecture and design choices shall be created and kept up to date with future development. This document shall include the base architecture of the Zephyr OS and an overview of important submodules. For each of the modules, a dedicated architecture document shall be created and evaluated against the implementation. These documents shall serve as an entry point to new developers and as a basis for the security architecture. Please refer to the *Zephyr subsystem documentation* for detailed information.

Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. These standards are included in the Zephyr Project documentation, specifically in its *Secure Coding* section. In [**?**], the following, widely accepted principles for protection mechanisms are defined to prevent security violations and limit their impact:

- **Open design** as a design principle incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [**?**] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [**?**].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [**?**].
- **Least privilege** describes an access model in which each user, program and thread shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.
- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [**?**] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure its usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth:** do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [**?**] paradigm shall be used.
- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely

used (a threshold of 80% is given in [**?**]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management:** to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

Based on these design principles and commonly accepted best practices, a secure development guide shall be developed, published, and implemented into the Zephyr development process. Further details on this are given in the *Secure Design* section.

Quality Assurance

The quality assurance part encompasses the following criteria:

- **Adherence to the Coding Conventions** with respect to coding style, naming schemes of modules, functions, variables, and so forth. This increases the readability of the Zephyr code base and eases the code review. These coding conventions are enforced by automated scripts prior to check-in.
- **Adherence to Deployment Guidelines** is required to ensure consistent releases with a well-documented feature set and a trackable list of security issues.
- **Code Reviews** ensure the functional correctness of the code base and shall be performed on each proposed code change prior to check-in. Code reviews shall be performed by at least one independent reviewer other than the author(s) of the code change. These reviews shall be performed by the subsystem maintainers and developers on a functional level and are to be distinguished from security reviews as laid out in the *Secure Design* section. Refer to the *Project and Governance* documentation for more information.
- **Static Code Analysis** tools efficiently detect common coding mistakes in large code bases. All code shall be analyzed using an appropriate tool prior to merges into the main repository. This is not per individual commit, but is to be run on some interval on specific branches. It is mandatory to remove all findings or waive potential false-positives before each release. Waivers shall be documented centrally and in the form of a comment inside the source code itself. The documentation shall include the employed tool and its version, the date of the analysis, the branch and parent revision number, the reason for the waiver, the author of the respective code, and the approver(s) of the waiver. This shall as a minimum run on the main release branch and on the security branch. It shall be ensured that each release has zero issues with regard to static code analysis (including waivers). Refer to the *Project and Governance* documentation for more information.
- **Complexity Analyses** shall be performed as part of the development process and metrics such as cyclomatic complexity shall be evaluated. The main goal is to keep the code as simple as possible.
- **Automation:** the review process and checks for coding rule adherence are a mandatory part of the precommit checks. To ensure consistent application, they shall be automated as part of the precommit procedure. Prior to merging large pieces of code in from subsystems, in addition to review process and coding rule adherence, all static code analysis must have been run and issues resolved.

Release and Lifecycle Management

Lifecycle management contains several aspects:

- **Device management** encompasses the possibility to update the operating system and/or security related sub-systems of Zephyr enabled devices in the field.
- **Lifecycle management:** system stages shall be defined and documented along with the transactions between the stages in a system state diagram. For security reasons, this shall include locking of the device in case an attack has been detected, and a termination if the end of life is reached.
- **Release management** describes the process of defining the release cycle, documenting releases, and maintaining a record of known vulnerabilities and mitigations. Especially for certification purposes the integrity of the release needs to be ensured in a way that later manipulation (e.g., inserting of backdoors, etc.) can be easily detected.
- **Rights management and NDAs:** if required by the chosen certification, the confidentiality and integrity of the system needs to be ensured by an appropriate rights management (e.g., separate source code repository) and non-disclosure agreements between the relevant parties. In case of a repository shared between several parties, measures shall be taken that no malicious code is checked in.

These points shall be evaluated with respect to their impact on the development process employed for the Zephyr project.

10.1.4 Secure Design

In order to obtain a certifiable system or product, the security process needs to be clearly defined and its application needs to be monitored and driven. This process includes the development of security related modules in all of its stages and the management of reported security issues. Furthermore, threat models need to be created for currently known and future attack vectors, and their impact on the system needs to be investigated and mitigated. Please refer to the *Secure Coding* outlined in the Zephyr project documentation for detailed information.

The software security process includes:

- **Adherence to the Secure Development Coding** is mandatory to avoid that individual components breach the system security and to minimize the vulnerability of individual modules. While this can be partially achieved by automated tests, it is inevitable to investigate the correct implementation of security features such as countermeasures manually in security-critical modules.
- **Security Reviews** shall be performed by a security architect in preparation of each security-targeted release and each time a security-related module of the Zephyr project is changed. This process includes the validation of the effectiveness of implemented security measures, the adherence to the global security strategy and architecture, and the preparation of audits towards a security certification if required.
- **Security Issue Management** encompasses the evaluation of potential system vulnerabilities and their mitigation as described in *Security Issue Management*.

These criteria and tasks need to be integrated into the development process for secure software and shall be automated wherever possible. On system level, and for each security related module of the secure branch of Zephyr, a directly responsible security architect shall be defined to guide the secure development process.

Security Architecture

The general guidelines above shall be accompanied by an architectural security design on system- and module-level. The high level considerations include

- The identification of **security and compliance requirements**
- **Functional security** such as the use of cryptographic functions whenever applicable
- Design of **countermeasures** against known attack vectors

- Recording of security relevant **auditable events**
- Support for **Trusted Platform Modules (TPM)** and **Trusted Execution Environments (TEE)**
- Mechanisms to allow for **in-the-field updates** of devices using Zephyr
- Task scheduler and separation

The security architecture development is based on assets derived from the structural overview of the overall system architecture. Based on this, the individual steps include:

1. **Identification of assets** such as user data, authentication and encryption keys, key generation data (obtained from RNG), security relevant status information.
2. **Identification of threats** against the assets such as breaches of confidentiality, manipulation of user data, etc.
3. **Definition of requirements** regarding security and protection of the assets, e.g., countermeasures or memory protection schemes.

The security architecture shall be harmonized with the existing system architecture and implementation to determine potential deviations and mitigate existing weaknesses. Newly developed sub-modules that are integrated into the secure branch of the Zephyr project shall provide individual documents describing their security architecture. Additionally, their impact on the system level security shall be considered and documented.

Security Vulnerability Reporting

Please see *Security Vulnerability Reporting* for information on reporting security vulnerabilities.

Threat Modeling and Mitigation

The modeling of security threats against the Zephyr RTOS is required for the development of an accurate security architecture and for most certification schemes. The first step of this process is the definition of assets to be protected by the system. The next step then models how these assets are protected by the system and which threats against them are present. After a threat has been identified, a corresponding threat model is created. This model contains the asset and system vulnerabilities, as well as the description of the potential exploits of these vulnerabilities. Additionally, the impact on the asset, the module it resides in, and the overall system is to be estimated. This threat model is then considered in the module and system security architecture and appropriate countermeasures are defined to mitigate the threat or limit the impact of exploits.

In short, the threat modeling process can be separated into these steps (adapted from **[?]**):

1. Definition of assets
2. Application decomposition and creation of appropriate data flow diagrams (DFDs)
3. Threat identification and categorization using the **[?]** and **[?]** approaches
4. Determination of countermeasures and other mitigation approaches

This procedure shall be carried out during the design phase of modules and before major changes of the module or system architecture. Additionally, new models shall be created, or existing ones shall be updated whenever new vulnerabilities or exploits are discovered. During security reviews, the threat models and the mitigation techniques shall be evaluated by the responsible security architect.

From these threat models and mitigation techniques tests shall be derived that prove the effectiveness of the countermeasures. These tests shall be integrated into the continuous integration workflow to ensure that the security is not impaired by regressions.

Vulnerability Analyses

In order to find weak spots in the software implementation, vulnerability analyses (VA) shall be performed. Of special interest are investigations on cryptographic algorithms, critical OS tasks, and connectivity protocols.

On a pure software level, this encompasses

- **Penetration testing** of the RTOS on a particular hardware platform, which involves testing the respective Zephyr OS configuration and hardware as one system.
- **Side channel attacks** (timing invariance, power invariance, etc.) should be considered. For instance, ensuring **timing invariance** of the cryptographic algorithms and modules is required to reduce the attack surface. This applies to both the software implementations and when using cryptographic hardware.
- **Fuzzing tests** shall be performed on both exposed APIs and protocols.

The list given above serves primarily illustration purposes. For each module and for the complete Zephyr system (in general on a particular hardware platform), a suitable VA plan shall be created and executed. The findings of these analyses shall be considered in the security issue management process, and learnings shall be formulated as guidelines and incorporated into the secure coding guide.

If possible (as in case of fuzzing analyses), these tests shall be integrated into the continuous integration process.

10.1.5 Security Certification

One goal of creating a secure branch of the Zephyr RTOS is to create a certifiable system or certifiable submodules thereof. The certification scope and scheme are yet to be decided. However, many certifications such as Common Criteria [**?**] require evidence that the evaluation claims are indeed fulfilled, so a general certification process is outlined in the following. Based on the final choices for the certification scheme and evaluation level, this process needs to be refined.

Generic Certification Process

In general, the steps towards a certification or precertification (compare [**?**]) are:

1. The **definition of assets** to be protected within the Zephyr RTOS. Potential candidates are confidential information such as cryptographic keys, user data such as communication logs, and potentially IP of the vendor or manufacturer.
2. Developing a **threat model** and **security architecture** to protect the assets against exploits of vulnerabilities of the system. As a complete threat model includes the overall product including the hardware platform, this might be realized by a split model containing a precertified secure branch of Zephyr which the vendor could use to certify their Zephyr-enabled product.
3. Formulating an **evaluation target** that includes the **certification claims** on the security of the assets to be evaluated and certified, as well as assumptions on the operating conditions.
4. Providing **proof** that the claims are fulfilled. This includes consistent documentation of the security development process, etc.

These steps are partially covered in previous sections as well. In contrast to these sections, the certification process only requires to consider those components that shall be covered by the certification. The security architecture, for example, considers assets on system level and might include items not relevant for the certification.

Certification Options

For the security certification as such, the following options can be pursued:

1. **Abstract precertification of Zephyr as a pure software system:** this option requires assumptions on the underlying hardware platform and the final application running on top of Zephyr. If these assumptions are met by the hardware and the application, a full certification can be more easily achieved. This option is the most flexible approach but puts the largest burden on the product vendor.
2. **Certification of Zephyr on specific hardware platform without a specific application in mind:** this scenario describes the enablement of a secure platform running the Zephyr RTOS. The hardware manufacturer certifies the platform under defined assumptions on the application. If these are met, the final product can be certified with little effort.
3. **Certification of an actual product:** in this case, a full product including a specific hardware, the Zephyr RTOS, and an application is certified.

In all three cases, the certification scheme (e.g., FIPS 140-2 [**?**] or Common Criteria [**?**]), the scope of the certification (main-stream Zephyr, security branch, or certain modules), and the certification/assurance level need to be determined.

In case of partial certifications (options 1 and 2), assumptions on hardware and/or software are required for certifications. These can include [**?**]

- **Appropriate physical security** of the hardware platform and its environment.
- **Sufficient protection of storage and timing channels** on the hardware platform itself and all connected devices. (No mentioning of remote connections.)
- Only **trusted/assured applications** running on the device
- The device and its software stack is configured and operated by **properly trained and trusted individuals** with no malicious intent.

These assumptions shall be part of the security claim and evaluation target documents.

10.2 Security Vulnerability Reporting

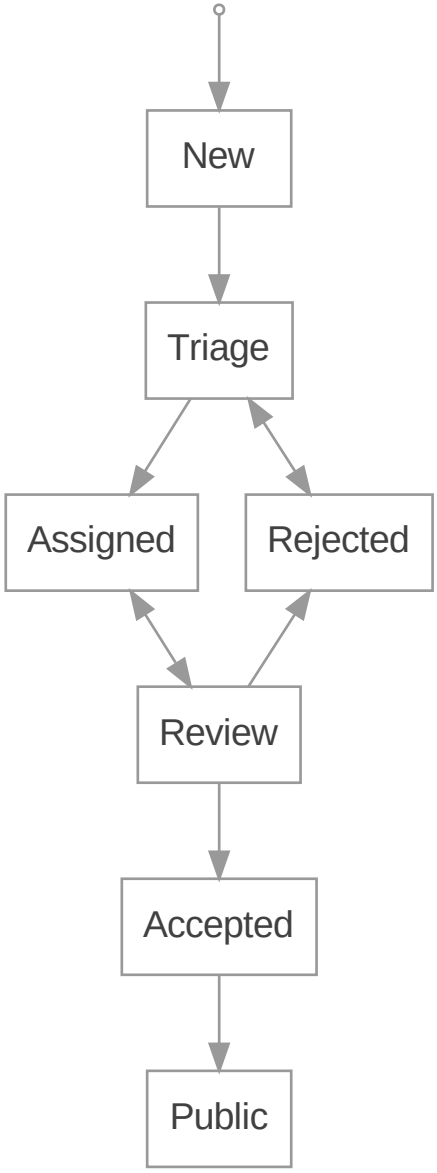
10.2.1 Introduction

Vulnerabilities in the Zephyr project should preferably be reported by opening a draft security advisory on the Zephyr repository's security advisories page. Alternatively, reports may be submitted to the project security incident response team via email to vulnerabilities@zephyrproject.org. These reports will be acknowledged and analyzed by the security response team within 1 week.

All vulnerabilities are tracked and managed through the Zephyr project's security advisories page on GitHub, where the original submitter will be granted access to view the issues that they have reported.

10.2.2 Security Issue Management

Issues within this bug tracking system will transition through a number of states according to this diagram:



- New: This state represents new reports that have been entered directly by a reporter. When entered by the response team in response to an email, the issue shall be transitioned directly to Triage.
- Triage: This issue is awaiting Triage by the response team. The response team will analyze the issue, determine a responsible entity, assign it to that individual, and move the issue to the Assigned state. Part of triage will be to set the issue's priority.
- Assigned: The issue has been assigned, and is awaiting a fix by the assignee.
- Review: Once there is a Zephyr pull request for the issue, the PR link will be added to a comment in the issue, and the issue moved to the Review state.
- Accepted: Indicates that this issue has been merged into the appropriate branch within Zephyr.
- Public: The embargo period has ended. The issue will be made publicly visible, the associ-

ated CVE updated, and the vulnerabilities page in the docs updated to include the detailed information.

The security advisories created are kept private, due to the sensitive nature of security reports. The issues are only visible to certain parties:

- Members of the PSIRT mailing list
- the reporter
- others, as proposed and ratified by the Zephyr Security Subcommittee. In the general case, this will include:
  - The code owner responsible for the fix.
  - The Zephyr release owners for the relevant releases affected by this vulnerability.

The Zephyr Security Subcommittee shall review the reported vulnerabilities during any meeting with more than three people in attendance. During this review, they shall determine if new issues need to be embargoed.

The guideline for embargo will be based on: 1. Severity of the issue, and 2. Exploitability of the issue. Issues that the subcommittee decides do not need an embargo will be reproduced in the regular Zephyr project bug tracking system.

Security sensitive vulnerabilities shall be made public after an embargo period of at most 90 days. The intent is to allow 30 days within the Zephyr project to fix the issues, and 60 days for external parties building products using Zephyr to be able to apply and distribute these fixes.

Fixes to the code shall be made through pull requests PR in the Zephyr project github. Developers shall make an attempt to not reveal the sensitive nature of what is being fixed, and shall not refer to CVE numbers that have been assigned to the issue. The developer instead should merely describe what has been fixed.

The security subcommittee will maintain information mapping embargoed CVEs to these PRs (this information is within the Github security advisories), and produce regular reports of the state of security issues.

Each issue that is considered a security vulnerability shall be assigned a CVE number. As fixes are created, it may be necessary to allocate additional CVE numbers, or to retire numbers that were assigned.

10.2.3 Vulnerability Notification

Each Zephyr release shall contain a report of CVEs that were fixed in that release. Because of the sensitive nature of these vulnerabilities, the release shall merely include a list of CVEs that have been fixed. After the embargo period, the vulnerabilities page shall be updated to include additional details of these vulnerabilities. The vulnerability page shall give credit to the reporter(s) unless a reporter specifically requests anonymity.

The Zephyr project shall maintain a vulnerability-alerts mailing list. This list will be seeded initially with a contact from each project member. Additional parties can request to join this list by filling out the form at the Vulnerability Registry. These parties will be vetted by the project director to determine that they have a legitimate interest in knowing about security vulnerabilities during the embargo period.

Periodically, the security subcommittee will send information to this mailing list describing known embargoed issues, and their backport status within the project. This information is intended to allow them to determine if they need to backport these changes to any internal trees.

When issues have been triaged, this list will be informed of:

- The Zephyr Project security advisory link (GitHub).
- The CVE number assigned.
- The subsystem involved.

- The severity of the issue.

After acceptance of a PR fixing the issue (merged), in addition to the above, the list will be informed of:

- The association between the CVE number and the PR fixing it.
- Backport plans within the Zephyr project.

10.2.4 Backporting of Security Vulnerabilities

Each security issue fixed within zephyr shall be backported to the following releases:

- The current Long Term Stable (LTS) release.
- The most recent two releases.

The developer of the fix shall be responsible for any necessary backports, and apply them to any of the above listed release branches, unless the fix does not apply (the vulnerability was introduced after this release was made). All recommendations for *vulnerability fixes* apply for backport pull requests (and associated issues). Additionally, it is recommended that the developer privately informs the responsible release manager that the backport pull request and issue are addressing a vulnerability.

Backports will be tracked on the security advisory.

10.2.5 Need to Know

Due to the sensitive nature of security vulnerabilities, it is important to share details and fixes only with those parties that have a need to know. The following parties will need to know details about security vulnerabilities before the embargo period ends:

- Maintainers will have access to all information within their domain area only.
- The current release manager, and the release manager for historical releases affected by the vulnerability (see backporting above).
- The Project Security Incident Response (PSIRT) team will have full access to information. The PSIRT is made up of representatives from platinum members, and volunteers who do work on triage from other members.
- As needed, release managers and maintainers may be invited to attend additional security meetings to discuss vulnerabilities.

10.3 Secure Coding

Traditionally, microcontroller-based systems have not placed much emphasis on security. They have usually been thought of as isolated, disconnected from the world, and not very vulnerable, just because of the difficulty in accessing them. The Internet of Things has changed this. Now, code running on small microcontrollers often has access to the internet, or at least to other devices (that may themselves have vulnerabilities). Given the volume they are often deployed at, uncontrolled access can be devastating[1].

This document describes the requirements and process for ensuring security is addressed within the Zephyr project. All code submitted should comply with these principles.

Much of this document comes from [**?**].

[1] An attack resulted in a significant portion of DNS infrastructure being taken down.

10.3.1 Introduction and Scope

This document covers guidelines for the Zephyr Project, from a security perspective. Many of the ideas contained herein are captured from other open source efforts.

We begin with an overview of secure design as it relates to Zephyr. This is followed by a section on *Secure development knowledge*, which gives basic requirements that a developer working on the project will need to have. This section gives references to other security documents, and full details of how to write secure software are beyond the scope of this document. This section also describes vulnerability knowledge that at least one of the primary developers should have. This knowledge will be necessary for the review process described below this.

Following this is a description of the review process used to incorporate changes into the Zephyr codebase. This is followed by documentation about how security-sensitive issues are handled by the project.

Finally, the document covers how changes are to be made to this document.

10.3.2 Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. In [**?**], the following, widely accepted principles for protection mechanisms are defined to help prevent security violations and limit their impact:

- **Open design** as a design guideline incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [**?**] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [**?**].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [**?**].
- **Least privilege** describes an access model in which each user, program, and thread, shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.
- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [**?**] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure their usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [**?**] paradigm shall be used.

- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in [**?**]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.
- **Change management**: to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

10.3.3 Secure development knowledge

Secure designer

The Zephyr project must have at least one primary developer who knows how to design secure software.

This requires understanding the following design principles, including the 8 principles from [**?**]:

- economy of mechanism (keep the design as simple and small as practical, e.g., by adopting sweeping simplifications)
- fail-safe defaults (access decisions shall deny by default, and projects' installation shall be secure by default)
- complete mediation (every access that might be limited must be checked for authority and be non-bypassable)
- open design (security mechanisms should not depend on attacker ignorance of its design, but instead on more easily protected and changed information like keys and passwords)
- separation of privilege (ideally, access to important objects should depend on more than one condition, so that defeating one protection system won't enable complete access. For example, multi-factor authentication, such as requiring both a password and a hardware token, is stronger than single-factor authentication)
- least privilege (processes should operate with the least privilege necessary)
- least common mechanism (the design should minimize the mechanisms common to more than one user and depended on by all users, e.g., directories for temporary files)
- psychological acceptability (the human interface must be designed for ease of use - designing for "least astonishment" can help)
- limited attack surface (the set of the different points where an attacker can try to enter or extract data)
- input validation with allowlists (inputs should typically be checked to determine if they are valid before they are accepted; this validation should use allowlists (which only accept known-good values), not blocklists (which attempt to list known-bad values)).

Vulnerability Knowledge

A "primary developer" in a project is anyone who is familiar with the project's code base, is comfortable making changes to it, and is acknowledged as such by most other participants in the project. A primary developer would typically make a number of contributions over the past year (via code, documentation, or answering questions). Developers would typically be considered primary developers if they initiated the project (and have not left the project more than three years ago), have the option of receiving information on a private vulnerability reporting channel

(if there is one), can accept commits on behalf of the project, or perform final releases of the project software. If there is only one developer, that individual is the primary developer.

At least one of the primary developers **must** know of common kinds of errors that lead to vulnerabilities in this kind of software, as well as at least one method to counter or mitigate each of them.

Examples (depending on the type of software) include SQL injection, OS injection, classic buffer overflow, cross-site scripting, missing authentication, and missing authorization. See the CWE/SANS top 25 or OWASP Top 10 for commonly used lists.

A free class from the nonprofit OpenSecurityTraining2 for C/C++ developers is available at OST2_1001. It teaches how to prevent, detect, and mitigate linear stack/heap buffer overflows, non-linear out of bound writes, integer overflows, and other integer issues. The follow-on class, OST2_1002, covers uninitialized data access, race conditions, use-after-free, type confusion, and information disclosure vulnerabilities.

Zephyr Security Subcommittee

There shall be a "Zephyr Security Subcommittee", responsible for enforcing this guideline, monitoring reviews, and improving these guidelines.

This team will be established according to the Zephyr Project charter.

10.3.4 Code Review

The Zephyr project shall use a code review system that all changes are required to go through. Each change shall be reviewed by at least one primary developer that is not the author of the change. This developer shall determine if this change affects the security of the system (based on their general understanding of security), and if so, shall request the developer with vulnerability knowledge, or the secure designer to also review the code. Any of these individuals shall have the ability to block the change from being merged into the mainline code until the security issues have been addressed.

10.3.5 Issues and Bug Tracking

The Zephyr project shall have an issue tracking system (such as GitHub) that can be used to record and track defects that are found in the system.

Because security issues are often sensitive, this issue tracking system shall have a field to indicate a security issue. Setting this field shall result in the issue only being visible to the Zephyr Security Subcommittee. In addition, there shall be a field to allow the Zephyr Security Subcommittee to add additional users that will have visibility to a given issue.

This embargo, or limited visibility, shall only be for a fixed duration, with a default being a project-decided value. However, because security considerations are often external to the Zephyr project itself, it may be necessary to increase this embargo time. The time necessary shall be clearly annotated in the issue itself.

The list of issues shall be reviewed at least once a month by the Zephyr Security Subcommittee. This review should focus on tracking the fixes, determining if any external parties need to be notified or involved, and determining when to lift the embargo on the issue. The embargo should **not** be lifted via an automated means, but the review team should avoid unnecessary delay in lifting issues that have been resolved.

10.3.6 Modifications to This Document

Changes to this document shall be reviewed by the Zephyr Security Subcommittee, and approved by consensus.

10.4 Sensor Device Threat Model

This document describes a threat model for an IoT sensor device. Spelling out a threat model helps direct development effort, and can be used to help prioritize these efforts as well.

This device contains a sensor of some type (for example temperature, or a pressure in a pipe), which sends this data to an SoC running a microcontroller. This microcontroller connects to a cloud service, and relays this sensor data to this service. The cloud service is also able to send configuration data to the device, as well as software update images. A general diagram can be seen in Figure 1:

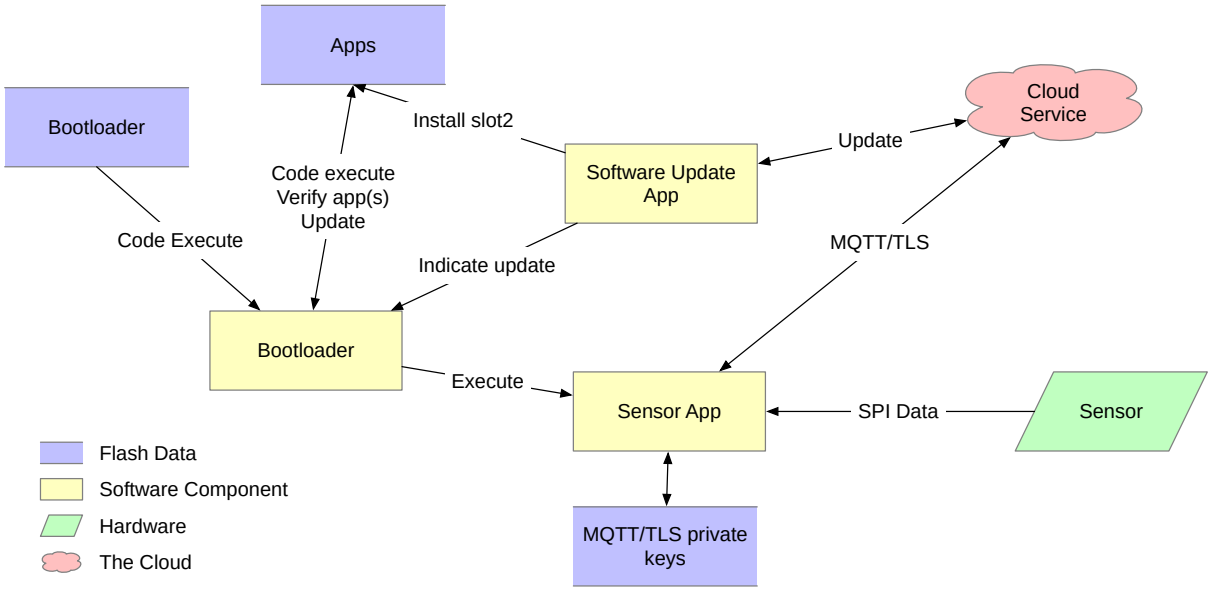


Fig. 3: Figure 1. Sensor General Diagram

In this sensor device, the sensor connects with the SoC via an SPI bus, and the SoC has a network interface that it uses to communicate with the cloud service. The particulars of these interfaces can impact the threat model in unexpected ways, and variants on this will need to be considered (for example, using a separate network interface SoC connected via some type of bus).

This model also focuses on communicating via the MQTT-over-TLS protocol, as this seems to be in wide use[1].

10.4.1 Assets

One aspect of the threat model to consider are assets involved in the operation of the device. The following list enumerates the assets included in this model:

1. **The bootloader**. This is a small code/data image contained in on-device flash that is the first code to run. In order to establish a root of trust, this image must be immutable. This model assumes that the SoC provides a mechanism to protect a region of the flash from future writes, and that this will be done after this image is programmed into the device, early in production [th-imboot].
2. **The application firmware image**. This asset consists of the remainder of the firmware run by the microcontroller. The distinction is made because this part of the image will need to be updated periodically as security vulnerabilities are discovered. Requirements for updates to this image are:
    a. The image shall only be replaced with an authorized image [th-authrepl].

[1] See https://www.slideshare.net/kartben/iot-developer-survey-2018. As of this writing, the three major cloud IoT service providers, AWS IoT, Google Cloud IoT, and Microsoft Azure IoT all provide MQTT over TLS. Some feedback has suggested that some find difficulty with UDP protocols and routing issues on various networks.

   b. When an authorized replacement image is available, the update shall be done in a timely manner [th-timely-update].

   c. The image update shall be seen as atomic, meaning that when the image is run, the flash shall contain either the update image in its entirety, or the old image in its entirety [th-atomic-update].

3. **Root certificate list**. In order to authenticate the cloud service (server), the IoT device must have a list of root certificates that are allowed to sign the certificate on the server. For cloud-provider based services, this list will generally be provided by the service provider. Because the root certificates can expire, and possibly be revoked, this list will need to be periodically updated [th-root-certs], [th-root-check].

4. **Client secrets**. To authenticate the client to the service, the client must possess some kind of secret. This is generally a private key, usually either an RSA key or an EC private key. When establishing communication with the server, the device will use this secret either as part of the TLS establishment, or to sign a message used in the communication.

   This secret is generally generated by the service provider, or by software running elsewhere, and must be securely installed on the device. Policy may dictate that this secret be replaced periodically, which will require a way to update the client secret. Typically, the service will allow two or three active keys to allow this update to proceed while the old key is used.

   These secrets must be protected from read, and the smallest amount of code necessary shall have access to them. [th-secret-storage]

5. **Current date/time**. TLS certificate verification requires knowledge of the current date and time in order to determine if the current time falls within the certificate's current validity time. Also, token based client authentication will generally require the client to sign a message containing a time window that the token is valid. Certificate validation requires the device's notion of date and time to be accurate within a day or so. Token generation generally requires the time to be accurate within 5-10 minutes.

   It may be possible to approximate secure time by querying an external time server. Secure NTP is possibly beyond the capabilities of an IoT device. The main risks of having incorrect time are denial of service (the device rejects valid certificates), and the generation of tokens with invalid times. It could be possible to trick the device into generating tokens that are valid in the future, but the attacker would also have to spoof the server's certificate to be able to intercept this. [th-time]

6. **Sensor data**. The data received from the sensor itself, and delivered to the service shall be delivered without modification or tampering.

7. **Device configuration**. Various configuration data, such as the hostname of the service to connect to, the address of a time server, frequency and parameters of when sensor data is sent to the service, and other need to be kept by the device. This configuration data will need to be updated periodically as the configuration changes. Updates should be allowed only from authorized parties. [th-conf]

8. **Logs**. In order to assist with analysis of security issues, the device shall log information about security-pertinent events. IoT devices generally have limited storage, and as such, these logs need to be carefully selected. It may also be possible to send these log events to the cloud service where they can be stored in a more resource-available environment. Types of events that should be logged include:

   a. **Firmware image updates**. The system should log the download of new images, and when an image is successfully updated.

   b. **Client secret changes**. Changes and new client secrets should be logged.

   c. **Changes to the device configuration**.

   [th-logs]

10.4.2 Communication

In addition to assets, the threat model also considers the locations where data or assets are communicated between entities of the system.

1. **Flash contents**. The flash device contains several regions. The contents of flash can be modified programmatically by the SoC's CPU.

   a. **The bootloader**. As described in the Assets section, the bootloader is a small section of the flash device containing the code initially run. This section shall be written early in the lifecycle of the device, and the flash device then configured to permanently disallow modification of this section. This configuration should also prevent modification via external interfaces, such as JTAG or SWD debuggers.

      The bootloader is responsible for verifying the signature of the application image as well as updating the application image from the update image when an update is needed.

      The bootloader shall verify the signature of the update image before installing it.

      The bootloader shall only accept an update image with a newer version number than the current image.

   b. **The application image**. The application image contains the code executed during normal operation of the device. Before running this image, the bootloader shall verify a digital signature of the image, to avoid running an image that has been tampered with. The flash/system shall be configured such that after the bootloader has completed, the CPU will be unable to write to the application image.

   c. **The update image**. This is an area of flash that holds a new version of the application image. This image will be downloaded and stored by the application during normal operation. When this has completed, the application can trigger a reboot, and the bootloader can install the new image.

   d. **Secret storage**. An area of the flash will be used to store client secrets. This area is written and read by a subset of the application image. The application shall be configured to protect this area from both reads and writes by code that does not need to have access to it, giving consideration to possible exploits found within a majority of the application code. Revealing the contents of the secrets would allow the attacker to spoof this device.

      Initial secrets shall be placed in the device during a provisioning activity, distinct from normal operation of the device. Later updates can be made under the direction of communication received over a secured channel to the service.

   e. **Configuration storage**. There shall be an area to store other configuration information. On resource-constrained devices, it is allowed for this to be stored in the same region as the secret storage, however, this adds additional code that has access to the secret storage area, and as such, more code that must be scrutinized.

   f. **Log storage**. The device may have an area of flash where log events can be written.

2. **Sensor/Actuator interface**. In this design, the sensor or actuator communicates with the SoC via a bus, such as SPI. The hardware design shall be made to make intercepting this bus difficult for an attack. Required techniques depend on the sensitivity and use of the sensor data, and can range from having the sensor mounted on the same PCB as the MCU to epoxy potting the entire device.

3. **Communication with cloud service**. Communication between the device, and the cloud service will be done over the general internet. As such, it shall be assumed that an attacker can arbitrarily intercept this channel and, for example, return spoofed DNS results or attempt man-in-the-middle attacks against communication with cloud services.

   The device shall use TLS for all communication with the cloud service [th-all-tls]. The TLS

stack shall be configured to use only cipher suites that are generally considered secure[2], including forward secrecy. The communication shall be secured by the following:

a. **Cipher suite selection**. The device shall only allow communication with generally agreed secure cipher suites [th-tls-ciphers].

b. **Server certificate verification**. The server presented by the server shall be verified [th-root-check].

   i. **Naming**. The certificate shall name the host and service the cloud service server is providing. **RFC 6125** describes best practices for this. It is permissible for the device to require the certificate to be more restrictive than as described in this RFC, provided the service can use a certificate that can comply.

   ii. **Path validation**. The device shall verify that the certificate chain has a valid signature path from a root certificate contained within the device, to the certificate presented by the service. **RFC 4158** describes this in general. The device is permitted to require a more restricted path, provided the server certificate used complies with this restriction.

   iii. **Validity period**. The validity period of all presented certificates shall be checked against the device's best notion of the current time.

c. **Client authentication**. The client shall authenticate itself to the service using a secret known only to that particular device. There are several options, and the technique used is generally mandated by the particular service provider being used [th-tls-client-auth].

   i. **TLS client certificates**. The TLS protocol allows the client to present a certificate, and assert its knowledge of the secret described by that certificate. Generally, these certificates will be stored within the service provider. These certificates can be self-signed, or signed by a CA. Since the service provider maintains a list of valid certificates (mapping them to a device identity), having these certificates signed by a CA does not add any additional security, but may be useful in the management of these certificates.

   ii. **Token-based authentication**. It is also possible for the client to authenticate itself using the *password* field of the MQTT CONNECT packet. However, the secret itself must not be transmitted in this packet. Instead, a token-based protocol, such as **RFC 7519**'s JSON Web Token (JWT) can be used. These tokens will generally have a small validity period (e.g. 1 hour), to prevent them from being reused if they are intercepted. The token shall not be sent until the device has verified the identity of the server.

d. **Random/Entropy source**. Cryptographic communication requires the generation of secure pseudorandom numbers. The device shall use a modern, accepted cryptographic random-bit generator to generate these random numbers. It shall use either a Non-Deterministic Random Bit Generator (True RBG) implemented in hardware within the SoC, or a Deterministic Random Bit Generator (Pseudo RBG) seeded by an entropy source within the SoC. Please see NIST SP 800-90A for information on approved RBGs and NIST SP 800-90B for information on testing a device's entropy source [th-entropy].

4. **Communication with the time service**. Ideally, the device shall contain hardware that maintains a secure time. However, most SoCs in use do not have support for this, and it will be necessary to consult an external time service. **RFC 4330** and referenced RFCs describe the Simple Network Time Protocol that can be used to query the current time from a network time server.

5. **Device lifecycle**. An IoT device will have a lifecycle from production to destruction and

[2] As new exploits are discovered, what is considered secure can change. Organizations such as https://www.ssllabs.com/ provide information on current ideas of how TLS must be configured to be secure.

disposal of the device. Aspects of this lifecycle that impact security include initial provisioning, normal operation, re-provisioning, and destruction.

a. **Initial provisioning**. During the initial provisioning stage, it is necessary to program the bootloader, an initial application image, a device secret, and initial configuration data [th-initial-provision]. In addition, the bootloader flash protection shall be installed. Of this information, only the device secret needs to differ per device. This secret shall be securely maintained, and destroyed in all locations outside of the device once it has been programmed [th-initial-secret].

b. **Normal operation**. Normal operation includes the behavior described by the rest of this document.

c. **Re-provisioning**. Sometimes it is necessary to re-provision a device, such as for a different application. One way to do this is to keep the same device secret, and replace the configuration data, as well as the cloud service data associated with the device. It is also possible to program a new device secret, but if this is done it shall be done securely, and the new secret destroyed externally once programmed into the device [th-reprovision].

d. **Destruction**. To prevent the device secret from being used to spoof the device, upon decommissioning, the secret for a particular device shall be rendered ineffective [th-destruction]. Possibilities include:

   i. Hardware destruction of the device.

   ii. Securely wiping the flash area containing the secret[3].

   iii. Removing the device identity and certificate from the service.

10.4.3 Other Considerations

In addition to the above, network connected devices generally will need a way to configure them to connect to the network environment they are placed in. There are numerous ways of doing this, and it is important for these configuration methods to not circumvent the security requirements described above.

10.4.4 Threats

10.4.5 Notes

10.5 Hardening Tool

Before launching a product, it's crucial to ensure that your software is as secure as possible. This process, known as "hardening", involves strengthening the security of a system to protect it from potential threats and vulnerabilities.

At a high-level, hardening a Zephyr application can be seen as a two-fold process:

1. Disabling features and compilation flags that might lead to security vulnerabilities (ex. making sure that no "experimental" features are being used, disabling features typically used for debugging purposes such as assertions, shell, etc.).
2. Enabling optional features that can lead to improve security (ex. stack sentinel, hardware stack protection, etc.). Some of these features might be hardware-dependent.

To simplify this process, Zephyr offers a **hardening tool** designed to analyze an application's configuration against a set of hardening preferences defined by the **Security Working Group**. The tool looks at the KConfig options in the build target and provides tailored suggestions and recommendations to adjust security-related options.

[3] Note that merely erasing this flash area is unlikely to be sufficient.

10.5.1 Usage

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t hardenconfig
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild hardenconfig
```

The output should be similar to the table below. For each configuration option set to a value that could lead to a security vulnerability, the table will propose a recommended value that should be used instead.

```
+--------------------------------------+-----------+---------------+----------------+
| Name                                 | Current   | Recommended   | Check result␣
↪  |
+======================================+===========+===============+================+
| CONFIG_BUILD_OUTPUT_STRIPPED         | n         | y             | FAIL        ␣
↪  |
+--------------------------------------+-----------+---------------+----------------+
| CONFIG_FAULT_DUMP                    | 2         | 0             | FAIL        ␣
↪  |
+--------------------------------------+-----------+---------------+----------------+
| CONFIG_MPU_STACK_GUARD               | n         | y             | FAIL        ␣
↪  |
+--------------------------------------+-----------+---------------+----------------+
| CONFIG_OVERRIDE_FRAME_POINTER_DEFAULT | n         | y             | FAIL        ␣

↪  |
+--------------------------------------+-----------+---------------+----------------+
```

10.6 Control Flow Integrity

Control Flow Integrity (CFI) is a security feature that ensures that the control flow of a program follows a predefined path, preventing attackers from diverting execution to malicious code. CFI is particularly useful in defending against control flow hijacking attacks, such as return-oriented programming (ROP) and jump-oriented programming (JOP).

CFI works by validating the control flow of a program at runtime, ensuring that function calls and returns are made to legitimate targets. This is typically achieved through instrumentation of the code, which adds checks to verify that the control flow adheres to the expected paths defined by the program's control flow graph.

10.6.1 Forward and return edges

In the context of CFI, control flow edges can be categorized into two types:

1. **Forward edges**: These represent the flow of control from one function to another, such as a function call. Forward edges are typically validated to ensure that the target of a call is a legitimate function within the program.
2. **Return edges**: These represent the return from a function back to the caller. Return edges are validated to ensure that the return address is legitimate and corresponds to a valid call site.

Forward edges can be supported by compiler instrumentation, which adds checks to verify that the target of a function call is valid. Return edges can be supported by maintaining a shadow stack or using other mechanisms to ensure that return addresses are legitimate.

Zephyr does support maintaining a shadow stack which can be enabled via `CONFIG_HW_SHADOW_STACK`. Then, the kernel will use macros like `K_THREAD_HW_SHADOW_STACK_DEFINE`, in tandem with other thread stack related macros, to provide the area for shadow stacks used by threads. Usually, applications only need to enable `CONFIG_HW_SHADOW_STACK` (and related ones, such as `CONFIG_HW_SHADOW_STACK_PERCENTAGE_SIZE` and `CONFIG_HW_SHADOW_STACK_MIN_SIZE`) to enable shadow stack support. The kernel will then automatically manage the shadow stack for each thread.

Implementation details

The `K_THREAD_HW_SHADOW_STACK*` family of macros does a minimal setup of the shadow stack parameters. Then, they invoke arch-specific `ARCH_THREAD_HW_SHADOW_STACK*` macros to perform the actual setup.

10.6.2 Hardware support

While CFI can be implemented in software, hardware support can significantly enhance its effectiveness and performance. Currently, Zephyr supports Intel Control-flow Enforcement Technology (CET), which provides hardware-based support for CFI.

Intel CET

Intel Control-flow Enforcement Technology (CET) is a set of hardware features that enhance the security of applications by providing support for CFI. CET includes two main components:

1. **Shadow Stack**: This feature maintains a separate stack for return addresses, ensuring that return addresses cannot be tampered with. When a function returns, the return address is popped from the shadow stack and compared to that of the regular stack, providing an additional layer of protection against control flow hijacking.
2. **Indirect Branch Tracking (IBT)**: This feature tracks indirect branches (such as function pointers) and ensures that they only target valid locations in the code. It prevents attackers from redirecting execution to arbitrary code through techniques like ROP.

These two features proved the return and forward edge validation, respectively. To enable shadow stack support in Zephyr, on supported hardware, you can use the `CONFIG_HW_SHADOW_STACK` Kconfig option. To enable IBT, use `CONFIG_X86_CET_IBT`.

As IBT is effectively implemented by the compiler, toolchain support is necessary. Currently, Zephyr SDK x86 toolchain can be used to build applications with IBT support. However, their precompiled artifacts, such as `libc` and `libgcc`, do not have IBT enabled. Therefore, for `libc`, one needs to build it as a module, for example, by using `CONFIG_PICOLIBC_USE_MODULE`. For other bits, one would need a custom toolchain.

Intel CET Limitations Currently, the shadow stacks that are created behind the scenes live on the global namespace. Thus, one *cannot* reuse thread stack names, even across different compilation units.

ARM Pointer Authentication and Branch Target Identification

ARM platforms provide hardware-based CFI features through Pointer Authentication (PAC) and Branch Target Identification (BTI), available on both Cortex-M and ARM64 (Cortex-A/R) architectures:

1. **Pointer Authentication (PAC)**: Signs return addresses and other pointers using cryptographic signatures. When a return address is pushed to the stack, it is signed with a key unique to each thread. Before returning, the signature is verified, ensuring the return address has not been tampered with. This protects against Return-Oriented Programming (ROP) attacks. Available in ARMv8.1-M Mainline (Cortex-M) and ARMv8.3-A and later (ARM64).
2. **Branch Target Identification (BTI)**: Marks legitimate indirect branch targets with special BTI landing pad instructions. The processor verifies that indirect branches land only on valid targets marked with BTI instructions. This protects against Jump-Oriented Programming (JOP) attacks. Available in ARMv8.1-M Mainline (Cortex-M) and ARMv8.5-A and later (ARM64).

These features provide return and forward edge validation, respectively. PAC and BTI can be enabled via the `ARM_PACBTI` menu. Available options include `CONFIG_ARM_PACBTI_STANDARD` (both PAC and BTI), `CONFIG_ARM_PACBTI_PACRET` (PAC only), `CONFIG_ARM_PACBTI_BTI` (BTI only), and other variants. Both features can be used independently or combined for comprehensive control flow integrity.

Like x86 CET IBT, these features require compiler support and proper C library instrumentation. PAC requires that functions use the appropriate signing and verification instructions, while BTI requires that all legitimate branch targets include BTI landing pad instructions. Precompiled C libraries from toolchains typically lack this instrumentation.

For BTI support, the C library must be compiled with `-mbranch-protection` flags to include BTI landing pads in all functions. Therefore, when using any option that enables BTI, only `CONFIG_MINIMAL_LIBC` or picolibc built as a module via `CONFIG_PICOLIBC_USE_MODULE` can be used. Newlib from toolchains is not supported with BTI.

PAC has less strict requirements as it primarily affects function prologues and epilogues, but for optimal security, building the C library with PAC support is recommended.

10.7 Vulnerabilities

This page collects all of the vulnerabilities that are discovered and fixed in each release. It will also often have more details than is available in the releases. Some vulnerabilities are deemed to be sensitive, and will not be publicly discussed until there is sufficient time to fix them. Because the release notes are locked to a version, the information here can be updated after the embargo is lifted.

10.7.1 CVE-2017

CVE 2017-14199

Buffer overflow in `getaddrinfo()`.

- Zephyr project bug tracker ZEPSEC-12
- PR6158 fix for 1.11.0

CVE 2017-14201

The shell DNS command can cause unpredictable results due to misuse of stack variables.

Use After Free vulnerability in the Zephyr shell allows a serial or telnet connected user to cause denial of service, and possibly remote code execution.

This has been fixed in release v1.14.0.

- Zephyr project bug tracker ZEPSEC-17
- PR13260 fix for v1.14.0

CVE 2017-14202

The shell implementation does not protect against buffer overruns resulting in unpredictable behavior.

Improper Restriction of Operations within the Bounds of a Memory Buffer vulnerability in the shell component of Zephyr allows a serial or telnet connected user to cause a crash, possibly with arbitrary code execution.

This has been fixed in release v1.14.0.

- Zephyr project bug tracker ZEPSEC-18
- PR13048 fix for v1.14.0

10.7.2 CVE-2019

CVE 2019-9506

The Bluetooth BR/EDR specification up to and including version 5.1 permits sufficiently low encryption key length and does not prevent an attacker from influencing the key length negotiation. This allows practical brute-force attacks (aka “KNOB”) that can decrypt traffic and inject arbitrary ciphertext without the victim noticing.

- Zephyr project bug tracker ZEPSEC-20
- PR18702 fix for v1.14.0
- PR18659 fix for v2.0.0

10.7.3 CVE-2020

CVE 2020-10019

Buffer Overflow vulnerability in USB DFU of zephyr allows a USB connected host to cause possible remote code execution.

This has been fixed in releases v1.14.2, v2.2.0, and v2.1.1.

- Zephyr project bug tracker ZEPSEC-25
- PR23460 fix for 1.14.x
- PR23457 fix for 2.1.x
- PR23190 fix in 2.2.0

CVE 2020-10021

Out-of-bounds write in USB Mass Storage with unaligned sizes

Out-of-bounds Write in the USB Mass Storage memoryWrite handler with unaligned Sizes.

See NCC-ZEP-024, NCC-ZEP-025, NCC-ZEP-026

This has been fixed in releases v1.14.2, and v2.2.0.

- Zephyr project bug tracker ZEPSEC-26
- PR23455 fix for v1.14.2
- PR23456 fix for the v2.1 branch
- PR23240 fix for v2.2.0

CVE 2020-10022

UpdateHub Module Copies a Variable-Size Hash String Into a Fixed-Size Array

A malformed JSON payload that is received from an UpdateHub server may trigger memory corruption in the Zephyr OS. This could result in a denial of service in the best case, or code execution in the worst case.

See NCC-ZEP-016

This has been fixed in the below pull requests for main, branch from v2.1.0, and branch from v2.2.0.

- Zephyr project bug tracker ZEPSEC-28
- PR24154 fix for main
- PR24065 fix for branch from v2.1.0
- PR24066 fix for branch from v2.2.0

CVE 2020-10023

Shell Subsystem Contains a Buffer Overflow Vulnerability In shell_spaces_trim

The shell subsystem contains a buffer overflow, whereby an adversary with physical access to the device is able to cause a memory corruption, resulting in denial of service or possibly code execution within the Zephyr kernel.

See NCC-ZEP-019

This has been fixed in releases v1.14.2, v2.2.0, and in a branch from v2.1.0,

- Zephyr project bug tracker ZEPSEC-29
- PR23646 fix for v1.14.2
- PR23649 fix for branch from v2.1.0
- PR23304 fix for v2.2.0

CVE 2020-10024

ARM Platform Uses Signed Integer Comparison When Validating Syscall Numbers

The arm platform-specific code uses a signed integer comparison when validating system call numbers. An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- Zephyr project bug tracker ZEPSEC-30
- PR23535 fix for v1.14.2
- PR23498 fix for branch from v2.1.0
- PR23323 fix for v2.2.0

CVE 2020-10027

ARC Platform Uses Signed Integer Comparison When Validating Syscall Numbers

An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- Zephyr project bug tracker ZEPSEC-35
- PR23500 fix for v1.14.2
- PR23499 fix for branch from v2.1.0
- PR23328 fix for v2.2.0

CVE 2020-10028

Multiple Syscalls In GPIO Subsystem Performs No Argument Validation

Multiple syscalls with insufficient argument validation

See NCC-ZEP-006

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- Zephyr project bug tracker ZEPSEC-32
- PR23733 fix for v1.14.2
- PR23737 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (gpio patch)

CVE 2020-10058

Multiple Syscalls In kscan Subsystem Performs No Argument Validation

Multiple syscalls in the Kscan subsystem perform insufficient argument validation, allowing code executing in userspace to potentially gain elevated privileges.

See NCC-ZEP-006

This has been fixed in a branch from v2.1.0, and release v2.2.0.

- Zephyr project bug tracker ZEPSEC-34
- PR23748 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (kscan patch)

CVE 2020-10059

UpdateHub Module Explicitly Disables TLS Verification

The UpdateHub module disables DTLS peer checking, which allows for a man in the middle attack. This is mitigated by firmware images requiring valid signatures. However, there is no benefit to using DTLS without the peer checking.

See NCC-ZEP-018

This has been fixed in a PR against Zephyr main.

- Zephyr project bug tracker ZEPSEC-36
- PR24954 fix on main (to be fixed in v2.3.0)
- PR24954 fix v2.1.0

- PR24954 fix v2.2.0

CVE 2020-10060

UpdateHub Might Dereference An Uninitialized Pointer

In updatehub_probe, right after JSON parsing is complete, objects[1] is accessed from the output structure in two different places. If the JSON contained less than two elements, this access would reference uninitialized stack memory. This could result in a crash, denial of service, or possibly an information leak.

Recommend disabling updatehub until such a time as a fix can be made available.

See NCC-ZEP-030

This has been fixed in a PR against Zephyr main.

- Zephyr project bug tracker ZEPSEC-37
- PR27865 fix on main (to be fixed in v2.4.0)
- PR27865 fix for v2.3.0
- PR27865 fix for v2.2.0
- PR27865 fix for v2.1.0

CVE 2020-10061

Error handling invalid packet sequence

Improper handling of the full-buffer case in the Zephyr Bluetooth implementation can result in memory corruption.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-75
- PR23516 fix for v2.3 (split driver)
- PR23517 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23547 fix for branch from v2.2.0

CVE 2020-10062

Packet length decoding error in MQTT

CVE: An off-by-one error in the Zephyr project MQTT packet length decoder can result in memory corruption and possible remote code execution. NCC-ZEP-031

The MQTT packet header length can be 1 to 4 bytes. An off-by-one error in the code can result in this being interpreted as 5 bytes, which can cause an integer overflow, resulting in memory corruption.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-84
- commit 11b7a37d for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10063

Remote Denial of Service in CoAP Option Parsing Due To Integer Overflow

A remote adversary with the ability to send arbitrary CoAP packets to be parsed by Zephyr is able to cause a denial of service.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-55
- PR24435 fix in main for v2.3
- PR24531 fix for branch from v2.2
- PR24535 fix for branch from v2.1
- PR24530 fix for branch from v1.14
- NCC-ZEP report (NCC-ZEP-032)

CVE 2020-10064

Improper Input Frame Validation in ieee802154 Processing

- Zephyr project bug tracker ZEPSEC-65
- PR24971 fix for v2.4
- PR33451 fix for v1.4

CVE 2020-10065

OOB Write after not validating user-supplied length (<= 0xffff) and copying to fixed-size buffer (default: 77 bytes) for HCI_ACL packets in bluetooth HCI over SPI driver.

- Zephyr project bug tracker ZEPSEC-66
- This issue has not been fixed.

CVE 2020-10066

Incorrect Error Handling in Bluetooth HCI core

In hci_cmd_done, the buf argument being passed as null causes nullpointer dereference.

- Zephyr project bug tracker ZEPSEC-67
- PR24902 fix for v2.4
- PR25089 fix for v1.4

CVE 2020-10067

Integer Overflow In is_in_region Allows User Thread To Access Kernel Memory

A malicious userspace application can cause a integer overflow and bypass security checks performed by system call handlers. The impact would depend on the underlying system call and can range from denial of service to information leak to memory corruption resulting in code execution within the kernel.

See NCC-ZEP-005

This has been fixed in releases v1.14.2, and v2.2.0.

- Zephyr project bug tracker ZEPSEC-27
- PR23653 fix for v1.14.2

- PR23654 fix for the v2.1 branch
- PR23239 fix for v2.2.0

CVE 2020-10068

Zephyr Bluetooth DLE duplicate requests vulnerability

In the Zephyr project Bluetooth subsystem, certain duplicate and back-to-back packets can cause incorrect behavior, resulting in a denial of service.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-78
- PR23707 fix for v2.3 (split driver)
- PR23708 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23964 fix for v2.2.0

CVE 2020-10069

Zephyr Bluetooth unchecked packet data results in denial of service

An unchecked parameter in bluetooth data can result in an assertion failure, or division by zero, resulting in a denial of service attack.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-81
- PR23705 fix for v2.3 (split driver)
- PR23706 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23963 fix for branch from v2.2.0

CVE 2020-10070

MQTT buffer overflow on receive buffer

In the Zephyr Project MQTT code, improper bounds checking can result in memory corruption and possibly remote code execution. NCC-ZEP-031

When calculating the packet length, arithmetic overflow can result in accepting a receive buffer larger than the available buffer space, resulting in user data being written beyond this buffer.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-85
- commit 0b39cbf3 for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10071

Insufficient publish message length validation in MQTT

The Zephyr MQTT parsing code performs insufficient checking of the length field on publish messages, allowing a buffer overflow and potentially remote code execution. NCC-ZEP-031

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-86

- commit 989c4713 fix for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10072

All threads can access all socket file descriptors

There is no management of permissions to network socket API file descriptors. Any thread running on the system may read/write a socket file descriptor knowing only the numerical value of the file descriptor.

- Zephyr project bug tracker ZEPSEC-87
- PR25804 fix for v2.4
- PR27176 fix for v1.4

CVE 2020-10136

IP-in-IP protocol routes arbitrary traffic by default zephyrproject

- Zephyr project bug tracker ZEPSEC-64

CVE 2020-13598

FS: Buffer Overflow when enabling Long File Names in FAT_FS and calling fs_stat

Performing fs_stat on a file with a filename longer than 12 characters long will cause a buffer overflow.

- Zephyr project bug tracker ZEPSEC-88
- PR25852 fix for v2.4
- PR28782 fix for v2.3
- PR33577 fix for v1.4

CVE 2020-13599

Security problem with settings and littlefs

When settings is used in combination with littlefs all security related information can be extracted from the device using MCUmgr and this could be used e.g in bt-mesh to get the device key, network key, app keys from the device.

- Zephyr project bug tracker ZEPSEC-57
- PR26083 fix for v2.4

CVE 2020-13600

Malformed SPI in response for eswifi can corrupt kernel memory

- Zephyr project bug tracker ZEPSEC-91
- PR26712 fix for v2.4

CVE 2020-13601

Possible read out of bounds in dns read

- Zephyr project bug tracker ZEPSEC-92
- PR27774 fix for v2.4

- PR30503 fix for v1.4

CVE 2020-13602

Remote Denial of Service in LwM2M do_write_op_tlv

In the Zephyr LwM2M implementation, malformed input can result in an infinite loop, resulting in a denial of service attack.

- Zephyr project bug tracker ZEPSEC-56
- PR26571 fix for v2.4
- PR33578 fix for v1.4

CVE 2020-13603

Possible overflow in mempool

- Zephyr offers pre-built 'malloc' wrapper function instead.
- The 'malloc' function is wrapper for the 'sys_mem_pool_alloc' function
- sys_mem_pool_alloc allocates 'size + WB_UP(sizeof(struct sys_mem_pool_block))' in an unsafe manner.
- Asking for very large size values leads to internal integer wrap-around.
- Integer wrap-around leads to successful allocation of very small memory.
- For example: calling malloc(0xffffffff) leads to successful allocation of 7 bytes.
- That leads to heap overflow.
- Zephyr project bug tracker ZEPSEC-111
- PR31796 fix for v2.4
- PR32808 fix for v1.4

10.7.4 CVE-2021

CVE 2021-3319

DOS: Incorrect 802154 Frame Validation for Omitted Source / Dest Addresses

Improper processing of omitted source and destination addresses in ieee802154 frame validation (ieee802154_validate_frame)

This has been fixed in main for v2.5.0

- Zephyr project bug tracker GHSA-94jg-2p6q-5364
- PR31908 fix for main

CVE 2021-3320

Mismatch between validation and handling of 802154 ACK frames, where ACK frames are considered during validation, but not during actual processing, leading to a type confusion.

- PR31908 fix for main

CVE 2021-3321

Incomplete check of minimum IEEE 802154 fragment size leading to an integer underflow.

- Zephyr project bug tracker ZEPSEC-114

CVE 2021-3510

Zephyr JSON decoder incorrectly decodes array of array

When using JSON_OBJ_DESCR_ARRAY_ARRAY, the subarray is has the token type JSON_TOK_LIST_START, but then assigns to the object part of the union. arr_parse then takes the offset of the array-object (which has nothing todo with the list) treats it as relative to the parent object, and stores the length of the subarray in there.

This has been fixed in main for v2.7.0

- Zephyr project bug tracker GHSA-289f-7mw3-2qf4
- PR 36340 fix for main
- PR 37816 fix for 2.6

CVE 2021-3581

HCI data not properly checked leads to memory overflow in the Bluetooth stack

In the process of setting SCAN_RSP through the HCI command, the Zephyr Bluetooth protocol stack did not effectively check the length of the incoming HCI data. Causes memory overflow, and then the data in the memory is overwritten, and may even cause arbitrary code execution.

This has been fixed in main for v2.6.0

CVE 2025-2962

Infinite loop in dns_copy_qname

A denial-of-service issue in the dns implementation could cause an infinite loop.

- Zephyr project bug tracker GHSA-2qp5-c2vq-g2ww

This has been fixed in main for v4.2.0

- PR 87753 fix for main
- PR 87925 fix for 4.1
- PR 87949 fix for 3.7

CVE 2025-7403

Bluetooth: bt_conn_tx_processor unsafe handling

Unsafe handling in bt_conn_tx_processor causes a use-after-free, resulting in a write-before-zero. The written 4 bytes are attacker-controlled, enabling precise memory corruption.

- Zephyr project bug tracker GHSA-9r46-cqqw-6j2j

This has been fixed in main for v4.2.0

- PR 90975 fix for main

CVE 2025-10456

Bluetooth: Semi-Arbitrary ability to make the BLE Target send disconnection requests

A vulnerability was identified in the handling of Bluetooth Low Energy (BLE) fixed channels (such as SMP or ATT). Specifically, an attacker could exploit a flaw that causes the BLE target (i.e., the device under attack) to attempt to disconnect a fixed channel, which is not allowed per the Bluetooth specification. This leads to undefined behavior, including potential assertion failures, crashes, or memory corruption.

- Zephyr project bug tracker GHSA-hcc8-3qr7-c9m8

This has been fixed in main for v4.2.0

- PR 93576 fix for main

CVE 2025-10457

Bluetooth: Out-Of-Context le_conn_rsp handling

The function responsible for handling BLE connection responses does not verify whether a response is expected—that is, whether the device has initiated a connection request. Instead, it relies solely on identifier matching.

- Zephyr project bug tracker GHSA-xqj6-vh76-2vv8

This has been fixed in main for v4.2.0

- PR 94080 fix for main

CVE 2025-10458

Bluetooth: le_conn_rsp does not sanitize CID, MTU, MPS values

Parameters are not validated or sanitized, and are later used in various internal operations.

- Zephyr project bug tracker GHSA-vmww-237q-2fwp

This has been fixed in main for v4.2.0

- PR 93174 fix for main

CVE 2025-9408

Userspace privilege escalation vulnerability on Cortex M

System call entry on Cortex M (and possibly R and A, but I think not) has a race which allows very practical privilege escalation for malicious userspace processes.

CVE 2025-9557

Bluetooth: Mesh: Out-of-Bound Write in gen_prov_cont

An out-of-bound write can lead to an arbitrary code execution. Even on devices with some form of memory protection, this can still lead to a crash and a resultant denial of service.

- Zephyr project bug tracker GHSA-r3j3-c5v7-2ppf

This has been fixed in main for v4.3.0

- PR 95061 fix for main
- PR 97518 fix for 4.2
- PR 97517 fix for 4.1

CVE 2025-9558

Bluetooth: Mesh: Out-of-Bound Write in gen_prov_start

There is a potential OOB Write vulnerability in the gen_prov_start function in pb_adv.c. The full length of the received data is copied into the link.rx.buf receiver buffer without any validation on the data size.

- Zephyr project bug tracker GHSA-8wvr-688x-68vr

This has been fixed in main for v4.3.0

CVE 2025-12035

Bluetooth: Integer Overflow in Bluetooth Classic (BR/EDR) L2CAP

An integer overflow condition exists in Bluetooth Host stack, within the bt_br_acl_recv routine a critical path for processing inbound BR/EDR L2CAP traffic.

- Zephyr project bug tracker GHSA-p793-3456-h7w3

This has been fixed in main for v4.3.0

- PR 97370 fix for main

CVE 2025-12890

Bluetooth: peripheral: Invalid handling of malformed connection request

Improper handling of malformed Connection Request with the interval set to be 1 (which supposed to be illegal) and the chM 0x7CFFFFFFFF triggers a crash. The peripheral will not be connectable after it.

- Zephyr project bug tracker GHSA-8hrf-pfww-83v9

This has been fixed in main for v4.2.0

- PR 89955 fix for main

CVE 2025-12899

net: icmp: Out of bound memory read

A flaw in Zephyr's network stack allows an IPv4 packet containing ICMP type 128 to be misclassified as an ICMPv6 Echo Request. This results in an out-of-bounds memory read and creates a potential information-leak vulnerability in the networking subsystem.

- Zephyr project bug tracker GHSA-c2vg-hj83-c2vg

This has been fixed in main for v4.3.0

- PR 98780 fix for main
- PR 98983 fix for 4.2

CVE 2026-1678

dns: memory-safety issue in the DNS name parser

`dns_unpack_name()` caches the buffer tailroom once and reuses it while appending DNS labels. As the buffer grows, the cached size becomes incorrect, and the final null terminator can be written past the buffer. With assertions disabled (default), a malicious DNS response can trigger an out-of-bounds write when `CONFIG_DNS_RESOLVER` is enabled.

- Zephyr project bug tracker GHSA-536f-h63g-hj42

This has been fixed in main for v4.4.0

- PR 99683 fix for main
- PR 99830 fix for 4.3
- PR 99829 fix for 4.2
- PR 99828 fix for 3.7

10.8 Security standards and Zephyr

Historically, organizations managed cybersecurity independently, defining their own assessment and response protocols. Today, governments are increasingly regulating this area through new mandates and security standards. These standards define specific guidelines and compliance requirements for connected products.

This section evaluates the implications of these security standards for the Zephyr project itself, as well as downstream product developers. The goal is to provide developers with the information needed to build certifiable, compliant products using Zephyr.

10.8.1 EU Cyber Resilience Act (CRA)

Warning

This document is for informational purposes only and does not constitute legal advice. Consult with your legal counsel for compliance guidance specific to your situation.

Overview

The Cyber Resilience Act ([**?**]) is an EU regulation that establishes cybersecurity requirements for products with digital elements (PDEs) placed on the EU market. It entered into force on December 10, 2024.

Key Dates

- **June 11, 2026**: Assessment bodies operational
- **September 11, 2026**: Manufacturers must report vulnerabilities and incidents
- **December 11, 2027**: Full regulation applies

This page explains how the CRA relates both to manufacturers using Zephyr in commercial products, and to the Zephyr Project itself in its role as an open-source software steward.

For manufacturers, the CRA imposes essential cybersecurity requirements (Annex I Part I) along with vulnerability handling and reporting obligations (Annex I Part II). For the Zephyr Project as an open-source software steward, the CRA introduces a tailored set of obligations, including maintaining a cybersecurity policy, reporting actively exploited vulnerabilities and severe incidents, and cooperating with market surveillance authorities.

For Manufacturers Using Zephyr

Does the CRA apply to my product? The CRA applies if you place a product with digital elements (PDE) on the EU market for commercial purposes. This includes hardware devices with embedded software, and standalone software products.

Which category does my product belong to? The CRA classifies products into categories based on risk: **Important Products** (Annex III) and **Critical Products** (Annex IV). Products not listed in either category are considered **Default** products and have lower requirements.

For example, default products can typically rely on self-assessment (see *Which compliance path must I choose?*) with fewer documentation and assurance requirements.

Category	Short description	Example Zephyr Use Cases
Default	Products with digital elements that are not listed as "important" or "critical".	• Wi-Fi smart bulb or switch (e.g., running Matter over Thread/Wi-Fi). • Wearable activity tracker or smartwatch for personal wellness. • Bluetooth LE audio accessory or wireless sensor tag.
Important (Class I)	Higher-risk products, often consumer-facing, performing security- or access-relevant functions.	• Smart door lock or access control reader for residential use. • Smart home hub or router managing network traffic. • Connected alarm system or security sensor.
Important (Class II)	Higher-risk products used in enterprise/industrial/infra contexts or with privileged network roles.	• Industrial Programmable Logic Controller (PLC) or robot controller. • Micro-controllers with Secure Enclave/TEEs used for device identity. • Industrial IoT gateway performing edge processing.
Critical	Products whose compromise could severely impact critical infrastructure or essential services.	• Smart electricity meter or water meter with remote shut-off. • Hardware Security Module (HSM) or smartcard firmware. • Safety-critical sensors used in energy or transport grids.

Core Functionality vs. Integration

Classification is determined by the **core functionality** of the final product, not by the individual components it integrates (Article 7).

- Integrating an important or critical component (e.g., a secure element, embedded browser) into another product does **not** automatically render that product important or critical.
- A product that *can* perform the functions of an important/critical category but whose core functionality is different is **not** considered to have that core functionality.

Examples:

- If you build a network firewall using Zephyr, the core function is security, making the product an Important Product (Class II).
- If you build a coffee machine using Zephyr, and you utilize Zephyr's networking stack features to protect the device, the core function remains making coffee. This is a "default" product.

In a nutshell, using security-critical Zephyr features (like cryptography or secure boot) in a device does **not** elevate that device to a higher risk class.

For detailed classification, see Annex III and Annex IV. The full list of product categories with technical descriptions is provided in Implementing Regulation (EU) 2025/2392.

Which compliance path must I choose? The CRA defines different conformity assessment procedures based on your product category. You must choose the path that corresponds to your classification and reliance on harmonized standards.

Table 1: CRA Product Categories & Assessment Routes

Category	Conformity Assessment Procedure	Third-Party Audit?
Default	Module A (Internal Control). Self-assessment by the manufacturer.	No
Important Class I	Module A **ONLY IF** harmonized standards are fully applied. Otherwise: Module B + Module C, or Module H.	Yes, if standards not fully used
Important Class II	Module B + Module C, or Module H. (Self-assessment is **NOT** allowed).	Yes (Mandatory)
Critical	**European Cybersecurity Certification** (e.g., EUCC) or Module B + Module C + Module H (pending delegate acts).	Yes (Mandatory)

The "Modules" refer to specific assessment procedures defined in Decision No 768/2008/EC ("New Legislative Framework") and adapted by the CRA in Annex VIII:

- Module A (Internal production control): You create the technical documentation, perform the risk assessment, and declare conformity yourself. No external auditor is required.
- Module B (EC-type examination) + Module C (Conformity to type): A Notified Body[1] examines the technical design (Module B) and issues a certificate. You then ensure production conforms to that type (Module C).
- Module H (Full Quality Assurance): A Notified Body[1] audits your Quality Management System (QMS) governing design, production, and testing.

What are my main obligations as a manufacturer? The CRA defines manufacturer obligations primarily in Article 13 (product requirements and due diligence) and Article 14 (vulnerability handling and reporting). Regardless of a product's classification, the following core obligations apply to all manufacturers of products with digital elements.

Risk assessment
: Assess and document cybersecurity risks throughout the product lifecycle.

Due diligence
: Exercise due diligence when integrating third-party components (including open-source software like Zephyr).

Vulnerability handling
: Handle vulnerabilities for at least 5 years (support period), including receiving reports and applying updates.

Incident reporting
: Report actively exploited vulnerabilities affecting Zephyr, as well as severe incidents affecting the project's infrastructure.

Technical documentation
: Create documentation per Article 31 and Annex VII.

Conformity assessment
: Assess conformity per Article 32 and Annex VIII.

CE marking
: Affix CE mark and draw up EU declaration of conformity.

What are the penalties for non-compliance?

- Up to EUR 15,000,000 or 2.5% of worldwide annual turnover (Article 13 & Article 14 violations).

[1] Notified Bodies will become operational by **June 11, 2026**.

- Up to EUR 10,000,000 or 2% of turnover (violations of other obligations).

What are the vulnerability reporting obligations? The CRA distinguishes between "ordinary" vulnerabilities (handled through your normal vulnerability management process) and cases that trigger strict notification timelines under Article 14: **actively exploited vulnerabilities** and **severe incidents**.

The tables below summarize the minimum reporting steps.

Table 2: Actively exploited vulnerabilities (Article 14 (1) and (2))

Step	Deadline	Content (minimum)
Early warning	Within 24 hours of becoming aware	Notify via the single reporting platform to your CSIRT coordinator and ENISA that an actively exploited vulnerability affects your product. Indicate, where known, in which Member States the product is available.
Vulnerability notification	Within 72 hours of becoming aware	Provide general information on the affected product, the general nature of the exploit and the vulnerability, corrective or mitigating measures already taken, and measures users can take. Indicate, where applicable, how sensitive you consider the notified information to be.
Final report	No later than 14 days after a corrective or mitigating measure is available	Describe the vulnerability, its severity and impact, any information on malicious actors exploiting it (if available), and details on the security update or other corrective measures made available.

Table 3: Severe incidents (Article 14 (3) through (6))

Step	Deadline	Content (minimum)
Early warning	Within 24 hours of becoming aware	Notify via the single reporting platform to your CSIRT coordinator and ENISA that a severe incident impacts the security of your product. Indicate whether it is suspected to be caused by unlawful or malicious acts and, where known, in which Member States the product is available.
Incident notification	Within 72 hours of becoming aware	Provide general information on the nature of the incident, an initial assessment (including impact/severity as known at the time), corrective or mitigating measures already taken, and measures users can take. Indicate, where applicable, how sensitive you consider the notified information to be.
Final report	Within 1 month after the incident notification	Provide a detailed description of the incident, including severity and impact, the type of threat or likely root cause, and applied and ongoing mitigation measures.

How can I obtain an SBOM (Software Bill of Materials)? Zephyr can automatically generate SBOMs for your application using the `west spdx` command.

See *Software bill of materials: west spdx* for details on how to configure and use this tool.

How should I handle Zephyr vulnerabilities? As a manufacturer integrating Zephyr into a product, you remain responsible for vulnerability management and, where applicable, CRA re-

porting. Zephyr provides vulnerability information, but you must assess and act on it for your own product.

A practical workflow is:

1. **Stay informed**. Register to the Zephyr Vulnerability Alert Registry to receive notifications when vulnerabilities are disclosed.
2. **Assess impact**. For each advisory, use your SBOM and configuration to determine whether the affected Zephyr component is present, reachable, and security-relevant in your product.
3. **Plan remediation**. Decide on the appropriate response (e.g., apply a patch, adjust configuration, ...).
4. **Deploy fixes**. Integrate, test, and roll out the chosen fix, and update your SBOM and product documentation as needed.
5. **Meet reporting obligations**. If the vulnerability affects your product and is actively exploited, or leads to a severe incident, report it in line with the Article 14 timelines and as per the previous section, *What are the vulnerability reporting obligations?*.

What timelines does Zephyr follow for vulnerability handling? Zephyr operates its own PSIRT process with target timelines for triage, notification, and disclosure. These are *project* timelines, not legal deadlines for manufacturers.

Your CRA reporting obligations as per Article 14 are triggered by when *you* become aware that your product is affected by an actively exploited vulnerability or a severe incident. This can be **earlier than** some of the Zephyr milestones below, meaning you might have to send an early warning or incident report even before a Zephyr fix is available or before public disclosure.

Zephyr uses private GitHub security advisories and an embargo period (at most 90 days) to coordinate fixes and disclosure. While the full process is described in *Security Vulnerability Reporting*, the key milestones are:

- **Within 7 days**: PSIRT feedback to initial reporter.
- **Within 30 days**: Manufacturers notified via alert registry and fix made available from the project.
- **Up to 90 days total**: Security-sensitive vulnerabilities are made public after embargo period.

Do I need to report vulnerabilities I find in Zephyr? **Yes**, under Article 13(6), if you discover a vulnerability in a component (including Zephyr) integrated into your product, you **must** report it. What's more, if you develop a fix for that vulnerability, you must also share the relevant code or documentation. See *Security Vulnerability Reporting*.

Additionally, consider voluntary reporting to CSIRT or ENISA per Article 15.

For Zephyr as an Open Source Steward

What is Zephyr's role under the CRA? Zephyr is an **"open-source software steward"** under Article 3 (14): a legal person that systematically provides sustained support for developing PDEs intended for commercial activities.

Zephyr's obligations under Article 24:

Cybersecurity policy
: Document security policies and vulnerability handling.

Cooperation
: Work with market surveillance authorities to mitigate risks.

Incident reporting
: Report actively exploited vulnerabilities for the project and severe incidents affecting Zephyr's infrastructure (to the extent Zephyr is involved).

Does the CRA apply to Zephyr contributors? **No.** The CRA does not apply to individual contributors to Zephyr (Recital 18).

Contributors developing features or fixing bugs are not subject to CRA obligations.

How is Zephyr meeting its steward obligations?

Article 24(1): Security policy (Complete)

- Documented at *Zephyr Security Overview*
- Vulnerability reporting process: *Security Vulnerability Reporting*
- Secure coding guidelines: *Secure Coding*

Article 24(2): Cooperation with authorities (In Progress)

- Registered CVE Numbering Authority (CNA) since 2017
- Active Zephyr Project Security Incident Response Team (PSIRT)
- **In Progress**: Identifying CSIRT coordinator for EU

Article 14(1) & Article 14(3): Incident reporting (In Progress)

- **In Progress**: Determining if NVD processes work for CSIRT/ENISA reporting
- Plan to align with EU reporting requirements

Article 14(8): User notification (Complete)

- Vulnerability Alert Registry for manufacturers and integrators
- CVE publication and security advisories

Article 52(3): Corrective actions (Complete)

- Established processes in place with CVE authorities
- Timely response through PSIRT

10.8.2 ETSI 303-645

ETSI EN 303 645, also known as "Cyber Security for Consumer Internet of Things: Baseline Requirements," is a standard developed by the European Telecommunications Standards Institute (ETSI).

The standard includes provisions for secure software updates, data protection, secure communication, and the minimization of exposed attack surfaces, among other things. It is part of a broader effort to address the challenges and risks associated with IoT devices.

Full version of the standard can be found here.

Terminology

Table 4: ETSI 303645 terminology

administrator	user who has the highest-privilege level possible for a user of the device, which can mean they are able to change any configuration related to the intended functionality.
associated services	digital services that, together with the device, are part of the overall consumer IoT product and that are typically required to provide the product's intended functionality.
authentication mechanism	method used to prove the authenticity of an entity.
authentication value	individual value of an attribute used by an authentication mechanism.
best practice cryptography	cryptography that is suitable for the corresponding use case and has no indications of a feasible attack with current readily available techniques.
constrained device	device which has physical limitations in either the ability to process data, the ability to communicate data, the ability to store data or the ability to interact with the user, due to restrictions that arise from its intended use.
consumer	natural person who is acting for purposes that are outside her/his trade, business, craft or profession.

continues on next page

Table 4 – continued from previous page

consumer IoT device	network-connected (and network-connectable) device that has relationships to associated services and are used by the consumer typically in the home or as electronic wearables.
critical security parameter	security-related secret information whose disclosure or modification can compromise the security of a security module.
debug interface	physical interface used by the manufacturer to communicate with the device during development or to perform triage of issues with the device and that is not used as part of the consumer-facing functionality
defined support period	minimum length of time, expressed as a period or by an end-date, for which a manufacturer will provide security updates.
device manufacturer	entity that creates an assembled final consumer IoT product, which is likely to contain the products and components of many other suppliers.
factory default	state of the device after factory reset or after final production/assembly.
initialization	process that activates the network connectivity of the device for operation and optionally sets authentication features for a user or for network access.
initialized state	state of the device after initialization.
IoT product	consumer IoT device and its associated services.
isolable	able to be removed from the network it is connected to, where any functionality loss caused is related only to that connectivity and not to its main function; alternatively, able to be placed in a self-contained environment with other devices if and only if the integrity of devices within that environment can be ensured
logical interface	software implementation that utilizes a network interface to communicate over the network via channels or ports.
manufacturer	relevant economic operator in the supply chain (including the device manufacturer).
network interface	physical interface that can be used to access the functionality of consumer IoT via a network.
owner	user who owns or who purchased the device.
personal data	Any information relating to an identified or identifiable natural person.
physical interface	physical port or air interface (such as radio, audio or optical) used to communicate with the device at the physical layer.
public security parameter	security related public information whose modification can compromise the security of a security module.
remotely accessible	intended to be accessible from outside the local network.
security module	set of hardware, software, and/or firmware that implements security functions.
security update	software update that addresses security vulnerabilities either discovered by or reported to the manufacturer.
sensitive security parameters	critical security parameters and public security parameters.
software service	software component of a device that is used to support functionality.
telemetry	data from a device that can provide information to help the manufacturer identify issues or information related to device usage.
unique per device	unique for each individual device of a given product class or type.
user	natural person or organization.

Provisions Assessment

The following table is a self-assessment using Table B.1 from ETSI EN 303 645, specifically focusing on the Zephyr RTOS as a component within IoT products.

According with ETSI 303 645, table B.1 provides a mechanism to give information about the implementation of the provisions presented in the standard. Zephyr has adopted the following notations used in the standard:

Table 5: ETSI 303645 Table B.1 notations

M	the provision is a mandatory requirement
R	the provision is a recommendation
M C	the provision is a mandatory requirement and conditional
R C	the provision is a recommendation and conditional
Y	The provision is supported by Zephyr
N	The provision is not supported by Zephyr
N/A	The provision is not applicable to Zephyr or it is product makers responsibility

Table 6: ETSI 303645 provisions assessment using table B.1

Provision	Description	Status	Support	Detail
Provision 5.1-1	Where passwords are used and in any state other than the factory default, all consumer IoT device passwords shall be unique per device or defined by the user.	M C	N/A	
Provision 5.1-2	Where pre-installed unique per device passwords are used, these shall be generated with a mechanism that reduces the risk of automated attacks against a class or type of device.	M C	N/A	
Provision 5.1-3	Authentication mechanisms used to authenticate users against a device shall use best practice cryptography, appropriate to the properties of the technology, risk and usage.	M	N/A	
Provision 5.1-4	Where a user can authenticate against a device, the device shall provide to the user or an administrator a simple mechanism to change the authentication value used.	M C	N/A	
Provision 5.1-5	When the device is not a constrained device, it shall have a mechanism available which makes brute-force attacks on authentication mechanisms via network interfaces impracticable.	M C	N	**TODO**
Provision 5.2-1	The manufacture shall make a vulnerability disclosure policy publicly available.	M	Y	*Vulnerability Management*
Provision 5.2-2	Disclosed vulnerabilities should be acted on in a timely manner.	R	Y	*Vulnerability Timeline*
Provision 5.2-3	Manufacturers should continually monitor for, identify and rectify security vulnerabilities within products and services they sell, produce, have produced and services they operate during the defined support period.	R	Y	Modules are covered
Provision 5.3-1	All software components in consumer IoT devices should be securely updatable.	R	Y	*Device firwmware upgrade*
Provision 5.3-2	When the device is not a constrained device, it shall have an update mechanism for the secure installation of updates.	M C	Y	*Device firwmware upgrade*
Provision 5.3-3	An update shall be simple for the user to apply.	M C	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.3-4	Automatic mechanisms should be used for software updates.	R C	N/A	
Provision 5.3-5	The device should check after initialization, and then periodically, whether security updates are available.	R C	N/A	
Provision 5.3-6	If the device supports automatic updates and/or update notifications, these should be enabled in the initialized state and configurable so that the user can enable, disable, or postpone installation of security updates and/or update notifications.	R C	N/A	
Provision 5.3-7	The device shall use best practice cryptography to facilitate secure update mechanisms.	M C	Y	*West Sign*
Provision 5.3-8	Security updates shall be timely.	M C	N/A	
Provision 5.3-9	The device should verify the authenticity and integrity of software updates.	R C	Y	Functionality provided by MCUboot. Also see *Device Firwmware Upgrade*.
Provision 5.3-10	Where updates are delivered over a network interface, the device shall verify the authenticity and integrity of each update via a trust relationship.	M	N/A	
Provision 5.3-11	The manufacturer should inform the user in a recognizable and apparent manner that a security update is required together with information on the risks mitigated by that update.	R C	N/A	
Provision 5.3-12	The device should notify the user when the application of a software update will disrupt the basic functioning of the device.	R C	N/A	Zephyr provides this information for its updates. Anyone using Zephyr in their products must check if they are affected
Provision 5.3-13	The manufacturer shall publish, in an accessible way that is clear and transparent to the user, the defined support period.	M	Y	Release Life Cycle and Maintenance
Provision 5.3-14	For constrained devices that cannot have their software updated, the rationale for the absence of software updates, the period and method of hardware replacement support and a defined support period should be published by the manufacturer in an accessible way that is clear and transparent to the user.	R C	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.3-15	For constrained devices that cannot have their software updated, the product should be isolable and the hardware replaceable.	R C	N/A	
Provision 5.3-16	The model designation of the consumer IoT device shall be clearly recognizable, either by labelling on the device or via a physical interface.	M	N/A	
Provision 5.4-1	Sensitive security parameters in persistent storage shall be stored securely by the device.	M	N	There is not secure storage within Zephyr
Provision 5.4-2	Where a hard-coded unique per device identity is used in a device for security purposes, it shall be implemented in such a way that it resists tampering by means such as physical, electrical or software.	M C	N/A	
Provision 5.4-3	Hard-coded critical security parameters in device software source code shall not be used.	M	Y	*Hardening Tool*
Provision 5.4-4	Any critical security parameters used for integrity and authenticity checks of software updates and for protection of communication with associated services in device software shall be unique per device and shall be produced with a mechanism that reduces the risk of automated attacks against classes of devices.	M	N/A	
Provision 5.5-1	The consumer IoT device shall use best practice cryptography to communicate securely.	M	Y	
Provision 5.5-2	The consumer IoT device should use reviewed or evaluated implementations to deliver network and security functionalities, particularly in the field of cryptography.	R	Y	
Provision 5.5-3	Cryptographic algorithms and primitives should be updatable.	R	N	The whole image must be updated
Provision 5.5-4	Access to device functionality via a network interface in the initialized state should only be possible after authentication on that interface.	R	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.5-5	Device functionality that allows security-relevant changes in configuration via a network interface shall only be accessible after authentication. The exception is for network service protocols that are relied upon by the device and where the manufacturer cannot guarantee what configuration will be required for the device to operate.	M	N/A	
Provision 5.5-6	Critical security parameters should be encrypted in transit, with such encryption appropriate to the properties of the technology, risk and usage.	R	Y	
Provision 5.5-7	The consumer IoT device shall protect the confidentiality of critical security parameters that are communicated via remotely accessible network interfaces.	M	Y	
Provision 5.5-8	The manufacturer shall follow secure management processes for critical security parameters that relate to the device.	M	N/A	
Provision 5.6-1	All unused network and logical interfaces shall be disabled.	M	Y	*Kconfig*
Provision 5.6-2	In the initialized state, the network interfaces of the device shall minimize the unauthenticated disclosure of security-relevant information.	M	Y	
Provision 5.6-3	Device hardware should not unnecessarily expose physical interfaces to attack.	R	Y	*Kconfig* and *Hardening Tool*
Provision 5.6-4	Where a debug interface is physically accessible, it shall be disabled in software.	M C	Y	*Hardening Tool*
Provision 5.6-5	The manufacturer should only enable software services that are used or required for the intended use or operation of the device.	R	Y	*Kconfig* and *Hardening Tool*
Provision 5.6-6	Code should be minimized to the functionality necessary for the service/device to operate.	R	Y	*Kconfig*
Provision 5.6-7	Software should run with least necessary privileges, taking account of both security and functionality.	R	Y	*Security Overview*
Provision 5.6-8	The device should include a hardware-level access control mechanism for memory.	R	Y	*Memory protection*

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.6-9	The manufacturer should follow secure development processes for software deployed on the device.	R	Y	*Security Overview* and *Coding guidelines*
Provision 5.7-1	The consumer IoT device should verify its software using secure boot mechanisms.	R	Y	Functionality provided by MCUboot. Also see *Security Overview*.
Provision 5.7-2	If an unauthorized change is detected to the software, the device should alert the user and/or administrator to the issue and should not connect to wider networks than those necessary to perform the alerting function.	R	N	Zephyr does not provide runtime detection / notification.
Provision 5.8-1	The confidentiality of personal data transiting between a device and a service, especially associated services, should be protected, with best practice cryptography.	R	Y	
Provision 5.8-2	The confidentiality of sensitive personal data communicated between the device and associated services shall be protected, with cryptography appropriate to the properties of the technology and usage.	M	Y	
Provision 5.8-3	All external sensing capabilities of the device shall be documented in an accessible way that is clear and transparent for the user.	M	Y	*Sensing Subsystem*
Provision 5.9-1	Resilience should be built in to consumer IoT devices and services, taking into account the possibility of outages of data networks and power.	R	Y	
Provision 5.9-2	Consumer IoT devices should remain operating and locally functional in the case of a loss of network access and should recover cleanly in the case of restoration of a loss of power.	R	Y	
Provision 5.9-3	The consumer IoT device should connect to networks in an expected, operational and stable state and in an orderly fashion, taking the capability of the infrastructure into consideration.	R	Y	
Provision 5.10-1	If telemetry data is collected from consumer IoT devices and services, such as usage and measurement data, it should be examined for security anomalies.	R C	N/A

Provision	Description	Status	Support	Detail
Provision 6.1-4	If telemetry data is collected from consumer IoT devices and services, the processing of personal data should be kept to the minimum necessary for the intended functionality.	R C	N/A	
Provision 6.1-5	If telemetry data is collected from consumer IoT devices and services, consumers shall be provided with information on what telemetry data is collected, how it is being used, by whom, and for what purposes.	M C	N/A	

Chapter 11

Safety

These documents describe the processes, developer guidelines and requirements for ensuring safety is addressed within the Zephyr project.

11.1 Zephyr Safety Overview

11.1.1 Introduction

This document is the safety documentation providing an overview over the safety-relevant activities and what the Zephyr Project and the Zephyr Safety Working Group / Committee try to achieve.

This overview is provided for people who are interested in the functional safety development part of the Zephyr RTOS and project members who want to contribute to the safety aspects of the project.

11.1.2 Overview

In this section we give the reader an overview of what the general goal of the safety certification is, what standard we aim to achieve and what quality standards and processes need to be implemented to reach such a safety certification.

11.1.3 Safety Document update

This document is a living document and may evolve over time as new requirements, guidelines, or processes are introduced.

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Safety Committee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

11.1.4 General safety scope

The general scope of the Safety Committee is to achieve a certification for the IEC 61508 standard and the Safety Integrity Level (SIL) 3 / Systematic Capability (SC) 3 for a limited source scope (see certification scope TBD). Since the code base is pre-existing, we use the route 3s/1s approach defined by the IEC 61508 standard.

Route 3s
Assessment of non-compliant development. Which is basically the route 1s with existing sources.

Route 1s
Compliant development. Compliance with the requirements of this standard for the avoidance and control of systematic faults in software.

Summarization IEC 61508 standard

The IEC 61508 standard is a widely recognized international standard for functional safety of electrical, electronic, and programmable electronic safety-related systems. Here's an overview of some of the key safety aspects of the standard:

1. **Hazard and Risk Analysis**: The IEC 61508 standard requires a thorough analysis of potential hazards and risks associated with a system in order to determine the appropriate level of safety measures needed to reduce those risks to acceptable levels.
2. **Safety Integrity Level (SIL)**: The standard introduces the concept of Safety Integrity Level (SIL) to classify the level of risk reduction required for each safety function. The higher the SIL, the greater the level of risk reduction required.
3. **System Design**: The IEC 61508 standard requires a systematic approach to system design that includes the identification of safety requirements, the development of a safety plan, and the use of appropriate safety techniques and measures to ensure that the system meets the required SIL.
4. **Verification and Validation**: The standard requires rigorous testing and evaluation of the safety-related system to ensure that it meets the specified SIL and other safety requirements. This includes verification of the system design, validation of the system's functionality, and ongoing monitoring and maintenance of the system.
5. **Documentation and Traceability**: The IEC 61508 standard requires a comprehensive documentation process to ensure that all aspects of the safety-related system are fully documented and that there is full traceability from the safety requirements to the final system design and implementation.

Overall, the IEC 61508 standard provides a framework for the design, development, and implementation of safety-related systems that aims to reduce the risk of accidents and improve overall safety. By following the standard, organizations can ensure that their safety-related systems are designed and implemented to the highest level of safety integrity.

Why IEC 61508?

The IEC 61508 standard was selected because it serves as a foundational functional safety standard applicable across various industry sectors. It provides a robust framework that can be used as base for specific standards for different industries. This makes IEC 61508 particularly relevant for Zephyr, as the operating system's versatility allows it to be effectively utilized across a wide range of industry sectors.

The following diagram illustrates the relationship between the IEC 61508 standard and other related standards:

11.1.5 Quality

Quality is a mandatory expectation for software across the industry. The code base of the project must achieve various software quality goals in order to be considered an auditable code base from a safety perspective and to be usable for certification purposes. But software quality is not an additional requirement caused by functional safety standards. Functional safety considers quality as an existing pre-condition and therefore the "quality managed" status should be pursued for any project regardless of the functional safety goals. The following list describes the quality goals which need to be reached to achieve an auditable code base:

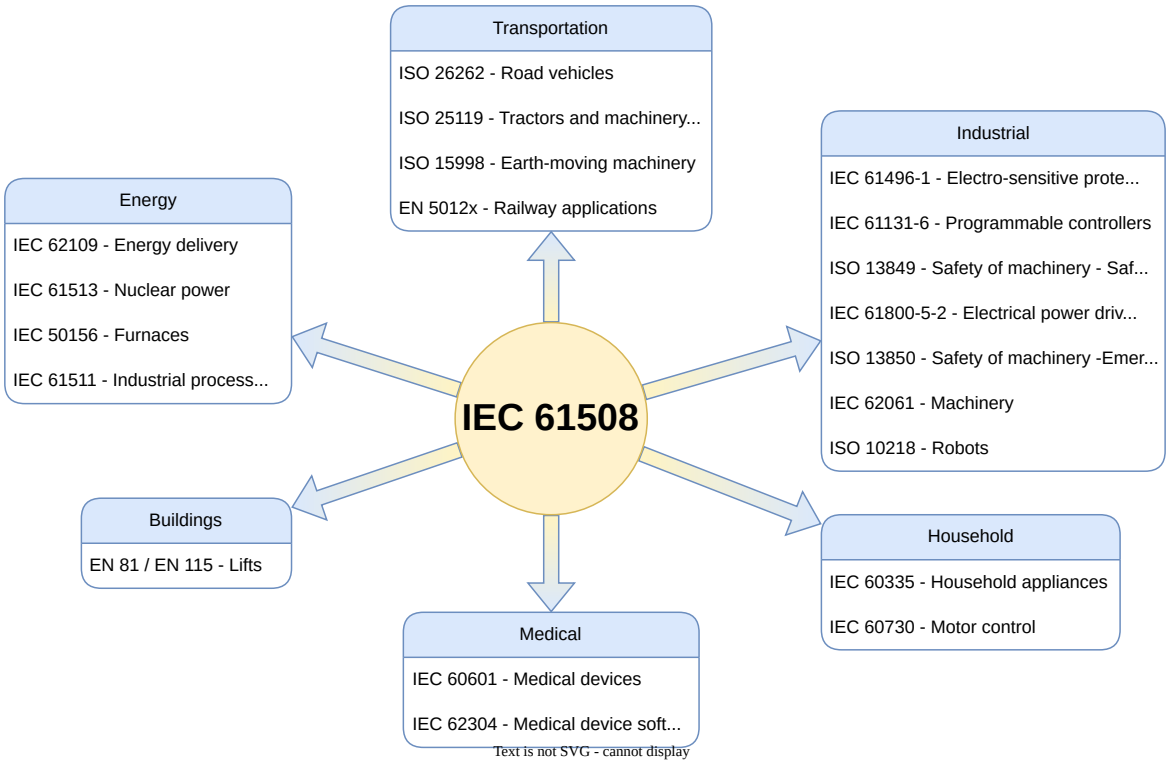

Fig. 1: IEC 61508 relation to other standards

1. Basic software quality standards
   a. *Coding Guidelines* (including: static code analysis, coding style, etc.)
   b. *Safety Requirements* and requirements tracing
   c. Test coverage
2. Software architecture design principles
   a. Layered architecture model
   b. Encapsulated components
   c. Encapsulated single functionality (if not fitable and manageable in safety)

Basic software quality standards - Safety view

In this chapter the Safety Committee describes why they need the above listed quality goals as pre-condition and what needs to be done to achieve an auditable code base from the safety perspective. Generally speaking, it can be said that all of these quality measures regarding safety are used to minimize the error rate during code development.

Coding Guidelines The coding guidelines are the basis to a common understanding and a unified ruleset and development style for industrial software products. For safety the coding guidelines are essential and have another purpose beside the fact of a unified ruleset. It is also necessary to prove that the developers follow a unified development style to prevent **systematic errors** in the process of developing software and thus to minimize the overall **error rate** of the complete software system.

Also the **IEC 61508 standard** sets a pre-condition and recommendation towards the use of coding standards / guidelines to reduce likelihood of errors.

The project TSC and the Safety Committee of the project agreed to implement a staged and incremental approach for complying with a set of coding rules (AKA Coding Guidelines) to improve quality and consistency of the code base. Below are the agreed upon stages:

Stage I (COMPLETED)
: Coding guideline rules are available to be followed and referenced, but not enforced. Rules are not yet enforced in CI and pull-requests cannot be blocked by reviewers/approvers due to violations.

Stage II
: Reviewers/approvers can block pull-requests due to violations of the coding guidelines in pull-requests across the codebase.

  Begin enforcement on a limited scope of the code base. Initially, this would be the safety certification scope. For rules easily applied across codebase, we should not limit compliance to initial scope. This step requires tooling, CI setup and an enforcement strategy.

Stage III
: Revisit the coding guideline rules and based on experience from previous stages, refine/iterate on selected rules.

Stage IV
: Expand enforcement to the wider codebase. Exceptions may be granted on some areas of the codebase with a proper justification. Exception would require TSC approval.

Note

Coding guideline rules may be removed/changed at any time by filing a GH issue/RFC.

Important

Current stage: The prerequisites to complete **Stage II** are currently being looked at: The tooling is in evaluation, CI setup and enforcement strategy is being worked on.

Requirements and requirements tracing Requirements and requirement management are not only important for software development, but also very important in terms of safety. On the one hand, this specifies and describes in detail and on a technical level what the software should do, and on the other hand, it is an important and necessary tool to verify whether the described functionality is implemented as expected. For this purpose, tracing the requirements down to the code level is used. With the requirements management and tracing in hand, it can now be verified whether the functionality has been tested and implemented correctly, thus minimizing the systematic error rate.

Also the IEC 61508 standard highly recommends (which is like a must-have for the certification) requirements and requirements tracing.

Test coverage A high test coverage, in turn, is evidence of safety that the code conforms precisely to what it was developed for and does not execute any unforeseen instructions. If the entire code is tested and has a high (ideally 100%) test coverage, it has the additional advantage of quickly detecting faulty changes and further minimizing the error rate. However, it must be noted that different requirements apply to safety for test coverage, and various metrics must be considered, which are prescribed by the IEC 61508 standard for the SIL 3 / SC3 target. The following must be fulfilled, among other things:

- Structural test coverage (entry points) 100%
- Structural test coverage (statements) 100%
- Structural test coverage (branches) 100%

If the 100% cannot be reached (e.g. statement coverage of defensive code) that part needs to be described and justified in the documentation.

Software architecture design principles

To create and maintain a structured software product it is also necessary to consider individual software architecture designs and implement them in accordance with safety standards because some designs and implementations are not reasonable in safety, so that the overall software and code base can be used as auditable code. However, most of these software architecture designs have already been implemented in the Zephyr project and need to be verified by the Safety Committee / Safety Working Group and the safety architect.

Layered architecture model The **IEC 61508 standard** strongly recommends a modular approach to software architecture. This approach has been pursued in the Zephyr project from the beginning with its layered architecture. The idea behind this architecture is to organize modules or components with similar functionality into layers. As a result, each layer can be assigned a specific role in the system. This model has the advantage in safety that interfaces between different components and layers can be shown at a very high level, and thus it can be determined which functionalities are safety-relevant and can be limited. Furthermore, various analyses and documentations can be built on top of this architecture, which are important for certification and the responsible certification body.

Encapsulated components Encapsulated components are an essential part of the architecture design for safety at this point. The most important aspect is the separation of safety-relevant components from non-safety-relevant components, including their associated interfaces. This ensures that the components have no **repercussions** on other components.

Encapsulated single functionality (if not reasonable and manageable in safety) Another requirement for the overall system and software environment is that individual functionalities can be disabled within components. This is because if a function is absolutely unacceptable for safety (e.g. complete dynamic memory management), then these individual functionalities should be able to be turned off. The Zephyr Project already offers such a possibility through the use of Kconfig and its flexible configurability.

11.1.6 Processes and workflow

The diagram describes the rough process defined by the Safety Committee to ensure safety in the development of the Zephyr project. To ensure understanding, a few points need to be highlighted and some details explained regarding the role of the safety architect and the role of the safety committee in the whole process. The diagram only describes the paths that are possible when a change is related to safety.

1. On the main branch, the safety scope of the project should be identified, which typically represents a small subset of the entire code base. This subset should then be made auditable during normal development on “main”, which means that special attention is paid to quality goals (*Quality*) and safety processes within this scope. The Safety Architect works alongside the Technical Steering Committee (TSC) in this area, monitoring the development process to ensure that the architecture meets the safety requirements.
2. At this point, the safety architect plays an increasingly important role. For PRs/issues that fall within the safety scope, the safety architect should ideally be involved in the discussions and decisions of minor changes in the safety scope to be able to react to safety-relevant changes that are not conformant. If a pull request or issue introduces a significant and influential change or improvement that requires extended discussion or decision-making, the safety architect should bring it to the attention of the Safety Committee or the Technical Steering Committee (TSC) as appropriate, so that they can make a decision on the best course of action.

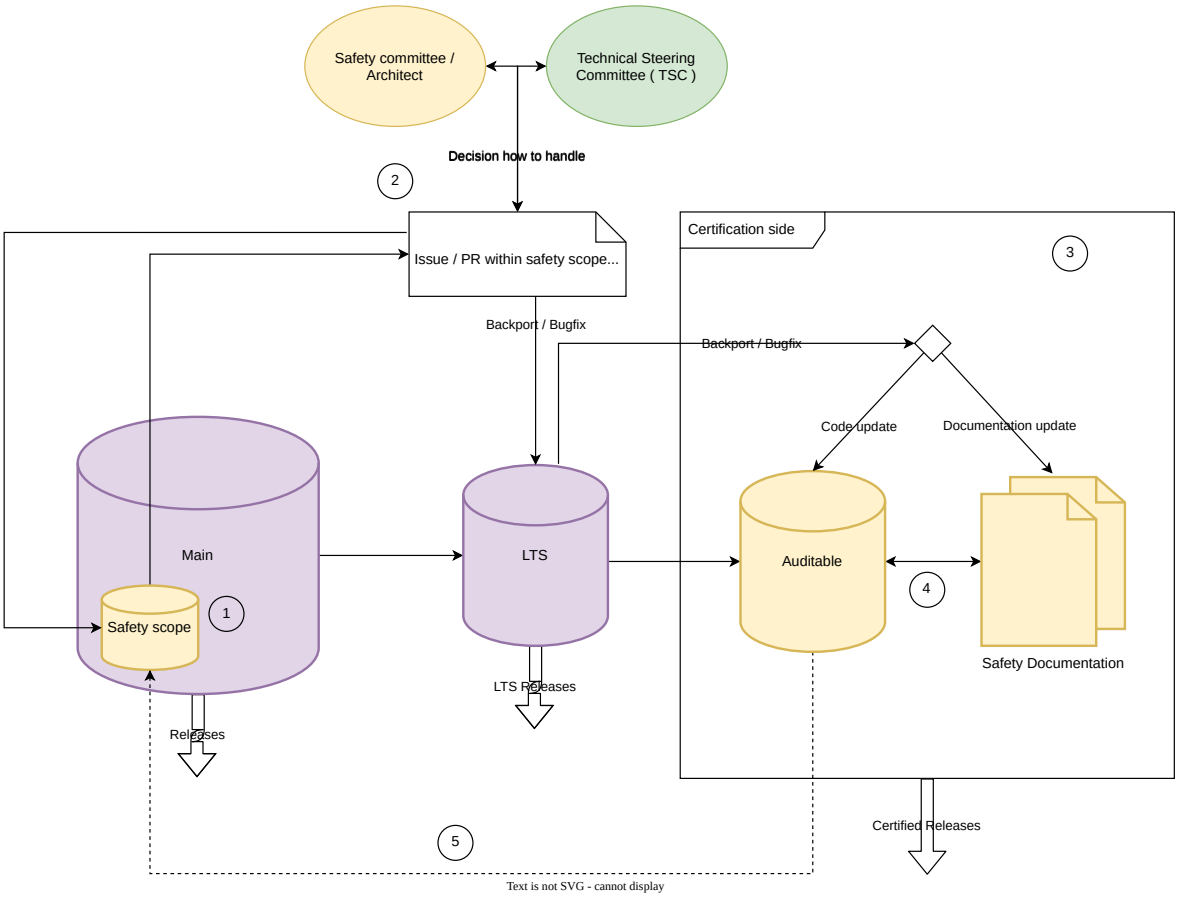

Fig. 2: Safety process and workflow overview

3. This section describes the certification side. At this point, the code base has to be in an "auditable" state, and ideally no further changes should be necessary or made to the code base. There is still a path from the main branch to this area. This is needed in case a serious bug or important change is found or implemented on the main branch in the safety scope, after the LTS and the auditable branch were created. In this case, the Safety Committee, together with the safety architect, must decide whether this bug fix or change should be integrated into the LTS so that the bug fix or change could also be integrated into the auditable branch. This integration can take three forms: First either as only a code change or second as only an update to the safety documentation or third as both.
4. This describes the necessary safety process required for certification itself. Here, the final analyses, tests, and documents are created and conducted which must be created and conducted during the certification, and which are prescribed by the certifying authority and the standard being certified. If the certification body approves everything at this stage and the safety process is completed, a safety release can be created and published.
5. This transition from the auditable branch to the main branch should only occur in exceptional circumstances, specifically when something has been identified during the certification process that needs to be quickly adapted on the "auditable" branch in order to obtain certification. In order to prevent this issue from arising again during the next certification, there needs to be a path to merge these changes back into the main branch so that they are not lost, and to have them ready for the next certification if necessary.

Important

Safety should not block the project and minimize the room to grow in any way.

Important

TODO: Find and define ways, guidelines and processes which minimally impact the daily work of the maintainers, reviewers and contributors and also the safety architect itself. But which are also suitable for safety.

11.2 Safety Requirements

11.2.1 Introduction

The safety committee leads the effort to gather requirements that reflect the **actual** state of the implementation, following the route 3s approach of the project's safety effort. The goal is **NOT** to create new requirements to request additional features for the project.

The requirements are gathered in the separate repository: Requirement repository

11.2.2 Guidelines

Below are the guidelines for the requirements repository and the expectations of the safety committee when adding requirements to the repository.

Scope

The scope of the requirements covers the KERNEL functionalities.

Consistency

Maintain consistency across all requirements. The language and choice of words shall be consistent. (See: *Syntax*)

Levels of requirements in the repository

System Requirements
: System requirements describe the behaviour of the Zephyr RTOS (= the system here). They describe the functionality of the Zephyr RTOS from a very high-level perspective, without going into details of the functionality itself. The purpose of the system requirements is to get an overview of the currently implemented features of the Zephyr RTOS. In other words a person writing these requirements usually has some knowledge of the Zephyr RTOS Project as the requirements are specific to an RTOS.

Software Requirements
: Software requirements refine the system-level requirements at a more granular level so that each requirement can be tested. These requirements define the specific actions the feature shall be able to execute and the behavior of the feature.

Requirement UID (Unique identifier) Handling

The tool used to manage requirements, strictDoc, is responsible for handling the Unique Identifier (UID) associated with each requirement. To manage UIDs, follow these steps:

1. Don't add a requirement UID and UID field for new requirements
2. After completing work on the new requirements execute: `strictDoc manage auto-uid .`
3. Establish links between the requirements with the new attributed UIDs if needed

After doing this, the requirements are ready and a pull request can be created. The CI in the PR will check if the requirements UIDs are valid or if there are duplicates in it. If there are duplicates in the PR, these need to be resolved by rebasing and re-executing the steps above.

Requirement Types

- Functional
- Non-Functional

Requirement title convention

Use short and succinct requirement titles.

Pull Request requirement repository

- Adhere to the *Contribution Guidelines* of the Zephyr Project.
  - As long as they are applicable to the requirements repository.
- Avoid creating large commits that contain both trivial and non-trivial changes.
- Avoid moving and changing requirements in the same commit.

Characteristics of a good requirement

- Unambiguous
- Verifiable (e.g. testable for functional requirements)
- Clear (concise, succinct, simple, precise)
- Correct
- Understandable
- Feasible (realistic, possible)
- Independent

- Atomic
- Necessary
- Implementation-free (abstract)

Characteristics of a set of requirements

- Complete
- Consistent
- Non redundant

Syntax

- Use of a recognized Requirements Syntax is recommended.
  - EARS is a good reference. Particularly if you are unfamiliar with requirements writing.
  - Other formats are accepted as long as the characteristics of a requirement from above are met.

Chapter 12

Glossary of Terms

API
: (Application Program Interface) A defined set of routines and protocols for building application software.

application
: The set of user-supplied files that the Zephyr build system uses to build an application image for a specified board configuration. It can contain application-specific code, kernel configuration settings, and at least one CMakeLists.txt file. The application's kernel configuration settings direct the build system to create a custom kernel that makes efficient use of the board's resources. An application can sometimes be built for more than one type of board configuration (including boards with different CPU architectures), if it does not require any board-specific capabilities.

application image
: A binary file that is loaded and executed by the board for which it was built. Each application image contains both the application's code and the Zephyr kernel code needed to support it. They are compiled as a single, fully-linked binary. Once an application image is loaded onto a board, the image takes control of the system, initializes it, and runs as the system's sole application. Both application code and kernel code execute as privileged code within a single shared address space.

architecture
: An instruction set architecture (ISA) along with a programming model.

board
: A target system with a defined set of devices and capabilities, which can load and execute an application image. It may be an actual hardware system or a simulated system running under QEMU. A board can contain one or more *SoCs*. The Zephyr kernel supports a variety of boards.

board configuration
: A set of kernel configuration options that specify how the devices present on a board are used by the kernel. The Zephyr build system defines one or more board configurations for each board it supports. The kernel configuration settings that are specified by the build system can be over-ridden by the application, if desired.

board name
: The human-readable name of a *board*. Uniquely and descriptively identifies a particular system, but does not include additional information that may be required to actually build a Zephyr image for it. See *Board terminology* for additional details.

board qualifiers
: The set of additional tokens, separated by a forward slash (/) that follow the *board name* (and optionally *board revision*) to form the *board target*. The currently accepted qualifiers are *SoC*, *CPU cluster* and *variant*. See *Board terminology* for additional details.

board revision
An optional version string that identifies a particular revision of a hardware system. This is useful to avoid duplication of board files whenever small changes are introduced to a hardware system. See *Multiple board revisions* and *Building for a board revision* for more information.

board target
The full string that can be provided to any of the Zephyr build tools to compile and link an image for a particular hardware system. This string uniquely identifies the combination of *board name*, *board revision* and *board qualifiers*. See *Board terminology* for additional details.

CPU cluster
A group of one or more *CPU cores*, all executing the same image within the same address space and in a symmetrical (SMP) configuration. Only *CPU cores* of the same *architecture* can be in a single cluster. Multiple CPU clusters (each of one or more cores) can coexist in the same *SoC*.

CPU core
A single processing unit, with its own Program Counter, executing program instructions sequentially. CPU cores are part of a *CPU cluster*, which can contain one or more cores.

device runtime power management
Device Runtime Power Management (PM) refers the capability of devices to save energy independently of the system power state. Devices will keep reference of their usage and will automatically be suspended or resumed. This feature is enabled via the `CONFIG_PM_DEVICE_RUNTIME` Kconfig option.

idle thread
A system thread that runs when there are no other threads ready to run.

IDT
(Interrupt Descriptor Table) a data structure used by the x86 architecture to implement an interrupt vector table. The IDT is used to determine the correct response to interrupts and exceptions.

internal API
Any internal function, structure or macro defined anywhere in the Zephyr source tree. Internal APIs are intended to "extend" Zephyr, and are to be used only between certain *software components*, usually in-tree but in some cases out-of-tree (e.g. adding an out-of-tree architecture or driver). Applications must not invoke internal APIs outside their own scope. The context where the API is called or implemented is well defined. For example, functions prefixed with `arch_` are intended for use by the Zephyr kernel to invoke architecture-specific code. Internal APIs are mostly kept stable, but with fewer guarantees than *public APIs*.

ISR
(Interrupt Service Routine) Also known as an interrupt handler, an ISR is a callback function whose execution is triggered by a hardware interrupt (or software interrupt instructions) and is used to handle high-priority conditions that require interrupting the current code executing on the processor.

kernel
The set of Zephyr-supplied files that implement the Zephyr kernel, including its core services, device drivers, network stack, and so on.

power domain
A power domain is a collection of devices for which power is applied and removed collectively in a single action. Power domains are represented by `device`.

power gating
Power gating reduces power consumption by shutting off areas of an integrated circuit that are not in use.

private API
: Any function, structure or macro defined anywhere in the Zephyr source tree which are only intended for consumption inside the *software component* where they are defined. Private APIs may change at any time and must not be used by code outside the corresponding software component.

public API
: Any function, structure or macro defined inside the `include/zephyr` folder that is not explicitly marked as private. Public APIs are intended for consumption by any and all in-tree or out-of-tree *software components*. Public APIs cannot be modified without following the provisions described in the *API lifecycle* section, which means they provide guarantees that they will remain stable over time.

SoC
: A System on a chip, that is, an integrated circuit that contains at least one *CPU cluster* (in turn with at least one *CPU core*), as well as peripherals and memory.

SoC family
: One or more *SoCs* or *SoC series* that share enough in common to consider them related and under a single family denomination.

SoC series
: A number of different *SoCs* that share similar characteristics and features, and that the vendor typically names and markets together.

software component
: A software component is a self-contained, modular, and replaceable part of the Zephyr source code. A driver, a subsystem or an applications are all examples of software components present in Zephyr.

subsystem
: A subsystem refers to a logically distinct part of the operating system that handles specific functionality or provides certain services.

system power state
: System power states describe the power consumption of the system as a whole. System power states are represented by `pm_state`.

variant
: In the context of *board qualifiers*, a variant designates a particular type or configuration of a build for a combination of *SoC* and *CPU cluster*. Common uses of the variant concept include introducing both secure and non-secure builds for platforms with Trusted Execution Environment support, or selecting the type of RAM used in a build.

west
: A multi-repo meta-tool developed for the Zephyr project. See *West (Zephyr's meta-tool)*.

west installation
: An obsolete term for a *west workspace* used prior to west 0.7.

west manifest
: A YAML file, usually named `west.yml`, which describes projects, or the Git repositories which make up a *west workspace*, along with additional metadata. See *Basics* for general information and *West Manifests* for details.

west manifest repository
: The Git repository in a *west workspace* which contains the *west manifest*. Its location is given by the *manifest.path configuration option*. See *Basics*.

west project
: Each of the entries in a *west manifest*, which describe a Git repository that will be cloned and managed by west when working with the corresponding *west manifest repository*. Note that a west project is different from a *zephyr module*, although many projects are also modules. See *Projects* for additional information.

west workspace
: A folder on your system with a `.west` subdirectory and a *west manifest repository* in it. You clone the Zephyr source code, as well as that of its *west projects* onto your system by creating a west workspace using the `west init` command. See *Basics*.

XIP
: (eXecute In Place) a method of executing programs directly from long term storage rather than copying it into RAM, saving writable memory for dynamic data and not the static program code.

zephyr module
: A Git repository containing a `zephyr/module.yml` file, used by the Zephyr build system to integrate the source code and configuration files of the module into a regular Zephyr build. Zephyr modules may be west projects, but they do not have to. See *Modules (External projects)* for additional details.

Bibliography

[f] AES Electronic Codebook Mode Encryption (ECB)

[g] Cipher Block Chaining (CBC) - Message Authentication Code with Counter Mode encryption (CCM)

[h] Accelerated Address Resolver (AAR)

[i] General Purpose Input Output (GPIO)

[j] GPIO tasks and events (GPIOTE)

[k] Temperature sensor (TEMP)

[l] Universal Asynchronous Receiver Transmitter (UART)

[m] Interprocess Communication peripheral (IPC)

[th-imboot] Must boot with an immutable bootloader.

[th-authrepl] Application image shall only be replaced with an authorized image.

[th-timely-update] Application updates shall be done in a timely manner.

[th-atomic-update] Application updates shall be atomic.

[th-root-certs] TLS must have a list of trusted root certificates.

[th-root-check] TLS must verify root certificate from server is valid.

[th-secret-storage] There must be a mechanism to securely store client secrets. The least amount of code necessary shall have access to these secrets.

[th-time] System must have moderately accurate notion of the current date/time.

[th-conf] The system must receive, and keep configuration data.

[th-logs] The system must log security-related events, and either store them locally, or send to a service.

[th-all-tls] All communications with the cloud service shall use TLS.

[th-tls-ciphers] TLS shall be configured to allow only generally agreed cipher suites (including forward secrecy).

[th-tls-client-auth] The device shall authenticate itself with the cloud provider using one of the methods described.

[th-entropy] The TLS layer shall use a modern, accepted cryptographic random-bit generator seeded by an entropy source within the SoC.

[th-initial-provision] The device shall have a per-device secret loaded before deployment.

[th-initial-secret] The initial secret shall be securely maintained, and destroyed in any external location as soon as the device is provisioned.

[th-reprovision] Reprovisioning a device shall be done securely.

[th-destruction] Upon decommissioning, the device secret shall be rendered ineffective.
